The potential of female entrepreneurship is manifested through a greater diversification between different economic sectors, younger entrepreneurs at the aggregate level, which means a greater number of business activities focused on the knowledge economy and production and lower concentration in the store. When starting the business the most important potential of women entrepreneurship is determined not to give up easily after the first attempt; The main disadvantages are a frequent entry into entrepreneurship because of the mere pressure of economic necessity and without sufficiently developed business ideas, while the obstacles are unfavorable resources to start, especially the lack of financial capital.

In most cases, entrepreneurs have expressed a conflict between business and family responsibilities, but this is usually not frustrating. On the contrary, they believe that they can manage to reconcile the two spheres of life. Their position in the family is more equal than that of the average for women in Serbia, and they are mostly satisfied with the lifestyle that goes with entrepreneurship.

It is necessary to establish a mechanism at the national level that would systematically deal with the many obstacles they face in their operations of micro and small businesses, particularly those owned by women. This certainly must be carried out in combination with progress in EU accession and adherence to the already accepted obligations from key EU documents such as the Small Business Act. Also, one must establish a time frame for each of the desired changes, in order to create a favorable and an enabling environment for doing business in Serbia.

In the future, more entrepreneurs would like to use membership in associations of business women, as well as recommendations of existing networks. There is a clear need for major improvements in the overall environment and the system in which micro and small businesses operate in Serbia. Particular attention should be given to sufficient and timely information to micro and small businesses. As is the practice in many countries, micro and small businesses are mainly about the state of the informal channels, but it is a challenge for providers of business services, which must be get closer to companies that use informal channels of information.

Abstract: *Vast majority of educational systems are unsuitable to respond to modern needs, and their evolutions is very slow and lengthy process. We propose debate as a method of education, with focus on courses that study environmental issues, and in this paper specifically on its implementation within tertiary education. We argue that it would provide deeper understanding of the problems planet is facing, bring up the quality of the discussion about relevant issues; improve both awareness raising and solution finding. This paper will try to prove the relevance, urgency and necessity of adaptation of educational systems, unsuitable for Information age, age of man-made climate change and environmental catastrophes which became so often and expected that we can easily say "common" – we don't even report any more on so many of them. Efficient improvements are needed, and that is especially true for environmental literacy, which raises awareness – without it, we cannot hope to achieve the bare sustainability of our environment, while the ideal of "sustainable development" dispatches to some imaginary realm. Debate as a method is perfectly suitable to answer to these challenges.*

Keywords*: environment, ecology, education, debate, awareness, critical thinking, sustainable development*

1. INTRODUCTION

Back in 1962 Thomas Kuhn (Kuhn, 2012) said that our textbooks are more and more alike touristic brochures – fact not the way, neither the counter attitudes of scientists which were also experts by current paradigms. Simplification of knowledge and omission of context which established dominant approach, followed by next 50 years in which ex-cathedra approach dominated, along with the cult of the professor – established not necessarily by the authority of knowledge but position (Weber, 2009).

It is also important to note that current educational system main form is to create a class of educated people, ready to, through their participation in the market, contribute to general prosperity. Throughout the process, most of the historical evolution is based on specialization combined with market's pace and inherited urge to spread. This resulted in a simplification of science, solidified with our desire for better and faster understanding.

"Exactly that is the product of educational system we currently have. It simplifies the science by simplifying the participants in educational process: firstly, domain is defined, isolated from the context and from its historical background, then to its narrow area of interest, special logic is given. The result is vast majority of educational systems designed to tell what we have come to, as a conclusion, standard, unit of measure or a fact – not how we've done it" (Feyerabend, 1993). Educational systems around the world have, trying to make knowledge more accessible and comprehensible to students, have detached the discussion about facts and postulates on which most sciences are founded – that moved away the debate about postulates of sciences from majority of students. Furthermore, while that led to few but still, harmful impacts in some areas. In areas such as environmental studies, which are comparatively still young areas of science, and which postulates did not pass through decades and centuries of academic scrutiny it led to much greater number of harmful effects. Evidences suggest that ecology as a concept existed even in 4th century A.D. but it's recognition and following development happened only recently, in the eve of 20th century (Odum, Howard, & Andrews, 1971): in 1992 during the summit in Rio de Janeiro, United Nations came to "Rio Declaration on Environment and Development", term "sustainable development" was crafted for the first time, in Norway in 1989, adopted by European Union year later (Rodale, 2015).

Not until the last decade of 20th century, humanity has recognized importance and necessity of development of ecology as a science, and additionally that this area is a prerogative for even hoping to solve some of the imminent problems we have created. World had to deal with environmental catastrophes of 1960's to recognize necessity and finally recognize ecology as a science, and as field of expertise that is highly needed. Even these catastrophes were not enough for our collective realization of how big of the problem life

on planet faces, let alone that each and every of them proved that we haven't had developed any mechanism of how to respond to consequences.

Inclusion of youth in the problem solving process is predicament for achieving sustainable development (Cirovic, et al., 2014) as ecological problems require long term policies. Awareness raising and education of youth and general public is infallible. It is important in order for policies to work and be supported to maintain general public as equal member in a debate, both as a rational marker and as an expanding pool of inventors. But we need to make sure that policy makers, scientists and whole academic community are able to verbalize justifications, explain discoveries and theories and shape the discussion objectively, respectively.

Here where we come to another specificity of ecology as a science, unlike other that had "luxury" of taking several hundred years of building on their importance and paving their way to what we understand as common knowledge.

Regarding that society needs environmental knowledge now, this is why it is the focus of this paper to argue the change in the way ecology is taught, and to consequently change the way by and narrative in which ecological issues are discussed. It will be argued that debate is student-oriented method, and that is therefore more efficient, as it is proved to provide better acceptance of knowledge and its adoption (UNESCO, 2011).

2. DEBATE AS A METHOD

More than two millennia's ago, debate was already recognized as powerful method of teaching (Freeley & Steinberg, 2005). Ecology in this relationship – demands approach that can include and adopt different ecological philosophies in order to create possibility of understanding the problems and their complexity (Tumposky, 2004).

2.1.Academic debate

Most of the people understand debate as some form of a public discussion, exemplified in political duels or debates produced for broadcasting – which are still largely dominated by demagogy, logical fallacies and unsupported assertions. Debate as a method was crafted by a need for competitive debate, defined as: "balanced and fair communicational event on certain subject, with advocates on opposed sides whose speeches are going one after another, before verdict is reached" (Snider, 2011).

Debate requires academic discipline, accuracy, impeccable logic, and analytical explanation of assertions and argumentation. Reason founded on arguments rather than assertions and without leaps of logic is more persuasive – because it is simply more understandable. Communication founded in the idea of expressible argument that requires structured knowledge brings deeper and more profound understanding of the matter in question (Maloy, 1993; Toulmin, 1973).

2.2. Student oriented method

Debate is completely student-oriented method of teaching, and very efficient – as studies have shown that active role during the learning process in comparison to passive one (listening only), makes learning faster (Bonwell & Eison, 1991). Active learning has many definitions, but in general it should depict: the opportunity for students to talk and listen, discuss and reflect their thoughts about certain problem, idea or curriculum (Mayers & Jones, 1993). No teaching method is perfect as students learn differently and respond to different methods and incentives they provide (Snider & Schnurer, 2002) but study has shown positive correlation between student's engagement, critical thinking and student's grades, especially among students with lower average grades (Carini & Klein, 2006). Study supports debate and its usage in education because it requires engagement from students, research, articulation and argumentation of certain position or view (Dundes, 2001).

Research also shows that debate provokes engagement among passive students during lectures. For professors struggling with unprepared students, debate is offering reward of public presentation and fear of presenting unprepared to fellow peers, serves as a mechanism that brings responsibility back to students (Goodwin, 2003). Despite critics that say that preparation for debate is an additional burden, students that have debated on certain topics, show deeper level of understanding of that part of curriculum, which proves

that debate is useful to students, more than the other methods (Combs & Bourne, 1994; Vygotsky, 1978; Osborne, 2005).

Most importantly, debate offers the possibility for students to go further from basics of the subject they study, and advance their argumentation to levels of "higher critical thinking", which is necessary for a good debate. Debaters need to analyse, evaluate and synthesize knowledge to be able to argument certain attitude, to oppose it, or to be able to make certain strategic choices (Elliot, 1993). They have to apply acquired knowledge to create solid arguments, that need to be understandable and persuasive not only to professor – but to their colleagues as well (Cronin, & Glenn, 1991). This process develops and advances oral communication skills and active listening skills that are necessary to be able to respond to the arguments and case of the other side (Gorman, Law, & Lindegren, 1981; Allison, 2002).

3. IMPLEMENTATION AND SIGNIFICANCE

Importance of debate training was documented by monumental study (Malton & Keele, 1984) of ex-debaters, which proves affirmative link between competitive debate engagement and goals of higher education. Debate is one of the most successful methods of teaching because it is inherently interactive, and studies show that interactive formats are more efficient and give better results in development of critical thinking, cognitive learning, problem solving, attitude re-evaluation and improvement of communicational skills. Out of six recommended methods of active learning, debate uses five (Nyquist & Wulff, 1990).

3.1. Arguing both sides

As students are not choosing the side they will argue on the given motion. Teams positions are given to them, which means that, on average, students will have to argue position counter to their own. In everyday life arguing different positions of what you believed till that very moment would be considered and labelled as hypocrisy, and yet, we are to argue that that is essential, as it is fundamental difference between debate and other educational methods.

Debate is always a clash of values, principles and mechanisms to solve specific problem that already exists in our society (either in practical or intellectual or moral domain) and that involves the analysis of a status-quo, stakeholders, possible consequences and implications of establishing certain paradigms. Here we come to the first rule – debate motion (resolution) needs to be balanced, as there is no point in debating one sided motions, as presumption behind one sidedness is that we have already solved the problem in question.

Building arguments and constructing case for the opposite side of the one student would intuitively choose, makes them:

- Create arguments, re-evaluate facts and attitudes to support them;
- Makes them understand the position opposite to theirs, which necessarily makes them more tolerant because it makes them more likely to understand and be aware of merits, shortcomings and flaws of any of the sides;
- Leads to re-evaluation of postulates that are the core values proposed in a debate – which is by definition critical thinking;
- Demands from debaters to recognize and precisely define issues of relevance to the topic.

Accepting the flaws of one's own attitude is the first and necessary step towards gaining the credibility that is needed to influence, and eventually change someone else's attitude (Popper, 1972). If we know anything about ecological problems that humanity is facing, we know that they are controversial by nature – and while it is not the focus of this paper to examine that, it is worth to notice that students without debate training are much more likely to stay unaware of causes of this differences presented to us by nearly all of public discourse participants.

3.2. Problem definition and value of clash

Process of debating is focused towards defining the particular problem within the scope of the motion given, and explaining the potential value of one of the proposed solutions. From one perspective, debate presents the analysis of the practical implications of certain decision, but at the same time it brings clash of abstract principles and underpinning values that are foundation and starting points for proposing any policy or decision that changes status-quo.

Opposite to any discussion or other form of arguing, debate by its rules requires usage of structured knowledge, active listening, so that valid reply or counter argument can be formed. This tells us that after this approach to the studying process, personal attitude and view person holds in regard to different philosophies or views are free, informed and chosen. These views now emerge through evaluation of other views and philosophies, values or systems in comparative analysis.

For us, this represents the peak of our interest: that the informed choice, a point of view built on constantly re-evaluated arguments, and not learned doctrine – is how we need to educate youth about imminent ecological threats, different eco-philosophies, and everything which is within the scope of ecology.

3.3. Case building

Teams in the debate present their case, which in comparative with cases (case statements) of other teams in a debate are more or less persuasive, or simply said, believable. The debate is always judged on comparative, which is important because it instils the metric for evaluation in real problems we're facing in today's world. Idea, policy or measure cannot be accepted and implemented without contrasting pros and cons, as one would say in debate jargon. Pros and cons here define consequences that change in status-quo that measure inflicts in all adjacent spheres, whether it is legislative, or change in behaviour which changes social interactions or laws that inflict immediate change – none of it exists in a vacuum. This means that all of this needs to be taken into account when evaluating the quality and depth of analysis presented in a team's case.

That is why case building is important for us in the context of this paper and its aims; case building need to answer basic questions: who, what, how, and what are the conditions that create context in which this proposal occurs.

To define these, at the first glance, students need to be aware of very basic questions:

- What the real problem is and what stops us to solve it (contextualization)?
- Who and how is effected by the proposed solution (stakeholder analysis)?
- Is there a better alternative (justification of the proposition)?

While answering these questions and trying to synthesize them in their case, students are well aware that every stance has a set of principles that are upholding it. Here we have to emphasize that this is when evaluation of known ecological philosophies, their values and perspectives come in play. They are not detached from students, nor obscure dogmatic definitions or contemplations, they become real through synthesizing knowledge as a platform from which arguments, attitudes and proposals are risen – and the gap between students and process of establishing scientific "truth" is narrowed if not closed – as they gain agency to play the main role in it. They become equipped with skills previously unavailable to them, which secure more profound understanding of matters in question.

4. CONCLUSION

Back in 1975, one study (Huseman & Goodman,1976) discovered that 55% percent of the U.K. Parliament attended some training in competitive debate, out of which outstanding 87% claimed that debating helped them in their professional carriers. No evaluation of debating as an educational activity was negative. This result, that may be surprising as we are back in the day looking at the world in which very few countries had a debate program, apart from the Commonwealth, and that even if they have had it, it was considered to be an extracurricular activity. Nevertheless, studies of Schroeder and Schroeder in 1995 have confirmed this – debating has a positive effect on person's professional development; skills they use they credit to debate, not university education. There are strong empirical evidences that debating teaches crucial skills – it inevitably advances communicational skills; offers unique techniques for complex analysis of current affairs in almost any sphere of human endeavour; focused critical thinking; improves probability of success in pursue of professional success. (Colbert & Biggers, 1985). Out of 100 people more than 90 believes that debate helped them in their professional career – and that is an outstanding score of recognition (Klopf & Lanham, 1967).

If we return all of these studies back to context, and if we remember that when most of them were done, we didn't even have ecology as a recognized science. This fact should alter the conversation: studies, research, and evaluation – all was done in context in which everything was different - world had no knowledge about how serious and fast we destroy our environment. We didn't have Internet – which means that we have had limited access to information, less accessible knowledge, and last but certainly not least, different and slower

communication. Skills that debating as activity develops, and mechanisms and requirements it imposes as educational method – were desirable, but now they are necessary.

It is also very important to note that today students are overloaded with information and data, and they need to be trained, and equipped with skills that would allow them to assess information they receive instantly, and to be able to do proper evaluation through research.

This, in context of this paper, means that when so called experts give side opinions and publish researches that diverge from what was established as problematic or worrying, they need to be able to see whether it was done because of pursuing scientific truth, or because there were other interests in place. We need to remember that even in 21st century we still have spokesmen of various industries (oil industry first and foremost) who not only actively underestimate damages done to the environment, but even go as far to disprove that human activity has any influence on it. That being noted – importance and relevance of critical thinking being trained and practiced during studies is clearly immense.

Intrinsic motivation for learning, that comes with honest satisfaction for the acquirement of new knowledge and widening of awareness spectrum is very rare to be seen in current educational systems. Motivation, that is driven from personal, inner goals, not by outer demand or even recognition – is the strongest and best motivation for process of learning. If you have students motivated in this way, implementation of high standards in educational system and their achievement becomes an easy process (Ames, 1992). As mentioned earlier, debating offers exactly that urge – in order to win, and represent yourself in the desired manner , you need to be better; in other words, you really need to know and understand what you are about to argue. That is where the inner motivation comes from, for a person to appear, especially in front of your peers, credible. Debate being specific as it was argued before in this context, unlike any other form of discussion, it is based on argumentation, not demagogy or rhetoric. So for student to be able to accomplish this goal really needs to know, understand, and learn how to show this in the best possible manner; it doesn't enable credibility to appear where there is no proper argumentation.

This is very important to notice, for acceptance and adoption of ecological values, principles and behaviour today, more than ever before: societies have need for high quality ecology education programs, which with success are raising the system of values, and change behaviour in direction of sustainability, by promoting conservation and appraisal of protection of environment and nature (Petrovic, 2012).

Accomplishing goals of United Nations infamous "Agenda 21" is completely compatible with proposed method of education. If a team proves that their proposal leads to better world, even if it is just an incremental improvement, then they win. Same is true in a debate, and as a reiteration, that is the biggest difference in narrative that this method would provoke, because it changes the goal of educational system. It is not teaching "facts that need to be preserved" no more, because it establishes a consensus that we are willing to change or challenge facts if we are to believe that that would mean an improvement. This is what is a necessity for achieving "ecological literacy" , that needs to be brought back to the processes of coming to scientific facts and achieving both academic and social consensus back to our education, if we want people to understand and adopt the changes in their lives necessary for our environment's sustainability (UNEP, 1992).

Lastly on this: level, depth and quality of acquired knowledge, as we have seen rise rapidly among students who had debate on the motion that covers certain area of studies. This is very easy to explain: people think in greater depth when they need to explain something to someone else. Debate requires that process to be impeccable, without any logical fallacies or shortcomings of elaboration, and persuasiveness – which demands that assertions and arguments be related to the audience. This produces both understanding and analysis that is incomparable to any other educational method used today. If we apply the rules of competitive debate, in which no usage of electronic devices is allowed during the preparation time, this method makes students perfect agents to enact change.

Change in narrative surrounding ecological issues, questions and problems is of utmost importance if we want all relevant actors to be included, ecology as a science simply doesn't have the luxury of becoming detached from general public, of becoming prestigious in any manner. This is prerogative for ecology education, since we had too many doubts loudly presented to us by scientists, politicians, experts: we came to consensus that human activity does cause global warming, only at the beginning of 21st century, and there is still incomprehensibly huge amount of people that reject that notion. Hence, as Schopenhauer argued, dialectic way is the most efficient tool of coming to realization; which can be especially true when having, as today, an overload of information (Schopenhauer, 2008).

Conclusion is that this method, integrated in education, promotes ecological literacy and development of skills that are necessary for life learning. This fosters efforts not only to engage general public in discussion about our environment, while it raises general conciseness and knowledge about ecological problems and environmental threats that we are causing (Petrovic, Jeremic, Petrovic, & Cirovic, 2013). Processes that are integrated in academic debate as a form of problem-solving mechanism, inherently require critical thinking, and decision making skills in general – this is what we need to strive for, in order to grow into population that will be aware of environmental problems (Petrović, Išljamović, Jeremić, & Drakulić, 2011), and that will consciously make decisions concerning ecology, or in other words – sustainability. This ought to be our imperative if we are to strive to ideal of sustainable development. (Petrovic, et al., 2013).

AIR POLLUTANTS AND GREENHOUSE GASES

Marjan Senegačnik[1], Drago Vuk[1] Nataša Petrović[2]
[1]Faculty of Organizational Sciences, University of Maribor, Slovenia
[2]Faculty of Organizational Sciences, University of Belgrade, Serbia

Abstract: *The purpose of this paper is to discuss some facts about air pollutants and greenhouse gases. Nevertheless both groups of substances are related and often derive from the same sources these two terms should not be confused. However, it seems that this often happens in discussions. Therefore, the intention of this paper is to present the main air pollutants as well as the most important greenhouse gases and their environmental impact. At first the impacts of air pollutants on air quality and their possible adverse effects on health are briefly discussed. Special emphasis is given to the role of some of the most important pollutants as are ground level ozone, particulate matter, carbon monoxide, nitric oxide, nitrogen dioxide, sulphur dioxide, hydrocarbons and lead. The main features of greenhouse effect are also briefly shown as well as the role of some the most potent greenhouse gases as are carbon dioxide, methane, chlorofluorohydrocarbons, ground-level ozone and nitrous oxide. Additionally, the relation between both groups of substances and certain ambiguities regarding this problem are briefly discussed. It is important to take care of adequate understanding of terms of air pollution and greenhouse effect in environmental educational programs.*

Keywords*: air pollutants, greenhouse gases, atmospheric pollution, global warming, environmental education*

1. INTRODUCTION

Atmospheric pollution results from various human activities (energetic, industry, traffic etc.) and presents an outstanding problem for decades. For a long time this problem was connected mainly with the aggravated air quality in urban environments as well as in industrial areas. In last two decades increasingly more attention is devoted also to the greenhouse effect which is recognized as the reason of global warming and undesired climatic changes. However, it seems that there is often some ambiguity in publicity when discussing these two problems. Nevertheless both problems derive often from the same sources and certain substances behave both as pollutants as well as greenhouse gases these two terms should not be confused.

In the last decades increasingly more attention is concerned to incorporate awareness about air-pollution into educational programs from the elementary school level up to the universities. The intention of these programs is to improve the basic comprehension of air pollution topics and to rise environmental awareness. Students should recognize the possibilities how to reduce the level of pollution and environmental degradation (Petrović, 2009, p.205). In addition to this should be mentioned more goal oriented programs designed for people suffering from some chronic diseases which are particularly sensitive to air quality as are by example asthmatic patients (Dorevitch et al., 2008). On the other hand the greenhouse effect and its consequences as are global warming and undesired climatic changes seem to become in the period after 2000 one of the most highlighted problems not only from an environmental point of view, but generally. People have become aware of the problem and also of possibilities of reducing greenhouse gases emissions. However, there still certain lack of understanding of physical and chemical processes connected with both air pollution and greenhouse effect can be found even among university students. Therefore both phenomena are often confused.

2. AIR POLLUTANTS

As air pollutants are classified all substances present in the air which are harmful to the human health and/or have some negative impact on the environment. Some of these substances can be present in the atmosphere also according to some natural processes as are forest fires, volcanic eruptions, organic matter decay etc. As such events often happen accidentally these substances are not normal components of the air. They are sometimes also named accidental components of the air as they appear in the atmosphere occasionally and their concentration in air is quite variable (Lazarini and Brenčič, 1984, p. 270; Oxtoby et al. p.99, 1999). However, according to pollution caused by human activities these substances are often continuously present in the atmosphere particularly in urban areas and industrial regions. This is connected with aggravated air quality and adverse effect on the health of the people living in these areas. The adverse effects of these substances are not always limited to the neighbourhood of their formation as they can be

transported by air flows on considerable distances – sometimes even several thousand kilometres. Therefore the control of air pollution is not only the problem of individual countries but it should be the subject of international cooperation. Into this purpose in 1979 the Convention on Long-range Transboundary Pollution was introduced (ARSO, 2016; UNECE, 2016.)

The following substances are submitted under the control (ARSO, 2016):

- Basic pollutants: sulphur oxides (SO_x), nitrogen oxides (NO_x), non-metane volatile organic compounds (NMVOC), ammonia (NH_3) and carbon monoxide (CO).
- Particles: particulate matter with diameter under 10 µm (PM 10), particulate matter with diameter under 2,5 µm (PM 2,5), total suspended particles (TSP) and black carbon
- Heavy metals: lead (Pb), cadmium (Cd) and mercury (Hg)
- Stable organic pollutants: polyaromatic hydrocarbons (PAH), dioxins and furanes (PCDD/PCDF), polychlorinated byphenils (PCB) and hexachloro benzene (HCB).

Similarly, also Clean Air act in United States requires Environmental Protection Agency to set EPA standards for six common pollutants – which are often named also “criteria” pollutants are (EPA, 2016 a):

- Ground level (tropospheric) ozone
- Particulate matter
- Carbon monoxide
- Nitrogen dioxide
- Sulphur dioxide and
- Lead.

Six main pollutants according to EPA are schematically shown in Figure 1.

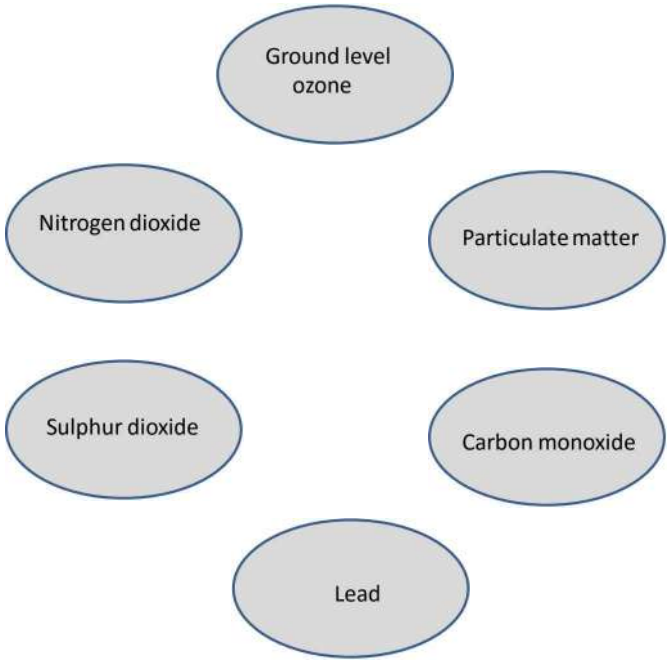

Figure 1: Six main pollutants according to EPA standards (EPA, 2016a).

Pollutants which concentrations in the air are regularly monitored in Slovenia are (ARSO, 2015):

- Particulate matter (PM 10 and PM 2,5)
- Ground level ozone
- Nitrogen oxides
- Sulphur dioxide
- Carbon monoxide and
- Hydrocarbons (Benzene).

Some main properties and adverse effects of particular pollutants are briefly discussed bellow.

Ozone

Ozone (O_3) is three atomic modification of oxygen. Unlike ordinary (two atomic) oxygen which is odourless and colourless gas ozone at normal conditions is blue gas with a pleasant odour. Ozone is strong oxidant and therefore chemically reactive substance ((Lazarini and Brenčič, 1984, p. 273). Ozone is harmful mostly for the respiratory system but also to cardiovascular system (Goudarzi et al., 2015). Its adverse effects affect particularly more sensitive parts of population like children and patients suffering from asthma. Ozone exhibits also negative impact on plant growth (Proietti et al., 2016).

When discussing ozone problems it is necessary to distinguish between stratospheric ozone (named also "good" ozone) and tropospheric or ground level ozone (named also "bad" ozone) (EPA, 2016a). It should be emphasized that in both cases this is the same substance – the difference exists only according to the position in the atmosphere.

Stratospheric ozone: Over 90% of ozone naturally is located in the stratosphere – actually between 15 to 20 km above sea level. Stratospheric ozone has no adverse effects as it cannot be breathed, but it has important role by absorbing harmful UV-B radiation. This ozone layer is called also ozone shield due to its protective effect. Ozone concentration in the stratosphere decreased in the last decades due to intensive use of chlorofluorohydrocarbons (CFC) in sprays, refrigerators etc. This effect is known as ozone holes and results in enhanced UV-B radiation intensity at the earth surface.

Ground level (tropospheric) ozone: In troposphere ozone naturally is not common. Ozone is formed by electrical discharging – for example by lightning. However, in polluted air ozone is formed as a by-product in photochemical reactions taking between nitrogen oxides and hydrocarbons. In the troposphere ozone cannot have any protecting role absorbing UV radiation but its negative impacts on human health and other living organisms are expressed. Ozone presents one of the most problematic pollutants in the last period. Its concentration raised particularly in summer as in hot sunny days there are very favourable conditions for photochemical reactions (ARSO, 2015). As ozone is not component of any exhaust gases but it is formed in the troposphere by reaction between other pollutants (nitrogen oxides and hydrocarbons) it is designated as secondary pollutant.

Particulate matter

Particulate matter or particulates include various solid particles which can have different chemical composition. They can derive booth from natural processes as well as from anthropogenic sources. Particularly problematic are soot particles resulting from incomplete fuel combustion often called also black carbon particles. They derive from various sectors as are traffic, energetics, industry and individual heating devices. Particulates are ordinarily divided into two classes:

- PM 10: particles with diameter less than 10 µm and
- PM 2,5: particles with diameter less than 2,5 µm.

Particulates present probably the most problematic kind of pollutants. They are the main reason for low air quality in urban areas and have been recognized as a reason for a great number of premature deaths. Contrary to the ground level ozone which is problematic particularly in the summer elevated concentrations of particulates are common in the cold part of the year (ARSO, 2015).

It is not surprising that PM 2,5 particulates are more dangerous as due to its smaller size they more easily penetrate into respiratory system. Particles generated by incomplete combustion (black carbon particles) are more problematic than particles deriving from other sources. Both short-term and long-term exposure to particulates results in health problems. Adverse effects can be observed on the respiratory tract (asthma, lung cancer) as well as on the cardio-vascular system (WHO, 2013; Simoni et al. 2015).

As one of the most problematic sources of particulate matter diesel (compression-ignition) engines have been emphasized which produce incomparably higher emissions of particulates than conventional petrol (spark-ignition) engines. Therefore, EURO emission standards determined permitted level of PM emissions for vehicles with diesel engines. The use of particulate filter is often necessary to fulfil the requirements of standards. However, the modern petrol engines with direct injection of fuel express even higher PM emissions than diesel engines and thus EURO 5 and 6 standard series also determine permitted PM emissions for direct injection petrol engines (Dieselnet, 2015).

Sulphur dioxide

Sulphur dioxide (SO_2) is generated by combustion of sulphur which is present in various fossil fuels (carbon, oil derivatives). Sulphur dioxide is at normal conditions colourless gas which is not poisonous but exhibits choking effect as well as irritating effect on mucosa and respiratory tract. Therefore elevated concentrations of sulphur dioxide in the air are harmful for living organisms. Sulphur dioxide is also important as acid rain precursor. (Lazarini and Brenčič. pp. 314-315).

Nitrogen oxides

Nitrogen oxides present a group of seven different compounds. All nitrogen oxides except nitrous oxide (N_2O) are toxic. Nitrous oxide is a green-house gas and will be briefly discussed in the following chapter. When discussing air pollution two other nitrogen oxides are important: nitric oxide (NO) and nitrogen dioxide (NO_2). They are often together designated as NO_x.

Nitric oxide (NO) is at normal conditions colourless gas. Nitric oxide is synthesised by high temperatures from nitrogen and oxygen which are constituents of air. Nitric oxide plays certain role in human metabolism where it serves as cellular signalling molecule and shows vasodilation effect (Abrams, 1996). However, its concentrations are recommended to be kept bellow 25 ppm (30 mg per m^3). At higher concentrations irritating effects on eyes, skin and respiratory system can be observed. Concentrations of NO above 100 ppm are immediately dangerous for life (CDC, 2011).

In air nitric oxide is oxidized to nitrogen dioxide. Nitrogen dioxide (NO_2) is at normal conditions brown gas. Nitrogen dioxide is poisonous gas which affects particularly respiratory tract. Exposure to nitrogen dioxide can lead to respiratory problems and lungs function decrease (WHO, 2003). Beside direct adverse effects nitrogen dioxide is problematic also as precursor of tropospheric ozone and acid rain.

Contrary to nitrous oxide both nitric oxide and nitrogen dioxide does not have an important direct greenhouse effect. However, as precursor of tropospheric ozone it contributes indirectly to global warming.

Carbon monoxide

Carbon monoxide (CO) is colourless and odourless gas. Carbon monoxide is result of incomplete combustion of fuels. It is extremely toxic due to its tendency for binding on hemoglobin where it prevents binding of oxygen. High concentrations of carbon monoxide can cause death what is especially dangerous in closed space. In external space the situation is not so critical however elevated carbon monoxide concentrations reduce oxygen delivery to the tissues. This can affect particularly people suffering from ischemic heart disease (EPA, 2016a).

Hydrocarbons

Hydrocarbons (HC) sometimes also designated as volatile organic compounds (VOC) or non-methane volatile organic compounds (NMVOC) are present in the air due to various reasons – they derive from traffic, energy sector, individual heating devices, industry etc. Automotive emissions present an important source of hydrocarbons, by example both petrol and diesel fuel contain mixtures of various hydrocarbons. These compounds to certain extent leave engine unburnt – in original form or only partly changed. More than hundred different hydrocarbons have been detected in the analysis of automotive exhaust. The majority of these compounds show some irritating effects but some of them (by example benzene) are carcinogenic (Mondt, 2000).

Lead

In addition to the kinds of pollutants listed above also some other pollutants are problematic as are heavy metals. As mentioned EPA standards include among six main pollutants also lead. Lead exhibit various negative affect on human organism affecting immune system, kidneys, cardiovascular system and nervous system. Lead is even in relatively low levels particularly harmful for developing nervous system in children and youth. Lead presence in the air derives mainly from metal processing, aircraft engines, waste incinerators and lead battery manufacturing. Lead was in the paste widely used for the rising of octane number of petrol. Therefore lead tetraethyl or lead tetramethyl were added to petrol. However after introduction of catalytic converters the use of lead compounds was abandoned and aromatic compounds are now used for improving the fuel octane number. According to the EPA data concentrations of lead in the air in USA decreased in the period 1980-2014 for 98 per cents (EPA, 2016 a). In European countries catalytic converters have been introduced in the beginning of 1990s. Therefore also leaded fuel use was abandoned slightly later – in Slovenia in 2001. In spite of this fact it does not happen so rarely that in some environmental discussions automotive emissions are still wrongly stated as source of lead emissions.

3. GREENHOUSE GASES

Greenhouse effect is caused by the fact that in the atmosphere exist certain substances which molecules are capable of absorbing infrared light. In such way these substances which are designated as greenhouse gases retain heath in the atmosphere. Greenhouse effect is to certain extent natural phenomena which is necessary condition that the life on the Earth is possible. Without any greenhouse effect the temperature on the Earth surface would be about 30 °C lower as it is and there would be very large fluctuations in the temperature. Therefore the greenhouse effect itself is by no means problematic. The problem exists in additional human contributions to the greenhouse effect – so called anthropogenic greenhouse effect. The main factor contributing to the natural greenhouse effect is water vapour. However in the case of water vapour there exists very efficient natural temperature regulation – when air becomes saturated with water vapour the excess vapour simply condenses. Therefore any human activity cannot increase the water vapour concentration in the air. However in the case of the other greenhouse gases there does not exist such regulating mechanism. This is the reason that concentration of these substances increased considerably in the past decades enhancing the ability of atmosphere to retain heath. This is believed by many scientists to be the reason for global warming and undesired climatic changes.

Substances contributing to the anthropogenic greenhouse effect derive mainly from the same sources as the air pollutants. Some substances also take both roles – as air pollutants and greenhouse gases. Nevertheless both roles should not be confused. In the case of classical pollutant the problem exists in the fact that substance is either poisonous or on some other way harmful to humans or other living organisms. In the case of greenhouse gases, however, the problem exists in the ability of substances to retain heath in the atmosphere. The contribution of the various gases to the anthropogenic greenhouse effect is shown in Figure 2.

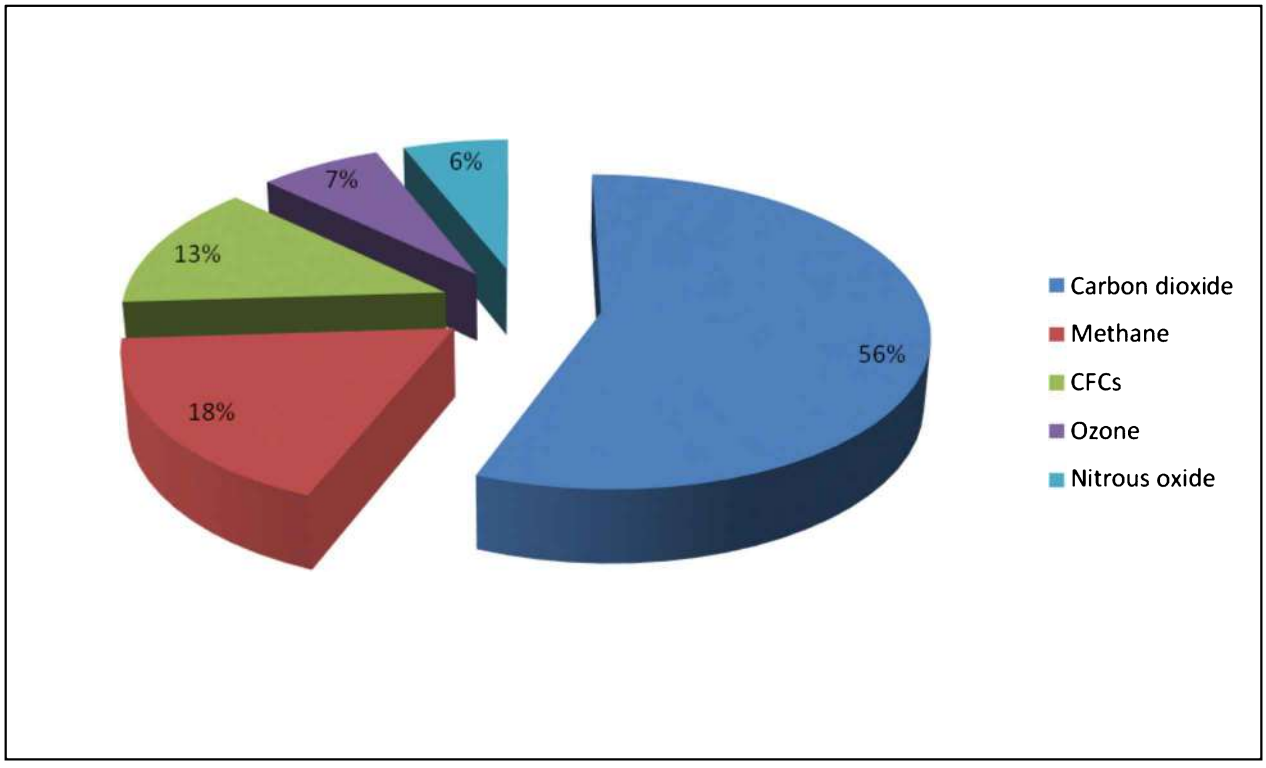

Figure 2: Contribution of various gases to the anthropogenic greenhouse effect (Botkin and Keller, 2003).

Carbon dioxide

As can be seen from Figure x carbon dioxide (CO_2) has by far the largest contribution to the anthropogenic greenhouse effect. On the other hand the presence carbon dioxide in the atmosphere has (unlike carbon monoxide) any direct harmful effect on human health or on other living organisms and is therefore not considered as air pollutant. Carbon dioxide is, of course, the product of cellular respiration. However, this does not present any problem as there has been established a perfect balance in nature – carbon dioxide produced by respiration is used in the photosynthesis. The problem exists in large additional quantities of carbon dioxide which are released in the atmosphere by combustion of fossil fuels. The final product of

combustion of any carbon containing fuel is carbon dioxide. In the case of fossil fuels – coal, oil or natural gas – great quantities of carbon which have been kept underground for millions of years are released into the atmosphere every year. Autotrophic organisms (plants, algae, cyanobacteria) are not able to process these additional quantities of carbon dioxide. The situation is still aggravated because of intensive deforestation in tropic areas.

Methane

Methane (CH_4) is product of anaerobic decay of organic matter. Nevertheless methane presence in the atmosphere derives also from natural sources human activities as are livestock breeding and waste deposition significantly contribute to the methane formation

Clorofluorohydrocarbons

Chlorofluorohydrocarbons (CFC) are problematic for the environment from two points of view. As mentioned in the previous chapter they are the main destroyers of stratospheric ozone forming in this way ozone holes. Besides this CFCs show considerable contribution to the greenhouse effect (Ramanathan, 1975; Ramanathan and Feng, 2009).

Groun-level (tropospheric) ozone

Tropospheric (ground level) ozone (O_3) has been also mentioned as one of the most problematic air pollutants. On the other hand tropospheric ozone is also important greenhouse gas.

Nitrous oxide

Nitrous oxide (or dinitrogen oxide, N_2O) is the only compound of nitrogen oxide group which is not toxic. It is known as laughing gas and is widely used as mild and very safe anaesthetic in dentistry and medicine (Sedation Dentistry 4U, 2016). Contrary to nitric oxide and nitrogen dioxide which are among the common air pollutants nitrous oxide is not designated as pollutant however it shows considerable greenhouse effect. The major source of nitrous oxide emissions is agriculture (EPA 2016 b).

4. RELATION BETWEEN AIR POLLUTANTS AND GREENHOUSE GASES

As mentioned in the introduction it seems that there is often some ambiguity when discussing about air pollutants and greenhouse gases. Nevertheless both groups of substances have negative impact on the environment and both often derive from the same sources – some substances like ground level ozone even belong also to both groups – some distinction exists between them which should be taken into account. It seems that in public discussions or by example by students when dealing with environmental content both terms are often confused.

Thus fossil fuels combustion presents both one of the main sources of pollutants as are particulate matter, hydrocarbons, carbon monoxide and nitrogen oxides as well as on the other hand also the source of carbon dioxide - the most important greenhouse gas. In the case of automotive exhaust emissions of pollutants can be efficiently lowered by catalytic converters or particle filters which have no effect on carbon dioxide emissions. Emissions of carbon dioxide can be lowered only by reduced consumption of fuel or use of alternative fuels or driving modes.

Biomass and biofuels are theoretically considered as carbon neutral. By the combustion of biomass or biofuels, of course, also carbon dioxide is formed. However, this is compensated by the photosynthesis during plant growth where the same amount of carbon dioxide is used. The net quantity of the entire cycle (plant growth – fuel production – fuel use) is zero. The carbon dioxide balance comparison for fossil fuels and biomass/biofuels is shown in Figure 3.

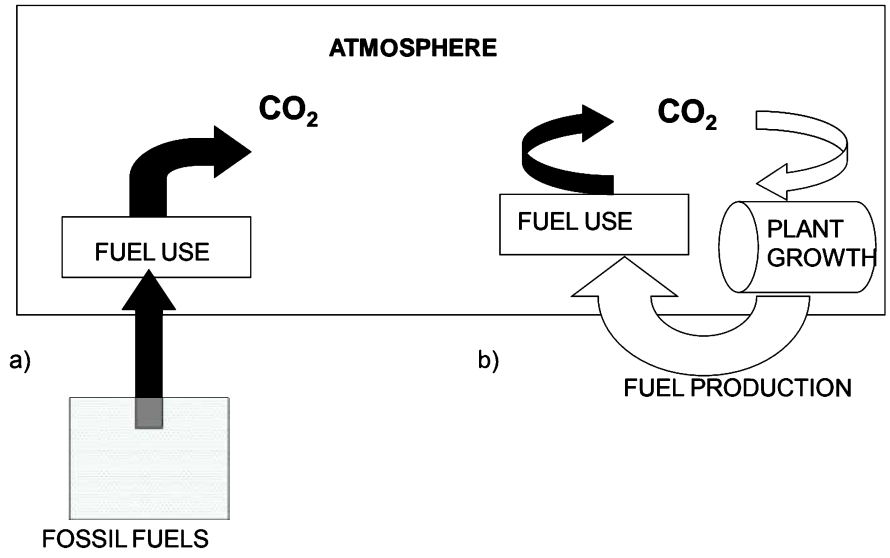

Figure 3: Balance of carbon dioxide emissions for a) fossil fuels and b) biofuels.

It should be emphasized that this is idealized picture and that in practice there are certain net emissions of carbon dioxide. Nevertheless, by the substitution of fossil fuels with fuel derived from biomass considerable lowering of greenhouse gases emission can be achieved. The actual lowering of carbon footprint depends on the source of biofuel and their mode of production. Therefore substitution of fossil fuels with fuels of biological origin is desired from the viewpoint of greenhouse effect. However, this does not necessarily mean that biofuels or biomass presents always the optimal solution when regarding pollutants emissions. In the last years, by example, in Slovenia many citizens due to increasing oil prices and insecurities in supply of natural gas have decided to change oil or gas heating for wooden pellets. Of course, their decision was motivated by economic reason. When considering environmental effects such change can be estimated as positive from the view point of greenhouse effect. However, when considering the pollutants emissions the effect is opposite as wooden biomass is problematic because of considerable emissions of particles. This can be connected with the expressed problem of elevated particle concentration in the air in urban areas in Slovenia (ARSO, 2015).

An example which also illustrates inadequate understanding of environmental topics is also by example that people still often think that lead emissions from automotive exhaust present considerable environmental problem. This really was the case in the past, however, the adding of lead to petrol in Slovenia was abandoned in 2001.

5. CONCLUSION

One of the important conditions for the comprehension of environmental problems is the ability to distinguish between different categories and terms. It seems that terms air pollutant and greenhouse gas are often confused. Nevertheless both categories are undesired from the environmental point of view and often derive from the same source and sometimes certain substance can even behave both as air pollutant and greenhouse gas these two terms should not be equated. The understanding of physical, chemical and biological processes connected with these phenomena are important for adequate understanding. Therefore it is important to devote adequate attention to this problem in environmental education programs. Rising of the level of environmental awareness is important part of environmental education and can be designated as necessary condition for improving the environment. However, adequate knowledge and comprehension of processes seems to be the sufficient condition that someone is capable of solving environmental problems.

APPLICATION OF EU LEGISLATION AIMED AT PREVENTING MAJOR ACCIDENTS IN THE CONTEXT OF ENVIRONMENTAL PROTECTION

Mirjana Kovačić[1], Astrid Zekić[1], Dundović Čedomir[1]
[1]University of Rijeka, Faculty of Maritime Studies, Croatia
mirjana051@gmail.com

Abstract:
Industrial plants are major pollutants of the environment. In order to prevent and control environmental pollution and reduce the consequences in the event of major accidents, mandatory environmental requirements have been prescribed for operators who handle hazardous substances. On accessing the EU, Croatia implemented obligations in the field of environmental protection in its legislation.
The authors examine the negative phenomena that accompany the technology of industrial plants and the measures that need to be implemented in a timely manner in order to minimize damage, but also preserve the health and lives of people and property. They analyse the content of the Safety Report and the Accident and Disaster Risk Assessment of the environment, documents which have to be prepared by each operator handling hazardous substances in their facility. The aim of the paper is to point to the importance of implementation of the legal obligation to prepare documents and apply them in industrial plants.

Keywords*: industrial plant, operator, major accidents, hazardous substances, environmental pollution*

1. INTRODUCTION

People, material and cultural goods can be exposed to different types of threats, classified by their sources into two groups:

- Natural (floods, earthquakes, other natural causes)
- Technical and technological hazards (accidents in industrial facilities, traffic, nuclear threats, epidemiological accident).

This paper investigates the technical and technological hazards caused by accidents in industrial facilities which in their work handle - produce, process or otherwise use, store or dispose of hazardous substances. The degree of risk of technical and technological accidents growing into a major disaster or catastrophe depends on the type, concentration and amount of hazardous substances used by an operator at the plant, its geophysical position, the distance from the nearest inhabited place, and the speed of reaction of rescue forces. According to the pace of the action it can be immediate (e.g. explosions), very fast (e.g. sudden release/discharge of large quantities of hazardous substances) of the ongoing gradual (e.g. the spread of dangerous substances in the air or water) or a long-term view of the ongoing and acting accident (Kulišić, 2010).
An accident in the technological plant can arise due to leakage and/or explosion of dangerous substances due to the use of faulty equipment, negligent operation or deliberate sabotage. Implementation of preventive measures to avoid accidents, restricted access to parts of the plant with hazardous substances only to authorized personnel, and responsible behaviour towards the environment demonstrated in informing the local population of the potential hazards, application of measures taken to prevent accidents and methods of self-defence until the arrival of protection and rescue forces in the event of an accident, are the obligation of all technological facilities.
The consequences and impact of such disasters on the environment can vary. Through their destructive effects on both the environment and the economy or safety of life, they affect the economic and social development of the regions exposed (Babut et al, 2015). Investments in safety are related not only to reduce financial losses, caused by industrial accidents, but they also represent an opportunity for sustainable business development and competitiveness leading to industrial growth (Kirin et al, 2012).

2. IMPLEMENTATION OF THE SEVESO DIRECTIVE INTO THE CROATIAN LEGAL SYSTEM

The incident that occurred in 1976 in Seveso, Italy from the ICMESA chemical plant for the production of herbicides and pesticides prompted the EU to regulate yet another segment of environmental protection, the one referring to the prevention and control of industrial pollution and risk management. Since then, numerous activities have been undertaken and many regulations and documents adopted in order to prevent and reduce the environmental impact of industrial plants. Protection of the environment consists in determining the thresholds for different forms of pollution, proposing legislation, and introducing preventive

and corrective measures in the event of non-compliance or any incident in the environment (Kondić & Piškor, 2010).
The Seveso Directive aims at the prevention of major accidents involving dangerous substances and their mixtures, but also at limiting the consequences of such accidents not only for human health but also for the environment and thus ensure a high level of protection across the EU in a consistent and effective way. The Directive defines certain special obligations of each legal entity/operator/company, namely, the operator, in taking measures to prevent major accidents, their obligations in the event of significant changes in the installation of the legal person/operator/company, obligations in the event of a major accident, procedures and obligations in the event of a major accident with cross-border effects, the obligation to reduce the consequences of a major accident, as well as other conditions and measures to prevent major accidents in accordance with internationally recognized standards and regulations; and the manner of submitting reports on the implementation of security measures and their mandatory content (Soflić, 2013).
At present, EU member states regulate accidents in industrial facilities handling hazardous substances according to the provisions of the Seveso III Directive. Substances and mixtures in the scope of the Seveso Directive are assigned to a generic entry based on hazard classification, or to a specific named entry when one is available (Petrus et al, 2013). Compared to the Seveso I and II (Directive 96/82 / EC), the Seveso III Directive (Directive 2012/18/EU) provides better access to information on the risks arising from the activities of industrial facilities that handle dangerous substances.
Upon its accession to the European Union, the Republic of Croatia fulfilled its obligations in the field of environmental protection and aligned its environmental policies with EU laws. Croatia aligned its legislation in the field of air, climate change, water, waste management, water and coastal areas, nature protection, industrial pollution and risk management, soil and land, chemicals and noise (Nekić & Krajnović, 2015).
The objectives of Council Directive 96/82/EC, Directive 2003/105/EC and Council Directive 2012/18/EU of the so-called Seveso II Directive, namely, the establishment of a safety management system and the shift from remedial to preventive action, were transposed into the Croatian legal system through the Regulation on the prevention of major accidents involving dangerous substances (Official Gazette 44/14). The Regulation stipulates the obligations of the operator for preventing major accidents by implementing a series of precautionary measures in accordance with the extent of the potential dangers recorded in the relevant facility.
The valid EU regulations were transposed into national legislation in 2008 with the Regulation on the prevention of major accidents involving dangerous substances, the Ordinance on the registry of installations in which dangerous substances are present and the Register of reported major accidents, the Law on Protection and Rescue, and the Regulation on the methodology for making risk assessment and protection and rescue plans. The Regulation on the prevention of major accidents involving dangerous substances prescribes the types of hazardous substances and groups of hazardous substances that are present in plants, their respective amounts and the criteria by which these substances are classified as dangerous. It also prescribes the special obligations of the operator and the plant in taking measures to prevent major accidents, the obligations in the event of a major accident, the procedure and obligations in the event of a major accident with cross-border effects, the obligation to reduce the consequences of a major accident, as well as other conditions and measures to prevent major accidents in accordance with internationally recognized standards and regulations.
The Seveso Directive obliges EU Member States to make sure that their operators who handle hazardous substances above the minimum amount implement the Policy of prevention of major accidents in their work. The policy of preventing major accidents established by the operator must be designed so as to guarantee a high level of protection of people and the environment by appropriate means, structures and management systems, all in accordance with the Regulation on the prevention of major accidents involving dangerous substances (Official Gazette 44/14).
The implementation of the Policy of prevention of major accidents is monitored through an internal control in the field of sustainable development, protection of health, safety and the environment, internal and external audits of the quality system, through a system of internal audits and through inspections. The consequences of non-compliance with the Policy are subject to penalty provisions. The Policy can be updated or revised when it needs to be harmonised with the new legislation, or when some irregularities have been detected during internal controls, audits or inspection. All employees are to be informed about the possible steps and trained for the proper procedures in their area of competence stipulated in internal documents. During regular activities of a facility, external contractors also have to receive proper training before they start working in it. The training should cover all the information about the risks, obligations and responsibilities of the contractor, and also an introduction to the Policy.
Safety reports and internal emergency plans are drafted and publicly presented for all facilities in which major accidents may occur. A safety report describes all the measures to be taken in order to prevent major accidents, as well as the structure of the safety management system.
Control is carried out thought a structural approach, which implies that the higher the presence of hazardous substances in a facility, the more stringent are the rules applying to it. Facilities with an elevated presence of hazardous substances area classified as upper tier, and those with a lower level as lower tier facilities.

The Environmental Protection Act (Official Gazette 80/13, 153/13, 78/15) defines hazardous substance as substances, mixtures or preparations present in a plant as raw materials, products, by-products, rest or semi-products, including the substances which may be expected to be created in the event of an accident and which may have harmful consequences for human health, property and the environment. The use of hazardous substances is indeed inevitable in industry, but their effect on human health and the environment can be disastrous. The direct impact of hazardous substances is reflected in the functional changes of the matter in which they act. Indirect effects of hazardous substances are most commonly manifested as fires, consequences of explosions and radiation of radioactive substances, due to the fact that some of them react with oxygen (fuel as flammable liquids, gases and solids, oxidizers, ignition devices, corrosive substances), quickly decompose chemically (explosives, explosive-filled objects), or react with substances with which they come into contact, e.g. with water or other substances (Pavelić, 2013).
The Regulation on the prevention of major accidents involving dangerous substances (Official Gazette 44/14) stipulates the method of determining the quantities, the permitted quantities and the criteria according to which these substances are classified as dangerous; the method of submitting and mandatory content of the notification of the presence of hazardous substances in a plant; the mandatory content of the Statement of conduct with regard to the prevention of major accidents; the mandatory content of the Safety report, the manner of application for approval of the Safety report; the mandatory content and manner of giving approval; the manner of application for extension of approval issued and the relevant deadlines; data confidentiality agreement; the manner and conditions of supervision of the implementation of activities and measures in accordance with the issued approval of the Safety report; special obligations of the operator in: taking measures to prevent major accidents, in the event of significant changes in the plant, in the event of a major accident, the procedure and obligations in the event of a major accident with cross-border effects, other conditions and measures to prevent major accidents in accordance with internationally recognized standards and regulations, the content and manner of keeping records of operators and their plants in which accidents with a domino effect may occur, and other relevant issues. The Annexes of the Regulation comprise:

- List of hazardous substances and the threshold quantities above which the substances are considered dangerous (Annex I.A)
- List of hazardous substances and the threshold quantities above which the substances are considered dangerous (Annex I.B.)
- Forms to be used to report on the presence of hazardous substances (Annex II).
- The form to be used to report on the presence of hazardous substances in the area of a plant with quantities below the threshold quantities under Annex I.A or Annex I.B of the Regulation (Annex II.A)

The Regulation applies to the areas of plants in which dangerous substances were identified in quantities equal to or greater than those listed in Annex I.A, parts 1 and 2, and in Annex I.B. of the Regulation.

3. SAFETY REPORT

The purpose of the Safety report is for the operator to demonstrate that they have taken all the technical, organizational and management measures to prevent major accidents and that all the possible risks of a major accident have been analysed. It is the operator's task to enable the competent authorities to evaluate the safety of a plant in terms of the possibility of major accidents occurring in it.
A safety report typically contains information on the management and organizational of the plant from the aspect of preventing major accidents, and refers to the policy of preventing major accidents and safety management system, which includes the organization and personnel, identification and assessment of significant risks, supervision of the plant operations, change management, planning for emergency, monitoring effectiveness, audit and inspection.
Description of the location of the plant area includes, in addition to its description, the identification, definition and analysis of adjacent facilities and areas, including public facilities such as hospitals or schools that could be the source of or increase the risk of accidents and their consequences through the domino effect. Preventive measures are implemented through permanent control of security systems, equipment maintenance and supervision of working procedures.
The operator must evaluate the possible consequences of a major accident for both human health and the environment, and calculate the size of the impact area according to the "worst case scenario". When formulating a scenario, the probability of natural disasters occurring within the area of the plant are taken into account and used as a starting point for predicting the measures, procedures and technologies that would be able to reduce the risks to a minimum considered (Plavšić, 2006). Description of all unwanted scenarios that could lead to a major accident in an industrial plant, the probability of their occurrence and the estimated effects require an accurate presentation of the results, including the "worst case scenario". Based on the results of such analyses, preventive, accidental and palliative procedures for reducing the effects on the area

affected by a major accident are defined (Toth et al, 2010). The operator must secure the safety feasibility report at all times (Buljan & Mikulić, 2010).
An integral part of the Safety report is the internal emergency plan, which must contain all the data and information contained in Annex V of the Regulation and the provisions governing protection and rescue. The internal emergency plan can be used for preparation of the external protection and rescue plans for operational and rescue forces in the event of accidents involving hazardous substances or those of natural and technical-technological causes that can result in disasters or major accidents, including the ravages of war and the consequences of terrorism. The preparation of external emergency plans is the obligation of the counties and the City of Zagreb pursuant to a decision of the Director of the State Administration for Protection and Rescue. After completion of a draft external emergency plan, its parts that are not confidential should be presented to the public, and interested and professional public invited to give their opinions, suggestions and comments. Public participation can also use the private sector so as to help it discover inefficiencies in the production process of raw materials, energy consumption, which can lead to an actual reduction in production costs (Ofak, 2009).

4. RISK ASSESSMENT OF THE POPULATION, MATERIAL AND CULTURAL GOODS AND THE ENVIRONMENT FROM DISASTERS AND MAJOR ACCIDENTS

Risk assessment of the population, material and cultural goods and the environment from disasters and major accidents is the baseline document for the development of plans, operational plans and civil protection plans. It is prepared and adopted for the territory of municipalities, cities, counties, the City of Zagreb and the Republic of Croatia. Such assessment also has to be made by all legal persons handling hazardous substances. The assessment includes the potential threat to the population, material and cultural goods and the environment from the occurrence and impact of disasters and major accidents, the necessary funds for protection and rescue, and the preparedness to act in the protection and rescue.
Due to the variety of accidents on the one hand, and their consequences on the other, analysis of the threat of natural and other disasters must consider several related aspects associated with the natural, civilisational and other phenomena that exist in the monitored area. It evaluates the likely intensity of these phenomena, the possible surprise effect, namely, the speed with which a given phenomenon may occur and develop, the degree of threat to people and property, the overall level of social organization, and the preparedness for prevention, protection and rescue, especially for those in charge of activities and tasks in the field of protection and rescue. Furthermore, account should be taken of the number of local population in a given time period that may be at risk, especially during the tourist season.
Hazard analysis includes methods of determining the sensitivity of a geographical area with regard to the discharge of hazardous substances, identification of potential sources of emissions of hazardous substances from stationary facilities that manufacture, process or otherwise use, store or otherwise dispose of substances that are generally considered dangerous. Using software and mathematical calculations and a series of elaborations by each individual case of threat, it is possible to calculate the degree of risk for the areas for which the assessment is being made.
The content of the assessment is determined by the Regulations on the methodology of development of threat assessment and protection and rescue plans (Official Gazette 38/08). The assessment includes:

1. the type, intensity and effects, and possible consequences of natural and technical-technological disasters and major accidents for the population, material and cultural goods and the environment
2. protection and rescue forces,
3. final assessment,
4. maps.

Local and regional governments define and prescribe preventive measures the implementation of which will reduce the consequences and effects of the natural and technological disasters and major accidents, and increase the level of safety of the population, material goods and the environment in the special excerpt from the Assessment, entitled Requirements for protection and rescue in physical planning documents.

5. ANALYSIS OF THE SITUATION IN THE REPUBLIC OF CROATIA

The Environmental Protection Act (Official Gazette 80/13, 153/13, 78/15) stipulates the introduction of implementing legislation governing the prevention of major accidents involving hazardous substances, and the adoption of the Ordinance which prescribes the manner of organization and content and method of keeping the Register of facilities in which dangerous substances are present and the Register of reported major accidents. The presence of hazardous substances in small quantities requires procedures in accordance with regulations governing protection and rescue, and the data submitted to the Environmental Protection Agency and the State Administration for Protection and Rescue.

The list of plant areas in Croatia in which dangerous substances of the lower and higher tier are present ("Seveso-bound") and those bound by Annex II.A is shown in Table 1.

Table 1: Facilities in which dangerous substances were present on 19/01/2016

Counties and the City of Zagreb	Facility area category - upper tier	Facility area category – lower tier	Facility rank – lesser amount	Facilities bound by Annex II.A	Facilities currently applying
Zagreb	3	3	0	27	21
Krapina-Zagorje	2	1	0	21	5
Sisak-Moslavina	5	5	0	3	26
Karlovac	1	4	0	9	18
Varaždin	0	2	0	21	2
Koprivnica-Križevci	1	0	0	14	1
Bjelovar-Bilogora	1	0	0	15	2
Primorje-Gorski Kotar	4	0	0	46	2
Lika-Senj	0	1	0	18	1
Virovitica-Podravina	0	1	0	8	2
Požega-Slavonia	0	0	0	12	3
Brod-Posavina	1	0	0	14	7
Zadar	0	0	1	25	5
Osijek-Baranja	1	4	0	35	1
Šibenik-Knin	0	0	3	13	4
Vukovar-Srijem	0	0	0	24	2
Split-Dalmatia	2	4	0	39	7
Istria	1	3	0	53	40
Dubrovnik-Neretva	1	0	0	19	2
Međimurje	0	1	0	17	1
City of Zagreb	3	4	0	58	9
Total	26	33	4	491	161

Source: authors according to the Register of installations in which dangerous substances are present

A total of 63 areas of the facilities bound by requirements of the Seveso Directive were found, of which 26 of the upper tier, 33 of the lower tier, and four areas with lesser amounts. There were 491 areas of facilities with quantities below the threshold values given in Annex IA that are bound by Annex IIA of the Regulation, and 161 business entities that are in the process of application in accordance with Annex IIA.

6. CONCLUSION

All business entities that use hazardous substances in their daily operation are exposed to the potential risk of accidents caused by fire, explosion or release of hazardous materials. In order to reduce such risks, a number of organizational and technical measures are applied.

It is the obligation of the operator to produce a safety report to demonstrate that appropriate measures will be taken for the identified risks of major accidents in the plant in order to prevent such accidents and limit their consequences. General and interested public must be informed about the possibility of a major accident occurring and its potential consequences. An appropriately drafted internal emergency plan can be used for preparing an external emergency plan.

Assessment of the level of risk of disasters and major accidents to which the population, material and cultural goods and the environment are exposed is used to define the threat and risks that could endanger local communities. The needs and possibilities of prevention, reduction and elimination of consequences of disasters and major accidents are also assessed.

Precautionary measures are taken, as far as possible, at the very source, i.e., in the facility, in order to minimize the possibility of a major accident. Timely preparation of an accident scenario and the acquired knowledge and skills can help prevent accidents and mitigate their consequences.

COMBINING LEAN AND GREEN IN LOGISTICS: A SURVEY OF LOGISTICS COMPANIES IN SLOVENIA

Vaska Pejić*[1], Andrej Lisec[1]
[1]Faculty of Logistics, University of Maribor
*Corresponding author, e-mail: vaska.pejic@um.si

Abstract:*Lean and green management practices represent a major opportunity for Slovenian logistics companies to competently respond to the escalating expectation of a global logistics market and achieving environmental performance profitably. In this paper, a survey analysis on lean logistics and green logistics among Slovenian logistics companies will be presented. Although similar analysis on lean and green do exist, only a few of them focus on the field of logistics as such and also none of them have been performed in Slovenia. Key findings indicate that the surveyed Slovenian logistics companies obtain more certificates and/or recognition concerning lean than green, most of them prove their leanness and/or greennesswith ISO standards ISO 9001 and ISO 14001 and that the surveyed companies in most implement lean and green concepts within their companies.*

Keywords*:logistics, lean, green, sustainable, ISO standards*

1. INTRODUCTION

A key task of a well function logistics system is that it has to guarantee that goods are in the right place, at the right time and in the strictly necessary quantity. The latter allows us to fully comprehend its real mission, which is to better ensure the space and time availability of goods through flows management (La Londe, 1983). Its activities are often identified with a high degree of manual control and human resource management of, which in turn greatly affects the execution of operations. Especially costly time interruptions, which result out of failure in material or information flows, explain the importance of a well-functioning logistics system (Christopher, 1992).

Maintaining low costs in a bid to gain/obtain competitiveness is of substantial significance; consequently, companies are forced to examine every part of their organization for potential improvements. It is therefore not surprising that there are many initiatives for possible improvements in logistics. We also have to acknowledge that global logistics costs were estimated at USD 9,177 billion in 2015 (Armstrong & Associates, 2014), so every failure, inconsistency or any kind of waste can represents great costs.

Besides eliminating non-value added activities in logistics, also assuring sustainable processes is one of modern companies‟ challenges. The environmental aspect and ecological consciousness have increased drastically over the last two to three decades, especially in the developed economies. This has been shown by BearingPoint research (*Supply Chain Monitor "How Mature is the Green Supply Chain?"* 2008), where 35% of global companies said that they have incorporated a green supply chain policy in the company‟s vision.

The area of logistics has been rarely exposed to research on lean and green, most of them were in fact made in other fields, mainly in the area of lean manufacturing management. Therefore, this study represents a contribution for academia and industry. For academia mainly due to the fact that this research is one of the first of its kind and it takes into account both paradigms in the area of logistics. For industrials it will provide an insight on the current state of lean and green logistics implementation in Slovenia‟s logistics companies, new trends and possible contributions from each paradigm.

The most important aim of this survey, of which this paper presents some results, is to analyse the respondent‟s familiarity with the terms „lean logistics‟ and „green logistics‟, their opinion on the implementation of both concepts within their own companies. Furthermore, the attempt has been made to highlight which certificates or recognition from both areas Slovenia‟s logistics companies hold.

2. METHODOLOGY

First of all an extensive analysis of previous research has been conducted. The search has been restricted to articles which contained specific keywords connected to lean logistics and green logistics in Emerald Online, Science Direct, Springer Link and Taylor and Francis portals. For keywords we firstly employed a brainstorming technique and then decided to narrow our choices and only focus on international journal articles which contained specific keywords closely associated to lean logistics and green logistics. At the same time keywords containing „supply chain", „production" or „manufacturing" were mainly excluded. The main reason lies in the fact that the aim was to narrow the scope of the research to a specific field – logistics rather than supply chain management or production and manufacturing.

It was further noted that some of the international journals have very little published articles, limited access to some of them, as well as the lack of a narrow focus on any part of lean logistics, green logistics and/or green and lean logistics.

Later on we prepared a research questionnaire and obtained 104 completed questionnaires.Our relatively small sample size required special attention to formulate appropriate conclusions, which is why we combined the statistical analysis with the abductive approach (Kovács & Spens, 2005) (see Figure 1).

The analysis was conducted through 4 phases: (1) theoretical overview where conceptual and descriptive methods were used, (2) the empirical phase features an empirical methodology which employs quantitative approaches to collecting primary data for our database and a statistical analysis.

Our survey was divided into two parts, where the first set consisted of 7 questions related to demographic issues. Second part consisted of 7 questions which were divided by individual areas of intralogistics, for which it was necessary to evaluate two aspects: lean logistics and green logistics aspect.

This means that individual company evaluated the importance of every part of intralogistics area. For the purpose of this paper we only focused on the first part, which also contained two questions regarding the familiarity with both of terms, their implementation in companies and also certificate or recognition connected to lean or green which companies could hold. (3) Theory matching between theory findings and statistical analysis findings; and at last (4) theoretical conclusions and application.

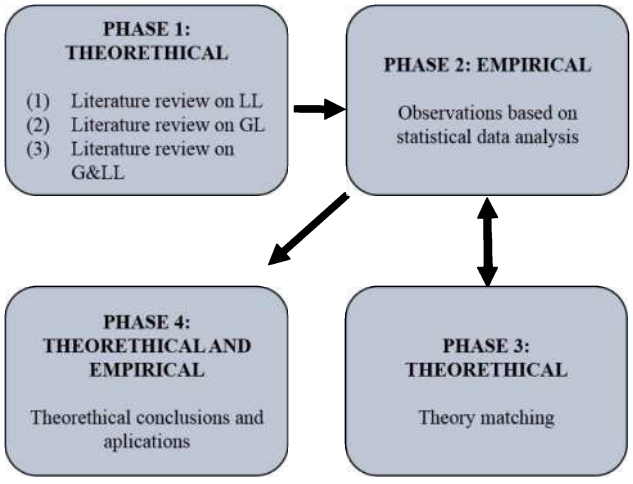

Figure 1: Abductive reasoning process

3. LEAN AND GREEN PARADIGMS IN LOGISTICS

Taiichi Ohno who was one of beginners of lean thinking and also worked in the Toyota Production System in the 80"s identified seven wastes, activities which add cost but no value: (1) production of goods not yet ordered, (2) waiting, (3) rectification of mistakes, (4) excess processing, (5) excess movement, (6) excess transport and (7) excess stock (Monden, 1993).

Since there are not only manufacturing or production created activities which add no value, industrials also started to put their focus on logistics non-value-added activities. From here on the new concept – lean logistics – appeared. By Baudin (2004), lean logistics is a logistical dimension of lean manufacturing. Its primary objective is to deliver the right materials to the right locations, in the right quantities, and in the right presentation; its second to do all this efficiently.

During 1990"s another practice of responding to environmental issues in a socially responsible manner – environmentalism has become increasingly important. It has been characterized as one of the most significant force shaping the economy (Limoubpratum, Shee, & Ahsan 2014; Murphy, Poist, & Braunschweig, 1995). Many articles based on concern for the environment have at that time also been written in the field of business and logistics (Van Hoek, 1999; Wu & Dunn, 1995).

The fundamentals of greening as a competitive initiative have also been discussed by Porter & van der Linde (1995). Their basic reasoning was that investments in greening can be resource saving, waste eliminating and productivity improving. They state that green initiatives could lower not only the environmental impact of a business but also raise efficiency, possibly creating major competitive advantages in innovation and operations. Skjoett-Larsen (2000) wrote a foresight work upon European companies facing new challenges in the next millennium one of which is also green logistics. The author stipulates that within the next five to ten years green supply chains will increasingly dominate the theory and practice in the logistics area. Moreover, with green logistics a completely new sub-sector of logistics appeared, using new models and tools as green logistics management. The trend is therefore to switch from traditional logistics to green logistics (Beškovnik & Twrdy, 2015).

There are separate streams of research on lean logistics and green logistics, however few researchers explore some intersections of these two paradigms (Banawi & Bilec, 2014; Garza-Reyes, 2015). This represents a critical point for companies which are most likely missing opportunities for synergies that are available with improved simultaneous introduction and also may fail in addressing important trade-offs that may occur when there is incompatibilities between strategic initiatives.

Lean, according to (2006) is based on the assumption that time contractions reveal hidden quality problems and their solutions lead to improved, cost-effective business processes. The authors further contend that if time contraction implies to lower emissions, then as by the emissions measurements, a lean system is always greener. If the reduction of time does not lead to reduced emissions, it is necessary to find a way or further changes of the lean system to become greener.

Researchers state that lean companies, which include green practices, achieve better lean results than companies which do not. Their findings indicate that only when both concepts are implemented simultaneously, they can disclose their full potential and make a greater contribution than if they were implemented separately. As such (Bergmiller & McCright, 2009), emphasize that while lean practices can lead to positive environmental contributions, conversely environmental practices often lead to improved lean practices.

Nevertheless, a waste of both paradigms is defined otherwise but both respectively target the removal of excess: the waste in the broadest sense. Lean logistics is focusing on removing 8 wastes related to efficient flow, while green logistics is focusing on green wastes in the form of inefficient use or waste production (Kleindorfer, Singhal, & Van Wassenhove, 2005).

4. ANALYSIS AND RESULTS

The following sub-sections present and discuss our results.

Analysis of demographic data referring to data on the respondents and companies in which respondents are employed. The data are presented in the following tables.

Table 1: Demographic data related to companies, in which respondents are employed

Variables	Replies	Percent (%)
D1 Company activity		
Service	81	38.21
Manufacturing	97	45.75
Trade	34	16.04
D2 Company size		
a) Up to 10 employees (micro enterprise)	76	35.85
b) Small (11-50 employees)	63	29.72
c) Medium (51-250 employees)	37	17.45
d) Large (more than 251 employees)	36	16.98
D3 Company as part of an international corporation		
a) Yes	41	19.43
b) No	170	80.57

A detailed examination shows that on the question »what is the main activity of the company according to the standard classification of activities« answered 212 respondents. The results show that most respondents come from manufacturing activities (45.75%), services (38.21%) and least from trade (16.04%).

Concerning question about company size reveals that most of the respondents come from micro enterprises (35.85%) and least from the category of large companies (16.98%). 80.57% of companies, participating in our survey state they are not part of an international corporation.

The following demographic data refers to data concerning our respondents (see Table 2).

Table 2: Demographic data related to the respondents

Variables	Replies	Percent (%)
D4 Working position		
a) Senior management	70	35.90
b) Head of Logistics	40	20.51
c) Head of Purchasing	8	4.10
d) Head of Production	5	2.56
e) Head of Warehouse	5	2.56
f) Technical Assistant in logistics	13	6.67
g) Head of processes/projects, which also deals with logistics	13	6.67
h) None of these	41	21.03
D6 Gender		
a) Male	113	58.85
b) Female	79	41.15
D7 Highest level of education completed		
a) High School or less	39	20.21
b) College	50	25.91
c) High Technical School	46	23.83
d) University degree or more	58	30.05

We have included senior managers (35.90%), heads of logistics (20, 51%), heads of purchasing (4.10%), heads of production (2.56%), heads of warehouse (2.56%), technical assistants in logistics (6.67%) and heads of processes/projects, which also deal with logistics (6,67%). 21.03% of respondents carry out other work.

Respondents‟ average age is 35 years. In survey participated 113 men (58.85%) and 79 (41.15%) women.

For the question concerning “completed education” largely participated in the survey those with a university degree or more (30.05%), followed by those with completed high school (25.91%), higher professional education (23.83%) and the last, the ones with high school or less (20.21%).

The next question was connected to certificates or recognition concerning lean and green management which companies could hold. There were more than one answer possible.

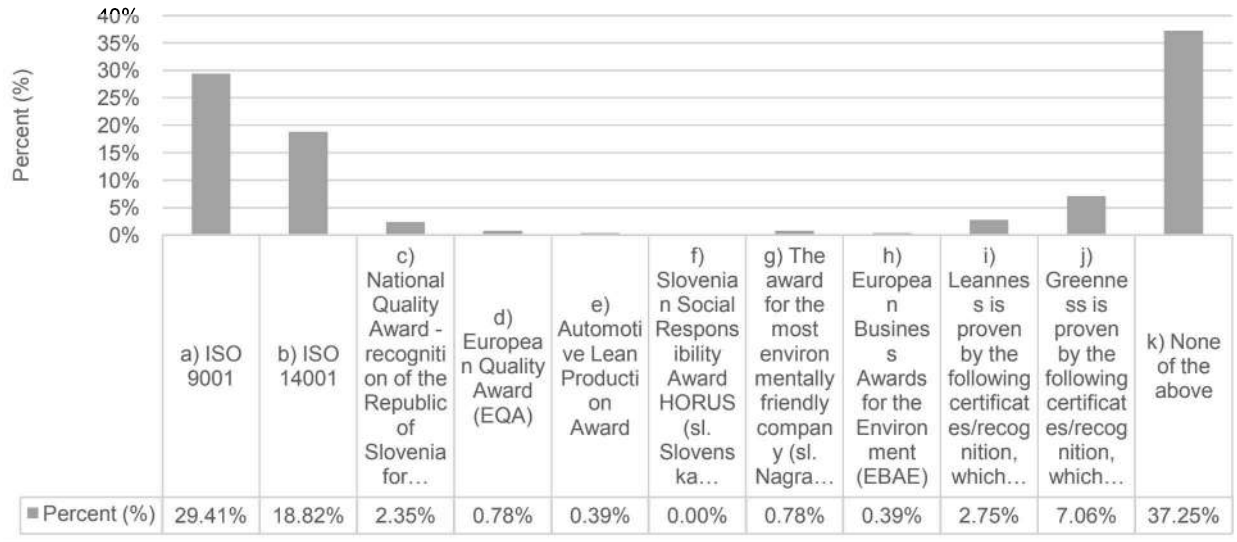

Figure 2: Data related to certificate or recognition obtained by surveyed companies

Figure 2 shows that 255 respondents answered this question of which most of the companies holds ISO 9001 (29.41%) and ISO 14001 (18.82%). 7.06% of respondents claim that they prove greenness by the following certificates/recognitions, which are not on the list and 2.75% claim that they prove leanness by the following certificates/recognitions, which are not on the list. 2.35% held the National award for quality - the recognition of the Republic of Slovenia for business excellence, 0.78% held the European Quality Award (EQA), and the prize for the most environmentally friendly company. 0, 39% of the companies held the Automotive Lean Production Award and European Business Award for the Environment (EBAE) and no one holds the Slovenian award for social responsibility HORUS.

Figure 3presents data related to the respondent"s opinion with regard to the implementation of lean and green concepts within their companies.

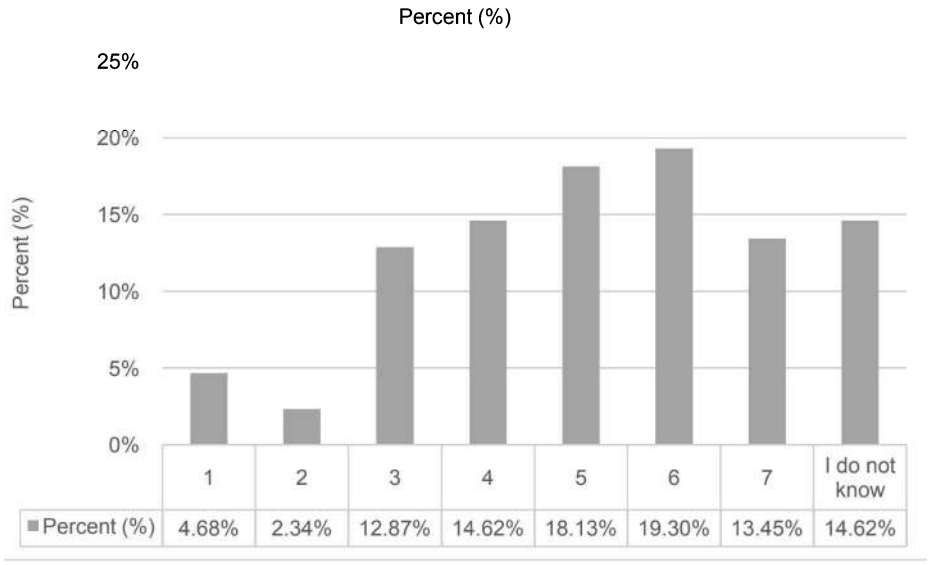

Figure 3: Data related to the respondent's opinion with regard to the implementation of a lean concept in their own company

The results show that for the opinion on the implementation of lean concept in their own company, the respondents on the 7 point Likert scale usually rated very highly, with level 6 (19.30%) and 5 (18.13%), but at least with grade 2 (2.34 %) and 1 (4.68%). The answer "I do not know" was given by 14.62% of the respondents. The arithmetic mean of the responses is 5.24.

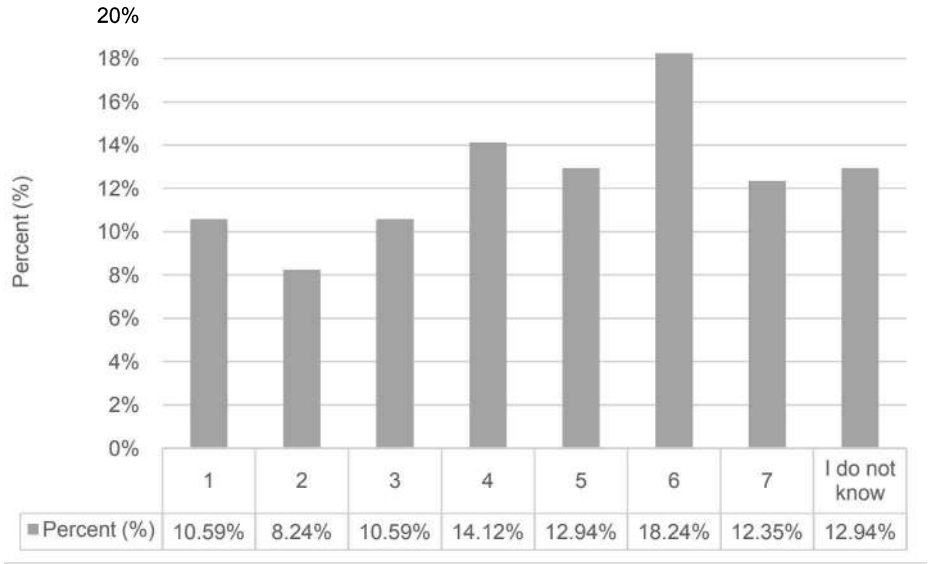

Figure 4: Data related to the respondent's opinion with regard to the implementation of a green concept in their own company

The results show that for the opinion on the implementation of green concept in their own company, the respondents rate on 7 point Likert scale usually as very high, with a rate of 6 (18.24%) and 4 (14.12%), but at least with grade 2 (8.24%), 1 and 3 (10.59%). The answer "I do not know" has given 12.94% of the respondents. The arithmetic mean of the responses is 4.79.

5. CONCLUSION

Survey findings indicate that most respondents come from manufacturing activities (45.75%) and most of the respondents from micro enterprises (35.85%). The first results are logical since the area of manufacturing is one of most developed and also largely represented Slovenia"s sectors. Also, majority of Slovenia"s companies are micro companies.

Approximately 80% of the surveyed companies are not part of an international corporation which provides an insight on a national level.

Most of our survey participants work in top management (senior managers and heads of logistics), are highly educated and are on average 35 years old. There were also almost equal parts of female and male participants participating in the survey.

In the analysis we were interested in any certificates or recognition regarding lean and green paradigms, which Slovenian logistics companies could hold. The results indicate that most of the companies hold ISO 9001 (29.41%) and ISO 14001 (18.82%) standards. Approximately 7% and 3% of respondents claim that they prove greenness/leanness by the following certificates/recognitions, which are not on the list. Approximately 2% hold the National award for quality - the recognition of the Republic of Slovenia for business excellence, less than 1% hold EQA, and the prize for the most environmentally friendly company. Only a few hold the Automotive Lean Production Award and EBAE and no one holds the Slovenian award for social responsibility HORUS.

From this on we conclude that surveyed Slovenian logistics companies obtain more certificates/recognitions concerning lean than green, also most of them prove their leanness/greenness by the mentioned ISO standards. The future research question remains which are the other certificates or recognitions with which they prove leanness/greenness within their own companies.

We were also curious about the respondents" opinion in regard to the implementation of lean and green concepts within their companies. The results show that on the opinion on the implementation of lean concept in their own company, the respondents on the 7 point Likert scale rated very highly (mean 5.24). On the implementation of green concept in their own company, the respondents also rated very highly (mean 4.79). From this we conclude that surveyed Slovenian logistics companies state that they mainly implement lean and green concepts within their companies. Our findings may be useful to suggest some missing areas or unresolved issues in our knowledge of lean logistics and green logistics. Also, in any business area, a new thought process will be embraced by many new practitioners who will put their own way of thinking on our survey results.

Abstract: *The last few decades were marked by the growing concern for the ever growing pollution of the environment. This forced professionals in all fields - the industry, the government, institutions and the non-government sector - to put more of their attention on strategies and management which aim to reduce these negative impacts and achieve the goals of sustainable development. This reflects the key role of environmental management, for the establishment of a company-wide environmental management programs and systems contributes to a significant reduction in negative environmental impacts and the efficient use of resources and energy. To support these listed requirements of sustainable development, this paper introduces the impact of environmental management trends and practices on sustainability.*

Keywords*: environmental management, sustainability, sustainable development, environmental management trends, environmental management practices*

1. INTRODUCTION

Environmental problems have reached their critical point in the 21st century (Bonnett, 2007; Mert, 2006; Robert , Flood , & Carson , 1993) and continue to grow rapidly: global warming, worsening living conditions, disruption of the ozone layer, the impact of conservation, increase of solid waste, radioactive contamination, destruction of forests, the extinction of plant and animal species... (Petrović, 2012). In parallel, an increase in the global population has led to an increase in inefficient consumption of natural resources (Vigon et. al., 1992).

Also, in the last few decades, it has become clear that environmental issues and the questions of environmental protection shape the future, not only of the industry, but of all human activities (Petrović, 2013). The growing public environmental awareness and concern for environmental protection has led to the conclusion that the issues and environmental problems cannot be solved at the national, but instead on an international level, and that actions must be carried out that will influence the government to enact environmental laws, policies and standards (Bary, 2007; Ehrenfeld, 1994).

It's environmental management's task to achieve the necessary reduction and elimination of negative impacts on the environment wherever possible, in order to achieve the goals of sustainable development, and bearing in mind the concept of sustainable development which is based on the principle of intergenerational justice, which is defined as meeting the needs of present generations without jeopardizing the ability of future generations to also meet their needs (WCED, 1987). The role of environmental management is particularly important because it represents a broad area that is developing rapidly, and its issue affects not only all people, but all their activities because of its key role in achieving sustainable development (Barrow, 2006). Further on, economic and social demand of environmental sustainability urges companies to embrace the strategic importance of environmental management trends and practices for competitive advantage (Sroufe, 2003; Yang Lin, Chan, & Sheu, 2010).

2. SUSTAINABILITY

At the United Nations Conference on Environment and Development (UNCED) (Earth Summit, 2002) participating countries agreed to start with the development and adoption of national sustainable development strategies. The consequence of that were amendments to the definition of sustainable development – together with environmental protection, economic and social goals added, having in mind that all these three pillars are of the same importance for achieving development and sustainability on local and global level (Berg, 2009; Roseland, 2000; Roseland, 2005).

Later on, these frameworks are improved with values that refer to natural, physical, economic, human, social and cultural capital (Roseland, 2005). Also, it was concluded that young people have a crucial role in the process of democratic decision making and public participation in all activities connected with sustainable development and sustainability (UNECE, 1998; Borojevic, Petrovic, & Vuk, 2014; Borojević, Petrovic, & Vuk, 2015).

Further on, there is much discussion about how one "defines" sustainability, and related concepts (WCED, 1987; Pezzey, 1989; Costanza, 1991; Pearce & Atkinson, 1993; Costanza & Patten, 1995). Besides that, all definitions of sustainability must meet the following criteria (Sustainable Measures, 2016):

- "Living within the limits.
- Understanding the interconnections among economy, society, and environment.
- Equitable distribution of resources and opportunities."

Some definitions of sustainability are:

- Sustainability refers to "improving the quality of human life while living within the carrying capacity of supporting eco-systems." (IUCN, 1991; WWF, 1991)
- Sustainability is defined "as long-term health and vitality of a region, including the cultural, economic, environmental and social aspects as one whole." (Sustainable Seattle, 2016)
- "Sustainability calls for a decent standard of living for everyone today without compromising the needs of future generations." (UN, 2016)
- "Sustainability is based on a simple principle: Everything that we need for our survival and well-being depends, either directly or indirectly, on our natural environment. To pursue sustainability is to create and maintain the conditions under which humans and nature can exist in productive harmony to support present and future generations." (EPA, 2016)

In the context of sustainability, we should definitely mention a new sustainable development agenda for the period of 2015-2030 - Transforming our world: the 2030 Agenda for Sustainable Development as well as its The 17 Sustainable development goals (UN, 2015):

- Goal 1: End poverty in all its forms everywhere.
- Goal 2: End hunger, achieve food security and improved nutrition and promote sustainable agriculture.
- Goal 3: Ensure healthy lives and promote well-being for all at all ages.
- Goal 4: Ensure inclusive and quality education for all and promote lifelong learning.
- Goal 5: Achieve gender equality and empower all women and girls.
- Goal 6: Ensure access to water and sanitation for all.
- Goal 7: Ensure access to affordable, reliable, sustainable and modern energy for all.
- Goal 8: Promote inclusive and sustainable economic growth, employment and decent work for all.
- Goal 9: Build resilient infrastructure, promote sustainable industrialization and foster innovation.
- Goal 10: Reduce inequality within and among countries.
- Goal 11: Make cities inclusive, safe, resilient and sustainable.
- Goal 12: Ensure sustainable consumption and production patterns.
- Goal 13: Take urgent action to combat climate change and its impacts.
- Goal 14: Conserve and sustainably use the oceans, seas and marine resources.
- Goal 15: Sustainably manage forests, combat desertification, halt and reverse land degradation, halt biodiversity loss.
- Goal 16: Promote just, peaceful and inclusive societies.
- Goal 17: Revitalize the global partnership for sustainable development.

These objectives are the new trends of sustainability, which should affect the actions over the next 15 years in areas of critical importance for humanity and the planet.

3. ENVIRONMENTAL MANAGEMENT TRENDS AND PRACTICES FOR SUSTAINABILITY

By the late 20th century the need for structured environmental management became evident because of global pollution, loss of biodiversity, soil degradation, and urban growth. These developments are not easily tangible even though advances have been made in understanding the structure and functions of the environment, in monitoring impacts, data handling and analysis, modeling, assessment, and planning. Basically, environmental management aims to coordinate and focus such developments, to improve human wellbeing, and lessen or prevent further damage to Earth and its organisms (Barrow, 2006).

Environmental management is related to environmental planning. Further, the focus of environmental management is on: implementation, monitoring, auditing, practice and coping with real world environmental issues. Environmental management is a field of study dedicated to understanding human-environment

interactions and the applications of science in solving environmental problems and achieving sustainable development goals.

We see that environmental management is an approach to environmental stewardship which integrates ecology, policy making, planning and social development and includes: the prevention and resolution of environmental problems; establishing and nurturing institutions that effectively support environmental research, monitoring and management; warning of threats and identifying opportunities; sustaining and, if possible improving, existing resources; where possible improving "quality of life"; identifying new technology and/or policies that are useful (Barrow, 2006). So, environmental managers are those whose livelihood is primarily dependent on the application of skill in the active and self-conscious, direct or indirect, manipulation of the environment with the aim of enhancing predictability and proactive acts in a context of social and environmental issues.

There isn't just one universal definition of environmental management, because of its very broad scope and the diversity of involved specialties.

However, environmental management has following characteristics: it is generic term; it promotes sustainable development; it is a multidisciplinary and interdisciplinary approach; it integrates science, policy making and planning; it concerns ranges from local to global; it shows opportunities, threats and problems; it emphasizes stewardship, rather than exploitation.

Some definitions of environmental management are:

- Management of the environmental performance of organizations, bodies and companies (Sharratt, 1995).
- Environmental management – a generic description of a process undertaken by systems-oriented professionals with a natural science, social science, or less commonly, an engineering, law, or design background, tackling problems of the human-altered environment on an interdisciplinary basis from a quantitative and/or futuristic viewpoint (Barrow, 2006).
- A multi-layered process associated with the interaction of state and non-state environmental managers with the environment and with each other (Wilson & Bryant, 1997).

Further on, environmental management systems (EMSs) create a culture of continuous improvement, employee empowerment, waste minimization, and pollution prevention (Dües, Tan, & Lim, 2013). Also they irepresent instruments of environmental management with a high degree of formalization and unification. ISO (The International Organization for Standardization) defines environmental management system (EMS) as a management framework for reducing environmental impacts and improving organizational performance over time. The system follows a repeating cycle (Figure 1). The cycle repeats, and continuous improvement occurs.

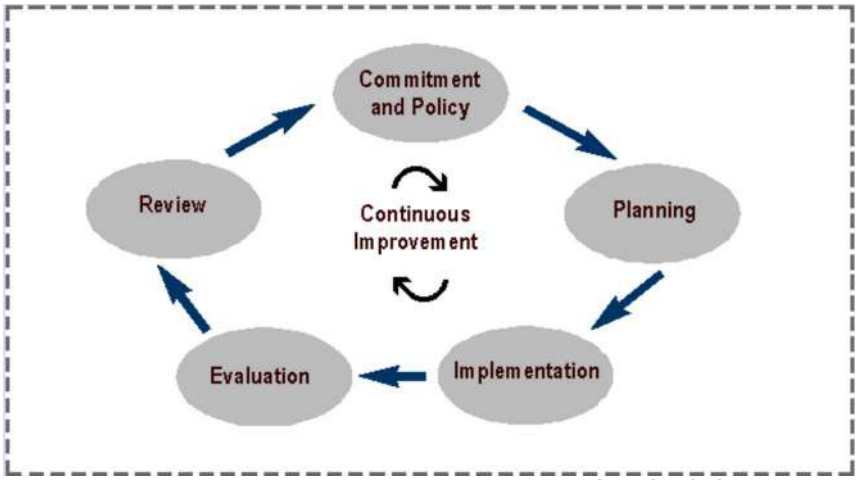

Figure 1: The continuous improvement cycle (Melnyk, Sroufe, & Calantone, 2003)

The summarized dimensions of environmental management systems are given in Table 1.

Table 1: Summarized dimensions of environmental management systems (Ross & Associates Environmental Consulting, Ltd., 2004)

Dimension	Environmental management system
Overall Type	Management system framework - Environmental management systems (EMS)
Waste Elimination Objectives	Eliminate environmental impacts and risks
Organizational Ownership/ Primary Participants	Environmental professionals, with involvement of all employees where appropriate
Drivers/Motivation	Need to better or more cost-effectively manage environmental compliance, risk, and performance, and to demonstrate this to external customers/stakeholders
Methods/Tools	Programs, processes and procedures designed by organization to support management system framework, and to meet objectives and targets
Culture Change	Employee-involved problem-solving culture; empowerment of decision-making to address needs where they occur
Improvement	Continual improvement, based on Plan-Do-Check-Act model

On the first place, the aim of environmental management is to promote sustainable development (Dorney, 1989). Also, firms which have successfully reduced their environmental impacts through implemented environmental management trends and practices also implemented practices for better sustainability of their businesses. Environmental management trends and practices have the goal of improving the organizations environmental and business performance.

Having in mind the previous studies from relevant industry, academic and non-profit entities, key environmental management trends and practices for sustainability are summarized below:

- elimination of waste and emissions,
- pollution prevention,
- maximizing energy efficiency,
- maximizing productivity,
- minimizing utilization of natural resources,
- resource management,
- investing in renewable sources of energy,
- introducing the lean manufacturing,
- introducing Kaizen approach,
- introducing green logistics,
- industrial ecology,
- cleaner production,
- sustainable production,
- clean manufacturing practices,
- energy-efficient design of equipments and products,
- water conservation,
- water management,
- reduction in the amount of packaging,
- usage of eco-friendly packaging materials,
- eco-design,
- design for environment,
- minimizing transport and travel,
- promoting environmental sustainability,
- interesting in developing eco-friendly buying behaviors,
- reducing carbon footprint,
- reusing,
- recycling,
- using more recycled materials,
- minimizing waste generation,
- waste management,
- zero waste strategy,
- environmental initiatives,
- mitigate climate changes,
- environmental reporting (voluntary as well as mandatory),
- reporting greenhouse gas emissions,
- reporting energy production,

- reporting energy consumption,
- energy management,
- usage of clean energy,
- usage of environmental performance indicators (EPI),
- building green image of company,
- environmental impact assessment,
- life-cycle analysis and life-cycle assessment (LCA),
- environmental security,
- sustainability reporting,
- adjustment with environmental regulations,
- managing corporate sustainability reputation,
- green marketing,
- sustainable marketing,
- environmental labelling,
- environmental risk management and assessment,
- increasing environmental and sustainability knowledge and understanding for all other workers,
- integrating sustainability throughout organisations and value chains.

4. CONCLUSION

During the end of the 20th century and into the 21st century environmental management emphasizes negative environmental impacts minimization and therefore have gained in popularity. Thus, trends and practices of environmental management became essential part of sustainable development as sustainable sound management that is trying to be well balanced with the Earth's capacity. Also, environmental management enhances environmental efficiency of the organization and the effectiveness of the organization's business which is also reflected in the area of cost reduction.

Several papers and researches summarized how an implementation of environmental management trends and practices show significant environmental improvements by more resource and energy efficiency. This paper contributes to this growing body of knowledge by identifying not only a role of integrating environmental management in a significant reduction of environmental burden, but also by summarizing all achievable environmental trends and practices as an excellent solutions for achieving sustainability.

MULTIATTRIBUTE METHODS AS A MEANS FOR SOLVING LAKE POLLUTION PROBLEMS

Bisera Andrić Gušavac, Milena Popović, Ana Katić *
University of Belgrade, Faculty of Organizational Sciences
*Corresponding author, e-mail: katic.ana92@gmail.com

Abstract: *The pollution of lake resources restricts its use for human need or a natural function in the ecosystem. Many lake pollution problems are solved using multiattribute methods, and for some problems, researchers use more than one method to overcome disadvantages of application of only one single method. Short literature review of application of multiattribute methods for lake pollution problems is conducted in this paper. This review pointed out two most commonly used methods for this type of problems - Promethee and AHP method, and therefore basic concept of these methods is presented.*

Keywords*: multiattribute methods, AHP, promethee, water resources, lake pollution*

1. INTRODUCTION

Natural resources are raw materials that come from Earth and exist without any human actions. Water as a natural resource refers to the groundwater and surface water in the environment. Humans have the great need for fresh water which represents around 2.5% of all water on Earth (Postel et al., 1996). Part of fresh water is locked in glaciers and ice caps, and the rest is in lakes, rivers, atmosphere etc. Fresh water can be considered as a renewable resource when the usage, treatment and release of water is in a balance with its capacity, which is necessary for its regeneration. Its significance is reflected in the fact that water is essential precondition for life of humans, animals, plants, etc. Because of that it is important to continuously implement various measures to protect water quality.

In rural areas people usually live around different sources of fresh water and food, which is near mountains, rivers and lakes. As the number of people continuously rises as well as their needs, the pressure on this resources in the environment is much stronger. Human activity is one of the main causes of water resources pollution. These activities lead to fast increase of ecological problems, nature resources and environment in which humans live and act. Biggest problems in rural inhabited areas, especially the ones near sources of fresh water, is the absence or undeveloped sewage systems or proof septic tanks as well as other protection measures which leads to soil contamination.

Rainfall, snowfall or melting of snow are common causes of runoff which is flow of water over earth's surface. Surface runoff can implicate environmental pollution through transport of water pollutants such as chemicals and sediments from roads and ground surface which end up in rivers, lakes or other water streams. On the other hand, groundwater collects contaminants from the soil and supply lakes with high level of nutrients and toxic compounds and makes the water unacceptable for any use and leads to eutrophication.

Eutrophication is one of the most widespread water quality problems in the world. Human negative influence on nature and lack of protection measures for fresh water reservoirs such as lakes, is one of the causes of eutrophication. Its main indicators are excessive plant and algal growth in water body as a response to increased levels of nutrients. This phenomenon indicates that there are crucial structural and functional changes of water ecosystem which result in toxic compounds and lack of oxygen that can cause death of aquatic animals and therefore is not fit for human use.

Eutrophication of waters is the phenomenon of an ecosystem becoming more productive by nutrient enrichment, stimulating primary producers. It is usually characterized by algal blooms, causing water quality deterioration and fish kills. It is becoming a global environmental crisis (Wang & Wang, 2010).

Focus of this paper will be on short review of multiattribute method application on one of the most common fresh water resources that humans use - lake pollution problems. These problems are mainly multiattribute and because of large number of available methods it is necessary to perform a review of multiattribute method applications to similar problems. In that way it is possible to point out most commonly used methods and apply them in purpose of bringing a good decision after reviewing results of different methods.

Multi-criteria decision analysis (MCDA) provides a systematic methodology in combining different inputs in order to rank selected alternatives and compare them. The development of MCDA methods has been motivated not only by a variety of real-life problems requiring the consideration of multiple criteria, but also by practitioners' desire to propose enhanced decision-making techniques using recent advancements in mathematical optimization, scientific computing, and computer technology (Wiecek et al., 2008). This paper pointed out two most commonly used methods for lake pollution problems - Promethee and AHP method. These approaches differ significantly in the way of how values are assigned and combined, meaning that the processes have different information and knowledge requirements and the calculated scores have different mathematical properties and thus slightly different meanings. Practitioners often view one of the various approaches as most appropriate due to the priority they place on its relative strengths and weaknesses (e.g.,Figueira et al., 2005; Beltonand Stewart, 2002).

This paper is organized as follows: literature review of multiattribute methods for lake pollution problems and most important findings are given in section 2. Sections 3 and 4 describe Promethee and AHP methods. Section 5 provides the concluding remarks.

2. MULTIATTRIBUTE METHODS REVIEW FOR LAKE POLLUTION PROBLEMS

It is not the purpose of this paper to give an exhaustive review of multiattribute methods application on the problem of lake pollution. Most of the work in this area is very much oriented towards water resource management, and there are few applications concerning lake pollution. We decided to structure this paper around some carefully selected examples of research studies and research.

Some of common types of water management decisions being supported with multiple criteria analysis techniques include (Hajkowicz & Higgins, 2008):

- Selection of alternative water supply and storage infrastructure options. Eder et al. (1997) use MCA to select locations and design options for hydro-electric power plants on the Danube River in Austria.
- Selection of water restoration or enhancement projects in light of constrained budgets. Al-Rashdan et al. (1999) prioritize projects designed to improve the environmental quality of the Jordan River using MCA.
- Allocating a fixed water resource amongst competing uses. Flug et al. (2000) use MCA to select water flow options for Glen Canyon Dam in Colorado providing for recreation, biodiversity, fishing and cultural uses.
- Selecting water management policies for an entire city or region. Joubert et al. (2003) use MCA to help choose water supply augmentation and demand management policies for the city of Cape Town in South Africa.

Water resource management decisions are typically guided by multiple objectives measured in different units, and therefore makes a multiple criteria analysis (MCA) a well suited decision support tool (Chung, Hong, Lee, & Burian, 2011). Despite an abundance of algorithms to solve an MCA problem once it has been structured, there are few methods to help analysts and decision makers choose criteria and decision options in the first place (Hajkowicz & Collins, 2007).

Water management covers a wide range of activities, in which technical, economic, environmental and social issues are involved (Anagnostopoulos et al, 2005). Given the complexity of the decision process, much attention has been paid to multiple criteria decision-making (MCDM) approaches in order to enhance the ability to make sound decisions in water resources management. Authors in (Anagnostopoulos et al, 2005) discuss that there is no method for choosing among them the most appropriate MCDM methods for a given decision problem and the choice is mostly subjective. Authors evaluate four alternative irrigation projects for the East Macedonia- Thrace District using the AHP and PROMETHEE multicriteria methods. The projects evaluation is based on economic, social, environmental and cost criteria.

More information about different applications of MCDM in water supply management can be found in Lai et al. (2008). For example, MCDM techniques have been applied to optimize policy selection in the remediation of contaminated sites, the reduction of contaminants entering aquatic ecosystems, the optimization of water and coastal resources, and the management of other resources (Huang et al., 2011).

From a wide range of MCDM methods, the most suitable ones for the design of alternative comparison are PROMETHEE and AHP (Balali, Zahraie & Roozbahani, 2014), and therefore we conducted a short survey on these methods regarding water resource problems, especially problems related to lake management.

AHP is widely used in water resources industry. For example, management and planning for a large watershed may include issues related to water quality and quantity, forest management, wildlife

management, and recreation. Input is required from subject matter experts in each of these disciplines in order to establish priorities and make informed decisions regarding spatial and temporal distributions of resources. In addition to its breadth of application, the AHP is relatively easy to apply, to understand, and to interpret (Schmoldt et al., 2013).

Authors in (Sener et al., 2010) select a landfill site for the Lake Beysehir catchment area in such way that the lake is protected. The Beysehir Lake is the largest freshwater lake and drinking water reservoir in Turkey. To determine the most suitable landfill site that must combine social, environmental and technical parameters, an AHP was combined with a geographic information system (GIS) to examine several criteria, and each criterion was evaluated with the aid of AHP.

In (Li, 2007) author researches the system that involves defining indicators in the following fields: society, economy, resources, environment and ecology. These indicators are proposed for eco-environmental quality assessment in Chaohu Lake basin. A hierarchical model with four levels is established and the weights of indicators and attributes are determined by combining Delphi method with the AHP.

In (Su et al, 1997) AHP was applied in water environmental quality assessment of the Songhua River, and the authors show that it has logicality, practicability and system that are appropriate to the real water environmental quality assessment.

The AHP provides a systematic method for comparison and weighting multiple criteria and alternatives that exists in integrated watershed management. An advantage of the AHP is that it is capable of providing numerical weights to options where subjective judgments of either quantitative or qualitative alternatives constitute an important part of the decision process. Such is often the case with IWM (De Steiguer et al.,, 2003).

Eutrophication is the most widespread water quality problem in many countries. Symptoms such as high level of chlorophyll, an excessive seaweed blooms, occurrence of anoxia and hypoxia have occurred in many areas in China (Xing, 2005). Evaluation of the trophic state of a lake is in fact a multivariate comprehensive decision making process quantifying the qualitative problem. Authors in (Xing et al., 2005) choose the trophic state index in order to assess the trophic state of the Lake Dianchi and they use AHP for weights calculation of the pollution indicators.

Authors in (Zhang, 2007) evaluate environmental comprehensive quality of water and sediment of Xuanwu Lake, Nanjing, China. An improved AHP method had been developed and the weights of pollution factors were completely related to the objective monitoring data through the standardization of these procedures. This improved AHP method can avoid arbitrariness of subjective judgment and can reflect the real influential factors of environment pollution in different periods or regions (Zhang et al., 2007).

Many water quality management decisions involve uncertain information, multiple and often conflicting objectives, and limited resources. In (Korfmacher, 1997) author presents an application of AHP to the selection of a water quality model for Lake Okeechobee in Florida. The aim of selected water quality model is to help guide research and management efforts at reducing algal blooms on the lake.

Authors in (Calizaya et al., 2010) apply AHP to solve the MCDA problem in the Lake Poopo basin and to identify the alternatives using the highest expected utility value in order to support stakeholders in managing their water resources.

In the study conducted by Hajkowicz and Collins (Hajkowicz & Collins, 2007) eight types of MCA application in water resource management were identified, and by reviewing the characteristics of the problem considered in this paper, two types of applications are a match:

- Project appraisal. These studies use MCA to rank or score a set of water management projects which often involve some form of water condition restoration activity. For example, Al-Rashdan et al. (1999) use Promethee and Nominal Group Technique to prioritize a set of projects aimed to improve the environmental quality of the Jordan River.
- Water quality management. These papers involved an application of MCA primarily involving the evaluation of options aimed specifically at improving water quality. They often involve human and ecosystem health objectives. An example comes from Lee and Chang (2005) where MCA is used to develop a water quality management plan for the Tou–Chen River Basin in northern Taiwan.

Papers reviewed in (Hajkowicz & Collins, 2007) employed 61 unique MCA techniques. The majority of studies applied more than one MCA method, usually to test the sensitivity of the result and in the authors

point out that the most commonly applied methods were fuzzy set analysis, compromise programming (CP), the analytic hierarchy process (AHP), ELECTRE and PROMETHEE.

In (Abu-Thaleb & Mareschal, 1995) authors describe the application of the PROMETHEE V multicriteria method to evaluate and select from a variety of potentially feasible water resources development options, so that the allocation of limited funds to alternative development projects and programs can proceed in the most efficient manner. The criteria set indicates that a successful combination of water options must include projects and programs that minimize groundwater extraction, ensure groundwater quality and quantity, have a high probability of cost recovery, maximize the supply of water and promote water conservation and efficiency.

A list of the papers on the topic of Hydrology and Water Management can be found in (Behzadian et al., 2010) and, according to the authors, most of the papers have been devoted to the sustainable water resources planning, water management strategies assessment, and irrigation planning using PROMETHEE applications.

3. PROMETHEE METHOD

The PROMETHEE method (Preference Ranking Organization Method for Enrichment Evaluations) is one of the most recent multi-criteria decision aid methods, developed by Brans in 1982 (Brans, 1982). The PROMETHEE includes PROMETHEE I for partial ranking of alternatives and PROMETHEE II for complete ranking of alternatives.

The basic principle of PROMETHEE II is based on a pair-wise comparison of alternatives along each recognized criterion. Alternatives are evaluated according to different criteria, which have to be maximized or minimized. The implementation of the PROMETHEE II requires two additional types of information (Behzadian, M., et al., 2010):

- Information on the relative importance (i.e. the weights) of the criteria considered. PROMETHEE II assumes that the decision-maker is able to weight criteria appropriately, at least when the number of criteria is not too large (Macharis, J., et al., 2004);
- Information on the decision-makers' preference function, which decision maker uses when comparing the contribution of the alternatives in terms of each separate criterion. In order to facilitate the selection of a specific preference function, Vincke and Brans (1985) proposed six basic types of criteria: (1) usual, (2) U-shape, (3) V-shape, (4) level, (5) V-shape with indifference and (6) Gaussian (Brans & Vincke, 1985). These six types are particularly easy to define. For each criterion, the value of an indifference threshold, *q*, the value of a strict preference threshold, *p*, and the value of an intermediate value between *p* and *q*, *s*, has to be defined (Brans & Mareschal, 2003).

Experts' opinions are set on various parameters such as selection and weight of the criteria. The team of experts who has cooperated in this research includes architects and information managers who are involved in hotel building design and operational research projects. The PROMETHEE method is implemented in five steps (Behzadian, M., et al., 2010):

Step 1. Determination of deviation based on pair-wise comparison (1):

$$d_j(a,b) = g_j(a) - g_j(b);\ \ j = 1,...,n \tag{1}$$

Where $d_j(a,b)$ denotes the difference between the evaluation of *a* and *b* on each criterion.

Step 2. Application of the preference function (2):

$$P_j(a,b) = F_j\left\lfloor d_j(a,b)\right\rfloor;\ \ j = 1,...,n \tag{2}$$

Where $P_j(a,b)$ denotes the preference of alternative *a* with regard to alternative *b* on each criterion, as a function of $d_j(a,b)$

Step 3. Calculation of an overall or global preferences index (3):

$$\forall a,b \in A,\ \pi(a,b) = \sum_{j=1}^{n} P_j(a,b)w_j \tag{3}$$

Where $\pi(a,b)$ of *a* over *b* (from 0 to 1) is defined as the weighted sum $p(a,b)$ of for each criterion, and w_j is the weight associated with j^{th} criterion.

Step 4. Calculation of outranking flows/ The PROMETHEE I partial ranking (4):

$$\phi^+(a)=\frac{1}{n-1}\sum_{x\in A}\pi(a,x) \text{ and } \phi^-(a)=\frac{1}{n-1}\sum_{x\in A}\pi(a,x) \quad (4)$$

Where $\phi^+(a)$ and $\phi^-(a)$ denote the positive outranking flow and negative outranking flow for each alternative, respectively.

Step 5. Calculation of net outranking flow/ The PROMETHEE II complete ranking (5):

$$\phi(a)=\phi^+(a)-\phi^-(a) \quad (5)$$

Where $\phi(a)$ denotes the net outranking flow for each alternative.

4. THE ANALYTIC HIERARCHY PROCESS (AHP)

Analytic Hierarchy Process – AHP was developed by Thomas Saaty in the early '70s of the last century (Saaty, 1977; 1980), in order to solve complex problems whose elements are: objectives, criteria, sub-criteria and alternatives. It is popular and widely used method for organizing and analyzing complex decisions, based on mathematics and psychology. AHP considers quantitative and qualitative attributes and combines them through the decomposition of complex problems into a model that has the form of a hierarchy. Each level of the hierarchy consists of elements that are influenced by the level above and which can be mutually compared hierarchically structured model of decision-making is generally made up of objectives, criteria and alternatives. The objective is on the top of the hierarchy, the criteria are compared to one another in relation to the set objective, while at the last level, the comparison of alternatives is made in relation to the criteria. AHP keeps all parts of the hierarchy in a relationship, so it is easy to see how a change in one factor affects other factors.

The main objective of this method is ranking of several alternatives, as well as the choice of the best one from a set of available ones, in situations where decision-making involves a larger number of decision makers, and where there are a larger number of criteria in different time-periods. The ranking/selection is made in relation to the set target.

The methodology of the AHP can be explained in following steps (Saaty, 1977; 1980):

Step 1: The problem is decomposed into a hierarchy of goal, criteria, sub-criteria and alternatives.

Step 2: Data are collected from experts or decision-makers corresponding to the hierarchic structure, in the pairwise comparison of alternatives on a qualitative scale. Experts can rate the comparison as equal, marginally strong, strong, very strong, and extremely strong.

Step 3: The pairwise comparisons of various criteria generated at Step 2 are organized into a square matrix. The diagonal elements of the matrix are 1. The criterion in the *i*-th row is better than criterion in the *j*-th column if the value of element (*i, j*) is more than 1; otherwise the criterion in the *j*-th column is better than that in the *i*-th row. The (*j, i*) element of the matrix is the reciprocal of the (*i, j*) element.

Step 4: The principal eigenvalue and the corresponding normalized right eigenvector of the comparison matrix give the relative importance of the various criteria being compared. The elements of the normalised eigenvector are termed weights with respect to the criteria or sub-criteria and ratings with respect to the alternatives.

Step 5: The consistency of the matrix of order n is evaluated. Comparisons made by this method are subjective and the AHP tolerates inconsistency through the amount of redundancy in the approach. If this consistency index fails to reach a required level then answers to comparisons may be re-examined. The consistency index, *CI*, is calculated as:

$$CI=(\lambda_{\max}-n)/(n-1) \quad (6)$$

where $\lambda_{\max}$ max is the maximum eigenvalue of the judgment matrix. This *CI* can be compared with that of a random matrix, *RI*. The ratio derived, *CI/RI*, is termed the consistency ratio, *CR*. Saaty (Saaty, 1977; 1980) suggests the value of *CR* should be less than 0.1.

Step 6: The rating of each alternative is multiplied by the weights of the sub-criteria and aggregated to get local ratings with respect to each criterion. The local ratings are then multiplied by the weights of the criteria and aggregated to get global ratings.

The AHP produces weight values for each alternative based on the judged importance of one alternative over another with respect to a common criterion.

5. CONCLUSION

Decision making in urban environmental management can be complex, principally because of the inherent trade-offs between environmental, ecological and economic factors. The eutrophication is natural phenomenon, and during the last 3 decades there are many techniques used in eutrophication problem-solving (Svircev, Krstic, Markovic, Plavsa & Lazic, 2008).

Eutrophication of lakes and reservoirs is a degradation process originating from the introduction of nutrients from agricultural run-off and untreated industrial and urban discharges. Accelerated eutrophication of lakes and reservoirs experiencing during last century in most parts of the world represents a serious degradation of water quality (Qin, 2009).

Application of multicriteria decision analysis in water resource management is widespread and growing (Hajkowicz & Collins, 2007). The use of MCDA techniques provides a reliable methodology to rank alternative, but none of them is considered the best for all kinds of decision-making situations. Based on Balali et al., (Balali, Zahraie & Roozbahani, 2014), we conducted a short survey on the PROMETHEE and AHP methods regarding water resource problems, especially problems related to lake management.

There aren't many applications of MCDA methods for lake eutrophication problem, but the studies conducted for the lake management problems are applicable to this particular problem. The literature review illustrated the value of the approach, but refinement and validation of the methods must continue such that they can eventually be incorporated into policy making. Recommendations for further research include real case application of selected methods for the eutrophication lake problem.

REACHING ENERGY EFFICIENCY THROUGH ENVIRONMENTALLY RESPONSIBLE HARDWARE AND SOFTWARE DEVELOPMENT

Matija Milekić[1], Marko Ćirović[1] Nataša Petrović [1]
[1]University of Belgrade Faculty of Organizational Sciences

Abstract: *Today's world is overflowing with electronic devices. There are more electronic devices in the world than humans. Such proliferation of electronic devices is increasing the electric energy consumption. As a result there are high levels of environmental degradation coming out of the increased energy demand. Considering that further proliferation of electronic devices is expected, the means of reaching more energy efficient electronic devices are examined. This paper analyses both hardware and software development options that can lead to lower energy demand. The aim is to evaluate practices of how hardware components are being built and the necessary inclusions in order to achieve a higher level of energy efficiency, as well as the kind of software development guidelines which should be followed in order to reach the same goal. Finally the paper answers the question of whether there are certain tradeoffs in pursuing the desired ends.*

Keywords*: environment, ecology, energy efficiency, smart computing*

1. INTRODUCTION

We are currently living in a world where pollution as a problem is growing worldwide. It's becoming something that is affecting both flora and fauna. By destroying natural habitats it is making conditions even worse for humans and animals alike. Numerous causes have led to these conditions. These examples are listed below (Bose, 2010):

- Air pollution is the most dangerous form of pollution. It is caused by many factors. Uncontrolled burning of fuel which is essential for our everyday lives and industrial activities; which emits an enormous amount of chemical substances in the air every day;
- Water pollution occurs due to several factors; the industrial waste dumped into the rivers and other water bodies cause an imbalance in the water leading to its severe contamination and death of both marine flora and fauna.
- Soil pollution is occurring due to the unwanted chemicals being absorbed in to the soil due to human activities. The use of insecticides and pesticides absorbs the nitrogen compounds from the soil making it unfit for plants to derive nutrition from.

Another cause which is appearing in the 21st century is the fact that now there are more electronic devices than humans which is increasing the electric energy consumption. Nowadays almost everyone has a computer because of the mass production and reasonable prices which are not helping the situation. The ICT's share in electricity consumption in national economy scales has continuously increased during the past decades (Kohler & Erdmann, 2004).

Three types of environmental degradation are caused by ICT products and infrastructures can be discerned: global resource depletion, energy use, and the emission of toxic substances over the lifecycle (consisting of production, use and disposal). For example, to make a single 32 MB DRAM memory chip of approximately 2 grams you need: 1.6 kg of fossil fuels, 27 g of diverse chemicals, 700 g of elemental gases, and 32 kg of fresh water. On top of that, to combine all of these materials we also need 41 MJ of energy per chip in the production chain of silicon wafers (Williams, Ayres, & Heller, 2002). For a complete personal computer including a CRT-monitor, the input of abiotic raw materials goes up to 1500 kg (Köhler & Erdmann, 2004).

And last but not the least important problem is the ignorance of people and their attitude that only the big companies are the ones who are polluting and destroying the environment. They are not aware that by looking after their consumption they can help a lot and make a big difference if we look at the population of one city or region.

In the last couple of decades, important attempts have been made to decrease the net power and energy consumption of electronic devices especially those which are battery powered. The idea of low-power hardware construction is a dominant field of research and multiple attempts for power and energy minimization and reduction have been made. However, since most of the hardware functions are controlled

by software, it is of fundamental importance to study the software impact on the hardware energy consumption (Großschädl, Avanzi, Savaş, & Tillich, 2005).

In information communication technologies, when arguing the modes of reaching energy efficient computing authors note two main fields with room for improvement, these being:
- Energy efficient hardware development
- Energy efficient software development

When considering energy efficient software development, guidelines for such software development are a relatively novel area of study, but they are continually improving, with the biggest concerns centered on the trade-off of performance versus energy efficiency. Different authors propose different approaches to overall energy efficient software development, but they all center around three specific goals (Roy & Johnson, 1997):
- reduction of the cost or frequency of memory accesses,
- selection of the least expensive instructions or instruction sequences,
- processor-specific optimizations.

When talking about energy efficient hardware development, for such development, a very important question of how to save energy comes to mind. Can we predict how much energy we are using, by determining our total energy consumption? (Landsiedel, Wehrle, & Götz, 2005).

2. IMPLEMENTATION AND SIGNIFICANCE

Goodman (2000) notes that today's processors come with an option of adjustable clock frequency and supply voltage. The adjustable voltage-frequency properties can be used with an appropriate voltage scheduler which decreases the energy usage in the period when computer response is less needed. It is possible to simultaneously dynamically adjust the supply voltage and clock rate of the processor in order to significantly reduce the energy consumption of the CPU during periods of low activity in which the computer user does not require full operability.

Phase-change memory (PCM) is one of the alternative types of memory that can replace flash memory in next-generation non-volatile memory devices. (Derbyshire, 2011; Wuttig & Yamda, 2007; Hamann, O'Boyle, Martin, Rooks, & Wickramasinghe, 2006). A phase-change material such as chalcogenide can be reversibly shifted between its crystalline and amorphous states through heating by applying appropriate voltage pulses, which cause a change in the resistance state. (Wuttig and Yamda, 2007; Loke, Lee, Wang, Shi, Zhao, Yeo, & Elliott, 2012). The measure of merit, with high switching speed, good endurance, excellent retention properties, low fabrication cost, and inherent scalability, makes PCM more appealing than flash memory. (Loke et al., 2012).

There are different kinds of research being conducted, concentrating on separate parts of the computer system and as a result of that these parts are being optimized independently (Tiwari, Malik, Wolfe, & Lee, 1996), which leads to dubious interpretations. On one hand it can be noted that in this way higher efficiency can be reached, while studies show that independent optimizations of system parts are less efficient and can be counterproductive (Wood & Newborough. 2005). For example Landsiedel et al., (2005) show that passive RFID system protocols must not be assessed independently because it leads to less accuracy, unless they are evaluated in the context of their codependence on implementing circuits they run on. This is due to the fact that both the circuit and the protocols have to be adjusted in their energy consumption efficiency based on their designed physical limitations, therefore meaning that both parts of the system have to be addressed simultaneously.

Different studies have researched the energy consumption of CPUs during different operating tasks including: sensing, routing, sending and receiving information, all being main CPU activities. Such studies present the opportunity to identify and address the energy consumption demanded by different procedures and most importantly the procedures that require the highest energy consumption. Landsiedel, et al. (2005) note that low level data handling, scheduling and timer handling consume are at the top of the list of procedures by the level of energy they consume just swing by a mere fact that they are not time efficient and hence demand longer processing. This has led authors to conclude that in order to increase energy efficiency in these procedures, the time that the processor spends dealing with them has to be decreased, and more specifically it means that in order to improve sensor node applications, energy efficiency ratio and the operating system implementation has to be improved. (Landsiedel et al., 2005).

3. HOW MUCH ENERGY ARE WE TALKING ABOUT?

If we were to apply a smart metering technology in our houses we would not only improve our knowledge of the appliances in our home, but would also start making our energy consumption more efficient. These devices would measure the electricity consumption of up to 16 the home appliances. The data would be transferred from the appliance to a main local collector unit (LCU) using radio waves. Each LCU stores a meter identity number and the current meter reading and the central POEM unit collects data from the LCU. The data is then sent down the telephone line for analysis elsewhere, when the phone is not in use. This system is purely a data collection system and the presentation of energy information to the customer is not its primary function. Marvin, Chappells, and Guy (1999), suggests that smart meter technologies could potentially help consumers to use their energy more effectively. The application of smart metering technologies in-home has the potential to reduce gas and electricity consumption and carbon emissions as well as domestic fuel bills (Darby, 2006). Cook (1979) reported a 12% decrease in electricity usage in households with an FEM

Additionally studies have shown that when pervasive computing is considered, the environmental impact that comes to be analysed in correlation with it, it can be noted that there are different degrees of ICT impacts to the environment. These impacts can be classified in three levels of environmental impact (Fichter, 2001; Schauer, 2003; Köhler & Erdmann, 2004):

- First-order effects: These include all environmental impacts that are a resulting consequence of ICT hardware lifecycle, starting from the idea, design plan, construction, production, usage and the final disposal.
- Second-order effects: These are the impacts that come as a cascade consequence of ICT usage. The use of ICT causes parallel processes that are also leaving an impact to the environment. With regard that many hardware components' production has been moved overseas in recent decades due to cheaper labor. The shipping of these components and industrial production and extraction of raw materials needed for the production are also having a huge impact and are usually left understated.
- Third-order effects: as a result of the proliferated use of ICT in daily life, economic structures and their many outcomes still cannot be predicted, in spite of their indirectly manifestation the expression of first- and second-order effects.

Due to the fact that ICT plays on increasingly important role within the everyday societal behavior it is of the highest importance to accurately measure the performance of all sorts of electronic devices. This is especially important when all sorts of ICT networks are in question such as sensor networks since energy is a scarce resource. The factor of the biggest significance to be measured is energy consumption, and evaluation of abilities for reaching higher energy efficiency of hardware is crucial, as well as finding ways of producing more durable hardware and hardware with a longer life span as well as introducing protocols that will be less time consuming for the CPUs. Products and devices now commonly come embedded with their environment which at the point when energy circuits stop functioning demands disposal of the entire devices just because parts of them are not responding, leading to product replacement and then consequently to a marked increase in usage of new raw materials for making new products. In the long run the entire process demands a behavioral change as well as a change in terms of how we perceive ICT devices and how we address their further usage (Landsiedel et al., 2005).

4. DISSCUSION

The growing demand for electronic devices, especially mobile ones, will continue to exist in the future as well. Considering that such growth is a result of several aspects, how we as a society deal with that will be of utmost importance. The causes are various; on the one hand we have been witnessing the change of lifestyle worldwide where individuals used to be able to participate within social structures offline, without missing out on their social and economical wellbeing. Nowadays in western capitalist liberal societies it is almost unimaginable to fully be integrated into society, work environment, and maintain a culturally relevant information feed without constantly being online. This has caused and will continue to cause dependence on electronic devices. Simultaneously, within these cultures the exists a general dependence on electronic devices, home appliances, and especially CPU run platforms and computers which will only continue to rise. On the other hand we see that societies that haven't had that kind of early ICT influence proliferation are heading the same route.

As the number of devices will increase inevitably the issue that has to be addressed is how these devices will be powered, or more specifically from which sources the energy will be drawn. Regarding that the global energy demand is expected to increase significantly in the upcoming decades. Moreover, in a world with a growing resource scarcity the main question that comes up is the ability to utilise present resources more efficiently.

More efficient energy usage is definitely one of the prime environmental questions, shifting from traditional energy resources such as fossil fuels will decrease the global carbon footprint enormously, but that does not mean that the story ends there. Regarding the growing global population and the expected average number of electronic devices per capita even though shifting to alternative energy sources will help in fighting environmental degradation, hardly will it suffice as an isolated act. Additional steps are necessary. Although alternative energy sources are clean in comparison to fossil fuels, that doesn't mean they are stripped of all the negative environmental effects. Reaching energy efficiency on a micro level just might give the desired results on a global level.

5. **CONCLUSION**

In the end it has to be noted that with growing pollution levels resulting from the increase in resource exploitation for the sole purpose of generating energy for powering regular daily activities dependent on CPU run electronic devices has to be addressed.

There are two ways of addressing it that are predominant in literature. One is by addressing the sources of energy, while the other is by addressing the demand itself.
Addressing the demand itself is contingent on two factors as well. The first factor is advocating a change in behavioural habits by raising the awareness of the issue. The second, from the point of view of this paper, is that although some behavioural changes are possible the civilisation is hardly going back to acknowledging the offline mode. This means that energy efficiency of the observed devices will become the most important issue regarding the entire problem presented here.

It can be stated that individual improvements of computer systems can give desired results, but in order to achieve optimal efficiency a holistic approach to ICT has to be endorsed. This is the reason why many authors advocate, both hardware and software development which is more energy responsible. In terms of hardware it can be concluded that adjustable supply voltage and clock rate system protocols made simultaneously can lead to creating more energy efficient computer units. In terms of software, changing the energy demand is based on creating the software with operations that demand less processing time and are less display intensive while also combining the operations that can be done simultaneously.

Finally, for many years it was thought that in order to achieve everything mentioned above tradeoffs in terms of user satisfaction are necessary. It therefore has to be concluded that such tradeoffs in terms of user experience might have been the issue in earlier stages of ICT development when CPU units were much slower, and hardware in general less durable. Nowadays this isn't the issue any more and especially with further development of the entire branch such tradeoffs will become scarce if any.

SELECTION OF EFFICIENT LOCATIONS FOR MEDICAL WASTES INCINERATION PLANTS

Kristina Stanojević*[1], Dragana Makajić Nikolić [1], Gordana Savić[1]
[1]University of Belgrade – Faculty of Organizational Sciences, Serbia
* Corresponding author, e-mail: kristina.stanojevic@fon.bg.ac.rs

Abstract: *The aim of this paper is to propose a methodology for selection of potential locations for facilities to incineration of medical waste. Medical waste is one special kind of hazardous wastes. If mishandled, it could cause disease spread and pollution of air and soil. The Republic of Serbia at the moment disposes medical waste on landfills or exports it to countries that have incineration facilities. Different factors can affect the selection of a suitable location for incineration facilities. These factors must be considered concurrently for the identification of efficient facilities locations. In this paper we use data envelopment analysis (DEA) as an approach for selection of locations for medical wastes incineration plants.*

Keywords*: medical waste, Incineration, data envelopment analysis (DEA), efficient locations, selection of district*

1. INTRODUCTION

National guide for safe medical waste management considers medical waste as every waste that originates from medical, dental, veterinarian, pharmaceutical or similar practices. This waste is a heterogeneous mix of simple garbage, infective waste, pathology and anatomy waste, pharmaceutical and laboratory waste, disinfectants and packaging, as well as radioactive and hazardous chemical waste. Medical waste may consist (partially or fully) of human or animal tissues, blood and other body fluids, secretion and excreta, medicines and other pharmaceutical products, swabs, cotton pads, gauze, bandages, needles, scalpels and other sharp instruments (Ministry of health of Republic of Serbia (MoH RS), 2008). In European catalogue, medical waste is registered under number 18 00 00 with subsets (SG, 2010a)

Until 2007 year, medical waste was sterilized in certain health institutions, most common in autoclaves that were very old. In health institutions, that were not able to sterilize medical waste, it was mixed with communal waste and disposed at city landfills (MoH RS, 2008). Ministry of health of Republic of Serbia together with the Ministry of agriculture and environmental protection, in the year 2007 started a project of "Technical support in medical waste management". Project was financed by the European Union, and in 72 medical centers, 78 autoclaves and shredders for medical waste sterilization were installed. Also, 25 vehicles for transport of medical waste were purchased, and conducted the training of workers for classification of generated medical waste. Apart from installed autoclaves and shredders for sterilization of medical waste, in the Republic of Serbia there are no modern facilities for medical waste treatment (SG, 2010b).

Hazardous medical waste that cannot be treated or disposed in an environmentally sound and efficient manner, due to the lack of technical capabilities and facilities in the Republic of Serbia, is being exported for treatment or disposal, in accordance with the law and regulations governing waste management, or international transport of waste (SG, 2010c).Trans boundary movements and disposal of medical waste is regulated by Basel Convention on the Control of Trans boundary Movements of Hazardous Wastes and their Disposal (1989). The agreement implies that the only legitimate transportation of hazardous waste is exported from the countries that do not have waste treatment facilities or qualified staff for safe disposal of waste, to the countries that have such facilities (MoH RS, 2008).

Incineration (burning) is appropriate for the elimination of the majority of medical wastes including some types of chemical wastes except radioactive wastes. During the incineration process of medical wastes, they are converted into gas (CO_2, NO_2, CO and other gases) and ashes (MoH RS, 2008). Incineration plants are any stationary or mobile technical units where waste is incinerated with or without recovery of the heat produced by combustion. In the incineration plants, high temperature oxidation of the waste and other thermal processes are conducted (SG, 2012a).

The goal of this paper is to propose a methodology for selection of efficient locations for medical wastes incineration plants. The paper is organized as follows. After introduction part, sections 2 and 3 refer to the

problems of potential locations and selection criteria. Section 4 gives theoretical background about DEA method. Section 5 illustrate the proposed methodology in the case of the Republic of Serbia.

2. SELECTION OF THE DISTRICT FOR INCINERATION PLANTS FOR MEDICAL WASTE

In terms of administrative and territorial division, the Republic of Serbia is divided into provinces, regions, administrative areas, the City of Belgrade, cities and municipalities. The Republic of Serbia has 30 administrative areas, 24 cities, 30 urban municipalities, 150 municipalities, 6,158 villages and 193 urban settlements (Statistical Office of the Republic of Serbia, 2015).

Table 1: Regions per number of cities, population, area, population density, number of cities/municipalities with more than 40.000 residents (Statistical Office of the Republic of Serbia, 2015) and number of health institutions (MoH RS, 2016).

Region	Number of cities	Population	Area km^2	Population density per 1 km^2	Number of cities/municip. with more than 40.000 res.	Number of health institutions
Vojvodina	6	1 659 440	21 614	89,4	13	92
Beograd	1	1 931 809	3 234	513,1	17	54
Šumadija & Western Serbia	10	2 031 697	26 493	76,7	14	101
South & Eastern Serbia	6	1 563 916	26 248	59,6	12	93
Kosovo & Metohija	1	-	10 910	-	-	-

Considering that the region Šumadija and Western Serbia takes the central place in the Republic of Serbia, has the most registered health institutions, largest area, population and most of the cities, as well as most of the cities/municipalities with more than 40.000 residents, it is chosen as the region where it is needed to determine efficient locations for medical waste treatment. Region Šumadija and the Western Serbia is divided into 8 districts, and has 14 cities/municipalities with more then 40.000 residents (Statistical Office of the Republic of Serbia). Those cities are considered separately as possible efficient locations for medical waste treatment.

3. SELECTION OF EFFICIENT LOCATIONS

As the long term objective of the Strategy of Waste Management is to ensure the capacity for burning (incineration) of organic industrial and medical waste, it is necessary to make a choice of efficient locations (SG, 2010b). First, it is necessary to determine the region within which it is still necessary to allocate potential locations, as input for further analysis and the criteria by which the efficient location will be determined. A schematic procedure for the selection of efficient locations is shown in the figure 1.

The criteria for determining efficient locations within the region are:

- The amount of generated medical waste that needs to be transported to the determined location - in order to eliminate the potential risk of spillage of the medical waste during its transportation. It is necessary to choose a location that requires the least amount of transport of medical waste. The amount of waste for the location contains the total waste generated in all of the cities gravitating to the given city as the center of medical waste collection in the area;
- The duration of the transport from all other locations to the given location - the location is necessary to occupy the best position in order to provide connections to other locations, requiring the shortest time of transport;
- Air pollution - the environment is one of the dimensions that must be taken into consideration in choosing efficient locations. Since incineration of medical waste involves the creation of certain gases such as CO_2, NO_2, CO and other gases, it is necessary to choose locations that have the least air pollution, specifically have the lowest risk of crossing the permissible limits of pollutants;
- The unemployment rate - as the waste incineration plant, from its construction and operation, requires certain trained staff, the location with the highest unemployment rate should be chosen, in order to achieve better economic effects;
- The safety from natural disasters - as a consequence of natural disasters, damage can be great to the plant and may represent a danger for environmental pollution, due to danger of medical waste. It is necessary to look for a location with the highest safety for the environment in the case of a natural disaster.

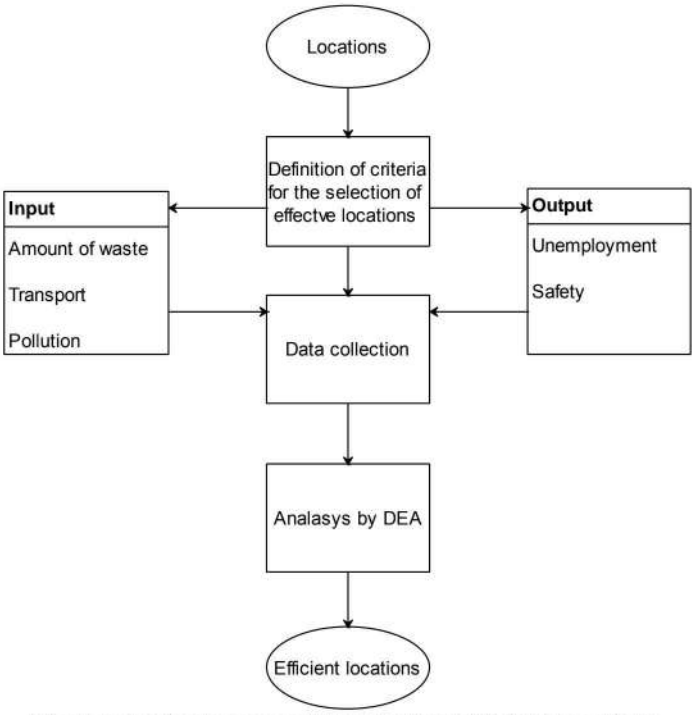

Figure 1: The process for selecting efficient locations

4. DEA

Data envelopment analysis (Charnes, Cooper, & Rhodes, 1978) was introduced for measuring relative efficiency of non-profit units, whose performance depends on multiple inputs and multiple outputs. These inputs and outputs are usually difficult to measure. Data envelopment analysis has lately received considerable attention in the construction of composite indicators. DEA can be defined as a linear programming technique used to find the optimal set of relative weights (u,v) that will give the highest possible efficiency ratio of outputs to inputs for the decision-making units (DMUs) being evaluated. Let us suppose that the following parameters are known:

n - number of DMUs

m - number of inputs

s - number of outputs

x_{ij} - known amount of i-th input of DMU$_j$ $(x_{ij} > 0, i = 1,2,...,m, j = 1,2,...,n)$,

y_{rj} –known amount of r-th output of DMU$_j$ $\left(y_{rj} > 0, r = 1,2,...,s, j = 1,2,...,n\right)$.

Having known parameters given above, Charnes, Cooper, and Rhodes (1978) formulated a mathematical model trying to maximize the relative efficiency h_k of DMU$_k$ (k=1,..,n) by optimizing weight of inputs v_i $(i = 1,...,m)$ and weight of outputs u_r $(r = 1,...,s)$. The calculation is more complicated if the model of fractional programming is used rather than the linear programming model. The linear model (1-4) and the dual linear program (5-8), corresponding to the model (1-4), are given below:

The linear model

$$(\max) h_k = \sum_{r=1}^{s} u_r y_{rk} \quad (1)$$

s.t.

$$\sum_{i=1}^{m} v_i x_{ik} = 1 \quad (2)$$

$$\sum_{r=1}^{s} u_r y_{rj} - \sum_{i=1}^{m} v_i x_{ij} \le 0, \quad j = 1, 2, ..., n \quad (3)$$

$$u_1,...,u_s \ge 0, v_1,...,v_m \ge 0 \quad (4)$$

Dual linear model

$$(\min) Z_k \quad (5)$$

s.t.

$$\sum_{j=1}^{n} \lambda_j y_{rj} \ge y_{rk}, \ r = 1,...,s \quad (6)$$

$$Z_k x_{ik} - \sum_{j=1}^{n} \lambda_j x_{ij} \ge 0, \ i = 1,...,m \quad (7)$$

$$\lambda_j \ge 0, \ j = 1,...,n \quad (8)$$

In the model (1-4), DMU maximizes the virtual output under the constraint that its virtual input is equal to 1. The constraint given by eq. (3) indicates that the optimal weights for the DMU_k must satisfy the condition that the virtual output of each of *n* DMUs cannot be greater than its virtual input. If the objective function is equal to 1, then virtual outputs of all inefficient DMUs will be less than the virtual inputs. If the value of the objective function is less than 1, the efficiency reference set for DMU_k can be constituted. It consists of DMUs with virtual output equal to virtual input and it forms frontier for measuring the level of efficiency. As already mentioned, virtual inputs $\sum_{i=1}^{m} v_i x_{ik}$ and virtual outputs $\sum_{r=1}^{s} u_r y_{rk}$ of DMU_k, are calculated as the sum of the product of known inputs x_{ik}, $i=1,...,m$ (outputs y_{rk}, $r=1,...,s$) and assigned weights, considered as variables in the model (1-4). The model (1-3) should be solved *n*-times, once for each DMU.

The objective function (5) shows the efficiency level of DMU_k. Its value is the same as an objective function value of primal model (1-4). Dual variables, λ_j, $(j=1,...,n)$ show the importance that is assigned to DMU_j ($j=1,...,n$), in defining the input-output mix of a hypothetical composite unit (efficiency reference set). The observed DMU_k is directly compared to a hypothetical composite unit. If DEA tries to minimize Z_k of DMU_k and it cannot find λ_j, $j=1,...,n$ multipliers that will generate an efficiency level below 1 (100%), DMU_k is evaluated as a relatively efficient unit (Z_k=1). In such case, λ_k is the only multiplier with a value greater than 0 ($\lambda_j = 0,\ j=1,...,n,\ j \neq k$).

In the DEA literature, a number of approaches have been proposed to introduce additional restrictions on the values that the multipliers can assume.

$$\alpha_i \leq \frac{v_i}{v_{i_o}} \leq \beta_i,\ i=1,...,m$$

$$\delta_r \leq \frac{\mu_r}{\mu_{r_o}} \leq \gamma_r, r=1,...,s$$

Here, v_{i_o} and μ_{r_o} represent multipliers which serve as "numeraires" in establishing the upper and lower bounds represented here by α_i, β_i and by β_r, γ_r for the multipliers associated with inputs *i*= 1, …, *m* and outputs *r* = 1, …, *s* where $\alpha_{i_0} = \beta_{i_o} = \delta_{r_o} = \gamma_{r_o} = 1$. The above constraints are called Assurance Region (AR) constraints as in Thompson et al. (1990).

5. CASE STUDY

The chosen region of Šumadija and Western Serbia has 14 potential locations for incineration plants. The DEA method was applied for the selection of efficient locations. The criteria defined in Section 3 are used as DEA inputs and outputs. Every location has three inputs: quantity of transported waste, transport time and pollution of the sites and two outputs: the unemployment rate and safety of the sites from natural disasters.

5.1. Amount of waste (x_{1j})

In Serbia, there is no precise data about the amounts of medical waste in the health care institutions. In order to determine the amount of medical waste generated in a particular location, we use estimated number of beds at each location. In the hospitals in Serbia, there are 15,000 beds (c_{bed}), with an average occupancy of 72% ($c_{occup.}$), while the assessment is that one bed generates 0.7 kg of waste per day ($c_{waste.bed.}$) (SG, 2010b). The number of beds were calculated based on total population 7,186,862 ($c_{popul.}$) and the number of residents in each location ($c_{popul.,j}$), which represents the total population of all the cities/municipalities in the field belonging to a given location (Statistical Office of the Republic of Serbia). Using the notation and equations given below, the amounts of waste that needs to be transported from other locations to the given location were calculated and shown in Table 5.

p_j – number of beds in the j-th location

w_j – amount of waste in the j-th location

$$p_j = c_{bed} \frac{c_{popul.,j}}{c_{popul}}$$

$$w_j = p_j \cdot c_{occup.} \cdot c_{waste.bed}$$

$$x_{1j} = \sum_{i \neq j, j=1}^{n} w_i$$

5.2. Transportation time (x_{2j})

Medical waste must be transported by specialized vehicles with a capacity of transport equal to the net weight of 80 kg of waste (Institute of Public Health of Serbia "Dr Milan Jovanovic Batut"). The time required for transport from one location to another is shown in the table 2 (Google Maps). Using the following equations, we get the values shown in Table 5.

Table 2: Time of transport in minutes

Location	1	2	3	4	5	6	7	8	9	10	11	12	13	14
Užice (1)	0	100	160	163	81	58	159	173	164	132	99	167	134	117

z_j – the number of vehicles for the waste transport from j – th location

q – the capacity of vehicles

d_{jk} – the time required for transport from j – th to k – th location

$$z_j = \frac{\lceil w_j \rceil}{q}$$

$$x_{2j} = \sum_{j=1}^{n} z_j d_{jk}, k = 1, \ldots, n$$

5.3. Pollution (x_{3j})

Because of the lack of data about pollution at each location for each pollutant, the pollutants that we were observed are SO_2, NO_2 and CO. Emission of polluting substances by locations are shown in Table 3. Data marked with (i), (ii), (iii) and (iv) are taken from the Annual air quality report in the Republic of Serbia for 2014, 2013, 2012, 2011 (Ministry of Agriculture and Environmental Protection, 2014; 2013; 2012; 2011). Other data was evaluated by using available data about the emission of pollutants by one company and the number of companies at the appropriate location. The input data for this criterion is based on annual average emissions. Categories of air quality indicate whether the pollutant exceeds a limit value or reaches a tolerance value (Ministry of Agriculture and Environmental Protection, 2014). Air quality indicator for each pollutant was determined as percentage of the corresponding limit value. Then, maximal value of air quality indicator among all pollutant was assigned to each location, because they carry the highest risk of crossing the limit (threshold) values. Input data of pollution are shown in Table 5.

A – set of pollutants

g_{aj} – average annual emission of a-th pollutants in j-th location, $a \in A$

t_a – limit value for emission a-th pollutants in j-th location, $a \in A$

$$x_{3j} = \max_a \left(\frac{g_{aj}}{t_a} \right)$$

Table 3: The annual average emission of pollutants

Location	SO_2 µg/m^3	NO_2 µg/m^3	CO mg/m^3
Užice	6,50[i]	32,20[i]	1,65[i]
Valjevo	17,30[i]	21,70[i]	1,69[i]
Loznica	21,60[iii]	23,90[iv]	0,60[i]
Šabac	30,10[iii]	19,60[i]	1,35[i]
Gornji Milanovac	5,55	9,62	0,44
Čačak	8,10[i]	8,80[i]	1,27[i]
Jagodina	7,51	13,01	0,60
Paraćin	13,00[ii]	26,70[ii]	0,60[ii]
Kruševac	12,80[ii]	15,10[ii]	1,30[i]
Trstenik	5,23	9,05	0,42
Kraljevo	5,60[i]	35,10[iii]	0,50[iii]
Novi Pazar	6,21	10,75	0,49
AranĐelovac	5,55	9,62	0,44
Kragujevac	14,10[iii]	26,90[ii]	0,60[ii]
Limit value	50[i]	40[i]	3[i]

5.4. Unemployment (y_{1j})

The unemployment rate is the number of unemployed people ($c_{unemp..,j}$) as a percentage of the labour force ($c_{lab.force.,j}$) (Statistical Office of the Republic of Serbia). The value of this output is shown in Table 5. The equation used for calculating these values is following:

$$y_{1j} = \frac{c_{unemp.,j}}{c_{lab.force.,j}}$$

5.5. Safety (y_{2j})

Safety was observed as the probability that some natural disaster in observed location does not happen. The main natural disasters in Serbia are earthquakes, floods, landslides and forest fires. For the territory of each location, a number of risk points from certain natural disasters was determined by using the map of risk of natural disasters (Emergency management sector). The number of risk points is shown in the table 4.

Table 4. Number of risk points in the city / municipality

Location	Earthquakes	Floods	Landslides	Fires
Užice			6	2
Valjevo		2	2	3
Loznica	1	1		1
Šabac		2	1	1
Gornji Milanovac	1	1	1	2
Čačak		1	1	2
Jagodina		2	2	2
Paraćin				
Kruševac		4	2	
Trstenik	1		3	
Kraljevo		2	3	3
Novi Pazar		2	1	2
AranĐelovac		1		2
Kragujevac	1	1	1	2

The probability of occurrence of earthquakes, floods, landslides and fires are 0.0971, 0.7734, 0.0288 and 0.1007, respectively (e_b). These values were determined on the basis of the evidence for the territory of Europe (International Federation of Red Cross and Red Crescent Societies). Notation and equation for obtaining values for this output are given below, while the final values are shown in Table 5.

B – set of natural disasters

f_{bj} – number of risk points from b-th natural disasters in the j-th location

$$y_{2j} = 1 - \frac{\sum_{b}^{`} f_{bj} e_b}{\sum_{j=1}^{n} \sum_{b} f_{bj} e_b}$$

5.6. Result analysis

Based on previously presented calculations, the values of defined inputs and outputs are obtained (Table 5).

Table 5: The values of inputs and outputs

Location	Inputs			Outputs	
	Amount of waste	Transport time	Pollution	Unemployment	Safety
Užice	5017,73	9291	0,805	0,1894	0,9792
Valjevo	5339,86	9749	0,56333	0,1724	0,8939
Loznica	5486,32	14292	0,5975	0,3322	0,9459
Šabac	5337,43	11742	0,602	0,2126	0,9067
Gornji Milanovac	5713,94	7201	0,24044	0,1534	0,9387
Čačak	5358,02	7274	0,42333	0,1994	0,9441
Jagodina	5468,85	9260	0,3253	0,2634	0,8995
Paraćin	5597,55	9723	0,6675	0,2768	1,0000
Kruševac	5316,27	9829	0,43333	0,3006	0,8246
Trstenik	5671,17	9001	0,2263	0,2094	0,9898
Kraljevo	5401,67	7720	0,8775	0,2241	0,8922
Novi Pazar	5392,39	13514	0,26873	0,3687	0,9011
AranĐelovac	5644,52	8910	0,24044	0,2439	0,9457
Kragujevac	5195,4	7636	0,6725	0,2829	0,9387

DEA CCR model was solved without limit of weights and with (AR) limit of weight for the transport, which must be higher or equal to the weight for the amount of waste and pollution. The resulting efficiency and ranks of each location are shown in Table 6. In the first case seven efficient location were obtained (Užice, Gornji Milanovac, Čačak, Trstenik, Novi Pazar, AranĐelovac and Kragujevac), while in the second case three efficient locations were obtained (Gornji Milanovac, Čačak and Kragujevac). The minimum efficiency is 0.9012 (Valjevo) in the first and 0.7142 (Šabac) in the second case. Average efficiency for the first and second case is 0.9778 and 0.8849, respectively. In DEA CCR-AR model, we note that these limitations contribute significantly less to the average and the minimum efficiency, resulting that some locations have become inefficient or have significantly lower efficiency. Based on obtained results, Gornji Milanovac, Čačak and Kragujevac can be considered efficient locations for medical wastes incineration plants.

Table 6. Efficiency and ranks of each location

Location	CCR model		CCR- AR model	
	Efficiency	Rank	Efficiency	Rank
Užice	1	1	0,9156	5
Valjevo	0,9012	14	0,7926	12
Loznica	0,9901	9	0,7618	13
Šabac	0,917	13	0,7142	14
Gornji Milanovac	1	1	1	1
Čačak	1	1	1	1
Jagodina	0,9832	10	0,8331	11
Paraćin	0,9804	11	0,8871	8
Kruševac	0,9945	8	0,9000	7
Trstenik	1	1	0,9027	6
Kraljevo	0,9225	12	0,9185	4
Novi Pazar	1	1	0,8843	9
AranĐelovac	1	1	0,8792	10
Kragujevac	1	1	1	1

6. CONCLUSION

Improper disposal of medical waste carries great risks for the pollution of the environment. Therefore, the Republic of Serbia should focus on the issue of its treatment. Since current medical waste treatment is based on sterilization and fragmentation, then disposal in a landfill, or export, construction of incinerators is certainly

necessary. Locations in which possible adequate treatment of medical waste having incinerator is possible, should meet a variety of environmental, social, economic and technical criteria. In this paper, the quantity of waste, time of transport, pollution, unemployment and safety in case of natural disasters were observed as criteria for the selection of efficient locations. By using these criteria as DEA input and output, we have obtained efficient locations for the construction of such a plant. Analysis was performed in accordance to the CCR model, and CCR model with restrictions on weight. In the first case, the result indicates seven efficient locations, while the second case recommends three efficient locations. It is possible to perform further analysis in order to allocate one efficient location by solving optimal location problem or by application of super efficiency. A choice of efficient locations for incineration of medical waste can contribute to better management of medical waste in the territories of the Republic of Serbia.

SUSTAINABILITY OF THE FASHION INDUSTRY: HOW DOES THE YOUTH FEEL

Jelena Andreja Radaković*[1], Marko Pepić[1], Dejana Stevanović[2]

Abstract: *The 21st century is characterized by an ever-growing concern over environmental problems, which is present through all human life and activities. This results in "louder" and stronger demands from environmentally aware consumers for environmentally friendly and "green" products. Therefore, it is no wonder that the fashion industry had to abide to these demands, answering them with new concepts of sustainable or so-called "slow fashion", which as its result lowers the negative impact of fashion on the environment. Other than concepts of sustainable fashion, in this paper we showed the results of a research based on the case study of sustainability of the international fashion company H&M, and the youth's opinion and attitudes on the company's sustainability practices and the sustainability of the fashion industry as well. An analysis of the results was carried out using the SPSS 22 software package.*

Keywords*: sustainability, fashion industry, sustainable fashion, slow fashion, youth, H&M*

1. INTRODUCTION

The fashion industry has gone through a lot of changes, with the most significant ones in the last 20 years, when the boarders of the industry started shifting (Djelic & Ainamo, 1999). Since then, the changes in the dynamic of the fashion industry, such as the fading of the mass production, increased number of fashion seasons, as well as modified structural characteristics of the supply chain, drove the sellers to strive to reduce their costs and achieve the flexibility of design, quality, delivery and speed of entering the market (Doyle, Moore, & Morgan, 2006).

Today's fashion market is highly competitive and the constant need for new products caused the inevitable step by the manufacturers – increased number of seasons, i.e. higher frequency of coming out with new and "fresh" products. This implies a shorter life cycle and bigger sales profit (Sydney, 2008). In addition, the desire for variety and instant gratification of needs, with the knowledge of prices and the market by customers, has led customers to prefer brands such as Zara and H&M (National Post, 2009). Several studies have observed the various aspects of the relationship buyer-producer through "fast fashion", aspects such as the design of the garment in relation to the fast response of the manufacturers (Forza & Vinelli, 1996), the role of the supplier in the rapidly changing industry (Doyle, Moore, & Morgan, 2006), consumer behaviour (Bruce, & Daly, 2006) and financial performance (Hayes & Jones, 2006). However, it seems that there is discord in the literature concerning the concept of "fast fashion" among studies of this type of fashion, because only a few focused on the aspects that concern consumers and what actually steers those changes in the fashion industry (Barnes & Lea-Greenwood, 2006).

Innovations that occur at the intersection of the fashion and technology industries are amazing and transformative. In many cases, the fashion industry today resembles nothing like the one of a decade ago, and will change more in the next decade. One of rising trends in the fashion industry is certainly the rise of sustainable fashion. The fashion industry realizes we cannot continue this trend of polluting the planet, and has slowly started the road towards more sustainable fashion which includes a total rethink of how many clothes we really need in our closets, more recycling and reduction of the use of pollutants.

2. SUSTAINABILITY AND FASHION INDUSTRY

"Second to oil, fashion and textiles is the most polluting industry in the world. Every stage in a garment's life threatens our planet and its resources. It can take more than 20,000 liters of water to produce 1kg of cotton, equivalent to a single t-shirt and pair of jeans. Up to 8,000 different chemicals are used to turn raw materials into clothes, including a range of dyeing and finishing processes." (BOF, 2016)

On the other hand, "over the past decade, sustainability and ethical conduct have begun to matter in fashion (Emberley, 1998; Moisander & Personen, 2002); companies have realized that affordable and trend-sensitive fashion, while typically highly profitable, also raises ethical issues" (Aspers & Skov, 2006; Joy, Sherry Jr, Venkatesh, Wang & Chan, 2012). Sustainability represents a primary issue of the 21st century and is often in relation to corporate social responsibility (Aguilera, Rupp, Williams, & Ganapathi, 2007).

When it comes to sustainability, it should be noted that there is no single accepted definition, although this term is usually associated with the following three interpretations:

- Sustainability refers to those activities that can last endlessly without casein damage to the environment (Fletcher, 2008).
- Sustainability presents not doing to others what we do not want done to us (Partridge, 2011).
- Sustainability presents satisfying the needs of present generations without comprising the future generations' abilities to satisfy their needs (WCED, 1987).

None the less, the most comprehensive definition was the one by (2007): "Sustainability is about much more than our relationship with the environment; it's about our relationship with ourselves, our communities, and our institutions."

We can conclude that sustainable fashion, supports living harmoniously with nature, employs trained artisans in safe and humane working conditions (Partridge, 2011). Also, sustainable fashion "demands a new way of thinking, which involves slowing down fashion cycles, understanding why and how a garment is made, seeking workable solutions in an era of urgency and crisis and redefine our scholarly approach to issues related to dress, body, and culture" (Root, 2009).

Considering all the above, it can be concluded that "fast fashion" is by no means sustainable since it is distinguished by cheap materials that have a harmful impact on the environment, as well as very short life cycle of its products, which quickly leads to the stage of waste if not recycled. Therefore, many authors are calling sustainable fashion – "slow fashion" (Clark, 2009; Fletcher, 2008; Patel & Davidson, 2003; Patel & Tebelius, 1987; Tran, 2008), as a logical name that is the opposite of fast fashion, bearing in mind that "slow fashion" is characterized by sustainable production and consumption, eco design, waste management, recycling and reusing, connected with quality, environmental awareness and balance, as well as something durable and made from recycled or organic materials (Holt, 2009). The issues of "slow fashion" are making garments that last longer in such material and style with the philosophy: less, but of the best. That is how "slow fashion" perfectly coincides with the concept of sustainable consumption.

3. THE RESEARCH

In order to provide a highlight of sustainability in the fashion industry, which became the main problem of this industry in the previous couple of years, partly thanks to Andrew Morgan's documentary "The True Cost" and the launch of the H&M Conscious program and the recycling program, the poster will feature the case study of the company H&M. The showed case study is dealing with the practices of sustainability of this company, as well is its contribution to the Sustainability Report 2014 (H&M, 2016a; H&M, 2016b).

3.1. Methodology

In order to provide an overview of how much the younger generation exactly is familiar with the sustainability of fashion, and whether it is important to them, the authors of the paper surveyed their colleagues from the University of Belgrade – Faculty of Organizational Sciences, Serbia on their attitudes on the sustainability of the fashion industry. An analysis of the results was carried out using the SPSS 22 software package. This research featured 321 participants (out of which 206 participants were female and 115 were male).

3.2. Results

Turning fashion into a more sustainable industry "remains an uphill battle, with plenty of technological, systematic, and business struggles to overcome" (Vogue, 2016). At Glasgow Caledonian University, New York, Simon Collins, former dean of the Fashion School at Parson's New School for Design, and Julie Gilhart, respected freelance fashion consultant, discussed some of these issues in their second "Fashion Garage" event conversation, giving free advice to young designers, with the focus of the most recent one being on making the production more environmentally friendly:

1. The product should always come first.
2. Use social media to your benefit.
3. Accept that consumer shopping habits won't change.
4. Focus on materials.
5. Vote with your wallet.

Having in mind all of this, the sustainable organization of H&M and their road to sustainability is commendable, and is characterized by (H&M, 2016b):

- *Conscious materials for a more sustainable fashion future* – the use of organic natural and recycled materials.
- *Cotton* – organic and recycled cotton. The company H&M is one of the leading users of organic cotton in the world.
- *Water* – promotion of responsible use of water along the product's lifecycle, from how cotton farmers water their crops, to how customers wash their clothes. The World Economic Forum states the water crisis as the risk with the biggest global impact. The H&M's partnership with WWF is ground-breaking – the water stewardship strategy goes far beyond the factory lines.
- *A fair living wage to garment workers* – responsible partners, working conditions, commitments, protecting childhood.
- *Animal welfare* – improving of the animal welfare in the supply chain, from involvement to education and training of suppliers and farmers.
- *Less use of planet's resources.*
- *Garment collecting* - changing the way of make, use and dispose of clothes. Of the thousands of tonnes of textiles that people throw away every year, as much as 95% could be re-worn or recycled.
- *Business concept* - fashion and quality at the best price in a sustainable way.

In order to evaluate the familiarity of the participants with the sustainability practices and actions, after a set of general questions, the following questions the participants marked on a rating scale from 1 to 5, based on the truthfulness of the statement, and we calculated the percentage of them that answered positively to these questions either with a 4 (I agree) or a 5 (I absolutely agree). The results based on the answers given by participants to our eight questions are shown in the Table 1.

Table 1: The results on the poll, featuring the questions on sustainability of the fashion industry

Question	Participants with positive attitudes toward sustainability in the fashion industry [%]
1. "When I buy clothes, I think of the way it was manufactured"	33.4
2. "If I knew that the workers that made the garment were treated poorly, it would make me rethink of buying the product"	96.7
3. "I believe that the fashion industry pollutes the environment"	86.4
4. "If I knew that the company was environmentally friendly, I would feel better about buying the product even if it was more expensive"	64.5
5. "I own clothes labelled as environmentally friendly"	46.7
6. "I know that H&M is environmentally friendly"	89.8
7. "I have participated in the H&M recycling program"	24.3
8. "I believe that the sustainability of the fashion industry is important"	93.4

4. DISCUSSION AND CONCLUSION

Having in mind that 2 billions of poisonous pesticides are used each year for farming the cotton meant for the textile industry – more than for any other agriculture crop and the fact that textile industry uses more water than any other branch of industry (except agriculture), and the amount of pesticides that get released into the

air during the production of the cotton necessary for the textile industry each year represents 16 percent of the total global amount of insecticides, for these reasons, we can see the importance of good sustainable practices of the company and brand H&M i.e. Hennes&Mauritz, which showed that you can have both a profitable business and a sustainable one with these following "green consequences":

- Better for the Earth.
- Better for people.
- Better for animals.
- Lasts longer.
- Easier and cheaper.
- Organic.

The results gained from our research show that even though at the first moment, the unaware youth does not think of the consequences and the background of the items they shop for (only 33.4 percent of the younger generation thinks about the way a garment was manufactured), as soon as the implications of their actions are brought to their attention, it is easy to change their mind (96.7 percent claims that if they knew that the workers were treated poorly it would make them rethink the purchase).

In addition, the participants showed that sustainability and environmentally friendly aspect of the manufacturing process does play a role in their shopping, as long as the price is still in their price range (64.5 percent of the participants said that if they knew that the product is environmentally friendly they would buy it even if it was more expensive).

Also, from our research, we can clearly see that the marketing campaign and the advertisement of a sustainable organization and its sustainability actions is very important, and that a good example of a this is precisely the one followed by H&M, because 89.8 percent of the participants of this research said that they are aware of the fact that this company is environmentally friendly.

However, our research has showed that this campaign still has to be worked on further because only a small number of students surveyed (24.3 percent) has actually participated in the H&M recycling program, while only 46.7 percent of the students owns environmentally friendly clothes.

Lastly one of the main goals of this research was to show that the younger buyers do care about sustainability of the fashion industry, and in that we have succeeded – 93.4 percent of the participants agree.

Fashion itself, shoes, dresses, suits and skirts, may seem irrelevant when compared to the real problems mankind is facing everyday in the 21st century such as: climate change, nuclear catastrophes, wars, poverty, and lack of drinkable water, disease and hunger. But when we take in concern the fact that the fashion industry around the world employs millions of people (from the fashion company workers, to models, photographers, journalists and retail store clerks), and that fashion is an unavoidable part of our everyday lives, ignoring the social and environmental impact of this industry would be very negligible on our part.

THE ATTITUDES OF ENVIRONMENTALLY EDUCATED STUDENTS ABOUT A NEW GLOBAL DEVELOPMENT AGENDA

Jasna Petković*[1], Jelena Andreja Radaković[1]

[1]University of Belgrade - Faculty of Organizational Sciences, Serbia
* Corresponding author, e-mail: petkovic.jasna@fon.bg.ac.rs

Abstract: *The aim of this paper is to shine light on the attitudes of environmentally educated postgraduate students about a new development agenda – 2030 agenda for sustainable development, and its 17 urgent goals. In order to evaluate postgraduate students' attitudes the authors used the Delphi method. The usage of the Delphi method is suggested having in mind that a lot of authors agree that this method has high applicability for sustainability foresight, as well having in mind the fact that it is one of the best-known qualitative methods of forecasting in the long run, especially when quantitative methods are not adequate, as it happened in this case.*

Keywords*: environmentally educated students, a new global development agenda, postgraduate students' attitudes, delphi method*

1. INTRODUCTION

Today, the environmental education represents a necessary education to shape a sustainable future. This means that the environmental education must include key sustainable development issues into the curriculum of the subject, with clear goals in order to motivate the student not only to learn, but to change their attitudes, behaviour and take environmental actions for sustainable development (UNESCO, 2016).

In light of the above, the authors of the paper chose to do their research on how environmentally educated students value goals of a new global development agenda.

For the panel group the authors chose postgraduate students enrolled at the Management of Environmental Protection course at the University of Ljubljana – Faculty of Administration, the Republic of Slovenia. For the purpose of this research the authors used the Delphi method for measuring students' attitudes about 17 sustainable development goals of a new global development agenda – 2030 Agenda for Sustainable Development.

2. A NEW GLOBAL DEVELOPMENT AGENDA – THE 2030 AGENDA FOR SUSTAINABLE DEVELOPMENT

Sustainable development (SD) has been discussed extensively in the theoretical literature since the concept was adopted as an overarching goal of economic and social development by UN agencies, by the Agenda 21 nations, and by many local governments and private-sector actors (WCED, 1987). The literature includes many alternative theoretical and applied definitions of sustainable development. The theoretical work spans hundreds of studies that are based on economic theory, complex systems approaches, ecological science and other approaches that derive conditions for how development paths can meet SD criteria (IPCC, 2007).

Several definitions have been presented to describe the principle of sustainable development; the most frequently quoted being the one presented in the Brundtland Report (Brundtland, 1987). According to this report sustainable development is "development that meets the needs of the present without compromising the ability of future generations to meet their own needs". It contains within it two key concepts:

- the concept of needs, in particular the essential needs of the world's poor, to which overriding priority should be given; and
- the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs.

More operational principles of sustainability were presented by the former Chief Economist for the World Bank, Herman E. Daly. These principles are known as Daly's rules and they define the condition of ecological sustainability:

- renewable resources such as fish, soil, and groundwater must be used no faster than the rate at which they regenerate;

- non-renewable resources such as minerals and fossil fuels must be used no faster than renewable substitutes for them can be put into place; and
- pollution and wastes must be emitted no faster than natural systems can absorb them, recycle them, or render them harmless (Smith, 2010).

The General Assembly of the United Nations adopted the new resolution on 25th September of 2015. This resolution is a new sustainable development agenda for the period of 2015-2030: Transforming our world: the 2030 Agenda for Sustainable Development: "The 17 Sustainable Development Goals and 169 targets which we are announcing today demonstrate the scale and ambition of this new universal Agenda. They seek to build on the Millennium Development Goals and complete what they did not achieve. They seek to realize the human rights of all and to achieve gender equality and the empowerment of all women and girls. They are integrated and indivisible and balance the three dimensions of sustainable development: the economic, social and environmental." (UN, 2015)

The 17 Sustainable development goals are (UN, 2015):

- Goal 1: End poverty in all its forms everywhere.
- Goal 2: End hunger, achieve food security and improved nutrition and promote sustainable agriculture.
- Goal 3: Ensure healthy lives and promote well-being for all at all ages.
- Goal 4: Ensure inclusive and quality education for all and promote lifelong learning.
- Goal 5: Achieve gender equality and empower all women and girls.
- Goal 6: Ensure access to water and sanitation for all.
- Goal 7: Ensure access to affordable, reliable, sustainable and modern energy for all.
- Goal 8: Promote inclusive and sustainable economic growth, employment and decent work for all.
- Goal 9: Build resilient infrastructure, promote sustainable industrialization and foster innovation.
- Goal 10: Reduce inequality within and among countries.
- Goal 11: Make cities inclusive, safe, resilient and sustainable.
- Goal 12: Ensure sustainable consumption and production patterns.
- Goal 13: Take urgent action to combat climate change and its impacts.
- Goal 14: Conserve and sustainably use the oceans, seas and marine resources.
- Goal 15: Sustainably manage forests, combat desertification, halt and reverse land degradation, halt biodiversity loss.
- Goal 16: Promote just, peaceful and inclusive societies.
- Goal 17: Revitalize the global partnership for sustainable development.

3. DELPHI METHOD

Technology forecasting in developed countries is a process focused on recognizing critical generic technologies, and most likely it will exert great influence on economic, environmental, and social development in general. However, for underdeveloped and developing countries, the role of technology forecasting is of great importance for identifying technology niches – technology domains in which it is possible to accomplish a competitive position on the world market (Albright, 2002). Technology forecasting began to play an important role in companies' strategic planning, as well as in their race for comparative advantage. Technology forecasts use different methods among which is the Delphi method that presents one of the most widespread methods for intuitive forecasting.

Delphi method is the most commonly known forecasting method that is based on series of written questionnaires with feedback and re-voting (Popper, 2008). There are two participant roles: the design group (sometimes just one person) that makes the questionnaires and the consensus of the expert group, and the expert group – a panel that answers the questionnaires. The members of the panel do not meet face-to-face; they are characterized by three important conditions: anonymity, iteration with controlled feedback, and statistical response. This is not an opinion survey, but rather, a way of systematically finding out and summarizing expert judgment in successive rounds of the Delphi forecasts (Mullen, 2003).

Despite some limitations, it has been recommended that studies employing the Delphi should be continued in order to further refine the technique and to explore its application. The first idea for applying the Delphi method in forecasting events in education came from the article "The Delphi Technique: A Possible Tool for Predicting Future Events in Nursing Education" by Bramwell L. and Hykawy E. in which the authors have presented the potential use of the Delphi method in this area (Bramwell & Hykawy, 1999). Despite the limitations they indicated, one suggestion supported by the panellist in the study was important, which is of special interest for the society in transition. They have suggested that the Delphi method seemed to have

promising application as a tool for teaching people to think and discuss about the future in a more complex way than they ordinarily would.

The Delphi method is one of the best-known qualitative methods of forecasting in the long run, especially when quantitative methods are not adequate. It is applied for forecasting the probability and time of the emergence of future events. In order to give a prognosis, a group of experts identifies and defines the given event, the probability of its development and possible time of future event. Delphi method is also important because of the impartiality of participants bearing in mind that opinions and presumptions of forecasting experts are based on collecting data through polls, i.e. on filling out the questionnaires. Experts fill out questionnaires independently of each other, which gives this method the impartial character when it comes to judgment (Makridakis, Wheelwright, Hyndman, & 1998).

The Delphi method is an attractive method for graduate students completing masters and PhD level research. It is a flexible research technique that has been successfully used in our paper to explain Postgraduate Students' Attitudes about Sustainable Development Goals. Delphi studies have been useful in educational settings in forming guidelines, standards, and in predicting trends (Skulmoski & Hartman, 2007). The Delphi method works especially well when the goal is to improve our understanding of problems, opportunities, solutions, or to develop forecasts.

Delphi studies have been useful in educational settings in forming guidelines, standards, and in predicting trends. The Delphi Technique will be useful for educators in developing curricula and learning experiences to prepare our students for future careers. Delphi studies are extremely useful for collecting data from students and alumni regarding the curriculum, and information science trends, and funding (Green, 2014).

4. POSTGRADUATE STUDENTS' ATTITUDES ABOUT SUSTAINABLE DEVELOPMENT GOALS – A CASE STUDY

For our research we chose the students of the University of Ljubljana – Faculty of Administration, which have in the November of 2014/2015 school year attended the course Management of Environmental Protection, and which joined the research only when they have successfully finished the course.

At this course, a framework and a curriculum for good environmental higher education are developed on a wide scale of scientific and practical knowledge of environmental science and sustainable development as a good benchmark for the adequate improvement of students' knowledge at postgraduate level, as well as a promotion of higher order thinking skills in a cooperative context for learning and evaluation (Petrovic et al., 2014). Having this in mind, the curriculum of this subject accents the following topics: the resources of the Earth, particularly soil, water, minerals, etc., the implications of the resource distribution in determining the nature of societies and the rate and character of economic development, the role of science and technology in the development of societies and the impact of these technologies on environment, cooperative international and national efforts to find solutions to common global issues, and to implement strategies for a more sustainable future, processes of planning, policy-making and action for sustainability by governments, businesses, non-governmental organizations and the public (NAAEE, 1996; Petrović, 2012; FOS, 2016).

4.1. Methodology

In this paper, we discussed the application of the Delphi method in evaluation of postgraduate students' attitudes about 17 sustainable development goals of a new global development agenda by using a five point scale (1 – *the most significant*, 2 – *very significant*, 3 – *significant*, 4 – *not so significant*, 5 – *the least significant/insignificant*).

We suggested the use of the Delphi method, having in mind that Bramwell and Hykawy (1999) have suggested that the Delphi method seemed to have promising application as a tool for teaching people to think and discuss about the future in a more complex way than they ordinarily would. It can be concluded that this method has high applicability for sustainability foresight, as well as it is one of the best-known qualitative methods of forecasting in the long run, especially when quantitative methods are not adequate, as it happened in this case.

4.2. Instruments

In order to evaluate the results of the questionnaire, we used statistical analysis for calculation of the arithmetic mean rating, variance and standard deviation:

- Calculation of the arithmetic mean rating ($t_n^{)}$ was made using the following equation :

$$t_n = \frac{1}{n}\sum_{i=1}^{k} f_i \cdot t_i \quad (1)$$

where k is the number of different rating scores, f_i is a number of experts that evaluated observed item with rating score t_i, and n represents the total number of experts ($n = \sum_{i=1}^{k} f_i$).

- Calculation the variance and standard deviation were made using the following equations:

$$\sigma^2 = \frac{1}{n}\sum_{i=1}^{k} f_i t_i^{\,2} - t_n^{\,2} \quad (2)$$

$$\sigma_n = \sqrt{\sigma_n^2} \quad (3)$$

where σ_n^2 is variance and σ_n is standard deviation.

5. RESULTS AND DISCUSSION

After calculating the results of students from the first questionnaire, arithmetic mean and variance were calculated. Summarized results of the first questionnaire are given in Table 1. As a significant agreement in responses has been detected, the second round of questioning was not necessary.

Table 1: The results of the first questionnaire

No.	Sustainable development goals	Arithmetic mean (t_n)	Variance (σ^2_n)
1.	End poverty in all its forms everywhere	1.47	0.77
2.	End hunger, achieve food security and improved nutrition and promote sustainable agriculture	1.13	0.25
3.	Ensure healthy lives and promote well-being for all at all ages	1.6	0.91
4.	Ensure inclusive and quality education for all and promote lifelong learning	1.93	0.61
5.	Achieve gender equality and empower all women and girls	2.13	0.79
6.	Ensure access to water and sanitation for all	1.13	0.12
7.	Ensure access to affordable, reliable, sustainable and modern energy for all	1.67	0.48
8.	Promote inclusive and sustainable economic growth, employment and decent work for all	1.67	0.48
9.	Build resilient infrastructure, promote sustainable industrialization and foster innovation	2.33	0.90
10.	Reduce inequality within and among countries	2.20	0.96
11.	Make cities inclusive, safe, resilient and sustainable	2	0.67
12.	Ensure sustainable consumption and production patterns	2.27	0.58
13.	Take urgent action to combat climate change and its impacts	1.87	0.50
14.	Conserve and sustainably use the oceans, seas and marine resources	1.67	0.48

15.	Sustainably manage forests, combat desertification, halt and reverse land degradation, halt biodiversity loss	1.73	0.60
16.	Promote just, peaceful and inclusive societies	2.13	0.53
17.	Revitalize the global partnership for sustainable development	2.27	0.58

Based on the responses gathered, we can conclude that, in the opinion of the respondents, the most important goals of sustainable development are to:

1. Ensure access to water and sanitation for all – with the arithmetic mean of 1.13, and variance of 0.12 which is more than a good mark and shows a fair compliance when it comes to the students' attitude.
2. End hunger, achieve food security and improved nutrition and promote sustainable agriculture – with the arithmetic mean of 1.13, and variance of 0.25 which again shows the same complient attitudes as before.
3. The third place "share" the following goals - to ensure access to affordable, reliable, sustainable and modern energy for all and to promote inclusive and sustainable economic growth, employment and decent work for all and to conserve and sustainably use the oceans, seas and marine resources – with their arithmetic mean being 1.67, their variance 0.48, which are excelent marks and present a fair compliance between the students.

6. CONCLUSION

The key aim of the research presented in this paper has been to provide an idea of implementing the Delphi method in evaluating environmentally educated postgraduate students' attitudes about a new global development agenda and sustainable development goals, and proving that the Delphi method could be a good tool for the measurement of environmental education and the education for sustainable development achievements as well.

Gained results from our research pointed out that this kind of use of the Delphi method can provide good results having in mind that the results gathered, not only show a compliance in the students' responses, which speaks of the good background knowledge they gained during their studies at the course of Management of Environmental Protection, but also that the Delphi method can be used for further analysis of the reasons behind their assigning high marks to specific goals of sustainable development, which depicts the image of the students' attitudes towards these goals.

A more in depth analysis of these results demands a larger number of respondents, and not students from only one university, but instead conducting a broader and more detailed research, which should be a possible direction of future research, especially when having in mind that "a basic premise of education for sustainability is that just as there is a wholeness and interdependence to life in all its forms, so must there be a unity and wholeness to efforts to understand it and ensure its continuation" (UNESCO, 2012).

*Corresponding author, e-mail: radovanovb@ef.uns.ac.rs

Abstract: *The study examines short and long run dynamics in the relationships between six emerging South East European stock markets applying a Markov Switching Vector Error Correction Model (MS-VECM). The long run dynamics are confirmed by a cointegrating vector which relates the stock indices of observed markets. The nonlinearity of the estimated model is justified by the Log-likelihood Ratio test and the information criteria. The MS-VECM with two regimes provides an adequate illustration the of level of market integration and stability from the perspective of a regional market position. Furthermore, the model shows an ability to capture every change in the financial time series data. Also, modeling the shifts can be encouraged by the fact that the change in and between regimes should be considered as a random, unpredictable event. Finally, the study have implications regarding market efficiency hypothesis which impacts international or regional portfolio diversification and the long term economic growth prosperities. Moreover, the results show that the diversification benefits for international investors with long horizon strategy in the stock markets are quite limited.*

Keywords*: vector error correction model, markov switching, integration, stock market*

1. INTRODUCTION

Along with the beginning of the financial crisis during the 2008, it became clear that financial markets worldwide are no longer national. Stock indices were falling dramatically, while market participants were desperately seeking for better investment opportunities by following information from other stock markets. In this way, mentioned investors are trying to find new ways to yield higher returns and better risk diversification of investment portfolio.

As capital becomes borderless, the improvements in allocation efficiency and reductions in volatility have elevating the benefits of economic growth (Masood et al., 2010). Furthermore, appearance of liberalization of financial markets promotes market integration with serious consequences on efficient implementation of investment politics. One should not be ignored that an increase of market integration and its openness could lead to an increase of volatility and exposure to unwanted market equilibrium disturbances. Therefore, a transmission of market turbulences is likely higher if international financial markets are well integrated (Assidenou, 2011). Emerging financial markets are becoming less isolated to main world market movements and economic growth created by efficient financial allocation and decreases of macroeconomic volatility (Baele et al., 2004).

A financial market cointegration becomes crucial not only to the economic theory, but to an active investment portfolio management. According to the financial theory, if there is a confirmation of accepting any of three versions of the efficiency market hypothesis, than returns, yielded by investment activity, can not be predicted using any kind of public financial data. Such a phenomenon disqualifies any adjustment among financial markets over time. Hence, with existence of cointegrating relations between financial markets, the market efficiency hypothesis is rejected since mentioned markets poses relevant information about each other. On the other hand, a lack of cointegrating relationships creates investment opportunities through better risk diversification of international investment portfolio.

With the development of first methods of measuring long-run relations among financial markets, there has been made several studies that helped in decision making process. Anyway, the stable equilibrium relationships conceived by the cointegration methodology are not appropriate for modeling the dynamics of stock market integration. The traditional linear model does not allow the parameters to adjust for the structural changes. Therefore, many previous works have adopted Markov switching framework in analyzing the relationships between markets. Allowing the involvement of regimes, the mentioned methodology is well suited to domestic and international cycling shifts that affect domestic market. Moreover, it allows for changing relationships among the stock market variables across different time phases. Linked with the basic Markov switching vector autoregression model created by Hamilton (1989), a Markov Switching Vector Error

Correction Model (MS-VECM) has recommended in case of unknown regime shifts of stock market prices. In other words, the model introduce state variable generated by the Markov chain, where the market state of tomorrow is driven only by the present market state (Krolzig, 1997).
Using similar methodology, Scheicher (2001) considers financial markets of Hungary, Poland and Czech Republic and finds that mentioned markets are more influenced by the regional movements. The same author, beginning with the assumption that mentioned markets have no significant long-run connection with major world financial markets, infers that global integration of three markets remains at the same level, while regional integration is significantly high. Comparable results are confirmed by Maneschiold (2006) and Masood et al. (2010) in case of countries from Baltic region. Also, Keneurgios and Samitas (2011) examined cointegration of five emerging Balkan markets through involvement of developed financial markets. These markets show higher integration during the period of financial market breakdown in 2008. Consequently, main goal of this study is to examine short and long run integration of financial markets in region of south east European countries with the attention on the position of Serbian financial market. Also, the focus remains on convergence level of domestic stock markets to new tendencies in the region.

2. METHODOLOGY

The methodology of measuring cointegration between economic variables (Engle and Granger, 1987; Johansen, 1988) is accepted in numerous studies of long-run co-movement among international financial markets. However, long-run equilibrium of cointegration given by the basic methodology is not appropriate in case of modeling dynamic processes of market cointegration. Due to the incomplete procedure which continues to generate strong variations in results over time, it is inevitable to upgrade previous procedure emphasizing the nature of time variations. To fulfill mentioned assumption, this paper contains three supplementing methodology segments:

- Unit root testing,
- Cointegration testing and
- Markov switching vector error correction modeling.

2.1. Unit root testing

In first step, the study examines a stochastic structure of time series by applying the Augmented Dickey-Fuller test (ADF test). The test performs in order to determine the stationarity of time series. The term of stationarity implies the mean reversion in long term and avoids imposed relations in regression. In other words, the presence of these time series leads to a biased implementation of regression analysis. The ADF test begins with the equation:

$$\Delta Y_t = \alpha + \mu T + \omega Y_{t-1} + \sum_{i=1}^{p} \delta \Delta Y_{t-i} + \varepsilon_t \quad (1)$$

Based on equation (1), one tests the null hypothesis about random walk of variable Y, which implies the presence of unit root versus stationary process with trend.

2.2. Johansen's cointegration test

According to cointegration theory, it is possible to determine a cointegration relationship between time series if their first differences are stationary. Such an analysis uses Johansen's procedure of maximum likelihood as a framework for estimation and testing of cointegration relations. Therefore, mentioned procedure incorporates different short and long-run dynamic relations in the multiple variable system, as fallows:

$$\Delta Y_t = \mu + \Pi Y_{t-p} + \sum_{i=1}^{p-1} \Gamma_i \Delta Y_{t-i} + \varepsilon_t \quad (2)$$

Where Π is a matrix of the coefficients with lagged variables and Γ_i is a matrix of coefficients with first difference lagged variables. The cointegration test is calculated using ranks of eigenvalues λ. The rank of matrix Π is equal to eigenvalues different from zero. Eigenvalues are sort ascending $\lambda_1 \geq \lambda_2 \geq ... \geq \lambda_g$. Using Johansen's approach, it is possible to form test statistics of the following form:

$$\lambda(r) = -T \sum_{i=r+1}^{g} \ln(1 - \hat{\lambda}_i) \quad (3)$$

Where r is the number of cointegrated vectors based on the null hypothesis, while $\hat{\lambda}_i$ is an estimated value of the i-th eigenvalue from matrix Π. $\lambda(r)$ is a mutual test where the null hypothesis represents the number of cointegrated vectors less than or equal to r versus an alternative hypothesis that the number is greater than r.

2.3. Markov Switching Vector Error Correction Model

A vector error correction model (VECM) means a type of vector autoregressive model (VAR) with cointegration constraints installed the model specification. The model design itself is made for estimating relations between nonstationary time series. Therefore, limited application of the model demands previous cointegration testing. Although a vector error correction model is considered as an alternative to basic vector autoregressive model in cointegration relations estimation, it also has numerous limitations (Phoong et al., 2014). In such a model, the constancy of variance and covariance over time can significantly affect a reliability of model estimation. Besides, the presence of autocorrelation becomes sensitive matter in terms of number of lags include in the model. All of this guides to the introduction of the new type of a model with Markov chains, where variance and covariance are followed by the probability (state) variable.

A MS-VECM represents a special form of model in different time series regimes. This model is specially recommended in cases when the price changes (price regimes) are unknown. Thus, price changes in this model have stochastic feature. In other words, the state variable is introduced and it generates by the Markov chains, where tomorrow state of market is driven only by the today's state (Krolzig, 1997). The form of a Markov switching vector error correction model can be presented as follows:

$$\Delta Y_t = \nu(s_t) + \alpha(s_t)(\beta(s_t)'Y_{t-1}) + \sum_{i=1}^{p-1} A_i(s_t)\Delta Y_{t-i} + \varepsilon_t \tag{4}$$

Where Y_t denotes a vector of stock market indices values, $\nu(s_t)$ is a vector of intercept term, $\alpha(s_t)$ denotes a vector of the speed of adjustment coefficients, $\beta(s_t)$ is a long-run cointegrating vector and A_i is a matrix of short-run parameters, capturing the autoregressive part of price movements. One should emphasized that the main segment of equation (4) is state variable $s_t = 1,...,M$. All parts of the model specification involving this variable. Therefore, the probability of being in state s in period t is presented in expression (5).

$$P\left(s_t | s_{t-i}, \Delta Y_{t-1}, \beta' Y_{t-1}\right) = P\left(s_t | s_{t-i}, \Pi\right) \tag{5}$$

Where the square matrix Π contains probabilities π_{ij} for switching from the regime in row i to the regime in column j, conditioned on the regime in the previous period.

3. EMPIRICAL ANALYSIS

This paper studies the relationships among six emerging stock markets of South East Europen Countries (Bulgaria, Bosnia and Hercegovina, Croatia, Romania, Serbia and Slovenia). We decide to study these markets separately from global financial trends, since the stock markets in this region remain small in terms of capitalization, turnover and liquidity compared to developed countries. Also, this paper uses the period of time after the financial crisis, i.e. from the first moment of an obvious positive trend of stock indices. Therefore, the sample of six major stock exchange indices in mentioned stock markets (SOFIX, SASX-10, CROBEX, BET, BELEX15 and SBITOP) is collected from August 15, 2009 to December 31, 2015 or 1610 daily observations of stock index values. Table 1 presents descriptive statistics of stock indices returns in observed period of time.

Table 1: Descriptive statistics

Stock index	BELEX15	SASX-10	CROBEX	SBITOP	SOFIX	BET
mean	0.00016	-0.00035	0.00000	-0.00007	0.00022	0.00038
st deviation	0.01134	0.00942	0.01024	0.00999	0.01602	0.01910
maximum	0.08317	0.05938	0.08563	0.03721	0.18171	0.15188
minimum	-0.07580	-0.06940	-0.07020	-0.06059	-0.13741	-0.13709
skewness	0.43307	0.21968	0.26851	-0.20866	-0.25598	-0.25621

kurtosis	10.19771	9.58702	13.05516	5.37702	11.60195	11.63244
ρ(1)	0.25156	0.11682	0.10412	0.08303	-0.01674	-0.00104
ρ(2)	0.11627	0.01205	-0.01613	-0.00911	0.06025	0.01670
ρ(3)	0.03600	0.01401	0.06805	-0.02782	-0.03048	-0.00926
ρ(4)	0.10170	-0.01088	0.03001	-0.00577	0.04637	-0.01435

Table 1 shows daily mean value of stock index returns in observed period of time where only SASX-10 and SBITOP had negative average of returns. Standard deviation of mentioned time series of returns is similar in case of markets from former Yugoslav Republics (BELEX15, SASX-10, CROBEX and SBITOP). First three observed indices had positive skewness, while next three had negative skewness in mentioned period. According to several authors, negative skewness is a feature of developed financial markets, although it brings higher risk of potential investment. All observed indices had leptokurtic distribution (kurtosis>3), which is one of the main characteristics of financial data. Finally, autocorrelation coefficients ρ(i) did not show any sign of significant correlations between current index return in time t and lagged return in time t-i.

After a brief analysis of descriptive statistics, the next phase is to test the existence of unit root in time series of index returns using ADF test.

Table 2: Unit root testing

Stock index	ADF test
BELEX15	-2.1341***
SASX-10	-2.9014***
CROBEX	-2.5453***
SBITOP	-1.1819***
SOFIX	-1.7901***
BET	-2.1612***

Table 2 presents the results of ADF test in case of all six indices. *** denotes the level of significance bellow 1%. Hence, all six time series of index values are nonstationary or integrated in first order I(1). Considering the results, the study takes the fallowing step by testing cointegration of nonstationary time series with λ_{trace} Johansen's test.

Table 3: Testing cointegrating relations

No. of CE(s)	Eigenvalue	Trace Statistic	Critical Value	Prob.
None	0.0367	129.4103	95.7537	0.0000
At most 1	0.0184	69.3414	69.8189	0.0545
At most 2	0.0131	39.5366	47.8561	0.2395
At most 3	0.0048	18.2677	29.7971	0.5463
At most 4	0.0036	10.4927	15.4947	0.2447
At most 5	0.0029	4.6413	3.8415	0.0312

According to the mentioned procedure of cointegration testing, the results from Table 3 notice one cointegrated vector (equation) with significance level bellow 1%. It infers that there is some long-run integration among observed time series.

Mentioned results encourage the application of a vector error correction model. This study applies two different model specificiation: linear and Markov switching vector error correction model. Both models are estimated and compared by Likelihood-ratio (LR) test and Akaike information criteria. The tests show superiority of nonlinear model, MS-VECM with two regimes. Consequently, the next sequence of the paper will contain only the results of MS-VECM in case of BELEX15.

Table 4: Transition probabilities matrix

From Regime to Regime	Regime 1	Regime 2
Regime 1	0.97636	0.02365
Regime 2	0.52516	0.47484

Table 4 represents the results of transition probabilities between regimes in case of index BELEX15 returns as a dependent variable in estimated model MS(2)-VECM(1). The regime 1 is the standard regime where the volatility of returns is not to high, while the regime 2 is an extreme one where the volatility of returns is high.

At the intersection of row and column in Table 4 are the probability results of transition between regimes. Regime 1 keeps the high level of probability if it stays in the same regime. On the other hand, regime 2 has smaller probability of staying in the same regime. The following Table 5 will present the estimated model MS(2)-VECM(1).

Table 5: Estimated model MS(2)-VECM(1) in case of BELEX15

Variable		Parameter	t - statistics
regime dependent intercept	v_1	0.03699	15.2174
	v_2	-0.00055	-1.68979
short run dynamics	$\Delta BELEX_{t-1}$	0.27759	9.81806
	$\Delta CROBEX_{t-1}$	0.07550	3.13114
	$\Delta SOFIX_{t-1}$	-0.02375	-1.83588
	$\Delta SBITOP_{t-1}$	0.08630	3.59641
	$\Delta SASX_{t-1}$	0.08474	3.12833
error correction	ecm_{t-1}	-4.65868	-235.252
long run dynamics	Regime 1	0.11095	4.66905
	Regime 2	0.18593	3.48221

Estimated Markov switching vector error correction model is presented in Table 5. There are three main components that could be identified by interpreting the results from the model: short and lon-run market integration, market stability and average regime duration.

The market integration will be investigated by the estimated parameters, presented in Table 5. Regime dependent intercepts v_1 and v_2 are the model starting point coefficients. These coefficients are significantly different between regimes. The parameters estimated with $\Delta BELEX_{t-1}$, $\Delta CROBEX_{t-1}$, $\Delta SOFIX_{t-1}$, $\Delta SBITOP_{t-1}$, $\Delta SASX_{t-1}$ represent the autoregressive parts of the model in short-run with non-switching parts. The index BET is excluded from the model due to the statistical significance. Therefore, we noticed some weaker linkage between BELEX15 index and BET index in short-run. In addition, the model shows a potential problem with the significance level in case of SOFIX index. Hence, in short-run the strong connections are noticed in case of four observed market indices from former Yugoslav Republics. The error correction term is highly statistically significant, which means that BELEX15 is able to adjust to new trends in the mentioned region. In other words, the region of South East European financial markets is highly integrated in long-run and partly in short-run. Long-run dynamics parameters show strong long run integration of BELEX15 in region of south east European stock markets in both regimes. These two parameters are also represented as elasticity parameters which show long run transmission of the price changes from the mentioned region to Serbian financial market. There is no significant difference in elasticity parameters between regimes.

The stability of the national financial market is investigated using filtered probabilities of dependent variable being in one of two mentioned regimes. Applying estimated MS(2)-VECM(1), Figure 1 represents distribution of those probabilities in observed sample period.

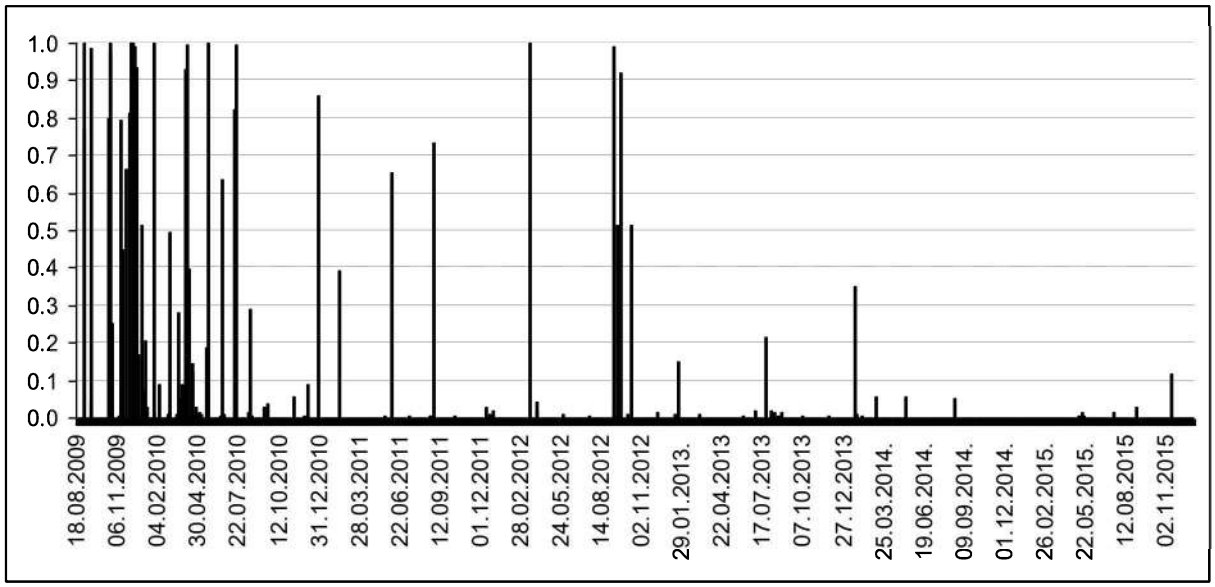

Figure 1: Filtered probabilities of being in regime 2

Figure 1 presents filtered probabilities of state variable being in regime 2 (regime of extreme changes). The most of the sample time the state variable was in regime 1. This figure points out that BELEX15 is in period of stabile price changes, especially in last 4 years where extreme regime appeared in only few observations and, what is even more important, it does not retain in following daily observations. Moreover, only 32 of 1610 daily observations, involved in the analysis, have the probability of being in regime 2 more than 50%.

To support the fact about market stability, the estimated MS(2)-VECM(1) provide the average time duration of each regime. Accordingly, dependent variable (BELEX15 index) retains in the period of stabile price changes for 42.2917 daily observations in average, while the period of extreme price changes last for 1.9042 daily observations in average.

4. CONCLUSION

Serbian financial market and other observed market due to their size and volume of trade belong to the category of small emerging markets in global scale. Therefore, it is inevitable to analyze international, as well as regional, financial effects before any investment decision making. Such an approach brings an opinion about the level of market integration and stability from the perspective of a regional market position. From the estimated results, it is obvious that the movement of BELEX15 index is highly connected with the signals from the neighboring financial markets. However, price stability in observed market shows that they became less immunized to external movements. For that reason, the results of the estimated MS(2)-VECM(1) indicate that both domestic and external factors shape the long-run equilibrium of mentioned stock markets.

According to growing integration between neighboring markets, the results have implications regarding market efficiency hypothesis which impacts international or regional portfolio diversification and the long term economic growth prosperities. In other words, the diversification benefits for international investors with long horizon strategy in the stock markets are quite limited. However, small number of significant extreme regime appearance probabilities in last three years creates favourable conditions to attract many domestic and foreign rational investors.

Abstract: *In this paper, we analyze the performance of the system for the administration of public revenues by mathematical modeling. Due to the economic crisis, the governments in many countries implement radical fiscal measures. Fiscal consolidation is a key element for creating a stable macroeconomic environment. In this regard, the establishment of an efficient tax administration is one of the key factors for creating macroeconomic stability and attractive business environment. The quality of a business environment has strong positive influence on the level of direct investments in every country. The obtained results have showed that the countries in which the tax administrations are efficient, resulting in a more stable macroeconomic environment, which leads to a higher levels of foreign direct investment. Strong institutions and a high level of foreign direct investments are the way to improve economy and to increase standard of living in countries.*

Keywords*: tax administration, data envelopment analysis, foreign direct investments*

1. INTRODUCTION

Tax Administration is essential for every country. In the situation with full tax compliance, which is extreme and an ideal situation, the role of the Tax Administration would be restricted to the provision of facilities for citizens to discharge their responsibilities to the society. In the case of non-compliance, the Tax Administration will have to play the role of policeman. Due to lack of resources and in the situation that it cannot play the role of a policeman to all taxpayers, one of the solutions is to support a voluntary compliance. In that sense, the fundamental role of the Tax Administration is to render quality taxpayer services and to encourage voluntary compliance of tax laws, to detect and penalize non-compliance. The extent of success of the Tax Administration in its role should be reflected through a higher revenue growth. Only with collected taxes, governments are able to provide all public services and to implement welfare programs. In addition, the level of grey economy is one of the parameters of a state in economy. It can be said that there is a connection between business environment regulations and the level of grey economy. Better environment regulations lead to a lower level of the grey economy because enterprises do not have incentives to go in the grey economy on one side and going into the grey economy is punishable on the other side. Adequate environment in which enterprises operate will encourage them to stay in formal economy. In other words, the level of grey economy is lower and enterprises are more responsible to pay taxes in a more regulated business environment. That creates culture where cheating the government is not acceptable and even more than that, it is punishable. In addition, quality of business environment has strong influence on the level of direct investments into every country. Having this in mind, a better regulated business environment will attract more foreign direct investments. In that sense, countries have to strive to attract direct investments in order to increase quality of their economies. To establish pro-business environment and to increase investments, an effective and efficient Tax Administration is a necessary element. The increasing efficiency and effectiveness of Tax Administration will surely be followed by decreasing level of the grey economy and a more friendly business environment for foreign investments.

The taxpayer's decision to comply, or not to comply, with his fiscal obligations has been the subject of considerable literature on the themes of tax evasion (Bird, 2004). There are two different paradigms that are used in order to encourage tax compliance, each with different implications for tax compliance behaviour. The first paradigm is a standard economic model of tax evasion based on the economic theory of crime that emphasizes repression of illegal behaviour through frequent audits and rigid penalties. The second paradigm recognizes the role of enforcement strategy (audit and penalties), but also emphasizes the role of tax administrators as facilitators and a providers of services to taxpaying. It stresses the role of social norms in tax compliance, in the sense that the government can change tax compliance by changing the social norm of tax compliance (Bird, Martinez-Vazquez & Alm, 2003: 156). Regarding Tax theory, focus will be on the services provided by the tax administration to increase tax compliance (second paradigm) but we should have to bear in mind that enforcement elements are the second very important part to increase tax

compliance (first paradigm). This paper aims to compare the efficiency of the systems for the administration of public revenues among different develop and developing countries. Similar attempt is made by Savić at. al (2015) who tried to establish the linkage between the tax administration efficiency and tax evasion in 17 European union members and non-members. They proposed two stage methodology consists of the data envelopment analysis for the tax administration efficiency evaluation and regression model defined to find out the relation between a level of grey economy and level of the tax administration efficiency, GDP level and other characteristics of economy. The results have shown the strongest impact of tax administration efficiency on the decreasing the level of grey economy. This paper is organized as follows. A DEA based methodology in given in the second chapter. A DEA efficiency measurement of the tax administration systems is given the chapter 3, followed by conclusion remarks and literature.

2. METHODOLOGY

The idea of efficiency measurement was developed by Farrell (1957) when he used non-parametric efficiency limits approach to measuring the efficiency of the relative distances from the efficient frontier. This measure, which is well known as empirical or relative efficiency was later expanded in the work of other researchers. Data Envelopment Analysis (DEA) was introduced by Charnes, Cooper and Rhodes (1978). Their model is known as CCR model. Business units, their activities or processes in the DEA terminology are seen as Decision Making Units (DMU). DMU is the unit that actually make business decisions, and whose performance is characterized by a set of inputs and outputs, and their interdependence. It operates with constant returns to scale (CRS) which implies that a change in the amounts of the inputs leads to the same proportional change in the amounts of the outputs. Efficiency ratio is scaled between 0 and 1, and all efficient units have the same ratio equal to 1. Following this model, Banker, Charnes, and Cooper (1984) have extended the original CCR model by introducing the assumption of variable returns to scale (VRS). In the literature this model is known as a BCC model. The VRS efficiency scores measure pure technical efficiency excluding the effects of scale operations. They are greater than the corresponding CRS efficiency scores. BCC model is able to distinguish between technical and scale inefficiency. Technical inefficiency is calculated by measuring how well the unit uses its inputs to create outputs, while scale inefficiency identifies whether increasing, decreasing, or constant returns to scale exist. There are two main orientation of DEA model: input and output orientation. Input-oriented DEA model aims to minimize the input with given level of output. On the other side, in output-oriented DEA model aim is to maximize the output with given level of input. In the envelopment model, the number of degrees of freedom will increase with the number of DMUs and decrease with the number of inputs and outputs. A rule of thumb which can provide guidance is as follows (Cooper, Seiford, and Tone, 2000): $n \geq \max\{m \times s, 3 \times (m+s)\}$; where n is number of DMUs, m is number of inputs and s is number of outputs. This pre-condition has been fulfilled by the analysis in this paper.

Consider a set of n DMUs, with each DMUj, j = 1,..,n, using m inputs x_{ij} (i = 1,...,m) and generating s outputs y_{rj} (r=1,...,s).Then the primal linear program for the (input-based) CCR model, that gives optimal efficiency score θ^* for DMU0, can be written as:

$$\theta^* = \min \theta \tag{1}$$

s.t.

$$\sum_{j=1}^{n} \lambda_j y_{rj} \geq y_{r0}, \quad r = 1,...,s \tag{2}$$

$$\sum_{j=1}^{n} \lambda_j x_{ij} \leq \theta x_{i0}, \quad i = 1,...,m \tag{3}$$

$$\lambda_j \geq 0, \quad j = 1,...,n \tag{4}$$

where θ is the efficiency score for the particular DMU, x_{i0} and y_{r0} are, respectively, the i-th input and r-th output for DMU_0 under evaluation, while λ_j represent unknown value assigned to DMUj, j=1,...,n. The efficient frontier consists of DMUs with $\lambda_j \neq 0$. The dual linear program to model (1)-(4) is

$$\max \sum_{r=1}^{s} u_r y_{r0} \tag{5}$$

s.t.

$$\sum_{i=1}^{m} v_i x_{i0} = 1 \tag{6}$$

$$\sum_{r=1}^{s} u_r y_{rj} - \sum_{i=1}^{m} v_i x_{ij} \leq 0, \quad j = 1, 2, ..., n \tag{7}$$

$$u_r \geq 0,\ r = 1,...,s$$
$$v_i \geq 0,\ i = 1,...,m \tag{8}$$

where u_r is the weight assigned to output r, r=1,..,s and u_i is weight assign to input i, i=1,..,m. A DMU_0 is said to be CCR efficient if and only if θ^*= 1 and all optimum slack values obtained by solving model (1)-(4).

In this paper DEA is used for comparative analysis of tax administration efficiency in the selected countries. Procedure of DEA method applying could be divided into following steps (Popović, and Martić, 2005):

1. Choosing and definition of DMU's,
2. Defining relevant inputs and outputs,
3. Choosing adequate DEA model, and
4. DEA model solving, analysing and interpretation of results.

At this point, we will emphasize the importance of choosing the adequate DEA model. This choice will depend on the context of research, and the previous two phases in its implementation. A set of countries that are assessed in this research consists of countries classified in the group of high income and countries with upper-middle income according to the World Bank classification. Therefore, it can be said that they belong to distinguish a group and adequate DEA models for the comparison between different systems and bilateral DEA model are going to be used.

Efficiency comparison between different systems is achieved by solving the mixed integer linear programming model (Cooper, Seiford & Tone, 2000). The set of n DMUs is divided into a set A and set B and model is defined as follows:

$$\theta^* = \min \theta \tag{9}$$

s.t.

$$\sum_{j \in A} \lambda_j^A y_{rj}^A + \sum_{j \in B}^{n} \lambda_j^B y_{rj}^B \geq y_{r0}, \quad r = 1,...,s \tag{10}$$

$$\sum_{j \in A} \lambda_j^A x_{ij}^A + \sum_{j \in B} \lambda_j^B x_{ij}^B \leq \theta x_{i0}, \quad i = 1,...,m \tag{11}$$

$$0 \leq \lambda_j^A \leq z_j^A, \quad j \in A \tag{12}$$

$$0 \leq \lambda_j^B \leq z_j^B, \quad j \in B \tag{13}$$

$$z_j^A + z_j^B = 1, \quad j \in B \tag{14}$$

$$\lambda_j^A \geq 0,\ z_j^A \in \{0,1\}, j \in A,\ \lambda_j^B \geq 0,\ z_j^B \in \{0,1\}, j \in B, \tag{15}$$

where z_j^A and z_j^B are binary variables define that production possibility set consists of DMUs belongs to the set A ($z_j^A = 1,\ z_j^B = 0$) or to the set B ($z_j^A = 0,\ z_j^B = 1$). For example, the reference set for $\mathrm{DMU}_0 \in A$ can be consists of DMUs in set A or B (*inter* and *within* comparison) and *vice versa*. The model can be solved as a sequence of two linear models and choosing an optimal value $\theta^* = \min\{\theta_A, \theta_B\}$. Strict *inter* comparison (the reference set for $\mathrm{DMU}_0 \in A$ can be consists exclusively of DMUs in set B and vice versa) can be done with by solving the following model:

$$\theta^* = \min \theta \tag{16}$$

s.t.

$$\sum_{j \in B}^{n} \lambda_j y_{rj}^B \geq y_{r0}, \quad r = 1,...,s \tag{17}$$

$$\sum_{j \in B} \lambda_j x_{ij}^B \leq \theta x_{i0}, \quad i = 1,...,m \tag{18}$$

$$\lambda_j \geq 0,\ j = 1,...,n \tag{19}$$

The two systems A and B can be compared by observing efficiency of each DMU in each system. For that purpose, nonparametric Wilcoxon Mann-Witney rank-sum is used to identify weather the difference between

two groups is significant. Presented models are used for the efficiency evaluation of tax administration systems in 94 countries.

3. DEA EFFICIENCY MEASUREMENT

In the DEA analysis the following input and output parameters have been used. The parameters are determined by goal definition that is measuring the efficiency of the tax administration. All input and output parameters relating to the year 2013. The following inputs are used:

- Time to comply–corporate income tax (I1)
- Time to comply –labour tax (I2)
- Time to comply –consumption tax (I3)
- Tax payment - profit tax (I4)
- Tax payment – labour tax (I5)
- Tax payment - other taxes (I6)
- Tax rate - profit tax (IN7)
- Tax rate - labour tax (IN8)
- Tax rate - other taxes (IN9)

Tax rates are non-discretionary variables, considering that management cannot influence the decision on their size, and they are out of reach decision makers. On the other hand, the output parameters are:

- The level of foreign direct investment, in dollars (O1)
- Gross domestic product in dollars (O2)

Tax administration plays an important role in ensuring overall macroeconomic stability, which has a positive impact on foreign direct investment (Barthel et al, 2008; Shahzad and Al-Świda, 2013). On the other hand, foreign direct investment is an important element of economic growth (Lim, 2001). Selected input and output parameters are important for tax administration businesses and they are derived on the basis of the existing models for assessing the performance of tax administration (European Commission, 2007; the International Finance Corporation, 2015; International Monetary Fund, 2012; World Bank, 2012). Input parameters represent the efficiency of the tax administration in establishing a stable macroeconomic and fiscal environment, while output parameters represent the level of development of the country and attractiveness for foreign direct investments. In this model, the tax administration has the role as a key factor for attracting foreign direct investment through the creation of preconditions for their attraction. The value of the input and output parameters is given in Table 1 in Annex. DMUs have been selected on high income countries and countries with upper-middle income defined by the World Bank classification. The total number of countries is 94, out of which 48 countries with high-income countries, and 46 countries with upper middle income.

Table 1. Descriptive statistics of results

		DEA CRS		Bilateral DEA CRS

	Min	1		0.319		0.013		0.013	
	Max	0.349		1		0.514		1	
	SD	0.216		0.091		0.109		0.339	

The efficiency assessment and comparison between two groups is done by CCR DEA (1-4) and (5)-(8) and system DEA model (9)-(15). A descriptive statistics of results is given in the Table 1. The models are solved using DEA Solver Pro software (Cooper, Seiford, &Tone K, 2000). The basic results show that there are 17 efficient out of 94 countries no meter if they are compared within or inter group. The second analysis, which compares efficiency of two groups, shows that all efficient countries are in the group 1 of high-income countries. Furthermore, based on descriptive statistics high-income countries with average efficiency scores of 0.634 performs better than upper-middle income counties, which will be check later by comparing efficiencies of two groups and performing rank-sum test.

Afterwards, countries are inter-compared ranked bya bilateral DEA model, and efficiency scores of tax administration are shown in the Table 2.

Table 2. DEA Bilateral Efficiency scores

Rank	DMU	Score	Rank	DMU	Score
1	Bahrain	657.030	49	Chile	0.514
2	Hong Kong SAR, China	276.321	50	Botswana	0.506
3	Netherlands	74.290	51	Iraq	0.459
4	Argentina	50.210	52	Kazakhstan	0.277
5	Croatia	49.668	53	Palau	0.259
6	Luxembourg	40.651	54	Namibia	0.246
7	Saudi Arabia	35.107	55	Libya	0.220
8	Singapore	32.497	56	St. Lucia	0.220
9	Oman	20.844	57	South Africa	0.218
10	Brunei Darussalam	19.861	58	Brazil	0.215
11	United States	19.708	59	Grenada	0.212
12	Australia	19.336	60	Mexico	0.212
13	Bahamas, The	19.273	61	Lebanon	0.200
14	Equatorial Guinea	15.343	62	Turkey	0.196
15	Canada	14.428	63	Romania	0.177
16	Ireland	12.725	64	Belize	0.160
17	Estonia	12.022	65	Thailand	0.157
18	Cyprus	9.901	66	St. Vincent and the Grenadines	0.151
19	France	6.334	67	Azerbaijan	0.139
20	United Kingdom	6.146	68	Bulgaria	0.134
21	Germany	5.827	69	Colombia	0.132
22	Seychelles	5.779	70	Macedonia, FYR	0.130
23	Iceland	5.472	71	Algeria	0.129
24	Spain	5.227	72	Maldives	0.129
25	Austria	5.214	73	Malaysia	0.128
26	Russian Federation	4.853	74	Tonga	0.125
27	Korea, Rep.	4.262	75	Peru	0.123
28	Italy	4.046	76	Dominica	0.117
29	Slovak Republic	3.848	77	Ecuador	0.112
30	Israel	3.762	78	Montenegro	0.111
31	Malta	3.683	79	Costa Rica	0.103
32	Portugal	3.502	80	Belarus	0.100
33	Greece	2.849	81	Gabon	0.095
34	Latvia	2.838	82	Fiji	0.094
35	Japan	2.786	83	Bosnia and Herzegovina	0.088
36	Czech Republic	2.514	84	Panama	0.083
37	Lithuania	2.417	85	Jordan	0.079
38	Slovenia	2.093	86	Marshall Islands	0.075
39	Trinidad and Tobago	1.597	87	Dominican Republic	0.074
40	Poland	1.546	88	Iran, Islamic Rep.	0.067
41	Barbados	1.540	89	Jamaica	0.056
42	St. Kitts and Nevis	1.385	90	Paraguay	0.051
43	Uruguay	1.105	91	Serbia	0.047
44	Venezuela, RB	1.020	92	Mongolia	0.046
45	United Arab Emirates	1.000	93	Albania	0.036
45	Chile	1.000	94	Mauritania	0.013
45	Kuwait	1.000			
48	Grenada	0.969			

Based on the results, the null hypothesis is rejected that the two groups have similar distribution of the results, with the test statistic 6.813. As it is expected efficiency of the group 1 prevailed efficiency of group 2. Tax administrations in high-income countries are more efficient then the tax administrations in upper-middle income countries.

Special attention is paid on tax administration efficiency in Serbia. Serbia belongs to a group of upper-middle income countries as 91 out of 96 countries. The input-output values, projections and reference set are given in Table 3. Obviously, all inputs, regardless of whether they are related to time to comply, tax payment or tax rate, should be reduced for more than 90% in order to become efficient tax administration with current level of outputs. On the bottom of the Table 3, last two rows show that average changes need for achievement of full efficiency is between 63% and 79% in group 1, while the average required changes for the group 2 are from 86% to 95%. Therefore, the required changes in Serbia are above average for the group 2.

Table 3. Serbia - efficiency results

4. CONCLUSIONS

In the paper, it was assessed the efficiency of the system for the administration of public revenues by DEA methods. It was used bilateral DEA model for conducting an analysis. The results have showed that the countries in which the tax administrations are efficient, resulting in a more stable macroeconomic environment, which leads to a higher levels of foreign direct investment. Actually, Tax Administration's influence on the level of direct investments is reflected through the set up an adequate business environment and in establishing macroeconomic stability. Furthermore, these two elements are complementary to each other. Namely, macroeconomic stability has a strong positive influence on business environment, and the other way around. In addition to that, both elements have positive influence on the level of direct investments in transition countries. Strong institutions and a high level of foreign investments are the way to improve economy and to increase standard of living in countries. Decreasing the level of grey economy and increasing the level of foreign investments are possible only with a strong Tax Administration. Moving Serbia towards EU will have positive influence on the capacity of the Tax Administration on one side and on the level of the underground economy (business environment) and macroeconomic (fiscal) stability on the other side. As a result, level of direct investments will increase and that will lead to higher living standard for all citizens in Serbia. Based on previous experience of new EU members, EU membership brings improvements to the capacity of Tax Administration, lower levels of grey economy and increasing levels of foreign direct investments. Accordingly, Serbia has to follow this path in order to improve its own economy and quality of life for all citizens.

PROGRAM BUDGETING OF LOCAL AUTHORITIES IN SERBIA – A TOOL FOR CITIZEN PARTICIPATION AND SUSTAINABLE DEVELOPMENT

Vladimir Jovanović[1], Snežana Knežević[2]
[1]Standing Conference of Towns and Municipalities, National Association of Local Authorities in Serbia, vladimir.jovanovicbg@gmail.com
[2] Faculty of Organizational Sciences, University of Belgrade, knezevics@fon.bg.ac.rs

Abstract: *This paper shows challenges in process of creating and executing program type budget, as a relatively new concept for local authorities in Serbia. It aims to show importance of this concept from the perspective of citizens' participation, and its relation with the process of strategic planning. The paper shows significance of realistic and reachable strategic goals foreseen in local strategic documents as a precondition for preparation of program budget for a budget and following two fiscal years.*

Keywords*: local authorities, budget, strategic plans, citizens' participation*

1. INTRODUCTION

Regardless of the political system in any given state, local self-government (if it exists as such) performs functions that represent counter-balance of central authorities, performing along the way corrective role of central government. The other reason for having local level of government is that it satisfies the needs of local citizens, which could not be fulfilled by central authorities. In countries that have established local authorities, apart from traditional division of authorities into independent branches (legislative, executive and judiciary), there is also a vertical division into central and one or more levels of local authorities.

Adopting a number of laws after year 2000, and Adopting the Constitution of the Republic of Serbia in 2006, foundations for modern local self-governments were set, and they remain, more or less unchanged till present day. Constitution of the Republic of Serbia (2006) in article 87, guarantees property of local authorities. The fact this is stated in the Constitution tells about determination of a country to pace a road of independence for local authorities and their autonomous functioning. Through a number of adopted laws that followed Constitution, local self-government in Serbia got clear systemic foundations, financial position was improved, new competences introduced, primary steps in establishing international cooperation taken and a number of projects supported by bilateral donations initiated and conducted.

Scope of activities of local self-governments is set in Constitution and Law on Local Self-Government (2007). Applying the method of enumeration in both of these legal acts, legislators strived for precise definition of whole spectrum of responsibilities and tasks that should fall under primary scope of work of local authorities. Apart from that, there is also a number of tasks that central authorities assign to local governments. Separate (so called sectorial) laws regulate these tasks. It is important to understand that these assigned tasks still lay under responsibility of central authorities, although performed by local ones. It would be reasonable that these assigned tasks are under responsibility of those by whom they are performed, and that they are followed by transfer of funds from central budget, so tasks additionally given to local authorities could be adequately performed. It is unfortunate that is still not always the case. Transferring just tasks without appropriate funds puts towns and municipalities in rather unsuitable position, making them provide and deliver new services out of already tight budget they have on their disposal.

Significant developments and improvements in the legal and regulatory framework, including the system of local government financing, are still expected in period ahead of us. Moreover, as Serbia approaches a potential date for EU accession, the need for preparations within local authorities will grow. Higher-quality services, enhanced dialogue with stakeholders and more efficient local administrations will be essential if municipalities, and indeed the country as a whole, are to meet EU standards and make the most of the opportunities that accession will bring.

2. STRATEGIC DOCUMENTS AND PRINCIPLE OF GOOD GOVERNANCE

Serbian national government has adopted several strategic documents in past several years, with particular emphasis on good governance and public administration reform. *The national objective identified in The*

National priorities for international assistance (2014-2017 with 2020 projections) is "to achieve standards of Good Governance by creating an efficient, effective, transparent and professional public administration that fits the needs of the citizens and business and contributes to sustainable social and economic development of Serbia" (p. 85). Another strategic document Fiscal Strategy of for 2015 with projections for 2016 and 2017 recognizes that in order to establish long-term sustainability of public finances, the implementation of the structural reforms of public sector should be speeded up, referring primarily to the public administration system, the public finances management, and local public finances management (p. 82-88).

In order to respond to requirements of EU accession process and adopted strategies of National Government, local governments of Serbia started addressing one of the many requirements put in front of them- they introduced rather new approach in Serbia in regard to local budget in form of program budgeting.

3. BUDGET AND PUBLIC FINANCES

It is very often the case that budget and public finances are mixed in sense of terminology but also in sense of understanding what these terms actually represent. Unlike public finances, which represent public revenue collection and making expenditures, i.e. spending of public funds, budget is a detailed, annual, obligatory systematized plan of collection and spending of public funds for a certain period, usually for one year. The budget foresees and allocates public expenditure and revenue, connects them, as provided by law, in a rational and coherent system of public finance. However, the budget is a key mechanism in public finances and represents a financial expression of working programs of the national or local government for a given year.

Local governments, being the closest to citizens of all levels of government, should be able to recognize the needs of its citizens, and those needs should be reflected in local budgets. This would practically mean that citizens are included in decision making process and those decisions are then reflected through expenditure of finances, i.e. through local budget. This creates circle of trust among local administration and citizens, and ideally, willingness of citizens to pay even higher taxes if they understand what money is spent on and how it is spent.

4. LOCAL BUDGET AND CITIZENS' INVOLVEMENT

John L. Mikesell in publication of World Bank edited by Anwar Shah (2007) points out that "The citizenry is more inclined to accept increased tax payments when it sees a clear link between payment of the tax and improved government services. When taxes are levied and collected at the central government level, that link can be hard to see. Payments disappear into the national treasury, and the funds get used in ways that have little identifiable consequence or impact on the taxpayer. The relationship can be radically different in the local fiscal structure. The governing body levies a tax for local roads, for example: the tax is collected locally, the money is spent on the local roads, and the citizenry can see the link between the tax and the service" (p. 18). The same parallel can be drawn in process of creating a budget and participation of citizens. The more citizens are informed on budget and included in process of its creation, the more they will approve local decisions. In many cases, when local citizens were not included in process of budget creation, it has been the case that local decisions and work of local government has been obstructed. This situation is not favorable neither for local politicians nor for the citizens- it stops progress, local services can not be fully provided, dissatisfaction raises.

In last several decades in Serbia, it cannot be judged that citizens were fully and appropriately involved in process of creating of local budgets. Although the process was always public in the sense that it has been published on local web page, local authorities did not put too much effort in actual citizen participation in the process. This kind of attitude and approach, i.e. exclusion of citizens from the process, has been justified by complexity of the process, inability of citizens to comprehend complicated budget lines etc, and thus it has very often been judged that involvement of citizens will additionally confuse already challenging and demanding process. On the other hand, citizens did not show too much enthusiasm for the process, estimating their involvement will not change anything, either way.

Ebdon and Franklin (2006) point out why participation process is valuable: „ Participation can be very useful in educating the public about key trade-offs and gaining valuable input from citizens about their priorities and preferences. Working with them to make these connections encourages citizens to participate in a more knowledgeable fashion rather than simply demand that their fi re station or library remain open without tax increases or other service cuts" (p. 444-445).

Process of budget adopting without too much of citizen involvement could have occurred during times when no strategies were being prepared, and thus no citizen or participation of professionals and experts and their input was needed. But, the process of creating local strategies was imposed to Serbian local governments as a pre-requisite for entering EU, i.e. for accessing European pre-accession funds. In that line, involvement of citizens through public debates and public fora is mandatory during the process of strategies creation. In parallel to this, when citizens realized they can influence decision making process in their community, through participation in creating local strategic document and budget accordingly, situation changes in a positive direction.

5. STRATEGIC PLANNING AND PROGRAM BUDGETING

Strategic planning is an important tool for adjusting to a changing environment. This kind of planning provides a clear definition of priorities and it determines the best ways of using the resources necessary for effective and efficient development, which are always limited. As such, it allows local authorities to effectively deal with the problems of development and growth. Local governments that develop and implement their strategic plans, are in general, more successful in managing local development, especially if they create strategies through a participatory process that includes the participation of all relevant subjects in the planning of the future of the local community.

In its course to reform and improve public finance management, Serbia decided to introduce Program budgeting, initially planned for 2009. It was postponed for 2015 according to article 112 stipulated in the Law on the Budget System (2015). This rather new approach for Serbia puts emphasis on prioritization and optimization of expenditure, in order to encourage economic growth and the efficient delivery and quality services of the public administration. But, in order to achieve this, several preconditions need to be fulfilled, *as stated in Budget process in the Republic of Serbia: Deficiencies and recommendations (2014): "Therefore, the preconditions for establishing a more efficient and more effective budget process include adequate political support, development of human and operational capacities, as well as the adoption of a consistent reform agenda in accordance with the best international experiences and adapted to the Serbian conditions" (p. 1).* Here may lay the explanation why the process of introducing Program Budgeting was postponed for more than a few years than it was originally planned - it shows that human capacities and political will were missing for this process. It is important to stress here that Program Budgeting is a process within which involvement of different stakeholders is needed, which is then leading to more transparency and easier access to information when, where and why finances were spent. Transitional countries almost by rule tend to keep budgeting process away from public eye, which leaves them a lot of space for maneuvering with public funds.

Regardless of this, Serbia showed political determination to accelerate the process of introducing Program Budgeting. As a country, Serbia judged, as literature states, program budgeting to be an effective mechanism for the implementation of public finance reform process, since it enables better performance management of public administration, greater responsibility of the budget beneficiaries, at the same time establishing a stronger link between local budget, local priorities and the implementation of public policies. In addition, Program Budget brings a greater transparency in the process of expenditure of financial resources, but is also regarded as a transparent tool in process of satisfaction of the citizens' local needs.

Budget of a certain town or municipality is considered to be one of most important acts adopted by the local assembly. Having this in mind, the process of budget creation should be approached in a serious and systematic way and with sufficient resources. Poor or inadequate budget that is not in line with local needs and development directions is a major constraint for the local community. Out of this reason, it is of high importance to have program budget aligned with strategic priorities and documents of local community. Since local strategic documents should set medium and long-term outputs an a realistic manner, it is not surprising that *Guidelines for the program budget development (2014) say that "Program budget enables matching alignment of medium-term outcomes and allocation of budget funds in order to improve the management of public policy. Public policy is reflected in the program budget because the expenditures are directly linked with the implementation of the program, program activities and projects that that lead to achievement and fulfilment of public policy. Program budget includes objectives and performance indicators and therefore allows monitoring of results of the implementation of public policies. Budget beneficiaries are expected to submit information on their programs, activities, projects and objectives, and make decisions on the allocation of budgetary funds accordingly. The aim of this type of budgeting is to improve the efficiency and budget expenditures" (p. 10).* Having this in mind, it can be concluded that strategic planning and program budgeting should be viewed as two segments of one process, which processes are interlinked and determine one another. Strategic plan, as an output of strategic planning is a basis for preparation of program budget for a budget year and two following fiscal years.

Preparation and executing of the budget, accountability and transparency of the expenditure evolved over the years. *Vujović (2012) says that "Traditionally, governments did little to justify the use of budget funds. They only had to provide evidence that budget resources under their control were used in line with the prevailing laws, rules and standards. The traditional accountability ended with a simple proof of (cost and input) compliance" (p. 20).* Situation has changed drastically in last decades, and now citizens want to be better informed on how public budgets are spent, and if the budgets could be spent in a more efficient way. In order to satisfy this public demand, concept of Program Budgeting provides some of the answers to the demand, which includes, relatively new concepts for Serbia, such are outputs, performance indicators and performance measurement. *Vujović (2012) says that "In its modern meaning, performance measurement (PM) is predominantly focused on performance monitoring in the broader context of public sector accountability. Used in conjunction with appropriately designed performance indicators (PI), they form the core of modern PM/PI systems that play a pivotal role in the evolution of performance oriented budgeting systems" (p. 18). Vujovic additionally notices that "Initially, the demand for more robust PM/PI systems originated from a desire to improve the quality of the budget process and move from input based line budgeting to output (program) based and, ultimately, outcome focused budgeting. Now advances in developing better and more robust PM/PI systems contribute to the constantly evolving quality and transparency of the budget process, help improve the efficiency of public resources in providing goods and services, as well as enhance efficacy in achieving stated objectives (i.e. immediate, intermediate and final outcomes)" (p. 22).*

6. LINE - ITEM AND PROGRAM BUDGETS - MAIN DIFFERENCE

For several reasons it became obvious that line-item budget had to be replaced with a different concept. One of them is greater focusing on results (outcomes), and efficiency and efficacy i.e. demand of the citizens to be completely informed what tax money is spent on. Line-item budget in a simple manner provides information on expenditure but not on the effects of spending. *Gianakis and McCue notice that "In focusing on the funds expended in specific categories, the line-item format drives policy and efficiency considerations into the background. It centers budget deliberations on the cost questions, rather than on how the work is done or what ends are to be achieved" (p. 21).*

Even it is relatively easy to prepare line-item type of budget, which is why the process of program budget has been postponed in Serbia, this type of budget does not provide required information on budget beneficiaries, activities nor local government. It provides simple information on amount spent on salaries, capital outlay, maintenance, purchase of goods etc. It does not give the information of the effects of such expenditure neither of kind of services provided for citizens. This type of budget does not say how many children are enrolled in kindergartens, how many kilometers of roads are repaired or cleaned. In order to respond to these questions, and to have broader perspective of how and on what public finances are spent, expenditures in budget ought to be re-arranged through variety of programs/ program areas, focusing on expected outcomes.

6.1. Program and Performance Budget Approach

Mukdad (2013) says that "Many writers separate "performance budget" and "program budget" as in many ways the latter was an evolutionary stage of the former" (p. 90). The same author finds, as many others, that program and performance budget are two sides of different coin (p.90). In effort to define program budget, Mukdad says "In very simple words, the idea behind the program and performance budget approach is, first, to propose that money distribute—customarily—to different departments according to specific types of expenditure . . . (line item); be spent, secondly, according to the developed, detailed listing of all activities of the whole organization or department . . . (program); in order to perform –thirdly—a listing of specific work in return . . . (performance)" (p. 91). Henry (2013) says that "We call it Program/Performance Budgeting, but this kind of budget, more commonly is known as either a Program Budget, emphasizing its budgeting of discrete governmental operations, or a Performance budget, stressing its focus on agency efficiency and effectiveness ant their measurement. In reality, when it was introduced to the nation in mid-twentieth century, it did both, so we call it Program/Performance Budgeting and define it as a system of resource allocation that organizes the budget document by operations and links the productivity of those operations with specific budget amounts" (p. 235).
In the program budget expenditures are classified by objectives and goals (in form of outputs and outcomes), and not by economic classification - accounts (such as salaries, costs of communication, travel, maintenance, etc.), nor by the organizational classification (by budget beneficiaries, such as: city/municipal administration, preschool institutions, directorates, cultural institutions). The primary goal of a program is to improve the prioritization of budget spending. In addition, with the increased attention paid to the

performance of budget beneficiaries, this type of budgeting aims to increase the pressure on the budget beneficiaries to improve efficiency and effectiveness.

One of the major accomplishments achieved in perusing and implementing Program budget is that it shows reasoning behind expenditures and results that are achieved by spending public money. But to achieve that, long-term outcomes are required, which are expected to be previously prepared in local strategic documents. Instead of focusing on what local government spends, the program budget focuses on the expected results in providing services to citizens. In the program budget, revenues and expenditures are connected by multi-annual programs which are defined by the local government. Program budget identifies expected results of these activities, which is its main and most important difference in comparison to other budget types.
It has been the case in many local self-governments of Serbia that strategic priorities are set too high and too ambitious, without relying on financial analyses and capabilities. In many cases, they just stayed on paper, not being followed by sufficient financial means for their fulfilment. One of the benefits of introducing program budgeting in local governments in Serbia was that it clearly showed what are the strategic objectives that are realistic and achievable, and which ones are not reasonable. Hence, program budget can serve as a tool used for reassessment of local strategic objectives. *As Mukdad clearly noticed in his paper (2013), there are several pre-conditions for establishing program budget: (a) goal has to be clearly identified; (b) objectives in order to achieve goal need to be identified; (c), programs, subprograms and units serving each goal need to be developed and classified and finally (d) inputs, i.e. money, manpower, materials etc. for each of the programs need to be determined (p. 92).* If any of these preconditions are fulfilled, or they are not realistic, sensible or achievable, program budgeting will not serve its purpose and will not be functional.

7. SUSTAINABLE DEVELOPMENT AND PROGRAM BUDGET

Underwood, Hackney, and Friesner argue that "sustainable community economic development policies satisfy three specific criteria: ecological holism, community centeredness, and institutional legitimacy. Under ecological holism, ecosystems must be managed to provide a continuous flow of resources to support provisioning without altering the structure, composition, and function of local ecosystems. Under community centeredness, development creates employment at living wages to reproduce the local institutional structure of the community. Under institutional legitimacy, all members within a community have a fair opportunity to benefit from economic development, even though benefits will not be equally distributed" (p. 1113).
Very important element of sustainable development is by all means environment and its vulnerability. *Bets (2015) says "as the scarcity of our natural resources and the fragility of our environment becomes increasingly evident and present in the minds of business and community leaders, economic development must respond by incorporating sustainability into the profession. Communities that respond quickly to this shift will be better prepared for a global economy that defaults to a triple bottom line approach. However, economic developers do not need to become geologists or transportation planners to embrace sustainability. Economic developers know how to identify and support their region's or community's cluster industries, a skill set that is crucial to the sustainability movement. One important role economic developers can play is to encourage the sustainability community to keep business-oriented solutions at the forefront when trying to meet socially-conscious end goals" (p. 49).*

If we take a closer look at two last criteria in Underwood, Hackney, and Friesner paper, they can obviously be seen and reflected in program budget. Involvement of wider community in process strategic planning and later in designing program budget creates space for economic development. Not only knowledge and expertise of different stakeholders in certain area will lead to creating strategic goals in such a manner they will exploit local advantages in highest possible level, but it is to be expected that these strategic orientation is more realistic and easier to achieve. As previously said, program budget must rely on strategic directions of certain community, and these directions (outcomes) ought to be reflected in a budget. In case strategic objectives are set too high and in unrealistic manner, which has been the case in many Serbian local authorities, their achievement is put under question. In that context, public finances are spent on goals that are not achievable or are unlikely to achieve, creating very little space for improvement of local community. Having in mind very high unemployment rates in Serbia, there is no space for mistakes and perusing the goals that are not reachable. Since local advantages are taken into account in creating strategic goals, it is to be expected that striving towards achievement of goals will lead to, among other things, increased local employment. If an employment is raised, local tax collection is at a higher stage, and local budget is augmented. Bigger local budget means more investments locally (not only for further employment and investment) in better living conditions for its citizens. And finally, if citizens are involved in creating budget and have a say in the process, it is to be expected they will have a fair opportunity to benefit from economic development.

8. CONCLUSION

Although introduced and accepted as a notion in half of 20th century, Program budget is almost completely unknown concept in Serbia. It was imposed by "outside factors" and did not come as inner need to prioritize objectives, strive towards reachable goals and in that manner create better living conditions for Serbian citizens. It was inflicted into Serbian society as a precondition for process of EU integration and reaching EU funds. Additional pressure to introduce program budgeting in Serbia was put by awareness raising of the citizens and their need to be included in planning process of their community, but also the need for their voice to be heard when it comes to say when and on what tax payers' money is spent on. These two factors paved the road for introduction of program budgets in Serbian local self-governments.

Additional burden for success of this process was the fact that strategic goals set in local strategic documents are not compatible with possibilities of their financing, i.e. the volume of local budget. There is a lot of confusion in using and transferring set strategic objectives from existing strategic documents into program budget, since too ambitious strategic objectives in existing local strategic plans do not allow proper creation and executing of program budget.

Both these assumptions lead to a conclusion that additional time is needed for program budgets of Serbian local self-governments to be fully implemented. Strategic documents ought to be re-examined and prepared in a realistic and achievable manner. Additional period for Serbian society and local administration is required in order to fully understand importance significance of citizens' participation, realize that inclusion of various stakeholders in process of strategic planning can only be advantage and that preparation of program budget in accordance to achievable local strategic documents only creates opportunities for future development.

HAS THE FINANCIAL CRISIS CHANGED THE RESEARCH AGENDA ON BANKING REGULATION AND SUPERVISION?

Jose Dias Lopes
Lisbon School of Economics and Management, University of Lisbon,
diaslopes@iseg.ulisboa.pt

Abstract: *The impacts of the financial crisis, which was developed from 2007, were many e very different. In this research we study those impacts in the research agenda on banking regulation and supervision. This study, performed from a 323 article sample, reveals a change in the published investigation's volume, evident after 2011. This situation indicates a time lag between the crisis outburst and the accomplishment of its growing interest for its inherent themes.This study also allows to testify a change concerning interest focuses, emerging themes such as: Politics, Basel-III (obviously), Systemic Risk and Regulatory Capture.On the opposite side, the Keywords associated to a Value-at-risk and to the second agreements of Basel, specifically, Basel-II, Basel Capital Accord and Market Discipline, lost some ground in literature.*

Keywords*: banking regulation and supervision; crisis; research agenda; regulation; keyword analysis; bibliometrics*

1. INTRODUCTION

The crisis, which has been installed in the world economies from 2007, is certainly going to be the most relevant economic and social fact of the beginning of this century. The crisis" dimension is frequently compared to the crisis which began in 1929, and which originated the long Great Depression. The 2007 crisis" exceptionality is also observed by the singularity of its associated occurrences, being them:

- The significant volume of support which the States had to ensure to the financial system, which corresponded to an effective use of €1.7 trillion, or 13 percent of EU GDP of government support to the banks between September 2008–December 2011 only in the European Union, according to the International Monetary Fund (IMF, 2013); or
- The society"s insecurity related to its banks, which has been materialized into a succession of bank runs or protests at their doors, which have been observed in Cyprus, Spain, Greece, Ireland, Portugal, United Kingdom, etc. For instance, according to Milne & Wood (2008), in 2007, the United Kingdom witnessed the first bank run with significant impact – The Northern Rock – since the reign of Queen Victoria (which ended in 1901).

This dimension and singularity of the financial crisis" events has led it to be felt and analyzed by the overall population. Therefore, the financial crises, besides the great value destruction at an economical level, and besides debilitating the bank system concerning financial stability, has also produced a collateral damage of great importance: it has significantly reduced the overall financial system and the banking system"s reputation in particular (see Jones, 2015, august, 25; or Rowe, 2012). The lack of confidence which has been installed related to the banking system is so prevalent that it has become a *cliché* (Springford, 2011). Confidence is not a disposable active of the financial system. On the contrary, as Singh & LaBrosse (2011) state, it performs a very important role in the system"s sustainability and, therefore, the current situation cannot stop having consequences in the definition of the collection of regulation solutions.

The idea that the regulation of the financial sector must be rethought does not deserve a great deal of protest. On the contrary, the need to reevaluate the process of regulation of the financial sector is relatively consensual, either amongst those who consider that the crisis is the result of excessive regulation (e.g.: Nichols et al. (2011) or Calabria (2009), either amongst those who consider that the crisis is the result of deregulation (e.g.: Stiglitz et al. (2009) or Chabrak & Gendron (2015)), in other words, the process of the financial markets" liberation based on the conviction that these could/should be self-regulated.

Could this appeal to reevaluate the process of banking regulation already find echo in the published investigation on this subject? Or, in a different way, could one talk about an investigation on banking regulation before and after the crisis? This is the main question of this paper, which will be answered through the analysis of the volume of the published investigation and the evaluation of the approached subjects.

2. METHODOLOGY

With this paper, it is intended to evaluate the evolution of academic production on banking regulation and supervision. In order to evaluate the published investigation, it is used bibliometric techniques. Frequently, these techniques provide a quantitate evaluation, through the counting of articles, and a qualitative evaluation through the analyses of Keywords. Similar studies in terms of goals and chosen method can be found in Romo-Fernández *et al.* (2013), Lee & Su (2010), Zhang *et al.* (2015) and Liu *et al.* (2012).

The study was divided in two parts. In the first part, it was evaluated the quantitate evolution of the published evaluation on banking regulation. In the second part, it was intended to analyze whether the crisis which began in 2007 caused changes concerning the most studied themes.

In order to perform the study, it was elaborated a sample of articles obtained through research of documents which contained the search key „Baking Regulation" OR „Banking Supervision" on the Topic Field (which in practical terms means that the research fell upon the following fields: Title, Abstract, Author, keywords and Keywords plus), on the Web of Science Core Collection of Thompson Reuteurs.

3. RESULTS AND DISCUSSION OF THE QUANTITATE ANALYSIS

The 323 articles of the original sample are classified in 40 different Web of Science categories. However, the majority of the articles is focused on five categories, presented in Table 1.

Out of the 323 articles of the original sample, 280 (86,69%) were classified into the five indicated categories. These 280 formed a subsample which will be named subsample(A).

Table 1: Sample articles by Web of Science Categories

Web of Science Categories	# of Articles(*)	% of articles(**)
Economics	162	50.15%
Business finance	123	38.08%
Law	42	13.00%
Political science	41	12.69%
International relations	26	8.05%
Subsample total (in the five categories)	280	86.69%

(*) Several articles are classified in more than one category.
(**) of 323 articles.
Source: Web of Science and self-made calculations.

In what concerns the years of publication, it is observed that the last years are the ones where a bigger number of articles is registered (see Table 2, 2nd column). The phenomena can have a specific component of the banking regulation theme or it can result from a global increment from newspapers and attached articles. In order to evaluated which of the two aspects is more significant to the verified growth, it was performed an auxiliary research, also on the Web of Science, with the same filters, and with the search key „Bank OR Banking". The obtained results were filtered, and only articles in the previously mentioned five Web of Science categories were considered. It was obtained a sample of 21,486 articles. This sample is comparable to subsample(A) (280 articles).

Table 2 presents the data of the last 25 years to the three collections of articles: the original sample on banking regulation and supervision (323 articles); the subsample of the latter in the five considered Web of Science categories (subsample(A)); and the unabridged sample of articles on Banking presented on the Web of Science in the five considered categories (21,486 articles).

As it is verified, there is an increasing evolution of the number of published articles, which is visible on any one of the three considered series. However, in the article samples on regulation/banking supervision (original and subsample), it is observed an additional increase of the published investigation after 2011 (2012 and the following), besides the already mentioned evolution.

Table 2: Comparison of the sample with the total of articles in the five WoS categories indicated in Table 1

Years	Articles (#323)		Articles (#280)		Articles (#21,486)	
Previous to 1991	8	2.48%	8	2.86%	3,274	15.24%
1991	1	0.31%	0	0.00%	187	0.87%
1992	2	0.62%	2	0.71%	286	1.33%
1993	3	0.93%	3	1.07%	286	1.33%
1994	6	1.86%	5	1.79%	343	1.60%
1995	4	1.24%	3	1.07%	349	1.62%
1996	3	0.93%	3	1.07%	385	1.79%
1997	2	0.62%	2	0.71%	390	1.82%
1998	2	0.62%	2	0.71%	451	2.10%
1999	4	1.24%	4	1.43%	537	2.50%
2000	7	2.17%	6	2.14%	508	2.36%
2001	7	2.17%	6	2.14%	466	2.17%
2002	6	1.86%	6	2.14%	507	2.36%
2003	8	2.48%	8	2.86%	512	2.38%
2004	11	3.41%	8	2.86%	530	2.47%
2005	9	2.79%	8	2.86%	549	2.56%
2006	11	3.41%	11	3.93%	687	3.20%
2007	12	3.72%	11	3.93%	705	3.28%
2008	15	4.64%	14	5.00%	957	4.45%
2009	16	4.95%	14	5.00%	1.026	4.78%
2010	19	5.88%	13	4.64%	1.078	5.02%
2011	19	5.88%	16	5.71%	1.286	5.99%
2012	33	10.22%	27	9.64%	1.401	6.52%
2013	36	11.15%	31	11.07%	1.549	7.21%
2014	38	11.76%	32	11.43%	1.605	7.47%
2015	41	12.69%	37	13.21%	1.632	7.60%

In the graphic of Figure 1, the change of the publication pace after 2011 is evident.

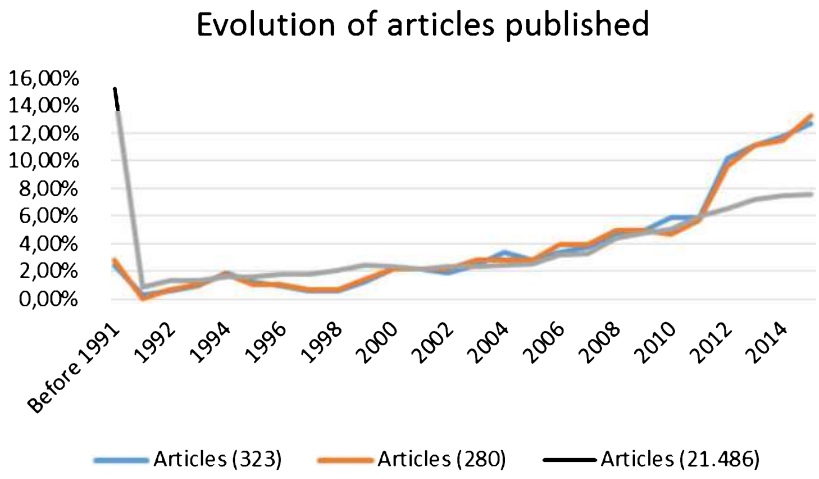

Figure 1: Evolution of the published articles
Source: Web of Science.

The increase of publications which is observed after 2011 results from the increment of investigation focused on studying the financial crisis. When one performs a research in the original sample (323 articles) and includes the expression „*Financial Crisis*" on the Topic field, one obtains the results presented in Table 3.

Table 3: Subsample of articles on the financial crisis

Years	Articles
2000	1
2003	1
2009	2
2010	1
2011	4
2012	8
2013	6
2014	12
2015	8
Total	**43**

Source: Web of Science.

With this new data, it became possible to have a better perception of the mentioned global evolution. The publication of articles which fall upon the financial crisis, practically inexistent before 2011, show a meaningful presence after that year.
Therefore, it can be affirmed that the investigation on banking regulation and supervision increased the pace of publication with the advent of the financial crisis. This increase can be associated to the outburst of lines of investigation precisely focused on the debate of financial crisis related matters. It is also observed that that increment is not immediate, mediating for about four or five years since the first indications of financial crisis, until a significant increase of the number of published articles becomes visible.
On one hand, this time lag is attributed to the design and research process and, on the other hand, to the process of elaboration, edition and article publication which was taking place.

4. RESULTS AND DISCUSSION OF THE KEYWORDS ANALYSIS

Out of the 323 articles of the original sample, only in 272 there were records of Keywords. Therefore, a subsample was built, constituted by these 272 articles (here on now named subsample(B)), which will be the object of study.

4.1. Characterization of the sample and description of the procedures

The number of registered Keywords (KW) was 2,172, which means 7.99 KWs per article, in the total of the subsample(B) (272 articles). The situation is very divergent throughout the sample, considering that the number of KWs per article presents a range from a minimum of one (in 14 articles) to a maximum of 21 KWS in one single article. The most frequent situations are 4 KW per article (in 28 occurrences); 6 KW per article (in 28 occurrences); 5 KW per article (in 26 occurrences); 7 KW per article (in 25 occurrences); 8 KW per article (in 24 occurrences); and 9 KW per article (in 19 occurrences).
There were identified 1,127 different KWs, being the three most frequent: Banking Regulation, which occurred in 82 articles, Banking Supervision, observed in 32 articles, and Deposit Insurance, which occurred in 23.
As it is frequent in these situations, it is convenient to perform an orthographic standardization of the KWs. This was done in a similar way to Lee & Su (2010) and Zhang *et al.* (2015). The performed standardization included the following changes in KW: (1) singular/plural standardization (e.g. from *Bank Failure* to *Bank Failures*); (2) standardization of the use of the hyphen (e.g. from *Basel-II* to *Basel II*); (3) standardization of orthographic variations (e.g. from *Crises* to *Crisis*; from *Basle II* to *Basel II*); (4) standardization of the use of the terms bank/banking (e.g. from *Bank Regulation* to *Banking Regulation*); (5) standardization of the use of abbreviations (e.g. from *BIS* to *Bank for International Settlements*). To fulfill these criteria, 63 KWs were standardized.
Besides the described procedures, 15 other standardizations were performed which allowed the elimination of another 28 KWs.

In the performed standardizations, the rule was always to choose the most frequent KWs.
This process led to repetitions of the same KW in the same article. There were registered 42 occurrences of this sort. These repetitions were eliminated, providing the result of a final list of 1,036 different KWs used 2,130 times.
After the standardization, it was elaborated a list of the most frequent KWs, presented in Table 5. On the first column, there is the KW"s code number; on the second there is the KW; on the third and fourth columns, the number of articles which possess that KW, in the period of time before 2012 and after 2011, respectively; and on the last column, the total of articles where the KW has occurred. This last column"s value was used to order the table.
While creating this KW list, it was established a thresholder. In other words, it is the line under which KWs stopped being considered for analysis. This thresholder was defined in eight articles, which means that the KWs which only occurred in seven or less articles were not considered for analysis.
The obtained list is composed by 43 different KWs (4.15% of the total of KWs), which were mentioned 680 times altogether (31.92% of the occurrences), in 237 articles (86.81% of the articles). If the thresholder were established at a lower number, seven for instance, it would implicate the analysis of more 12 KWs and the addition of only 5 new articles. The trade-off between the complexity of analysis and the KWs coverage of the sample articles justify the indicated value of the thresholder.
Some of the KWs do not add any value to the analysis, either because they only reflect the theme of the study (*Banking Regulation, Banking* or *Financial Regulation*), either because their meaning is related to aspects which are not the object of study (*EU* (European Union)). Therefore, the following KWs were not considered for analysis: Banking Regulation, Banking Supervision, Banking, Banks, Financial Regulation, Regulation, EU (European Union) and G21 (JEL code G21: Banks, Depository Institutions, Micro Finance Institutions, Mortgages.). The list of KWs for analysis was reduced to 35 KWs.
The number of articles of the subsample(B) posterior to 2011 (2012, 2013, 2014 and 2015) was 136, and 137 of all the period before (from 1991, when an article was registered for the first time, to 2011). This inclination is fruit of the already mentioned increase of publications over these more recent few years.
Since two values are practically equal, the incidence of KWs per article in each of the periods can be evaluated by the simple comparison of the number of articles belonging to a period of time and to the other.

Table 4: Most frequent Keywords

id.	Keyword	Before 2012	After 2011	Total
	Banking Regulation	**49**	**44**	**93**
	Banking Supervision	**15**	**19**	**34**
1	Capital Requirements	18	12	30

4.2. Analysis of the results per KW

In this section, it will be performed the analysis of each one of the 35 most frequent, meaningful KWs to this study. Throughout all the analysis, all the investigation published until 2011 inclusive will be considered pre-crisis academic production. And the investigation published after 2001 will be considered post-crisis academic production, accordingly to what has been stated in previous sections of this paper.

While comparing the pre and post-crisis academic production, the occurrences in which there are 75% or more of the articles where a KW is particularly used in a period of time will be pointed out.

Figure 2 summarizes the obtained results. It shows the 35 most frequent KWs. Some KWs are pointed out in a particular way because they:

- **Have gained importance** over the last few years (pointed out in Bold with a solid line around it, and with an arrow (➔) before the KW;
- **Have lost importance** over the last few years (pointed out in italic with the mark (**X**) before the KW).

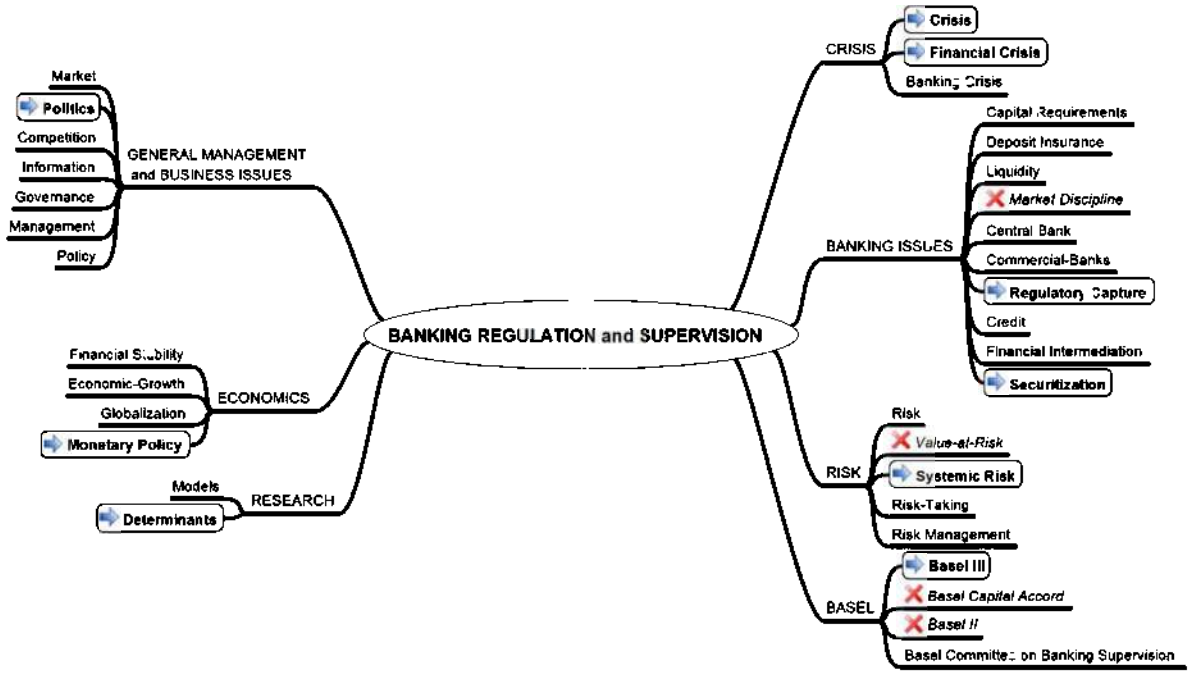

Figure 2: The Keywords map on banking regulation and supervision

This Figure could be seen as the genetic map of banking regulation and supervision. As it can be verified, recent changes in some "genes" were pointed out, as a result of changes in the "environment" in which regulation is produced and developed. Time will tell if these changes correspond to lasting mutations or just momentary adjustments; if the changes are only circumscribed to the signaled ones or if other "genes" will change as well.

A final note, not related to the presented KWs, but related to the absences or barely approached themes.

The study allowed the identification of various theme collections, whose KWs have been dominating the literature, such as: Banking issues, Risk, Basel; Crisis, Economics, Management and Research. The most surprising fact is the absence of a collection on one of the themes of banking regulation, where perhaps it could be included *Market Discipline*, *Regulatory Capture* and, for instance, *Moral Hazard* (related to this subject, the following KWs were registered: *Dynamic Moral Hazard* (once), *Moral Hazard and Bank Supervision* (once), and *Moral Hazard* (six times)) or *Self-regulation* (when it comes to this theme, there have been identified the following KW: *Enforced, Self-Regulation, Market Self-Regulation and Self-Regulation* (there is only one single occurrence for each of them), or where it could be discussed the meaning of new institutions to banking regulation, such as the Financial Conduct Authority in the United Kingdom or the already mentioned Consumer Financial Protection Bureau in the USA.

5. FINAL CONSIDERATIONS

In this paper, it was evaluated the evolution of the recent investigation on banking regulation. For that, it was analyzed the volume of production and the used KWs in published articles on the theme. The study shows a growth on the published investigation, which is evident after 2011. This indicates the existence of a time gap,

of about four or five years, between the first signs of the phenomena (crisis) and the boom of publications where the phenomena is already an object of study.
Concerning the frequency in the use of KWs, it was established a stable core of 35 most used ones. These KWs are considered to describe well the majority of the published investigation on the theme. On this most frequent KWs list, a change concerning interest focuses is verified, emerging themes such as: *Politics, Basel-III, Systemic Risk* and *Regulatory Capture.* On the opposite side, KWs associated to *Value-at-risk,* to the Basel accords, particularly, *Basel-II, Basel Capital Accord,* and *Market Discipline* lost some ground in literature.
The analysis proves the importance of the Basel Accords and the centrality of BIS in the process of developing banking regulation. Besides this central importance of BIS, the following were also pointed out as relevant strands:

- Banking nature, where it is possible to stand out themes such as Capital Requirements, Deposit Insurance, Risk (several dimensions), Liquidity, Credit and Securitization:
- The economical one, which includes Financial Stability, Economic-Growth, Globalization and Monetary Policy;
- Business and Management, where it is possible to find themes such as Market, Competition, Information, Governance and Management.

In order to answer the question asked in the beginning of this paper, one can, in fact, observe changes either quantitate, either in contend in the publish investigation on banking regulation and supervision before and after the crisis.
For the last decades, banking regulation has suffered profound changes. The agenda on the process of implementation of these changes, the evaluation of their impact and the establishment of new ways towards regulation were, on a large scale, defined by regulator forums or institutions of a similar nature. In this debate, the academy appeared many times to be more reactive than proactive. As a consequence, its research agenda frequently reflected themes and subjects established in other forums and other institutions. It is important to the academy to recover the role of a relevant player in the debate on banking regulation, because only the academy can provide to this debate the only contribution which derives from the diversity of points of view which exist within it, and from the autonomy with which these points of view can be expressed.

AN APPLICATION OF NEURAL NETWORKS AND FUNDAMENTAL ANALYSIS FOR AUTOMATED TRADING: BELGRADE STOCK EXCHANGE CASE

Aleksandar Rakićević*[1], Ana Milovanović[1], Rastko Aničić[1]
[1]Faculty of organizational sciences, University of Belgrade
*Corresponding author, e-mail: aleksandar.rakicevic@fon.bg.ac.rs

Abstract: *This research demonstrates an application of neural networks for automated trading using fundamental analysis on Belgrade Stock Exchange. Our main goal is not to try to predict stock prices, but rather to determine whether the process of stock market trading can be learned and performed by artificial neural network with a positive outcome. In order to train the proposed feed-forward network mechanism for market trading we use fundamental analysis ratios as inputs, while the output is a trading signal. Further, we incorporate the proposed artificial neural network into a virtual trading machine, created for the purpose of trading simulation. We test the proposed approach on the stocks from Prime Listing of Belgrade Stock Exchange.*

Keywords*: automated trading, fundamental analysis, neural networks, Belgrade Stock Exchange.*

1. INTRODUCTION

Automated trading represents a special type of trading on financial markets where a computer program or another kind of automated system is used to collect data, analyze it, make trading decisions and execute trading orders on the market. This area of finance has arisen since the end of 1980s when first fully electronic communication and execution networks were developed in financial markets. Since then, it has been developing rapidly following the expansion of information and communication technologies. Automated trading become very popular in 2000s, reaching almost 75% of total market trading volume in 2009 (Kissel, 2013).

There are two common forms of financial analysis: fundamental and technical analysis. Main focus in this research will be on the fundamental analysis and its ability to suggest the possible profitable stocks. Fundamental analysis is the cornerstone of investing. Its largest part involves delving into the financial reports. It utilizes quantitative tools, mainly the financial ratios, as well as other indicators such as management policy, marketing strategy and product innovation to determine the value which can be compared with a stock's current price (Lam, 2004).

This research represents the extend of the previous studies in a way of further use of ANNs as a trading tool. In this study, we developed a system for automated stock market trading. The proposed system combines fundamental analysis and neural networks to create a trading algorithm used for investment decision making. We use feed-forward network as well-known and most commonly used ANN structure. Fundamental analysis is used to obtain learning inputs, which are used by the ANN to understand the underlying process of the market. To obtain learning outputs we extract the historical trading signal using a ZigZag indicator of trend. Further, we create a virtual trading machine in order to simulate real market trading and test the proposed system. The proposed system is tested on BSE stock market data.

The remainder of this research is organized into four sections. In the next section we present the literature review. Section 3 describes the proposed methodology. In section 4 we present data, trading settings, trading signal extraction method and final results and discussion. The last, fifth section concludes the paper and provides further research suggestions.

2. LITERATURE REVIEW

ANNs have been widely used for financial research, especially in financial market forecasting. In their extensive research on soft computing techniques for financial forecasting, Atsalakis and Valavanis (2009) gave an considerable review of neural and neural-fuzzy techniques. Their review showed that feed-forward networks are the most commonly used networks for financial forecasting, including one-third of all surveyed articles. The most likely reasons for this are the simplicity, seed and their easy implementation. Further, the

review also showed that authors mostly use networks with one or two hidden layers. Long ago, Bishop (1994) has shown that there is no need to consider more complex structure since the ANN with one hidden layer has universal approximation capabilities.

Even though ANNs were extensively used for financial forecasting for more than 30 years, long time passed until authors started to use their forecasting power within the automated trading systems. Several authors tried to use ANN in combination with fundamental analysis in order “to beat” the market or some well known investment strategy. Eakins and Stansell (2003) used simple feed-forward structure with 2 hidden layers (6 and 3 nodes) and backpropagation learning algorithm to enhance the process of stock selection. In order to train their ANN to learn to pick stocks they use fundamental valuation ratios. Testing their system on more than 20 years of stock market data they conclude the ANN consistently outperformed 7 benchmark portfolios, among them both S&P 500 and Dow Jones Industrial Average market portfolios. Later, Krishna *et al.* (2010) replicated their research methodology on Bombay stock exchange and confirm their findings.

Olson and Mossman (2003) used ANN to forecast one-year-ahead Canadian stock returns based on 61 accounting ratios. Further, they built a trading strategy that converts these forecasts into portfolio holdings. Finally, they compare the proposed ANN approach with ordinary least squares (OLS) and logistic regression (logit) approaches. They conclude that simple backpropagation network can outperform best regression alternatives in forecasting, which translated into greater profitability of the trading strategy. Vanstone et al. (2012) used ANN with Aby’s filter, which incorporates 4 fundamental ratios, to create an automated trading system for the Australian stock market. Their results showed the proposed approach performs well in terms of profitability, but experienced high volatility of returns. Another important paper is the one written by Vanstone and Finnie (2009), who presented a methodology for designing and testing stock market trading systems using ANNs.

3. TRADING SYSTEM

In this research we propose an automated trading system for stock market trading. It is a complex system consisted of two components (Figure 1). The first component is used for pre-processing of stock market data. It consists of two sub-components, one for fundamental analysis and the other one for trading signal extraction. The second component represents the trading logic and is used for investment decision making. It consists of artificial neural network and the trading algorithm. The purpose of ANN is to use fundamental data to forecast trading signal which is used by trading algorithm to generate trading orders.

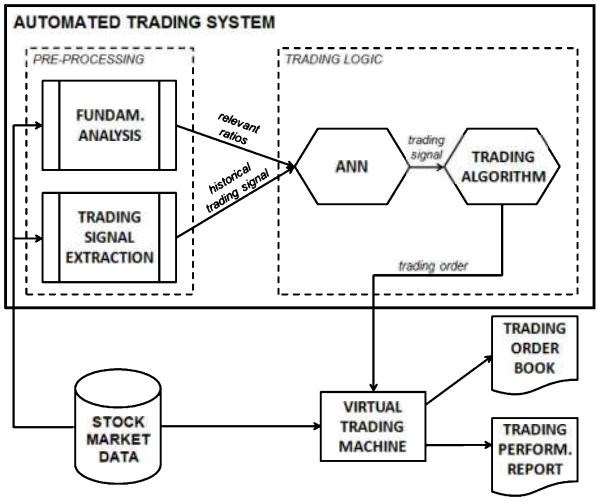

Figure 1: Automated trading system structure

3.1. Artificial neural network

The term "network" is used to refer to any system of artificial neurons. This may range from something as simple as a single node to a large collection of nodes in which each one is connected to every other node in the net. Each node first aggregates its input in a linear manner using simple weighted sum and then use activation function to make nonlinear relation between input variables and nodes output. Nodes are arranged in a layered structure, and each layer can be consisted of one or more nodes.

In this study we use the feed-forward network structure, which is the oldest and simplest type of ANN. In this network, information moves only forward and there are no loops. Each input signal has to pass through all hidden layers before reaching the output layer. To train our network we use backpropagation learning mechanism.

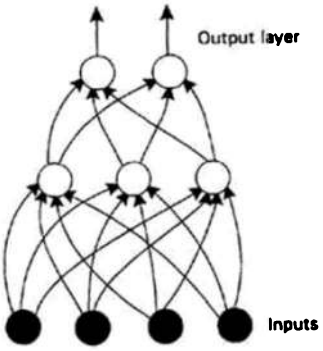

Figure 2: Neural Network architecture (Gurney, 1997)

It is important to notice that our network use tan-sigmoid function as activation function. Tan-sigmoid has the following formula:

$$\sigma(n) = \frac{2}{1+e^{-2n}} - 1 \tag{1}$$

As Gurney (1997) suggests, it is typically used when input pattern needs to be classified into one of several classes. In the case of our trading system, output variable represent trading signal which has three classes: buy, hold and sell. The signal can take all numeric values between -1 and +1, which also perfectly corresponds to tan-sigmoid function (Fig. 3).

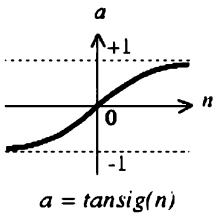

Figure 3: Tan-sigmoid function graph

Trading does not start when the system activates. Certain number of observations must be analyzed, which are used as initial trading set. Network then uses the set in order to learn underlying model of the market. Input parameters for the network are ratios gathered from the fundamental analysis. Additionally, NN uses historical trading signal extracted from special preprocessing component. When trained on initial set of data, NN starts predicting trading signals which are then sent to the trading algorithm component. It does so until actual trend changes. System then stops trading and activates retraining of neural network. Furthermore, it is retrained using all observations from the beginning until the change of trend.

3.2. Fundamental analysis

Within the fundamental analysis sub-component we use three well-known valuation ratios: price-per-earnings (PE), price-per-sales (PS) and price-per-book (PB) ratios. First of them, PE is measuring the current share price relative to its per-share earnings:

$$PE = \frac{Market\ value\ per\ share}{Earnings\ per\ share}. \tag{2}$$

Secondly, the PS is an indication of the placed value on each monetary unit of a company's sales or revenues:

$$PS = \frac{Stock\ price}{Revenue\ per\ share}. \tag{3}$$

Finally, the PB value compares the stock's market values to its book value:

$$PB = \frac{Stock\ price}{Book\ value\ per\ share}\ . \tag{4}$$

3.3. Trading signal extraction

In order to learn ANN to trade based on fundamental ratios we need to provide a trading signal as the output variable. We extract trading signal from trend data obtained using modified version of ZigZag indicator. The indicator is constructed using a general definition of trend: a tendency in data that creates a positive or a negative change in data level over certain period of time. Hence, the two key parameters of a trend are its time duration and the size of the underlying change. The indicator track these two parameters measuring the change in price and duration of that change from the previous maximum/minimum value. If both parameters cross the threshold values, indicator changes its direction.

Fig. 4 shows an example of trend extraction using two sets of different threshold values on the same data set. As it can be seen from the graph, the smaller the threshold values are, the indicator is more sensitive to changes in price. Therefore, the extracted trend data will depend on the choice of threshold values.

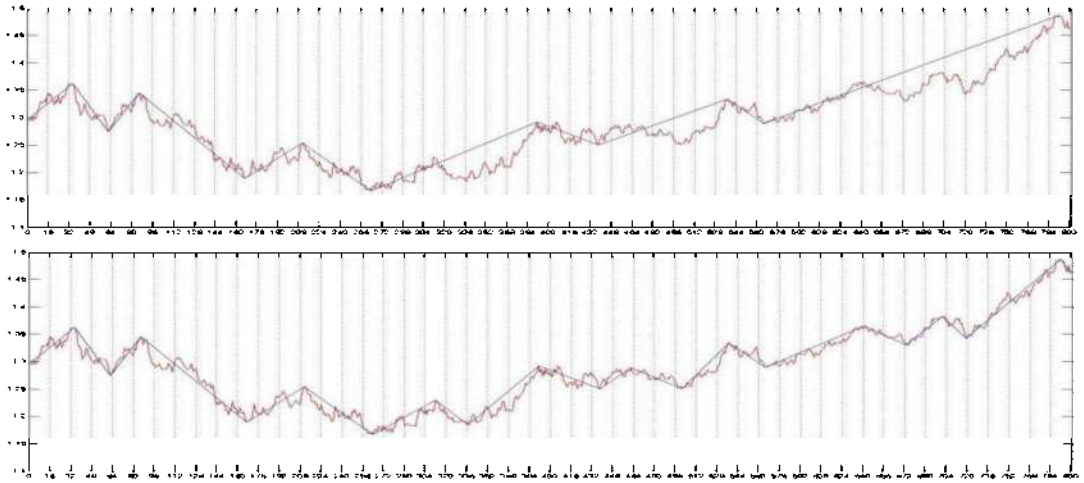

Figure 4: An example of trend extraction using modified ZigZag indicator with different threshold values

Further, to extract the trading signal we use simple linear transformation which transforms trend data into time series of values between -1 and +1. These extreme values are associated to reversal points in trend data. When trading signal takes value -1 it means that one should sell the instrument, while the opposite stands for +1.

3.4. Trading algorithm

Trading algorithm starts working when receives the forecasted trading signal from ANN. If the signal is negative and is bellow the determined threshold value, the algorithm sends buying order to the virtual trading machine. On the other hand, when signal is positive and above the determined threshold value, the trading algorithm issues the selling order. Trading algorithm separates the trading account value into several lots, which are calculated as the certain percentage of the current account balance. Trading algorithm keeps purchasing/selling stocks until all the lots are spent. Transaction costs are incorporated into trading orders to accomplish more realistic approach.

3.5. Virtual trading machine

The main purpose of the virtual trading machine (VTM) is to simulate stock market trading by using the real prices from the BSE. VTM manages trading orders received from trading algorithm, charges trading commission, takes care about currency and equity accounts, records transactions and calculated performance measures. Finally, when the trading simulation is done, VTM delivers the trading report which indicates how successful the trading system was.

4. RESULTS

The results of our research presented in this section are based on real stock market data. Summary results are presented in Table 3, while the individual results are discussed separately in chapters 4.4.1 to 4.4.4.

4.1. Data

As mentioned before, the proposed system has been applied on BSE stock data. Companies from Prime Listing, which is the most attractive market segment on BSE, has been selected for testing purpose. The selected companies are: „Aerodorm Nikola Tesla“ (AERO), „Energoprojekt holding“ (ENHL), „Naftna industrija Srbije“ (NIIS) and „Sojaprotein“ (SJPT). Official financial statement data are used to calculate necessary fundamental ratios used as input data to our neural network. Our dataset consists of data from different time frames, which are presented in Table 1. The price and financial statement data were obtained from official BSE website.

Table 1: Stock market data used in this research

Company	Start date	End date	Number of observations
AERO	7.2.2011.	31.12.2015.	1237
ENHL	1.10.2005.	31.12.2015.	2768
NIIS	23.8.2010	31.12.2015.	1349
SJPT	3.3.2008.	31.12.2015.	1979

The selected companies are the leading companies in different sectors. Different industry branches were used in the research to determine whether the trading algorithm is universal and suitable for application in opposite industries. For instance, NIIS is one of the largest vertically integrated energy companies in Southeast Europe. Its principal activities are exploration, production and refining, sales and distribution of a broad range of petroleum products, as well as the implementation of energy projects (NIS Official Website). Furthermore, SJPT is the largest soybean processing factory in Serbia, and thanks to the diversity, quality of its products and a processing capacity, it is ranked among the most important soybean processors in Central and Eastern Europe (Sojaprotein Official Website). In addition, AERO is the largest regional (Western Balkan) airport. Finally, ENHL is one of the leading construction companies in Serbia, withmain focus on research and development, consulting and engineering, construction and designing. (Energoprojekt Official Website) As a result, the inputs into the ANN are calculated daily ratios and close prices of all the previous companies.

4.2. Experimental settings

In order to test the proposed approach we use the following thresholds: duration threshold of 10 days and price change threshold of ±15%. Further, ona eventully eed-forward structure with one hidden layer consisted of 15 neurons has been implemented.

Virtual trader initial account balance is 1.000.000 monetary units. Having in mind that the trading strategy is used on BSE, we can assume that currency is Serbian Dinar (RSD). One trading lot used in this research equals 10% of the current account balance. Trader keeps purchasing stocks until the account is spent. Trading fees were introduced to the algorithm to accomplish more realistic approach. Trading fee equals 0.5% of the transaction value, which has exceeding resemblance to the one in realistic market. Fees are calculated both in short and in long positions opened. Trading regulations of Belgrade Stock Exchange forbid entering the short position.

Table 2: Automated trading system parameters

Parameter	Value
Initial account balance	1.000.000
Initial lot size	100.000
Trading fee	0,5%
Trading signal	±1
Duration threshold	10 days
Change threshold	±15%
Hidden layer size	15 neurons

4.3. Performance measures

Profit/loss (P/L) and return on investment (ROI) are relevant indicators on the precision of algorithm's trend recognition. Profit factor indicates the number of monetary units earned per ones spent. It takes values from interval (0;+∞). Values above 1,00 indicate that the final account balance is greater than the initial one, while values below 1,00 specify the opposite. Maximal drawdown represents the absolute difference between highest and lowest account balance values. Average profit per trade indicates illustratively virtual trader's successfulness.

4.4. Results and discussion

Table 3 presents summary results. Output parameters are listed along with the trading companies. Parameters are divided into three clusters. First one is regarding the total number of trades while the other two indicate on long and short trades committed respectively.

Table 3: Summary of trading results

Indicator/Company	NIIS	AERO	ENHL	SJPT
Total Trades	9	5	20	10
Trades won	44,44%	80,00%	35,00%	40,00%
Net profit	270.260	2.016.597	-715.474	127.093
ROI	27,03%	201,66	-71,55	12,70
Profit factor	1,62	13,37	0,23	1,17
Max. drawdown	-15%	-14%	-34%	-40%
Avg. profit per trade	30.029	403.319	-35.774	12.709
Long trades won	25%	100%	40%	40%
Long trades avg. profit	12591.65	798042.97	-18111.61	1.16
Short trades won	60%	66.67%	30%	40%
Short trades avg. profit	45527.2561	143661.02	-53361.85	15405.26

Total number of trades can imply on how dynamical the strategy is. The least dynamical was AERO, which was expected because of its business field. During the whole business year, airport activities are evenly distributed. That is why only 5 transactions were opened and, what is more, 4 out of 5 successful ones. The most dynamical was ENHL with 20 trades, which means that the algorithm has recognized trend variation approximately 20 times. Being a construction company, ENHL gains profit seasonally by project agreements. That is why there were many oscillations on the stock market and is quite hard to *pick up* the right trend line opportunely. As expected, ENHL total profit factor is below 1,00 and announces that the trading environment is turbulent and not likely predictive. The next two clusters represent some of the mentioned indicators, only separate long from short trade positions. Figures 6 to 9 more intuitively show the indicators.

Upcoming figures represent results of data testing. Each figure is consisted of three subplots. Topmost shows the closing price for every trading day from the beginning of the trading observations to the end of year 2015. The artificial neural network has been trained to recognize short and long position signals. The behavior of the trader will depend on the signal given, which is shown on the second subplot, and finally, the third subplot represents response to the signal.

4.4.1. AERO

The account balance is showing a significant growth and eventually, considerable profit. Despite the backward learning, trader correctly interpreted the signals on the account balance and the positive economic performance proves the accurately given signals.

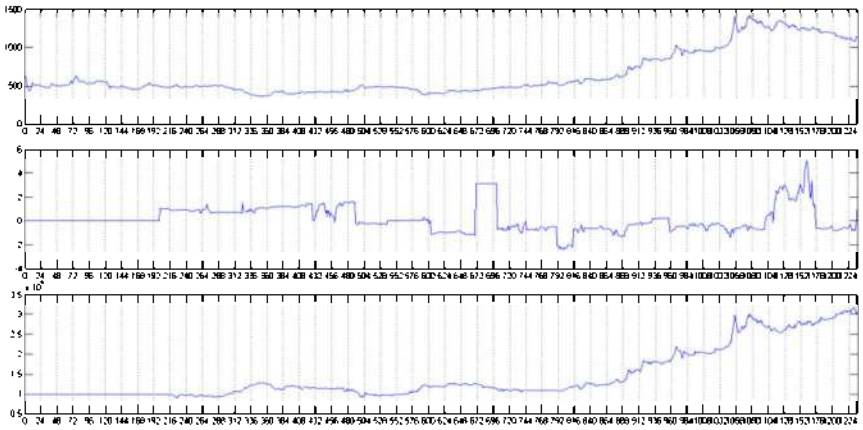

Figure 5: AERO Trading results

4.4.2. ENHL

The following Figure 6 presents the graph with trading results for ENHL. The figure presents the account balance is showing increase in the beginning and then the momentous fall at the end. Final results suggest that neural network is unable to read the market behavior.

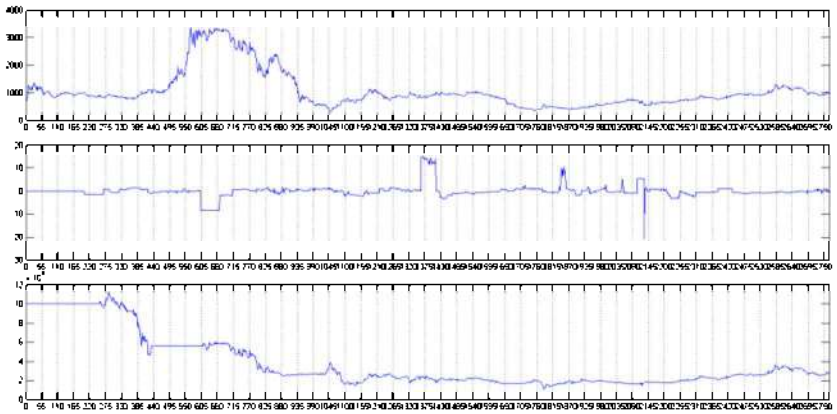

Figure 6: ENHL Trading results

4.4.3. NIIS

In NIIS example, neural network trades with variable success, but mostly profitable. This is an example of successful learning process in which neural network is able to discover underlying market fundamentals.

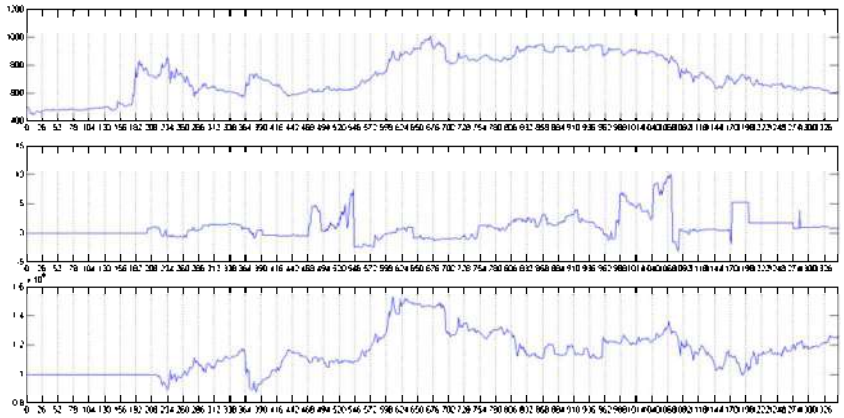

Figure 7: NIIS Trading results

4.4.4. SJPT

SJPT is tested using relatively longer time series within our sample. The obtained results are not very good, indicating the network is not a stable solution. The system starts well, but in some point become very unprofitable. Finally, very close to the end of test period it regain its profitability and recover losses.

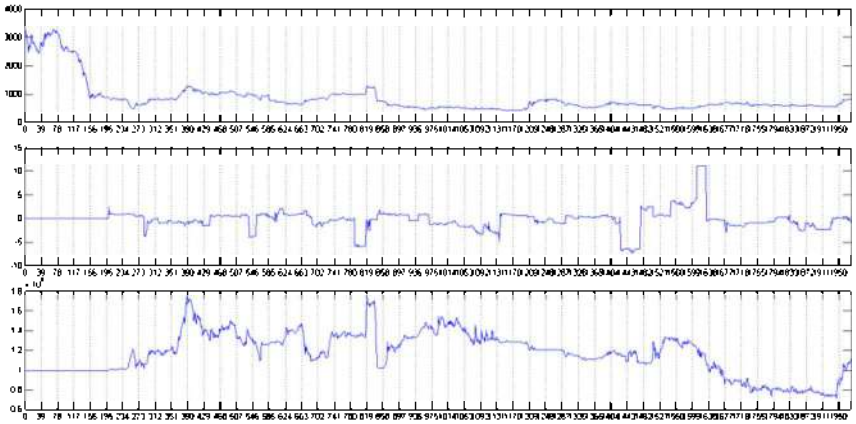

Figure 8: SJPT Trading results

5. CONCLUSION

In this research, the information available in the financial market were gathered and the variables that drive stock prices were taken into account. On the basis, of the fundamental analysis, the calculation of the investing ratios has been made. Thus, the neural network parameters consist of the data from official financial reports from companies of different sectors.Having in mind the results, it is possible to apply neural network algorithm to Belgrade Stock Exchange and obtain satisfying results. However, the network has not provided us with the wanted results in more turbulent trading environment. ENHL's stocks prices are vaguely foreseeable and neural network was not able to predict its trend in the right time. It was always *one step behind.* Moreover, that total account balance was positive in 3 out of 4 trading attempts;therefore, it is acceptable to say that the trader performed well overall and that the algorithm is applicable but not completely accurate.

To conclude, by using the real data to evaluate the trading signal neural network may show satisfying results on the data given with a room for improvement. The neural network tested in this paper has been using fundamental data and closing price generated every day on the stock exchange. It was applied only once on each dataset. To gain more accurate results, network should be executed for at least one thousand times, so that the middle value could be extracted. In that way, more relevant results could be gathered. To further improve its performance, a neural network should be using more complex algorithm. Therefore, the next step is to train a neural network to behave with a positive outcome in more complex environment as well as with more sophisticated algorithm. The step further is to demonstrate its performance on expanded stock market data. Besides that, the methodology presented may also be adapted to other enterprises and their stocks. This is the future research direction.

PERFORMANCE OF EVENT-DRIVEN HEDGE FUNDS' STRATEGIES

Vesna Bogojevic Arsic
Faculty of Organizational Sciences, University of Belgrade, Serbia
Corresponding author, e-mail: bogojevic-arsic.vesna@fon.bg.ac.rs

Abstract: In our days hedge funds represent the fastest growing group within the alternative investment. The hedge funds are usually defined by the investment strategy they implement. There is variety of different hedge funds" investment strategies. Having in mind, the consistency and use of different hedge funds" classification, the paper was based on HFR classification of hedge funds because it enables to examine one special group of hedge funds, i.e. event-driven hedge funds. These funds represent probably the most challenging and promising hedge funds due to their specific character that enables the performance enhancement when and if specified event occurs. The aim of paper is to analyze and evaluate performance of event-driven hedge funds against the performance of hedge fund industry performance and traditional investing.

***Keywords**: hedge funds, strategy, event-driven, performance, Sharpe ratio*

1. INTRODUCTION

Although hedge funds originated from the end of 1940s, there is no precise definition of hedge funds until today, instead numerous definitions exists. Originally, hedge funds were private partnerships that took long and short equity positions to reduce net market exposure by accepting a lower return on investments. However, today the term hedge fund has a much broader meaning because of different portfolio characteristics. Hedge funds represent a type of alternative investment and their activities have a substantial share in trading volume in many traditional markets. Structures of hedge funds commonly enable them to be widely regulated although the pressure toward adequate regulations has grown since the financial crisis in 2007. Hedge funds are usually private pools that can avoid reporting and other requirements as well as restrictions in fees. However, the majority of hedge funds have a certain number of common characteristics, such as: unusual legal structure (e.g. limited partnerships or limited liability companies in the U.S.A.), active management (that affect their performance), flexible investment policy (that enables the fund managers to take positions according to their perceived return or risk expectations), limited transparency, limited liquidity (funds are focused to daily liquidity), orientation to specific investors (e.g. high net worth individuals) and, strategies are not adjustable (but depend on manager"s skill and the investments availability). This could cause problems with transparency and liquidity, low rate of attrition (measured by number of survived funds over specified period of time) (Gregoriou (2002)), exposure to asset risk (because of investing in illiquid asset and use of leverage), tax inefficiency and biases in reported data.

Hedge funds are the fastest growing group within the alternative investment over the last fifteen years. At the end of 2014, the assets under management of the global hedge fund industry was $2.25 trillion and the number of hedge funds exceeded 11,000 (Eurekahedge (2016). This remarkable growth led to substantial differentiation among hedge funds (especially in investment styles used). So, it was impossible to create hedge fund classification. Hence, the special characteristics of a specified hedge fund are mostly result of investment strategy that is implemented. Consequently, the hedge funds can be classified based on investment strategy. In this regard many different hedge fund classifications created by a number of companies exist (e.g. Morningstar, Hedge Fund Research (HFR), Morgan Stanley Capital International (MSCI), Center for International Securities and Derivatives Markets (CISDM), Credit Suisse/Tremont etc.). Regardless the hedge fund classification used, each hedge fund manager will pursue his/her own strategy, which will be developed and changed over time due to fast development of hedge fund industry. In fact, the hedge fund classification by using investment strategy criterion is a result of hedge funds" fast development. The goal of hedge funds classification is to create the funds that will satisfy the investors" needs. Besides this, over time emerged vendors of hedge funds" performance monthly and daily data. These companies collect data of thousands of hedge funds can sell the information to those investors interested in monitoring and/or evaluating hedge funds" performances. The hedge fund managers could be interested in the use of data provided by specific company because in this way they can show their performance within the industry and may attract new investors. Of course, hedge funds are free to provide or not to provide reports to vendors, and this may result in lack of information in situations when they are preparing for new investment or when they returns are deteriorating. Namely, hedge fund data (or the lack of data) are of the key

significance for hedge fund indices creation as well as their reliability. The creation of hedge fund indices enabled the measurement of performance of hedge funds.
Because the aim of paper is to analyze and evaluate performance of event-driven hedge funds against the performance of hedge fund industry performance and traditional investing, we decide to use Hedge Fund Research (HFR) hedge fund classification with a focus to event-driven strategies only. According to HFR hedge funds or hedge fund strategies are classified as (HFR (2016)): equity hedge, event-driven, macro, relative value and fund of funds. Equity hedge funds are oriented in investing in equities by using market neutral strategy, fundamental growth or value strategies, quantitative directional strategy, sector investing strategy, short bias strategy and multi strategy. Event-driven hedge funds are engaged in investing in companies that became attractive for investment because of specific event(s) has happened. The event-driven strategies are: activist, credit arbitrage, distresses/restructuring, merger arbitrage, private issue (regulation D), special situations and multi strategy. Hedge funds that use macro investing may apply: active trading, commodity investing, currency investing, discretionary thematic investing, systematic diversified investing and multi strategy. Relative value hedge funds implement: fixed income– asset backed investing, fixed income–convertible arbitrage, fixed income–corporate investing, fixed income–sovereign investing, volatility investing and multi strategy. In addition, the performance of event-driven strategies is examined by using HFR indices, i.e. Global Hedge Fund Index, HFR Event-driven Index and HFR Event-driven subindices (HFRX Indices (August 2015)).

2. CHARACTERISTICS OF EVENT-DRIVEN HEDGE FUND STRATEGIES

Event-driven hedge fund strategies are loosely defined. Regardless this, event-driven hedge funds try to achieve return on investments in companies that might experience occurrence of specific events over their lives. Such events may include recapitalizations, reorganizations, restructuring, mergers and acquisitions, initial public offerings, buybacks of shares and bankruptcies. The probability of these events occurrence creates an opportunity for hedge funds to make correct anticipation. Hedge funds usually use different types of securities (common shares, preferred shares, bonds etc.) which prices are considered mispriced. These strategies could be considers non-directional ones because they greatly dependent on company-specific situations that are low correlated or not correlated to market movements. Hedge funds managers commonly allocate their assets on distressed securities, merger and acquisitions and other special situations. Advantages of event-driven strategies are: possibility of achieving returns with limit market risk; returns are based on specific events of the company; less correlation with equity markets because of possibility to invest in different securities. Although the event-driven strategies attractiveness to investors, they can have certain disadvantages, such as investing in relatively illiquid securities which may affect the returns, as well as their broadly and imprecisely definition that requires the time for identifying the potential investment opportunity.
When the event has been announced (e.g. in press), hedge funds managers would analyze what is happening and would try to anticipate the outcome of an announced event (and not the event occurrence). Managers will perform fundamental analysis by combining strategic, operational, financial and legal effects in order to estimate what will happen and to take appropriate position. In this regard, managers may decide to invest in events with favourable outcome expectations, but they can also take positions in events with unfavourable outcome by betting on non-occurrence of the events. Besides this, managers have to determine an investment horizon and to select the securities that can be used to profit from event occurrence/non-occurrence. The securities analysis will be related (is related) to securities" prices analysis and risk analysis. Finally, managers will have to specify the securities in which the positions will be taken (partial or full) as well as the ways in which the taken positions could be closed. Before investment decision is made, event-driven hedge fund managers will determine the spread between the market value of a security and their own estimation of the value of the security. They will search the event that could change the attractiveness of the company because of its market value change. Managers will assess the time necessary for both event visibility and company"s market value change. The key risks of event-driven strategy implementation are related to the uncertainty of events outcomes, i.e. inability of foresight the occurrence of the events, outcome, time necessary to achieve the goal and, the change in securities" prices. Because of that the managers will try to diversify their portfolios and to combine positions in equities, bonds and derivatives (to hedge equity or bond portfolios).
The analysis of event-driven hedge funds strategies is based on Hedge Fund Research, Inc. classification (HFR (2016)) that divides all event-driven strategies into following substrategies: activist, credit arbitrage, distresses/restructuring, merger arbitrage, private issue (regulation D), special situations and multi strategy. Their markets are cyclical, which means that each substrategy will achieve the best performance at certain periods over cycles. While the hedge funds involved in special situations could be active at any phase of the cycle, the hedge funds oriented to active investing and/or mergers and acquisition would be the most active during the during expansion. Finally, the distressed companies as well as non-distressed ones may become attractive after the recession. Apart from cyclical nature of event-driven substrategies, most hedge funds" managers are specialized in particular substrategy according to their risk-return profiles.

2.1. Characteristics of activist hedge funds

The number of activist hedge funds is increasing because of the successful development of hedge fund industry. Activist hedge funds do not exist in many countries, and the largest funds are those that operate in the U.S.A. and the United Kingdom (Brav et al. (2008)). The goal of activist hedge funds is to invest in companies that may have better performances if a specific event happens. Activist hedge funds may be friendly (work with the company"s management in order to make necessary changes) or unfriendly (work with the company"s large shareholders in order to make necessary changes). Regardless this, these hedge funds will analyze the companies so that can identify the most promising ones if some changes were to be performed (e.g. strategic reorientation, change in management, sale of business units etc.). The financial strength of particular hedge fund will influence on whether to invest in medium-sized or small companies.
In order to accomplish the goal, activist huge fund manager would have to identify the market(s) in which the funds are to be invested by focusing on specific sectors and specific companies within the chosen sector and to value them (absolutely and relatively). Usually, the hedge funds would invest in undervalued companies, companies that have been profitable over the enough long period of time but in which the cost need to be reduced or cash management has to be improved. Besides this, hedge funds would be interested to invest in low profitable companies (to make them more profitable), smaller fast growing companies that need financing or expertise knowledge and in undervalued companies that are leaders in particular sectors (because their real values are difficult to estimate). Usually, the hedge funds would invest in underpriced companies, companies that have been profitable over the enough long past period of time but in which the costs need to be reduced or cash management has to be improved, low profitable companies (to make them more profitable), smaller, fast growing companies that need financing or expertise knowledge and, undervalued companies that have leading positions in sectors (because of problems in estimate their real values). Thus, by improving the company"s inefficiency and by eliminating the market price discount, hedge funds receive a premium (Boyson, and Mooradian (2011).
After the sectors and companies are identified, the managers would have to analyze the companies" management and to find the tools to create the value of the company which may require time (up to two or three years). That"s why managers would take limited number of active positions and would have a certain number of so-called sleeping positions in their portfolios. Moreover, the value of a company could be changed because of many global factors influence, which may lead to hedge fund"s risk exposure. Hence, the hedging is not advisable because this can even increase the overall risk of the portfolio (e.g. company"s management opposite view to what has to be changed). So, the key source of risk is the portfolio concentration (large positions relative to the company"s size). Besides this, the funds might be exposed to risk of investing in low profitable companies, risk of strategy implementation etc. In reality, hedge funds could earn desirable return from investing in just one company. Hence, the most important factor of this strategy success is to have specialized and experienced fund manager capable to improve the value of the chosen company.

2.2. Characteristics of credit arbitrage

Credit arbitrage strategies try to identify the return potentials in corporate debt securities, such as bank loans, senior and subordinated bonds issued by the company and structured position with quite low credit risk exposure. Hedge funds „managers commonly use fundamental credit analysis to evaluate the probability of issuer"s credit rating improvement. The market of corporate debt securities is liquid, which enables the manager to use general hedging techniques in order to reduce the credit risk exposure.
Credit arbitrage hedge funds seek to have minimal monthly volatility along with acceptable return. Managers of these funds will commonly take both long and short positions in different corporate debt securities. In other words, managers want to take advantage of any perceived mispricing in capital structure related to the corporate debt securities issuance.

2.3. Characteristics of distress/restructuring investments of hedge funds (hedge funds)

Distressed securities are securities of companies which are in financial distress (involved or to be involved in restructuring, reorganization, bankruptcy or liquidation) which means that companies cannot fulfil their credit obligations (cannot make interest payments or cannot repay the loans or face value of bonds). Company may fall into distress for a number of reasons, such as overleveraged, liquidity problems, credit rating downgrade, poor operating performance etc. Distressed securities are commonly have low credit rating (CCC and below). Because of distressed market inefficiency, distressed securities are selling with significant discounts. Types of distressed securities are: trade claims and receivables, common shares, preferred shares, private investment in private equities, rights and warrants, high yield bonds, corporate bonds, municipal bonds, below par bank loans, debtor in possession loans, mezzanine loans, bridge loans, collateralized debt, second lien notes, real estate assets, futures, options, swaps and indices. Investors in

distressed companies" securities are specific compared to investors in non-distressed securities because some investors are not allowed to own securities below a certain credit rating or to own post-reorganization securities or just because they cannot provide fresh capital to the company. In this respect, the investors in distressed securities are: hedge funds, money managers, mutual funds and private equity firms. However, hedge funds represent the largest buyers of distressed securities.
Distressed securities hedge funds „managers combine the fundamental analysis of a company of interest with knowledge of restructuring and bankruptcy in order to identify whether to investment in distressed company or not. In other words, managers would try to forecast and, if necessary, to influence the outcome of the bankruptcies and reorganizations. In general, hedge funds can profit from investing in distressed company by estimating the intrinsic value of the company. Namely, if the market value of a security is significantly below the estimated intrinsic value and managers expect that the security"s market value will increase and reach the intrinsic value hedge funds will take position in distressed securities or will increase the already taken position. On the other hand, hedge funds can have combined positions in securities that are considered relatively mispriced (buying cheap securities and taking short position in more expensive securities). Hence, distressed securities hedge funds" managers will commonly invest long and short in the distressed securities of companies undergoing financial rather than operational distress (i.e. good companies with bad figures in their balance sheets). According to their expertise knowledge, hedge funds" managers will be concentrated on certain sectors and will implement active or passive investment approaches. Active investment approach means that managers will attempt to influence the restructuring through active participation in a creditor committee, while the passive investment approach is oriented to buying and holding distressed securities until they appreciate.

Distressed securities hedge funds can provide relatively high returns regardless the current market conditions because the returns are the result of managers" skills. The main disadvantage of distressed securities investments is illiquidity (i.e. it"s hard and sometimes impossible to liquidate the positions taken by the hedge funds). Hedge funds" managers" decision to invest when the financial distressed emerged or to wait and invest later is based on expectations of company"s recovery. The greater the likelihood that the company will be recovered, the hedge fund will invest earlier.
Distressed securities hedge funds are exposed to risk. Because of this, managers of hedge funds have to manage the portfolio risk by diversifying across various industries, companies and securities. Managers can use different hedging instruments.

2.4. Characteristics of merger arbitrage

Merger arbitrage hedge funds are funds that are investing in companies undergoing mergers and acquisition in order to achieve arbitrage returns. In other words, managers take a long position in equity of a target company and simultaneously take short position in equity of an acquirer. Managers of these hedge funds strive to profit from the uncertainty of the announced event (e.g. bid announcement). Merger arbitrage (or risk arbitrage) can be realized by friendly takeover (return is a difference in the buy and sale share prices) or hostile takeovers (hostile public offerings of shares that requires the probability that target company"s shareholders will be forced to sell their shares) or partial sale (of a company which price is either below market value or intrinsic value).
The main advantage of this strategy is that it offers achievement of attractive returns with a relatively limited market risk exposure (returns dominantly depend on company events). The strategy has a much shorter investment horizon compared to other event-driven strategies. Finally, the investing decisions are based on available information only. On the other hand, merger arbitrage strategy disadvantages are inability to offer the same return over investment period and relatively high volatility.
Before the investment decision is made, manager of hedge fund has to identify the company of interest and to analyze it so that can estimate the probability of event success as well as the market reaction to the specific event. Based on this, hedge fund manager will try to determine whether to take position in the company or not. If manager is about to take position in company, the availability of information will affect the size of the position that should be taken. In addition, the market price at which the company"s shares could be sold and the uncertainty of transaction effect on buyer"s price have to be taken into accounts. The aim is to hedge positions.
The main risk of merger arbitrage is related to merger and acquisition process incompletion. Should the acquisition deal not be completed, the target"s stock price will fall and merger arbitrage hedge fund could incur significant loss. Nevertheless the level of risk undertaken varies among the merger arbitrage hedge funds. Some hedge funds" managers will invest in announced mergers and acquisition only, while others will invest before the merger or acquisition is officially announced.

2.5. Characteristics of private issue/regulation D

Private Issue/Regulation D strategies which employ an investment process primarily focused on opportunities in equity and equity related instruments of companies which are primarily private and illiquid in nature. These most frequently involve realizing an investment premium for holding private obligations or securities for which a reasonably liquid market does not readily exist until such time as a catalyst such as new security issuance or emergence from bankruptcy proceedings occurs. Managers employ fundamental valuation processes focused on asset coverage of securities of issuer firms, and would expect over a given market cycle to maintain greater than 50% of the portfolio in private securities, including Regulation D or PIPE transactions.

2.6. Characteristics of special situations

Special situations represent a strategy that is related to all events other than mergers and acquisitions or bankruptcies. In other words, this strategy is referred to situations, such as companies with depressed values of their shares, unannounced mergers and acquisitions, recapitalization, refinancing, reorganization, public offering, leveraged buy-out, government privatization etc. The position taken in these situations can be combined with the positions that are already taken in distressed securities or in mergers. This substrategy is focused on opportunities in equity and equity-linked securities of companies that are involved in different corporate situations. In other words, strategy include both announced and non-announcement events. The managers are oriented to corporate investing in a numerous forms (e.g. distressed securities, issuance of bankruptcy securities, asset sales etc.) that are identified by fundamental analysis. Strategies do not employ leverage, but returns on investments made exhibit greater volatility than other event-driven hedge funds.

2.7. Characteristics of multi strategy

Multi strategy represents a hedge fund strategy that combines two to five investment strategies in order to offer a diversified product. That means that the company may offer individual funds, multi strategy fund or a diversified portfolio only. Each strategy is typically managed independently. In order to limit exposure to manger and to reduce the risk of strategy implementation, the capital is allocated among various managers.
The strategy collapse may be stable over time or can be actively managed. When the strategy is managed in-house, the breakdown between strategies will tend to be stable or to evolve within bands. When external teams are used, the lead manager of the global portfolio usually retains the right to change the capital allocation over time. In this case rebalancing will usually be carried out monthly, quarterly or semi-annually (Capocci (2007) and Capocci and Hubner (2004)).
Multi strategy is characterized by a number of advantages. Multi strategy offers a diversified exposure to hedge funds. The provided liquidity is usually similar to liquidity of underlying strategies or can be even better. The strategy enables the hedge funds to diversify the risk of individual strategy. Multi strategy does not require a due diligence on underlying manager which influence the cost reduction. Finally, this strategy enables monthly (or quarterly) or consistently rebalancing. On the other hand, the multi strategy has its limitations. The main drawback of multi strategy hedge funds is the lack of freedom in making decision regarding the underlying manager. Hedge funds tend to stick to the same manager even if performance is poor. In addition, multi strategy hedge funds" managers can have a different level of transparency and invisibility to potential investors.

3. PERFORMANCE OF EVENT-DRIVEN STRATEGIES OF HEDGE FUNDS

Hedge funds performance evaluation is enabled by creation of hedge funds indices. Although these indices are still suffering from lack of continuous and complete data, they are capable of indicating the recent hedge funds" performances with a small error and can help investors determine expectations of their own hedge funds. Even though no universal hedge fund index can adequately represent the hedge fund industry as a whole and although existing indices differ in composition and performance, hedge fund indices are enough good indicators of hedge funds" performances. There are different providers of hedge fund indices, but despite this the indices are usually divided according to investment strategy of a hedge fund. Most firms publishing indices have an index for each hedge fund strategy and commonly subindices within the particular strategy. So, the investors can track with reasonable confidence the performance of hedge funds that pursues a specified investment strategy. In addition, the today"s development of hedge funds indices is supported by the inception of investable indices, i.e. the indices that mimic the aggregate performance of individual hedge fund strategies (e.g. Morgan Stanley Capital International Inc. and Standard&Poor"s). Having this in mind, the investors should carefully choose a hedge fund index because of its representativeness of industry performance as well as the imperfect hedge fund databases.

Performance of hedge funds strategies is usually evaluated based on detailed analysis of daily, monthly or quarterly returns and their standard deviations, correlations among different hedge funds strategies and among hedge funds indices and equity and/or bond indices. The frequently used performance measure is Sharpe ratio. Sharpe ratio was introduced by William Sharpe (Sharpe (1966)) as a measure of mutual funds performance. Sharpe proposed a term reward-to-variability ratio (Sharpe (1975)) that indicates the expected differential return per unit of risk associated with the differential return (ex ante ratio) or the historic average differential return per unit of historic variability of the differential return (ex post ratio). Specifically, measures the return adjusted for each level of risk undertaken. It represents a ratio between the difference in average return on investment and risk-free rate and standard deviation of the returns. This ratio can be applied to different hedge funds regarding return and volatility relationship. The higher the value of Sharpe ratio, the higher return investors can expect to receive for additional risk accepted by investing in riskier assets. Several authors pointed out to drawbacks of Sharpe ratio and other traditional performance measures. Among them, the most attention deserve Cappoci, Duquenne and Hubner (2007) who developed an extended risk measure that integrates the specific features of alternative strategies. Besides, some authors proposed and examined the use of Sortino ratio (van Dyk, van Vuuren and Heymans (2014) and Omega ratio (Botha (2007). Despite a number of shortages, the most consistent and widely used measure of hedge funds" performances is Sharpe ratio and this is the performance analysis of event-driven hedge funds is based on this ratio.

Capocci (2009) and Cappoci and Hubner (2004), Agarwal (2001), Agarwal and Naik (2000), Bertelli (2007), Fung and Hseih (2002b) and Gregoriou et al. (2006) had analyzed the general or partial performance of hedge funds. Nevertheless, there are is analysis focused on event-driven strategy. That"s why the paper tries to analyze this specific and important group of strategies. Availability and consistency in data represent a relatively great weakness, but we tried to overcome this problem by the use of publicly available date of event-driven hedge funds" index and subindices of HFR (HFRX Indices (August 2015)).

According to HFR hedge fund strategies classification, the event-driven strategy has substrategies, and their performance is could be traced by values of strategy"s index and subindices (event-driven index, activist index, credit arbitrage index, distressed/restructuring index, merger arbitrage index, special situations index and multi strategy index). Performance of private issue/regulation D could not be analyzed because for this hedge fund strategy no subindex exists.

The performance of event-driven strategies is analyzed on the basis of data provided by Hedge Fund Research of HFRX Global Hedge Fund Index (HFRXGL), HFRX Event-driven index (HFRXED), MSCI US$ World Index (MSCI (2016) and S&P 500 w/dividends over the 1998-2014. In order to analyze the performance of event-driven hedge funds, we firstly compare the data that may indicate the performance of the event-driven hedge fund index with the performance of Global hedge fund index (the observed period was the same). The HFRX Global Hedge Fund Index (HFRXGL) is designed to be representative of the overall composition of the hedge fund universe. Over the period of concern (1998-2014) HFRXGL had geometric average monthly return of 0.39%, which was higher than the returns both on 3-month LIBOR and MSCI World Index (0.21% and 0.27% respectively). Standard deviation of monthly returns was 1.8, i.e. the volatility was greater than for 3-month LIBOR (0.19) but significantly lower than for MSCI World Index (4.56). Annualized return of HFRXGL was 4.82% and was higher than both 3-month LIBOR and MSCI World Index (2.59% and 3.24% respectively). The annualized standard deviation of returns was 6.24 and that was higher than 3-month LIBOR (0.65) and significantly lower than for MSCI World Index (15.80). The risk-free rate over the analyzed period was 2.11%. Correlation between HFRXGL and 3-month USD LIBOR was low positive (0.17), while was significantly positive between HFRXGL and MSCI World Index (0.63). Finally, Sharpe ratio as a measure of global hedge fund performance was 0.45 or better than ratio for MSCI World Index (0.15) but weaker than for 3-month LIBOR (0.69). The HFRX Event-driven Index (HFRXED) is designed to be representative for all hedge funds pursuing event-driven strategies. Over the period of concern (1998-2014) HFRXED had geometric average monthly return of 0.37%, substantially higher than the returns on MSCI index (0.27%) and slightly lower the returns on both S&P 500 w/dividends and HFRXGL (0.49% and 0.39% respectively). Standard deviation of HFRXED returns was 1.93, which was slightly greater than the standard deviation of HFRXGL (1.8) and substantially lower than the standard deviations of both MSCI and S&P 500 indices (4.55 and 4.46 respectively). Annualized return on HFRXED was 4.52% which were lower than the return on S&P 500 (6.04%) and higher than the returns on both MSCI index and HFRXGL (3.24% and 4.82% respectively). Annualized standard deviation of HFRXED returns was 6.68 and it was slightly greater than for HFRXGL (6.24) but substantially lower than the standard deviations of both MSCI and S&P 500 indices (15.80 and 15.45 respectively). This can be partly explained by financial crisis influence on hedge fund industry and especially on hedge funds that followed some event-driven substrategies. Correlation between the HFRXED and MSCI World index was 0.70 which was greater than the correlation coefficient for HRFXGL (0.63). Finally, Sharpe ratio as a performance measure was 0.38 for HFRXED, which was higher than ratios values for both MSCI and S&P 500 indices (0.15 and 0.32 respectively), but lower than ratio of HFRXGL (0.45). This may suggest that because of specific characteristics of event-driven strategies, the hedge fund industry performed slightly better. In general, it seemed that hedge funds as a whole performed better than

event-driven hedge funds. Hence, it would be difficult to give the final conclusion regarding event-driven hedge funds" performance. In other words, more detailed analysis should be done.

Event-driven hedge funds attempt to enable investors to diversify their investments. In general, the rational for diversification would depend on correlation between the assets within the investment portfolio. The correlation is measured by correlation coefficient that may take values from -1 to + 1. Ideally, the best diversification and risk reduction would be obtained if coefficient had value of -1 (negative correlation). On the other hand, diversification wouldn't reduce the risk exposure if coefficient is +1. In general, as long as acceptable positive correlation exists between assets, it would've been worth of adding asset in the given portfolio. Having this in mind, the table 1 is created with a goal to give the information regarding the historical correlations between event-driven hedge funds and classical indices.

Results presented in table 1 are in accordance to what could've been expected from event-driven substrategies. All event-driven substrategies are positively correlated to both MSCI World index and S&P 500 w/dividends, except for activist hedge funds, which can be explained by the specific active role they commonly undertake in companies of interest. Apart from this, we tried to determine the correlation between event-driven strategies over the whole period, but the inconsistency in data and the lack of data for some years, not allowed us to do so. However, we managed to determine the correlation between only two event-driven substrategies (distressed/restructuring and merger arbitrage). In this regard, correlation coefficients were 0.57 which could be considered attractive to further portfolio diversification. With further development of event-driven hedge fund data collection and creation of wider range of subindices, the correlation would be possible to examine and to make useful conclusion about how to combine event-driven substrategies in order to enhance the hedge funds" return.

Table 1: Correlation between event-driven substrategies and market indices (1998-2014)

	Correlation with MSCI World index	S&P 500 w/div
Activist index	– 0.60	0.65
Credit arbitrage index	0.67	0.62
Distressed restructuring index	0.49	0.61
Merger arbitrage index	0.44	0.41
Special situations index	0.75	0.69
Multi strategy index	0.66	0.59

*GAMR - Geometric average monthly return; SDMR - Standard deviation of monthly returns; Standard deviation of annualized returns.

Finally, on the basis of date used, the performance of event-driven substrategies was analyzed by comparison of returns (monthly and annually), standard deviations (monthly and annually) and Sharpe ratio. The aim was to research in more details the performance of event-driven hedge fund substrategies because this issue have been insufficiently explored. Table 2 shows the results that indicate the performance and potential of particular event-driven substrategies. In summary, table 2 suggests that best performing strategies are credit arbitrage and merger arbitrage which is in line with the market conditions deterioration after the financial crisis emergence in 2007 and strategies" orientations. Activist and multi strategy were "medium-performed" ones, while the weakest performing were distressed/restructuring and special situations strategies. The results should be analyzed in broader context, especially because of the fact that distressed/restructuring and special situations strategies are commonly low correlated to traditional investments (e.g. shares and bonds) and frequently related to low liquid assets.

4. CONCLUSION

Hedge funds are the fastest growing group within the alternative investment over the last fifteen years because of unique characteristics and the return potential with medium or low volatility and commonly medium or low risk exposure. The hedge funds are usually defined by the investment strategy they implement. Hedge funds loosely regulation and commonly lack of transparency led to wide range of hedge funds" strategies which are formulated to suite the investors need. Over time investors required more and more information about their investments returns and performance. As a result specialized companies emerged and started to provide data of hedge funds" operations and shortly after this, created hedge fund indices. This encouraged more investors to invest in hedge funds. There is variety of different hedge funds" investment strategies. Having in mind, the consistency and use of different hedge funds" classification, the paper was based on HFR classification of hedge funds because it enables to examine one special group of hedge funds, i.e. event-driven hedge funds. These funds represent probably the most challenging and promising hedge funds due to their specific character that enables the performance enhancement when and if specified event occurs. The performance of event-driven hedge funds can be measured, not only in terms of returns (daily and month) and standard deviation of returns, but also by using Sharpe ratio as widely used measure of hedge funds" performance. The analysis of event-driven hedge funds" performance showed relatively good performance though slightly weaker than the performance of hedge funds industry as a whole. Compared to widely used market indices (such as MSCI World Index and S&P 500), performance of event-driven strategies was better. Best performing strategies were credit arbitrage and merger arbitrage which is in line with the market conditions deterioration after the financial crisis in 2007 and strategies" orientations. Activist and multi strategy were "medium-performed" ones, while the weakest performing were distressed/restructuring and special situations strategies.

USING FINANCIAL STATEMENT DATA TO EXPLAIN STOCK PRICE MOVEMENTS - BELGRADE STOCK EXCHANGE CASE

Teodora Mešić*[1], Jovan Milovanović[1], Aleksandar Rakićević[1]
[1]University of Belgrade, Faculty of organizational sciences,
*Corresponding author, e-mail: mesicteodora1@gmail.com

Abstract: *This study uses regression as a tool to create regression models that are able to explain stock price movements based on selected financial statement data and financial ratios. For the purpose of this study, we build both univariate and multivariate linear regression models. The proposed models are used to explain stock price movements for Prime Listing companies in Belgrade Stock Exchange. To explain stock price movements, we use in total nine financial statement items and five ratios as independent variables in our regression models. The results shows that the best method to explain and predict future price movements is to analyze raw financial statement data. Good results are also achieved using DuPont decomposition ratios.*

Keywords*: stock price, regression, financial ratios, financial statements, forecasting*

1. INTRODUCTION

In the analysis of rational investment behavior it is necessary to observe two key things: possible profit and risks. Often the investment motives are tested by investing in equities that are the most extensively traded and most valuable in stock markets. Stock prices are the basic and most important indicator to observe successfulness of the company. More precisely, positive movements in share prices indicates success and higher valuation. Therefore, using stock prices we can learn a lot about companies' operating quality, efficiency and effectiveness of governance for the future of the company. It is important to understand stock price movements and their dependence on various factors.

Research aim or research questions need to be fairly well defined. This is an important point. We always need to have a clear focus on what we want to find out. Without a clear research question, it becomes much harder to understand both which data sources to look for and which techniques to employ. In applied research, we use a range of statistical techniques. We tend to distinguish between univariate(summaries and inferences about a *single* [uni-] variable), bivariate (summaries and inferences about the relationships between *two* [bi-] variables) and multivariate (summaries and inferences about the relationships between *three* or more [multiple] variables) statistics.

In this study, we focused on bivariate and multivariate statistics. The idea was to use statistics as a model of real world problems. In other words, we used mathematical models in order to understand and explain events regarding the study theme. We used regression to explain influence of the data from financial reports and ratios calculated based on this data on stock price movements, namely correlation between these two. Linear regression is used for experiments where only one factor that influences stock price is observed, in our case the influence of one valuation ratio on stock price. On the other side, we used multiple regression when more factors have to be taken into account (influence of several ratios on stock price). We divided input data in two sections: financial statement data (net profit, interest expenses, short term liabilities, etc) and ratio data derived from financial statement data (return on assets, return on equity, profit margin, asset turnover, financial leverage).

The rest of the paper is organized as follows. In the next section we give a brief background about this subject, and mention some of the most important work. Detailed explanation of methodology and our model is provided in Section 3. Section 4 gives brief explanation of data sample and presents results of our experiment with the corresponding discussion. Section 5 concludes our paper and give some thoughts for further work.

2. BACKGROUND

Analyzing correlation between current earnings, income and financial statement data in general, and stock prices is very important topic in finance. Understanding this relationship is crucial, especially for those who are participating stock markets. Beaver (1998) says that one link, theoretically speaking, between earnings and stock prices is that current earnings and other data from financial reports provide information to predict

future stock prices and thus future earnings. Based on this statement, researches have looked for current financial report information to predict future movements in stock price and earnings, pointing out that this should be one of the main goal of fundamental analysis (Penman, 1992; Lee, 1999).

Sloan (1996) decomposed earnings into accruals and cash flows and found that companies with higher operating accrual tend to have lower future earnings and returns. Lewellen (2004) studied whether financial ratios like dividend yield can predict aggregate stock returns. He showed that dividend yield can predict market returns in a whole sample, while book-to-market and price-per-earnings ratios have predictive power in the shorter sample. Soliman (2004) investigated in his study whether the industry-adjusted DuPont analysis is a useful tool in predicting future changes in return-on-net-operating-assets and obtained positive results.

3. METHODOLOGY

In this study, the problem we are focusing on is whether is there a direct dependency between changes in financial statements data (and therefore also changes in financial ratios) and stock price movements. In order to find out the answer on this question we will employ different regression models. The first part of this section will provide a brief overview of regression method. Further, we will present our univariate and multivariate regression models. Finally, at the end of this section, valuation method is provided.

3.1. Regression

Regression is a dependency model. Its' idea is to explain the variation in a certain variable (income, profit, expenditure etc), as a function of explanatory variable(s). In other words, regression tries to figure out to what extent does the variation in explanatory variables explain the variation in the dependent variable?

The basic linear regression model can be set up in the following way:

$$Y = \beta_0 + \beta_1 X + \varepsilon , \tag{1}$$

where β_0 is *Y*-intercept, β_1 is a slope coefficients and ε is a random error term. In this univariate model, changes in *Y* are assumed to be caused by changes in *X*.

If the one independent variable is not enough to explain behavior of dependent variable, we can set a multiple regression model with k independent variables:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \ldots + \beta_k X_k + \varepsilon , \tag{2}$$

where $\beta_0, \beta_1, \ldots, \beta_k$ are regression coefficients and ε is a random error term.

3.2. The proposed model

In our study we perform several experiments. First, we studied stock price movements based on the changes of single variable (return-on-assets, return-on-equity), and second, we studied those movements based on the changes of multiple variables (multiple financial statement data, multiple ratios). Therefore, we used both univariate and multivariate regression models.

Our first model type is the following:

$$P = \beta_0 + \beta_1 R + \varepsilon , \tag{3}$$

where *P* represents stock price, while *R* stands for return-on-equity (ROE) or return-on-assets (ROA) ratio.

Our second model type is the following:

$$P = \beta_0 + \beta_1 PM + \beta_2 AT + \beta_3 FL + \varepsilon , \tag{4}$$

where *PM* represents profit-margin ratio, *AT* stands for asset-turnover and *FL* is financial-leverage ratio. These three ratios represent DuPont decomposition ratios of ROE ratio. We believe that these components of ROE, when put in regression model, have greater explanatory power that the ROE.

Our final model studies influence of financial statement components on stock price movements. Using several items from financial report we build the following regression model:

$$P = \beta_0 + \beta_1 A + \beta_2 C + \beta_3 STL + \beta_4 DTL + \beta_5 LTL + \beta_6 I + \beta_7 EBIT + \beta_8 IE + \beta_9 NP + \varepsilon \,, \tag{5}$$

where *A* represents total assets, *C* is capital, *STL* means short-term liabilities, *DTL* is differed tax liabilities, *LTL* stands for long-term liabilities, *I* is total income, *EBIT* is earnings-before-interest-and-taxes, *IE* are interest expenses, while *NP* is a net profit.

3.3. Method valuation

To determine influencing factors and method success we observed T-statistic, P-Value and R Squared.

R Squared (R^2)

R Squared is a coefficient of determination and represents the portion of the total variation in the dependent variable that is explained by variation in the independent variable.

Table 1: Examples of approximate R^2 value

R^2= 1	R^2 between 0 and 1	R^2= 0
100% of the variation in Y is explained by variation in X	Some but not all of the variation in Y is explained by variation in X	The value of Y does not depend on X (None of the variation in Y is explained by variation in X)

T-test for a population slope

We are trying to understand a linear relationship between X and Y. We have null and alternative hypotheses

$$\begin{aligned} H_0 &: \ \beta_1 = 0 \ \text{(no linear relationship)} \\ H_1 &: \ \beta_1 \neq 0 \ \text{(linear relationship does exist)} \end{aligned}, \tag{6}$$

Test statistic is

$$t = \frac{b_1 - \beta_1}{sb_1} \,, \tag{7}$$

where b_1 is a regression slope coefficient, β_1 is a hypothesized slope, sb_1 is a standard error of the slope. Confidence level is by default 0,95 so $\alpha = 0{,}05$.

In Table 2 we present an example of analysis of influence of ROE on stock price which is the part of our analysis.

Table 2: t-test example

	Coefficients	Standard Error	t Stat
Intercept	98,24833	58,03348	0,12892
ROE	0,10977	0,03297	3,32938

Regression slope coefficient is $b_1 = 0{,}10977$, $sb_1 = 0{,}03297$, while $t = 3{,}32938$.

Further, we look at the T distribution critical value table, and decide whether the *t*-value for ROE falls into the specific interval (which is determined by the critical value table). Since the value for *t* does not fall into critical area, the decision is to reject H_0.

P-Value Method

In this method we starts with the same hypotheses. The following Table 3 presents an example from our analysis.

Table 3: p-value example

	Coefficients	Standard Error	t Stat	P-value
Intercept	98,24833	58,03348	0,12892	0,12892
ROE	0,10977	0,03297	3,32938	0,01039

This is a two-tail test, so the *p*-value is $P(t>3,329)+P(t<-3,329)=0,01039$ (for 8 d.f.). If the *p*-value is smaller than $\alpha=0,05$, we reject H_0. The bigger the *t*-value is, the smaller the *p*-value, and consequently the stronger is the evidence against the H_0 hypotheses. In this example from our study, there is sufficient evidences that ROE affect the stock price.

4. EXPERIMENTAL RESULTS

In the first part of this section we will present data sample used in this study. In the next part we will structure results and provide appropriate comments.

4.1. Data

We used data from the financial reports of Prime Listing companies listed on Belgrade Stock Exchange (BELEX), given the fact that these companies are obliged to inform public quarterly on their results. BELEX Prime Listing is consisted of four companies: Energoprojekt holding (ENHL), Naftna Industrija Srbije (NIIS), Sojaprotein (SJPT) and Aerodrom Nikola Tesla (AERO). Data are taken from the official financial reports of these companies, and can be found on www.belex.rs. Data ranges from the first quarter of 2006 to the last quarter of 2015.

We organized data from the reports, and calculated relevant financial ratios: return-on-equity (ROE), return-on-assets (ROA). In order to analyze relationship between stock price and these ratios more efficiently, we also did DuPont decomposition (Soliman, 2008) of ROA into profit margin (PM) and asset turnover (AT), and ROE into PM, AT and financial leverage (FL).

Table 4: Financial ratio and stock price data

Company	Stock price	ROA	ROE	PM	AT	FL
ENHL	3232	0,039	0,043	0,972	0,040	1,096
	2901	0,034	0,041	0,852	0,040	1,213
	2101	0,034	0,047	0,134	0,254	1,380
	1600	0,079	0,111	0,299	0,265	1,404
	…	…	…	…	…	…
NIIS	506	0,129	0,849	0,151	0,850	6,603
	481	0,177	0,488	0,197	0,902	2,752
	580	0,225	0,692	0,268	0,842	3,071
	624	0,066	0,197	0,074	0,888	2,977
	…	…	…	…	…	…
SJPT	2970	0,047	0,094	0,040	1,179	1,996
	2490	0,079	0,156	0,082	0,960	1,983
	1042	0,092	0,251	0,114	0,806	2,718
	840	-0,009	-0,027	-0,009	1,016	2,985
	…	…	…	…	…	…
AERO	526	0,051	0,056	0,263	0,194	1,092
	484	0,068	0,075	0,300	0,228	1,092
	515	0,088	0,098	0,363	0,243	1,115
	460	0,064	0,070	0,271	0,238	1,092
	…	…	…	…	…	…

4.2. Summary results

Using Excel and its Data analysis tools we tried to determine the dependence between stock price and all factors previously mentioned. Through testing of each individual factor and its impact on the price as well as their combinations, we came to the following results shown in Figure 1.

Company	ROA	ROE	DuPont decomposition ratios*	Financial statement items**
ENHL	✗	✗	✗	✓
NIIS	✗	✗	✓	✓
SJPT	✗	✗	✓	✓
AERO	✓	✓	✓	✓

Figure 1: Summary results

*We use ROE decomposition which include Profit margin, Asset turnover and Financial leverage.
**All items from financial reports are Total assets, Capital, Current liabilities, Deferred tax liabilities, Long-term liabilities, Income, EBIT, Interest expenses, Net profit.

Our summary results shows interesting conclusions. ROA and ROE factors are able to explain stock price movements only in one case – AERO. Further, DuPont decomposition of these ratios into PM, AT and FL gives more explanatory power for stock price prediction. It successfully explained price movements for three stocks: AERO, ENHL and NIIS. It is important to note here, that SJPT experienced several stock splits and also suffered huge losses during the selected time period, which could be a reason why it was difficult to explain its price movements. Finally, using raw financial statement data we obtained the best results in explaining stock market movements. All four stock price movements were explained successfully.

4.2.1. ROE results

The following regression Table 5 presents detailed results for our ROE model.

Table 5: Regression statistics for ROE

Company	R Square	t Stat	P-value
AERO	0,59599	4,02830	0,00199
ENHL	0,01644	0,60640	0,55046
NIIS	0,07712	1,04230	0,31627
SJPT	0,03812	0,95483	0,34962

From the regression table, which examines relationship between ROE and stock price movement, we can see that there is a relative strong influence of ROE on AERO price changes. However, other three companies do not show statistical significance for ROE influence, which means that ROE cannot be used to explain neither predict price movement of these stocks. It is interesting to mention, that analysis of price movements of these stocks showed, that AERO is the only company among these four with relatively steady price trend through time observed.

4.2.2. ROA results

The following regression Table 6 presents detailed results for our ROA model.

Table 6: Regression statistics for ROA

Company	R Square	t Stat	P-value
AERO	0.60199	4.07894	0.00182
ENHL	0.00001	0.01897	0.98503
NIIS	0.00000	0.00334	0.99738
SJPT	0.03021	0.84644	0.40603

ROA, as well as ROE has strong influence on stock price movement in the example of AERO. And again, as in the previous example, this influence is not significant for other three companies.

5. CONCLUSION

In this paper linear regression is used to establish the relationship between data from financial statements and financial ratios, and stock price movements. Experiment was conducted for Prime Listing companies on Belgrade Stock Exchange including Aerodrom Nikola Tesla, Energoprojekt holding, Naftna Industrija Srbije, Sojaprotein.

Our results have shown that the biggest influence on stock price movements have the raw financial statement data. In a way, this was expected result since it is only logical that deep analysis of financial statement items can give us detailed insights in companies performances. The second results were obtained using DuPont decomposition ratios for ROE and ROA profitability measures. Finally, using only ROA and ROE factors seems not to be very helpful for those who wants to understand stock price movements. Our final conclusion is that in financial analysis one should never underestimate a detail inspection of financial statements and other internal factors that influence companies' performances in order to obtain good insight in investment perspective of the stock.

As for the future research, we plan to include more factors in our analysis and to use other statistical and machine learning methods in order to explain stock price movements.

APPLYING A NEURO FUZZY SYSTEM FOR CREDIT RISK EVALUATION

Nevena Vranić[1], Javorka Djurić[1], Ivana Dragović[1]
[1]Faculty of Organizational Sciences, University of Belgrade
nevena.vranic@gmail.com

Abstract: *One of the most relevant issues in financial analysis is credit score calculation. In order to solve this problem, numerous methods have been proposed in the literature for credit risk evaluation. In this paper, to create the prediction model for creditworthiness, Neuro-Fuzzy approach has been used, more specifically, an adaptive neuro-fuzzy inference system (ANFIS). In order to reduce the dimensionality problem Principal Component Analysis (PCA) was employed. The system was trained and tested with different number of inputs.*

Keywords*: fuzzy logic, neuro-fuzzy system, ANFIS, Principal Component Analysis, credit risk*

1. INTRODUCTION

In the past years, financial analysis has developed significantly on account of bigger complexity of business systems. Thus, the need for advanced calculations and used techniques has also increased. Conventionally, creditworthiness and other types of assessments have been done using various statistical methods and, in general, creditworthiness assessment has been a statistical category.

One of the most relevant issues in financial analysis is credit score calculation. A credit score is primarily based on a credit report information. Lenders, such as banks, use credit scores to evaluate the potential risk posed by lending money to companies. Lenders use credit scores to determine who qualifies for a loan, at what interest rate, and what credit limits.

To predict the model for credit score, there are number of techniques like: Statistical techniques, Neural Network, Genetic Algorithm, Fuzzy Logic and hybrid approaches, such as Neuro-Fuzzy. As it is fact that each technique has their own pros and cons.

In this paper, to create the prediction model for creditworthiness, Neuro-Fuzzy approach has been used, more specifically, an adaptive neuro-fuzzy inference system (ANFIS). Neuro-Fuzzy approach is applied because the combination of Neural Network and Fuzzy Logic results in such hybrid intelligent system that is having learning ability to optimize its parameters with the use of neural network and to represent the knowledge in an interpretable manner, with the use of Fuzzy System. Created system does not require an expert in finance.

Model in this paper is based on financial information, represented by 23 financial ratios, regarding 150 companies located in Serbia for the period 2011-2013. In order to optimize the given data set and reduce number of ratios, Principal Component Analysis is used.

The paper is structured as follows: Sections 2, 3, 4, 5 provide the basic concepts of Fuzzy Logic, Neural Networks, Neuro-Fuzzy Systems and ANFIS. Related work is given in Section 6. In Section 7 the concept of Principal Component Analysis is introduced. Section 8 is devoted to the experimental results and their analysis and finally, Section 9 concludes the paper and discusses future work.

2. FUZZY LOGIC

The theory of fuzzy sets was initiated by Lofti Zadeh in 1965. In his influential paper named Fuzzy Sets he pointed out that such imprecisely defined sets or classes “play an important role in human thinking, particularly in the domains of pattern recognition, communication of information, and abstraction” (Zadeh, 1965.).

Fuzzy set, as the name says, is a set without a crisp boundary. That is, the conversion from “belonging to a set” to “not belonging to a set” moves gradually, and this fine gradation is defined by membership functions that give

fuzzy sets adaptability in modeling, a concept similar to commonly used linguistic expressions, such as “the man is tall” or “he is driving quite fast”.

Definition of fuzzy sets and membership functions is:

If it is assumed that X is a collection of objects expressed generically by X, then a fuzzy set A in X is described as a set of ordered pairs:

$$A = \{(x, \mu_A(x)) | \forall x \in X\} \tag{2}$$

$\mu_A(x)$ is called the membership function (MF for short) of x in A The MF maps each element of X to a continuous membership value (or membership grade) between 0 and 1 (Jang & Sun,1995.).

2.1. Fuzzy rules and fuzzy models

The process of drawing conclusions based on fuzzy rules is called fuzzy inference and the system made of it is called Fuzzy inferencing system – FIS. A fuzzy if-then rule (fuzzy rule, fuzzy implication or fuzzy conditional statement) presumes the form

$$if\ x\ is\ A\ then\ y\ is\ B \tag{3}$$

where A and B are linguistic values described by fuzzy sets on universes of discourse X and Y, respectively (Jang & Sun,1995.).

Two kinds of Fuzzy logic systems (FLS), the Mamdani and the Takagi-Sugeno-Kang (TSK) FLSs are widely used and they are currently adopted by the scientific community. Mamdani FLS is an intuitive and numerical system that maps crisp (deterministic) inputs to a crisp output (Mamdani & Assilian, 1975). Takagi-Sugeno-Kang FLS is very similar to Mamdani FLS. It is a special FLS which is also characterized by *if-then* rules, but its consequent is a polynomial. Its output is a crisp value obtained from computing the polynomial output, so it does not need a defuzzification process (Sugeno & Kang, 1988.; Takagi & Sugeno, 1985.).

3. NEURAL NETWORK

Artificial neural networks generalize the mathematical models of the human cognition and neural biology. Artificial neural networks show the ability to learn from the environment in an interactive fashion and show remarkable abilities of learning, recall, generalization and adaptation in the wake of changing operating environments (Azam, 2000.). The simplest neural network model is called a perceptron which can be trained to discriminate between linearly separable classes. For more complex tasks of classification or regression, models with multiple layers of neurons are necessary. This artificial neural network model is generally referred to as a multi-layer perceptron (MLP). This architecture consists mainly of three types of neuron layers, namely input layer, hidden layer(s) and an output layer. The nodes in an input layer encode the data presented to the network for processing. These nodes do not process the information, but simply distribute the information to other nodes in the next layer. The nodes in the middle layers are called hidden nodes. These neurons provide the nonlinearities for the network and compute an internal representation of the data. The nodes in the output layer are referred to as output neurons: they encode possible desired values assigned to the input data. A typical multilayer perceptron neural network model is shown in Figure 1.

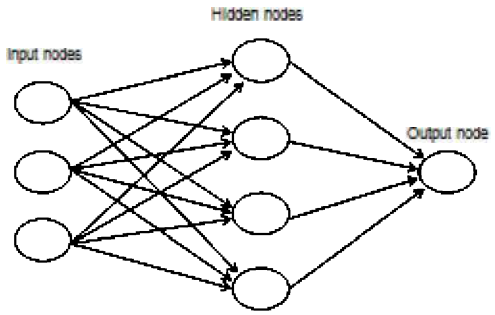

Figure 1: Artificial neural network

3.1. Neural network learning

Neural networks enable the intelligent processing without previosly defined model or algorithm, but based on information about particular system behaviour. Neural networks learn from experience. The process of learning is called training and it can be divided into three phases: calculating the output, comparing the obtained value with the desired value, adjusting the weight coefficients and going back to the first step. Learning algorithm that is mostly used is backpropagation algorithm. Neural network adjusts the weight coefficients according to error values assigned to each node. The calculating is done backwards, starting from the output layer to hidden layers and the process ends on the input layer. After the modification of parameters is completed, the process of training continues until the network is able to give outputs with a satisfying accuracy.

4. NEURO-FUZZY SYSTEMS

From the point when fuzzy systems started to be applied in industrial purposes, it has been clear that the progress of a fuzzy system that gives good results is not a simple task. The difficulties of defining membership functions and suitable rules is usually an exhausting process of tries and mistakes. Eventually the idea of combining learning algorithms with the fuzzy systems had been created. The neural networks, that have efficient learning algorithms, had been given as a solution to automate or to help the improvement of tuning fuzzy systems.

The combination of neural networks and fuzzy systems in order to join their good sides and to fix their separate flaws. Neural networks bring up their computational characteristics of learning in the fuzzy systems and take in from them the interpretation and the precision of systems representation. Thus, the parameters of the fuzzy systems can be fixed by the neural networks' competences. These concepts complement each other, which validates its use as a combination.

5. ANFIS

Adaptive neuro-fuzzy inference system (ANFIS) represents a multilayered adaptive network that uses fuzzy inference system with its membership functions. Adaptive neuro-fuzzy inference system's structure consists of network's directly connected nodes. Each node is defined by a function with adaptive or fixed parameters. Functions included in ANFIS build a fuzzy inference system using given input and output parameters. The ANFIS model uses Sugeno fuzzy inference system, and fuzzy if-then rules for describing complex system behaviour (Jang, 1992).

5.1. ANFIS architecture

ANFIS (Jang,1993) has an architecture that consists of five layers as shown in Figure 2. The first hidden layer is used for fuzzification of the input variables and T-norm operators are used in the second hidden layer to calculate the rule of the prior part. The function of the third hidden layer is to normalize the strengths of the rules. Next hidden layer is the place where the consequent parameters of the rule are concluded. Output layer estimates the total input as the incoming signals complete sum. ANFIS applies backpropagation learning algorithm in order to set parameters of the premise (to learn the parameters associated with membership functions) and least mean square estimation to determine the consequent parameters.

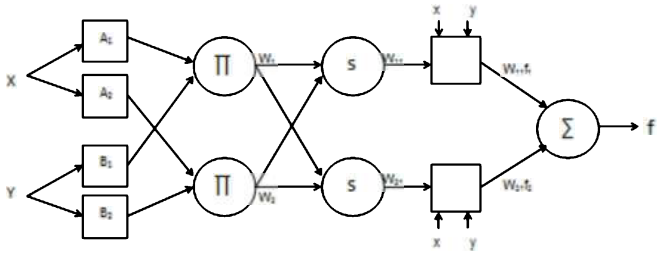

Figure 2: ANFIS architecture

6. PRINCIPAL COMPONENT ANALYSIS

The univariate statistical analysis, generally used to treat a large amount of data, could cause misunderstanding and error in the interpretation. In this paper, Principal Component Analysis (PCA) was used, in order to reduce the dimensionality problem. Highly dimensioned data set is reduced by explaining the correlation amongst a large number of variables in terms of a smaller number of underlying factors (principal components or PCs) without losing much information (Beatriz et al, 2000).

In fact, PCA creates linear combinations of variables. The first linear combination of variables is adequate for the most of the variation in the sample; the second combination is used for the second largest amount of variance in a dimension and there is no dependence between the first and the second combination; and so on (Petroni & Braglia, 2000). One of the advantages of the PCA methodology is to be quite simple to exploit. The analysis that is illustrated in the following has been carried out by using the SPSS computer package.

7. RELATED WORK

ANFIS has been very popular in solving many problems of financial nature, especially the ones dealing with some kind of prediction. (Trinkle, 2005) successfully anticipates stock prices at U.S. Stock Exchange Trade and (Chang et al, 2011) use ANFIS for anticipating stock prices trends and (Schott & Kalita, 2011) apply time series trends to Tehran stock exchange by combining ANFIS with three neural networks.(Ansari et al, 2010) use ANFIS for prediction of patterns and for trading support in financial markets. Combining ANFIS with KERNEL algorithm (Efendigil et al, 2009) predict emergency orders to pre-adjust the available capacity and production plan. Using ANFIS, satisfactory results were obtained in prediction of annual profits. (Abraham et al, 2001) (Efendigil & Önüt, 2012) used ANFIS for credit analysis.

(Bagheri et al, 2014) investigate the possibilities of particle swarm optimization (PSO) technique for determining the value of subtractive clustering parameters and ANFIS models for forecasting business failures based on five financial ratios. A new hybrid model that uses technical indicators as factors affecting the prediction and the use of three new methods (correlation matrix, subtractive clustering method and ANFIS) is proposed. (Melin et al, 2012).

8. MODEL DESCRIPTION

A credit score is a statistically derived numeric expression of a person's creditworthiness that is used by lenders to access the likelihood that a person will repay his or her debts. It is usually calculated using different complex statistical methods which require expert knowledge of financial concepts and elements that affect company's credit score. Knowing the disadvantages of the previously described approach, the idea of creating an ANFIS model for credit score calculation emerged as a logical response. In order to build the wanted system, the only necessary thing is an adequate database, while the system itself creates the neuro-fuzzy system that determines the credit score values. The experiment described in this paper is based on information regarding 150 companies settled in Serbia. All the information was obtained from Cube Risk Management Solution, a company that provides business information and credit risk services. The used database contains values of 23 financial ratios for each individual company for the period 2011-2013 and their credit score values in the same period.

Financial ratios represent relationships derived from a company's financial information and used for comparison purposes. In general, financial ratios can be divided into four main categories: profitability or return on investment, liquidity, leverage, and operating or efficiency, with several specific ratio calculations prescribed within each.

The main database provides information about following ratios: EBITDA margin, profit margin, net margin, return on assets, the operating cash flow ratio, quick ratio, return on equity, debt-to-equity ratio, fixed assets to equity ratio, long-term debt to total assets ratio, fixed assets to long-term liabilities ratio, amortization period for a loan, days sales outstanding, days payable outstanding, days inventory outstanding, cash conversion cycle, total assets turnover ratio, fixed assets turnover ratio, working capital turnover ratio, trend in income, EBITDA trend, working capital trend and short-term liability trend.

In order to reduce the dimensionality of the given data set and retain the most relevant information, the method of principal component analysis was applied.

8.1. Correlation between variables

PCA is based on the diagonalization of the correlation matrix. The observation of that matrix is useful because it can point out associations between variables that can show the global coherence of the data set (Beatriz et al, 2000). Table 1 shows the correlation matrix of the variables. Usually, significant correlations (at a P =0.05 level) are searched for. We can observe highest and positive correlations between credit score and six following ratios: net margin, profit margin, EBITDA margin, return on assets, the operating cash flow ratio and the quick ratio. Given correlation matrix shows that credit score is most correlated with EBITDA margin where the value of correlation coefficient is 0.529. In general, computed correlation indicates that the connection between credit score and presented financial ratios is not very strong.

Table 1: Correlation matrix

Ratio	1	2	3	4	5	6	7	8
1	1.000	0.913	0.732	0.578	0.336	0.382	0.423	0.529
2	0.913	1.000	0.846	0.620	0.386	0.394	0.436	0.497
3	0.732	0.846	1.000	0.683	0.410	0.474	0.518	0.490
4	0.578	0.620	0.683	1.000	0.761	0.223	0.229	0.465
5	0.336	0.386	0.410	0.761	1.000	0.049	0.068	0.183
6	0.382	0.394	0.474	0.223	0.049	1.000	0.909	0.222
7	0.423	0.436	0.518	0.229	0.068	0.909	1.000	0.201
8	0.529	0.497	0.490	0.465	0.183	0.222	0.201	1.000

1- EBITDA margin 2-Profit margin 3-Net margin 4- Return on assets 5- Return on equity 6- The quick ratio 7 -The operating cash flow ratio 8- Credit score

The main part of the PCA is creation of principal components. A rule-of-thumb for determining the number of components to extract is to consider the “eigenvalue greater than one” criterion (Petroni & Braglia, 2000).

In the present analysis, nine components are a workable solution (since the residual components have all eigenvalues less than 1). The first nine components account for approximately 75 percent of the total variance of the variables (Table 2).The percentage of variance explained by each component represents its relative importance.

Table 2: Total variance explained

Component	1	2	3	4	5	6	7	8	9
Initial Eigenvalues Total	4.702	2.788	2.286	2.078	1.773	1.289	1.131	1.051	1.016
% of Variance	19.591	11.618	9.526	8.658	7.388	5.371	4.712	4.380	4.232
Comulative %	19.591	31.208	40.735	49.393	56.781	62.152	66.864	71.244	75.476

Highest values of component loadings in each of the components, presented in the component matrix, belong to the following ratios respectively:

- **net margin** tells what percent of profit is made from sales (Griffin, 2009),
- **fixed assets to equity ratio** is computed by dividing the fixed assets by the company’s equity,
- **the cash conversion cycle (CCC)** is a net time-interval between actual cash expenditures on purchase of productive resources and the ultimate recovery of cash receipts from product sales (Ortín-Ángel & Prior, 2004),
- **total assets turnover ratio** measures a firm’s efficiency at using its assets in generating sales or revenue – the higher the number the better (Griffin, 2009),
- **the quick ratio** measures a company’s ability to meet its short-term obligations with its most liquid assets by subtracting inventory from total current assets (Griffin, 2009),

- **days sales outstanding** (DSO) gives a measure of the number of days it takes for the company's inventory to turn over, i.e. to be converted to sales. (Marr, 2012)

trend in income, EBITDA trend, working capital trend.

The first six variables were kept as the result of the principal component analysis whose purpose was the optimal reduction of the data set.

After creating a new data set that contains companies' information expressed with seven financial ratios including the credit score, the created data set was used for preparing inputs for ANFIS.

8.2. Data

In order to perform the ANFIS analysis, Matlab R2011 software was used and its neuro-adaptive learning techniques incorporated in the anfis command provided by the Fuzzy Logic Toolbox. Fuzzy inference system is formed with the process of training, done on input data. As a result, a single output values is obtained which represents the value of company's data score based on given inputs. In the process of testing the new, unlabeled data, the final task is comparing whether the output corresponds to the output of given data set.

The training set included information from 2011 and 2012, which involved 300 records, and the testing was done for the period of 2013, which involved 150 records.

Considering the nature of the problem, fuzzy inference system parameters were set:

- For each input three membership functions were assigned
- Membership functions are generalized bell curve (gbellmf)
- Membership type of the output was selected to be a constant, which means we made zero-order Sugeno model.

One of the chosen parameters for training the network was the hybrid method of optimization, i.e. a combination of the backpropagation algorithm and the least squares method. The process of training is done intwo phases. In the first phase, the least squares method is used for defining output membership functions which are positioned on the fourth layer of the ANFIS architecture model. In the second training phase, the backpropagation algorithm adjusts the parameters of input memebership functions.

The data set was divided into two subsets, one for the training part and one for the testing part. This was done in order to enable neuro-fuzzy model testing. Training data set was used for network learning and adjusting weights in network, while testing data set was used to test if the network was properly formed, based on new, unlabeled data. Initial data set was split with the ratio 70:30.

8.3. The experiment and the results

The first set used for training in ANFIS contained six inputs (net margin, fixed assets to equity ratio, the cash conversion cycle, total assets turnover ratio, the quick ratio and days sales outstanding) and one output (credit score). Training the FIS required approximately 90 minutes to be done. After testing the FIS and plotting the results against training data, relative error, regarding measured and actual credit score values, was calculated. It is expressed in percents and its value is 6.13%.

The second set used for training contained five inputs (net margin, fixed assets to equity ratio, the cash conversion cycle, total assets turnover ratio and the quick ratio). Training of this FIS lasted approximately five minutes and the value of calculated relative error after testing the FIS was 6.73%.

Data set that included four inputs (net margin, fixed assets to equity ratio, the cash conversion cycle and total assets turnover ratio) was used for training that demanded approximately one minute to be finished. After testing the FIS using the data set with the same four inputs and their values for the different period (2013), the value of the relative error was 6.81%.

With the final reduction of the number of inputs, data set with three inputs (margin, fixed assets to equity ratio and the cash conversion cycle) was created and used for training the FIS. The process of training required less than a minute to be completed. The difference between measured and actual values of credit score values after testing the FIS, expressed by the relative error, was 7.14%.

Comparing the results represented by time needed for training and the relative error values after the process of testing, the conclusion is that values of the relative error increase by reducing the number of inputs in a data set. By increasing the number of inputs, number of corresponding fuzzy rules also increases, and consequently, the total amount of stored data grows larger which leads to more time required for training the system. The chosen combination and the most satisfying by means of time and error is the one regarding four inputs.

Considering that there are three membership functions for each input, regarding the chosen model with four inputs, that means that $4^4 = 256$ if-then rules are defined, and therefore 256 output membership function are defined, too. Inside the fifth layer, the output value is defined as a constant and it represents the value of credit score. The process of training was done after 20 epochs, and the built network included 193 nodes and 117 parameters.

Figure 3 shows the correspondance between the actual and the measured values of credit score through the epochs after the process of testing was done. The circular points in blue color represent the testing data output and the star points in red color represents the predicted outputs of the trained FIS.

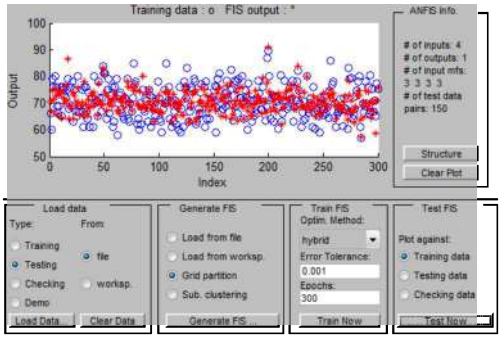

Figure 3: Testing error

The value of the relative error was not significantly increased in comparison to the error regarding the data set with five inputs. However, training required five times less time and that difference would be more evident for larger data sets. ANFIS model with three inputs completed its training process for significantly shorter period of time. However, the value of the relative error of the model is significantly higher, comparing to four-input model, for approximately 0.33% and that was the reason for not taking into consideration further input reduction.

9. CONCLUSION

Creditworthiness prediction is one of the most complex financial problems which commonly requires a thorough understanding of company's financial information and various statistical methods. Experts are always searching for simpler techniques that give satisfying results.

Neuro-fuzzy systems are used for exploiting the capacities of neural network learning in the best possible way in order to improve the fuzzy inference system performance. Additionally, fuzzy inference system represents the most important tool for modelling, based on the theory of fuzzy sets. The adaptive neuro-fuzzy inference system (ANFIS) is a good choice for modelling a system with already known inputs and outputs. Knowledge of the system and its processes is not necessary.

In this paper, authors formed an adaptive neuro-fuzzy inference system for determining credit score for 150 companies, based on values of financial ratios for a two-year period. The system was trained and tested. After doing a comparative analysis regarding system's performance by changing number of inputs i.e. ratios in the initial data set, it was concluded that data set with four inputs (net margin, fixed assets to equity ratio, the cash conversion cycle, total assets turnover ratio) gives the best results, by means of time needed, the amount of data and error in prediction. Hence, it can be concluded that ANFIS applied on the problem of creditworthiness assessment gives satisfying results in reasonable time.

In future work, it would be interesting to explore and apply other neuro-fuzzy models or different network learning algorithms in order to examine the possibility of obtaining more accurate results or less time for the process of training the network.

Abstract: *Having in mind recent financial crisis and liquidity shortages which banks have to face on regular basis, bank liquidity management has become one of the main concerns within this industry. Automated mathematical solutions accurately predict currency supply and demand and this may enable banks to reduce costs, especially costs of keeping significant exceptional sum of money in ATMs. In today's business environment which is characterized by tremendous competitiveness and globalization of business, cash management has become a critical success factor. Despite comprehensive literature reviews on similar topics, studies focused on cash management in ATMs in Serbia are still at the initial phase. This paper aims to decide on the optimal amount of money that will be placed in an ATM for minimizing opportunity costs as well as meeting clients' daily uncertain demands. The biggest challenge for this study is to calculate the amount of money that is sufficient to provide services to ATM customers and small enough to avoid any losses to the bank due to holding too much cash in the ATM. The study offers quality basis of information for banks and academics. The results we have obtained clearly show that the costs which arise when the ATM is filled to the optimal amounts of money are lower than those if the ATM is at full recommended value.*

Keywords*: Bank cash management, ATMs, optimization*

1. INTRODUCTION

Banks are nowadays willing to reduce liquidity tensions and optimize all functions having impact on liquidity management. Despite the fact that every model has its imperfections, banks put a lot effort to improve distribution channels in order to reduce liquidity tensions. In order to meet their customers' demand, banks have created extensive cash outlet networks, which consist of both bank branches and automatic teller machines (ATMs). ATM is a computerized telecommunication device that provides a financial institution's customers a method of financial transactions in public space without any human support needed (Simutis et al., 2015). Cash management in ATMs is certainly among activities that can make difference within tight competition in banking. Purpose of this paper is to decide on the optimal amount of money that will be placed in an ATM, which is placed within bank office, for minimizing opportunity costs as well as meeting clients' daily uncertain demand. The biggest challenge for this study is to calculate amount of money sufficient to provide service to ATM customers and small enough to avoid any losses to the bank due to the fact of holding too much cash in the ATM. This surplus could be used for generating money when invested in other bank products such as bills, certificates of deposits, commercial paper and any other money bank instruments.

Banks are now thinking from the customer's point of view and trying to bring most services door to door. Efficient bank cash management guarantees effective collection and payment technique, proper disbursements of free funds, and help for urgent cash requirement. The problem of cash management in automatic teller machines (ATMs) is similar to cash management in branches. These problems are characteristic for every bank and have to be analyzed according to future unknown probabilistic demand. In a very competitive bank market in Serbia, decision support systems for liquidity management activities in banking can make a significant difference within banks. In general, cash management in ATMs (and similarly in branches) is a well-known problem faced by any bank, hence worth researching.

This paper is structured as follows: in section 2, literature overview is presented; In section 3, cash management in ATMs is discussed; In section 4, methodology is defined; In section 5, some experimental results are presented and analyzed, followed by conclusions and future work.

2. LITERATURE OVERVIEW

Having in mind recent financial crisis and liquidity shortages which banks have to face on regular basis, bank liquidity management has become one of the main concerns within this industry. Numerous researchers have brought about significant improvements in cash management, which began by Baumol (1952) and

Tobin (1956), continued with Miller and Orr (1966) and more recently with Roman and Sargu (2014) who presented the research with the aim to evaluate the liquidity risk of banks operating in Bulgaria and Romania in the context of the EU affiliation process. The authors have investigated role and impact that a series of financial indicators for the capital adequacy, assets quality, management quality and profitability have on the liquidity risk of the banking institutions. Vuillemey (2014) in his paper made a conclusion that the increase in banks' probabilities of default in most banking sectors in the Euro area during the latest financial crisis is mostly attributable to liquidity risk.

In addition, DeYoung and Jang (2015) have conducted research 'Do Banks Actively Manage their Liquidity?' Authors have been testing whether and how US commercial banks actively managed their liquidity positions between 1992 and 2012 and made conclusion that as banks increase in size, they set lower liquidity targets, but manage those targets more efficiently.
Ekinci et al. (2015) have been focused on one of the main banking goals: how to use fewer resources (e.g. cash kept in ATMs, trucks for loading cash, etc.) for meeting fluctuating customers' demands. Their article proposes grouping ATMs into nearby-location clusters and also optimizing aggregates of daily cash withdraws in order to minimize costs of replenishing cash, cash-interest charge and potential customer dissatisfaction. Venkatesh et al. (2014) have built a time series model for each ATM by analyzing prediction of cash demand for groups of ATMs with similar day-of-the week cash demand patterns. The main conclusion of their research is that the cluster wise cash demand forecast helps the bank's top management to design similar cash replenishment plans for all the ATMs in the same cluster. This means that banks can optimize operational costs geographical regions. Yan et al. (2015) have proposed a daily vehicle routing model for minimizing the total cost of replenishing inventory within a supply chain. Scholtz et al (2013) have done a case study for Orion in order to solve the cash management problems of ATMs with stochastic discrete-event simulation in retail banking. Their decision support system integrates four Operations Research methods: the vehicle routing problem, the continuous review policy for inventory management, the knapsack problem and stochastic, discrete-event simulation. The results have shown that the use of vehicle routing methods is especially useful when the bank has substantial control over transportation cost. According to Teddy and Ng (2011) conventional global learning computational intelligence models may not be efficient enough in order to record complex and time-varying characteristics of time series data. The authors have proposed a new model - cerebellar-inspired associative memory network, which can produce accurate forecasts of ATM cash demands.

On the basis of what we have described above, one may conclude that liquidity management is a very comprehensive topic, analysis of which may hugely contribute to health and quality of the overall banking sector. ATM cash management has been an integral part of bank management mechanism asking for a clearly defined steps aiming at enhancement. One approach to this problem solution will be elaborated on in the next part of this paper, nonetheless there are undoubtedly many research issues that would be worth analyzing in the future.

3. CASH MANAGEMENT IN ATMs

It is widely believed that advanced operational research methods can optimize demand forecasting and contribute to proactively currency management. Automated mathematical solutions accurately predict currency supply and demand and this may enable banks reduce costs, especially costs of keeping significant exceptional sum of money in ATMs.

Serving ATMs network takes employees' time to optimize the network and make decisions about cash management. Moreover, it involves high operating costs and needs proper currency management in order to avoid having cash in ATMs. In a very competitive market, banks are willing to provide the most efficient way for cash management. Transportation and servicing costs are of a great interest within banking industry. As previously said, banks can conduct work itself or they can hire companies specialized for money transportation and filling of ATMs. Either way banks need an effective tool that determines the lowest cost of distribution. These tools are based on accurate supply and demand forecasting and optimization procedures with the aim to lower operational expenses and enhance return on cash assets.

Historical demand by using data from actual cash-in transactions and cash-out transactions is a starting point for every research on cash management in ATMs. Only when precise currency demand is defined it is possible to create software for monitoring, management and optimization of the ATM network. It is very important to have in mind that demand depends on additional factors, such as paydays, holidays, and seasonal demand in a specific area. Analytical models should be developed according to experience of the bank's daily operations, as well as additional events that occur under certain conditions. Procedures to determine the optimal cash demand for each ATM is the same regardless of most known solutions for ATM

network cash management. Firstly, based on the daily cash demand, transport and money upload costs should be calculated. Usually cash drawings are subject to trends and generally follow weekly, monthly and annual cycles. It is noticed that people draw relatively large sums of cash at the beginning of each month as well as before Christmas. ATMs placed in shopping centers are mostly used on Fridays and Saturdays. During summer holidays drawing rates decline considerably.

4. METHODOLOGY

In this paper, we consider ATM Cash Management as a newsvendor problem i.e. single period stochastic inventory problem. The newsvendor problem is related to the situation in which a decision maker needs to order a quantity of some goods each day in the circumstances of uncertain demand (Phillips, 2005). Three main characteristics of the newsvendor problem are (Brandimarte & Zotteri, 2007): a) it observe single-product and single-period and single-echelon inventory problem; b) demand is uncertain and its distribution is known; c) the objective is to minimize expected overall costs consisting the excess costs and the shortage costs i.e. costs of purchasing too many and too few.

Considering the previous characteristics, replenishment of ATMs can be formulated as a newsvendor problem: decision makers need to determine an amount of single product - cash for ATM refilling each day; daily cash demand is uncertain; excess and shortage of cash in ATMs entail certain costs. In order to formulate ATM Cash Management as a newsvendor problem, the following notation will be used (Krcevinac et al, 2004; Shapiro & Dentcheva, 2014)):

- c_h - excess cost per units expressed through the opportunity costs;
- c_p - shortage cost per unit;
- x - daily cash demand;
- Q - amount of cash stocked in ATM.

Overall daily cost depending on daily demand and amount of cash in ATM can be expressed as:

$$C(Q,x) = c_h(Q-x)^+ + c_p(x-Q)^+ \tag{1}$$

where $(Q-x)^+ = \max\{(Q-x),0\}$, $(x-Q)^+ = \max\{(x-Q),0\}$.

Since cash demand is uncertain, the expected overall costs are:

$$c(Q) = E[C(Q,x)] = c_h\int_0^Q (Q-x)\varphi(x)dx + c_p\int_Q^\infty (x-Q)\varphi(x)dx \tag{2}$$

where $\varphi(x)$ is demand probability density function and $\Phi(x)$ is cumulative distribution on demand.

Optimal Q^* that minimize expected overall cost $C(Q)$ satisfies:

$$\Phi(Q^*) = \frac{c_p}{c_p + c_h} \tag{3}$$

Therefore, the goal is to find Q^* such that:

$$Q^* = \Phi^{-1}\left(\frac{c_p}{c_p + c_h}\right) \tag{4}$$

The main prerequisite for the application of the proposed approach is the existence of data about demand for cash in the previous period. If data is available, the methodology for optimal ATM Cash Management introduced in this paper can be conducted through the following steps:

1. Separation of demand by date and removing outliers from datasets. The assumption of the proposed methodology is that the cash demand is similar within the same date, notwithstanding the month. However, certain deviation can appear. For instance, demand might depend on additional factors, such as paydays, holidays, and seasonal demand in a specific area. Consequently, outliers should be removed from obtained datasets.
2. Grouping of data by average demand similarity.
3. Determination of the probability distribution of demand for each obtained data group.
4. Determination of the opportunity costs and shortage cost per unit.
5. Calculation of optimal using equation (4) the expected overall cost.

5. FINDINGS AND DISCUSSION

The model which is presented in this paper is tested against real data. The ATM, which was observed is located within the branch and current practice is that once per day the manager checks the status of the cash in the ATM. The manager devotes a part of their time to this activity and risks their own safety as well as the security of the money. As well, it was observed that there is a need for systematization, because there is the opportunity cost of holding excess cash. In addition, the bank has no record of the cost penalty in terms of the number of clients who were planning to withdraw money, but they could not due to lack of cash in the ATM. To always be on the safe side, banks deposit more cash than necessary in ATMs and thereby miss an opportunity to make a profit, in other words they have the opportunity costs of holding excess cash. To test the model we had data on demand from 1.1.2013 until 31.12.2015. The results are presented according to the steps described in the previous part of this paper.

5.1. Steps 1 – 3

After separating the demand by date and removing outliers, average demands by dates are obtained. The values shown in Figure 1 are expressed in thousands of RSD.

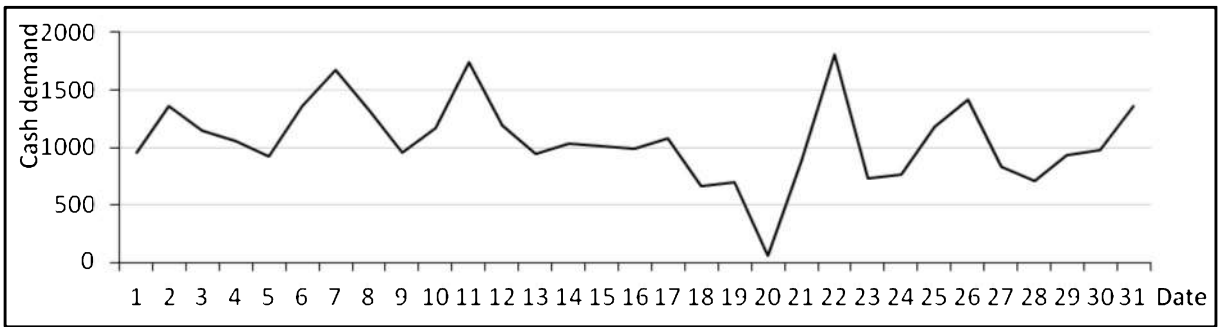

Figure 1: Average cash demands by dates

In an interview with bankers we came to the conclusion about the key dates for withdrawing money from ATMs 9 and 24, due to the pensions that were received on those days, as well as the salary received by the Serbian military on the 5th and 21st. In addition, the Serbian Ministry of Interior receives their salaries on the 10th and 25th of each month. The previous graph shows peaks in the average demand on those dates.

Based on the obtained average values and their similarities, six groups of dates are created. Dates that belong to each group as well as the average demands and demand probability density functions with corresponding parameters are listed in Table 1.

Table 1: Groups of dates and corresponding demand probability density functions

Group	Dates	Average	Probability distribution
1	7,11,22	1725.673	GenExtreme (0,02953; 493,26; 1426,1)
2	2,6,8,26,31	1392.737	Cauchy (295,47; 1361,7)
3	3,4,10,12,14,15,17,25	1102.875	Cauchy (644,6; 1155,6)
4	1,5,9,13,16,21,27,29,30	941.161	Cauchy (689,08; 946,34)
5	18,19,23,24,28	716.082	Frechet (0,27993; 0,82341; 0,49142)
6	20	57.386	Cauchy (0,0919; 0,77301)

5.2. Steps 4 and 5

Excess cost per units is expressed through the opportunity costs. Depending on the strategy of the bank, the most profitable form of investment of surplus cash is chosen. Some banks invest in over-night deposits, others lend cash to other banks, while some invest in government securities. After talking with experts from the bank we came to the conclusion that it would be optimal to use the value of the repo rate of the National Bank of Serbia as an opportunity cost, given that it is usually the rate used in pricing of deposits and loans.

The analysis of the average repo rate during the past year, the value for the parameter is estimated to be 0.0329. Since the shortage cost per unit could not be precisely determined, we examined two scenarios: the first one involves the same importance of excess and shortage of cash in ATMs while the second one considers the shortage more significantly than excess of cash. Scenarios characteristics are as follows:

- Scenario 1: $c_p = c_h = 0.0329$. By applying equation (3) it follows that $\Phi(Q^*) = 0.5$.
- Scenario 2: $c_p = 2 \cdot c_h = 0.0658$ and $\Phi(Q^*) = 0.6667$.

The optimal amounts of cash that should be stocked in an ATM are shown, each group of dates are calculated using equation (4) and based on corresponding probability function from Table 1. Summarized results are shown in Table 2 (expressed in thousands of RSD).

Table 2: Optimal amounts of cash for an ATM

	Q*	
Group	cp=ch	cp=2ch
1	1607.9	1877.5
2	1361.7	1532.3
3	1155.6	1527.8
4	946.34	1344.3
5	3.541	21.209
6	0.77301	0.82609

As expected, the obtained optimal amounts of cash are higher in the second scenario because higher shortage cost leads to higher probability of optimal amount and, consequently, higher optimal amount of cash for an ATM. Comparing these values with the average values from Table 1, it may be noted that the optimal values in the first scenario are mostly lower than average while those in the second scenario are higher than average.

In order to evaluate the proposed methodology, we have compared overall expected costs based on the optimal solution with overall costs caused by the application of the bank's replenishment policy. It is recommended for bankers to fill ATMs with 1.7 million RSD on weekdays and 2.5 million RSD on weekends. Since those amounts were determined based on historical data and insufficient analysis, we saw the space to create a model that would be able to more reliably predict the optimum quantity for refilling ATMs. Also, in order to compare the results in this paper we have used the recommended amount of 1.7 million RSD because the days of the weekend were excluded from the analysis. The ATM that we observed is distinctive because it is part of the branch that does not work on Sundays and Mondays.

Table 3 shows the overall expected costs for scenarios 1 and 2. Rows 1(opt) and 1(1700) are related to the Scenario 1 and give costs per group of dates and total costs if amounts of cash that should be stocked in an ATM were optimal and 1700, respectively. Rows 2(opt) and 2(1700) contain the same data for Scenario 2. Costs are calculated for each day of the entire period using the equation (1) and summarized by corresponding groups of dates.

Table 3: Overall expected costs

	group						
scenario	1	2	3	4	5	6	total
1 (opt)	857.606	1810.741	4871.345	5007.249	2661.637	33.611	15242.190
1 (1700)	867.934	2153.240	5852.324	6389.690	4519.970	972.756	20755.913
2 (opt)	1333.011	2622.292	6799.877	6638.002	5305.919	67.170	22766.272
2 (1700)	1325.129	2744.631	6980.933	7200.299	4950.999	972.756	24174.746

The same results are graphically presented in Figure 2.

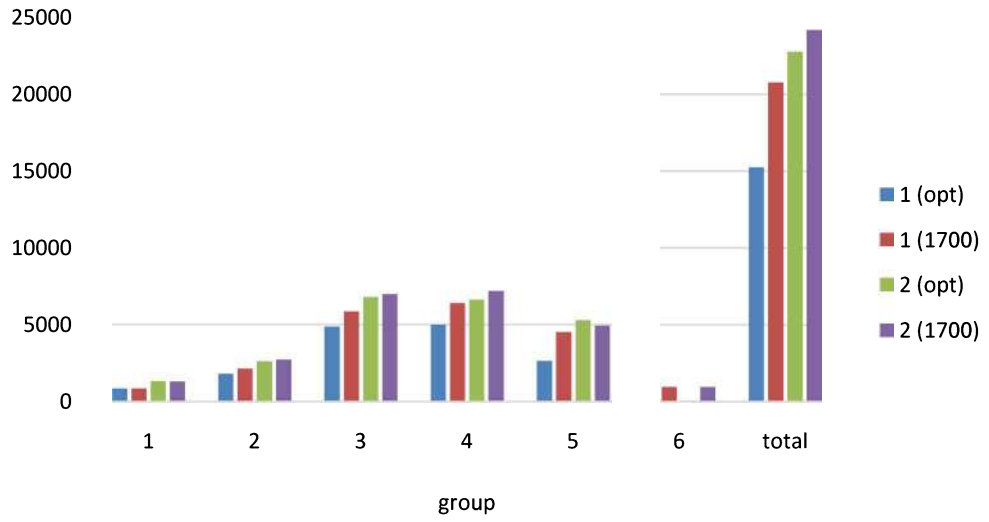

Figure 2: Overall expected costs comparison

In both variants it shows amount of cash that should be stocked in an ATM (optimal and 1700), the overall costs in Scenario 2 are higher than those in Scenario 1 due to the higher shortage costs. In addition, the optimal amounts of cash are higher. However, in both scenarios, the overall costs with optimal amounts are lower than corresponding costs with bank replenishment policy, separately per groups and in total. Furthermore, optimal costs in Scenario 2 – 2(opt) are not significantly higher than the bank policy cost in Scenario 1 – 1(1700) although they have higher shortage cost. The results show that it is better to stock the ATM with the amount of cash corresponding to the expected demand for that date than the same amount every day. The selection of scenarios that will be applied depends on the attitude of decision makers to the excess and shortage of cash in the ATM.

6. CONCLUSION

On the basis of what we have described above, one may conclude that liquidity management is a very comprehensive topic, analysis of which may hugely contribute to health and quality of the overall banking sector. ATM cash management has been an integral part of the bank management mechanism asking for clearly defined steps aiming at enhancement.

The purpose of this paper is to decide on the optimal amount of money that will be placed in an ATM for minimizing opportunity costs as well as meeting clients' daily uncertain demands. The biggest challenge for this study is to calculate the amount of money that is sufficient to provide services to ATM customers and small enough to avoid any losses to the bank due to the fact of holding too much cash in the ATM. The study offers quality basis of information for banks and academics. The results we obtained clearly show that the costs which arise when the cash dispenser is filled to optimal amounts of money is less than the costs that arise if the ATM is at full recommended value of 1.7 million RSD. The selection of scenarios that will be applied depends on the attitude of decision makers to the excess and shortage of cash in the ATM. The conclusion of the investigations show that improving systems and procedures in the bank should be worked on.

The study incorporates both quantitative and qualitative data on cash management for ATMs, the basic limitations are related to the assumptions that we have made in terms of opportunity cost and shortage cost of cash in the ATM. In addition, the test model used is one particular bank ATM. However, the limitation of the analysis provide interesting research directions to further investigate models for improving cash management in ATMs. The models for cash management in ATMs can be extended in several ways to fit the particular banking reality. For example, the model could be applied to different ATMs in order to observe the group results and the results of each ATM. Moreover, more attention can be devoted to the cost structure, which was analyzed in terms of representation of the various opportunity costs and shortage costs that arise if there is insufficient cash in an ATM.

DRIVERS OF HOTEL PROFIT MARGINS: A STUDY OF THE BELGRADE HOTEL SECTOR

Miloš Milosavljević*[1], Nemanja Milanović[1], Slađana Benković[1]
[1]University of Belgrade, Faculty of Organizational Sciences
*Corresponding author, e-mail: milosavljevic@fon.bg.ac.rs

Abstract: *Tourism and hospitality have received an immense attention from scholars, policy holders, decision makers and other important stakeholders in Belgrade, a main tourist destination of Serbia. The aim of this paper is to analyze different drivers of profitability, such as size, market concentration, market share and customer perception, that affect the profitability of hotels in Belgrade. The results indicate that customer perception is a paramount factor driving the financial performance of hotels.*

Keywords*: profit margin, hotels, customer perception, Belgrade*

1. INTRODUCTION

Tourism and hospitality industry has been highly on the agenda of policy holders and decision makers in Serbia (Milosavljević, Milanović & Benković, 2015), particularly in Belgrade as it accounts for the majority of arrivals and nights of tourists in Serbia. The rationale for this is the high impact of tourism to the economic development of the Belgrade region and the economy as a whole. Academic publications almost equally intensively elaborate on the importance of tourism, the sources of development, the features of processes in the industry and its economic effects (Dimitrovski, Todorović & Valjarević, 2012; Mulec & Wise, 2013). However, there is a paucity of scholarly contribution to the origins of financial performance of the Belgrade's hotel sector, and the main drivers of its profitability.

This research gap sets a scene for the main aim of this paper. The aim is to analyze different drivers of profitability, such as size, market concentration, market share and customer perception, that affect the profitability of hotels in Belgrade. In particular, the study aims to test the influence of 10 different factors to determine their correlation to the hotels' financial performance, and

The studies of this kind are a hot topic in academic and practitioners' publications. For instance, Ben Aissa & Goaied (2016) empirically tested the main determinants of 27 Tunisian hotels. Lado-Sestayo et al. (2016) conducted a study encompassing nearly 9000 hotels in Spain to test the impact of location on profitability in the Spanish hotel sector. However, the originality of this study is based on two important pillars. Firstly, to the best of authors' knowledge, the study is unique in this geographical region. Some aspects of the Belgrade hotel sector, such as the change in offer have been discussed in the extant literature (Šimičević & Štetić, 2015), but non of the papers dealt with the profitability of the sector. Secondly, the study is unique in the developed set of indicators selected as the main drivers of profitability

The remainder of the paper is organized as follows. Section 2 deals with theoretical background. Particular emphasis is given to the business case for hotel industry in Belgrade. Section 3 elaborates on the methodology used in the study. Section 4 depicts the results and discusses the main findings. Section 5 provides concluding remarks, dealing with the resume of key findings, managerial and other implications, limitations and further recommendations.

2. THEORETICAL BACKGROUND

2.1. Profitability drivers in hotel industry

Profitability drivers are frequently elaborated in the extant literature. Ever since the pioneering attempts of Kotas (1982), Sheldon (1983) and Croston (1995) researches have been examining various determinants of profitability striving to find the best methodology for analysis of financial operations and appropriate business strategy. Currently, several streams of publications regarding the set of variables selected as the main determinants of profitability are specifically important.

The first stream are scholarly publications emphasizing the importance of market power, location and concentration. Singh & Dev (2015) have analyzed hotels as winners and losers in the aftermath of the recession, suggesting that marketing expenses play an important role in financial success. Lado-Sestayo et al. (2015) explored the influence of location, market power and other factors to the profitability of the Spanish hotel sector. They find that profitability depends largely on the market structure and the level of demand of the tourist destination.

The second stream are the papers dealing with operational and financial efficiency. Zeglat (2008) finds that profitability is positively influenced by sales growth, as a consequence of customer retention, and negatively influenced by premium price by analyzing the UK hotel sector. Chiu and Huang (2011) analyzed the effects of occupancy rate and operational efficiency on profitability of Taiwanese hotels and found that occupancy rate and increase in sales are not the best way to increase financial performance. This is not in line with the main findings of O'Neill & Ma Instead, they suggested optimal occupancy rate and focus on operational efficiency. Another study from the same country deals with the effects of service quality, and indicates that, for instance, food and beverage quality has non-linear relationship with profitability (Chen & Lin, 2012). In the example of Croatian hotel industry, Škuflić & Mlinarić (2015) find that size, concentration, liquidity, solvency and productivity significantly affect hotel profitability.

The third stream are studies examining the role of online hotel presence and the effects of social media on hotel performances. The results are to some extent adverse. For instance, Neirotti, Raguseo, & Paolucci (2016) find that the increasing importance of user-generated reviews in online communities for tourists is "shifting hotel competition from unit profit margin to volumes and to higher room occupancy rates, with online retailers capturing most of the value created in online transactions through social media features and with a limited effect brought on net profitability". Using a more sophisticated approach of neural networks, Phillips et al. (2015) the interactive effects of online reviews on the determinants of Swiss hotel performance, finding a positive effect of four nodes to a hotel performance.

Some studies do not fit into this three-stream pattern. Certain studies address macroeconomic features and their influence over the profitability (Pan, 2005). On the other side, a broad body of evidence takes into consideration the human factor as an important pillar of the profitability. For instance, Morey & Ditman (1995) examined the effects of general managers efficiency to the hotel profitability. Finally, profitability is examined through the prism of long term yields generated from the adequate customer profitability analysis (Noone & Griffin, 1999).

2.2. A short business case for hotel sector in Belgrade

Belgrade accounts for more than a third of all tourist capacities of Serbia, which puts a spotlight to the importance of this industry to the total economic output of the country. Belgrade is the most important tourist destination in Serbia. The following figures illustrate the portion of total arrivals and nights of tourist in Serbia and in Belgrade in specific (RZS, 2015).

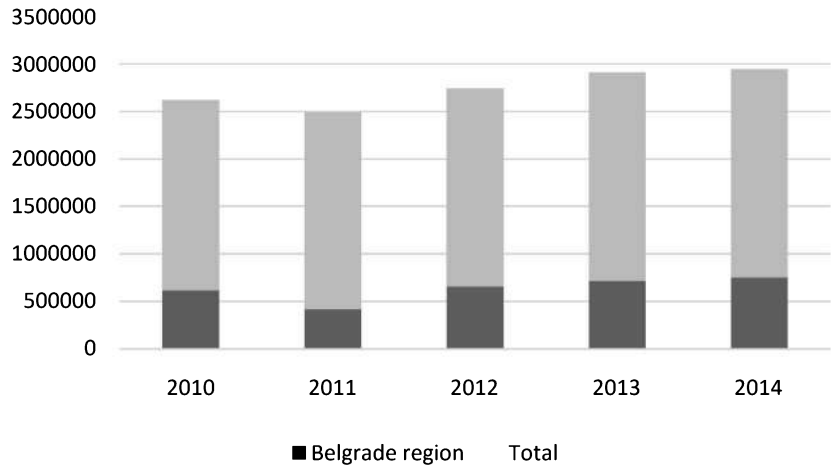

Figure 1: Total arrivals of tourists in Serbia and in Belgrade

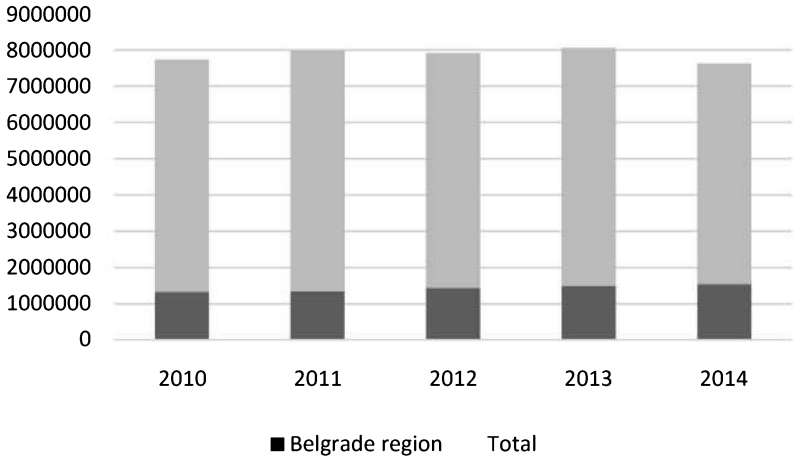

Figure 2: Total nights of tourists in Serbia and in Belgrade

According to Horwath (2015), internationalization of the demand profile is evident, followed by permanent increase in the relative share of foreign hotel overnights in total overnights. This study points out the international demand as a primary source of demand for Belgrade hotels, with annual growth rate of 10% (2009-2014).

3. METHODOLOGY

3.1. Variables

The study used one dependent and 10 independent variables. They are summarized in the table below:

Table 1: Variables, variable type, indicators, calculations and hypothesized influence over dependent variable

Variable	Type	Indicator	Calculation	Hypothesized influence (+/-)
Hotel profitability	Dependent	Profit margin	EBIT/Revenue	n/a
Location	Independent	Distance from three focal points – city center, central bus station and airport	(Dcen+Dbus+Dair)/3	+
Market power	Independent	Market share (revenue based)	Net revenue for a hotel/Total revenue for industry	+
Economy of scales	Independent	Size	Natural logarithm of hotel assets	+
Financial structure	Independent	Financial leverage	Liabilities/Equity	-
Social reach	Independent	Social media reach	No of Facebook page likes	+
Customer satisfaction	Independent	Aggregate hotel ranking	Booking.com ranking	+
Word-of-mouth	Independent	Net promoter score	Highest to lowest ranks of customers	+
Margins	Independent	Net margin	Net income/Revenue	+
Capacity	Independent	Total accommodation share	No of beds of a hotel/No of beds of all hotels	+
Hotel rating	Independent	Category of a hotel	No of stars	+

3.2. Sampling and data collection

The study examined 42 hotels located in the city area of Belgrade. The sample was randomly generated from the total of 530 hotels.

The study is based on secondary data collected from different reliable sources. Financial data (assets, operating revenues, operating income, net income, liabilities, equity, average number of employees, foundation date) were retrieved from the Serbian Agency for Business Registers. These data refer to the year 2014. The data on the location and the distance from three aforementioned focal points were generated from Google Maps. The data on customer satisfaction were retrieved from the *booking.com* online service for hotel bookings and rankings, where the scores from 1 to 10 assigned by hotel customers were used as an input. Social media reach as an important variable for this study was analyzed through the usage of Facebook. The data on number of hotel Facebook page likes and scores from 1 to 5 awarded by page visitors were collected. The data on number of available beds and rooms were retrieved from hotels official websites and Tourist organization of Belgrade. Hotel ranking, reputation and luxury were measured by number of stars retrieved from Tourist organization of Belgrade. Foundation dates were collected on hotel official websites.

3.3 Data analysis

After filtering the collected data, the lack of data on booking.com scores for several hotels was noticed. The software Orange Canvas was used to replace the missing values with the average value of the booking.com scores available for other hotels. Furthermore, Orange algorithm recognized few outliers and excluded them from database before proceeding with analysis. Due to perceived anomalies, the data on hotels Constantine The Great and Zepter were also excluded. Finally, statistical analysis of refined data was conducted through SPSS software.

4. RESULS AND DISCUSSION

4.1. Descriptive statistics

The following table displays the descriptive statistics: means and standard deviation for 37 observed hotels.

Table 2: Descriptive statistics

	Mean	Std. Deviation
Profit margin (%)	1.02711	31.693632
Average distance (km)	8.67805	3.206473
Market share (%)	2.30195	2.296098
LN(assets) (#)	19.77232	1.521281
Financial leverage (#)	8.144443	92.881617
No of Facebook likes (#)	3812.19	6449.961
Average score on Booking (#)	8.308	.8855
Net Promoter Score (%)	55.23511	28.186677
Net margin (%)	-11.57597	48.096229
Accommodation capacity (%)	2.00535	1.499629
Number of stars (#)	3.68	.626

4.2. Hypotheses testing

In order to test the hypotheses the study employed correlation analysis (Pearson moment two-tailed correlation) and multiple regression. Correlation analysis is performed as a preliminary analysis in order to assess the strength of relationships among the variables in the study. The results of correlation analysis are displayed in the following table. The correlation coefficients reflected low to medium values and therefore did not indicate a potential multicollinearity among variables.

Table 3: Correlation matrix

	Profit margin (%)	Average distance (km)	Market share (%)	LN(assets) (#)	Financial leverage (#)	No of Facebook likes (#)	Avg. scr. on booking.com (#)	Net Promoter Score (%)	Net margin (%)	Accommodation capacity (%)	Number of stars (#)
Profit margin (%)	1.000	.040	.212	-.013**	.006**	.102	.788	.367	.634	.082	.438
Average distance (km)	.040*	1.000	.008**	-.271**	-.080**	-.236**	.037*	.284	.024*	-.152**	-.151**
Market share (%)	.212	.008	1.000	.556	.023	.389	.277	.011*	.107	.338	.400
LN(assets) (#)	-.013**	-.271**	.556	1.000	-.260**	.307	.138	-.217**	.073	.410	.445
Financial leverage (#)	.006**	-.080**	.023*	-.260**	1.000	.225	.051	.014*	.201	.001**	-.194**
No of Facebook likes (#)	.102	-.236**	.389	.307	.225	1.000	.281	-.304**	.143	.300	.320
Avg.scr. on Booking (#)	.788	.037*	.277	.38	.051	.281	1.000	.204	.535	.009**	.561
Net Promoter Score (%)	.367	.284	.014*	-.217**	.014*	-.304**	.204	1.000	.501	-.116**	-.036**
Net margin (%)	.634	.024*	.107	-.073**	.201	.143	.535	.501	1.000	.149	.126
Accomm. capacity (%)	.082	-.152**	.338	.410	.001**	.300	.009**	-.116**	.149	1.000	.169
Number of stars (#)	.438	-.151**	.400	.445	-.194**	.320	.561	.036*	.126	.0169*	1.000

The correlation matrix shows the highest correlation of average score on Booking to profit margin. The results of employed t-test underlines this variable as the only statistically significant variable for profit margin. The next variable according to the value of correlation coefficient is net margin, followed by number of stars, implying that hotels with higher ranking, reputation and luxury generates higher profit margin. The analysis of correlation between independent variables shows that the most correlated variables are number of stars and average score on Booking, with the value of correlation coefficient 0.634. The correlation of LN(assets) to market share
(0.556) confirms that hotels that achieve economies of scale take greater market share.

Table 4: Regression model and ANOVA

Regression model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error			
1	Constant	-112.747	70.341		-1.603	.121
	Average distance (km)	-.729	1.128	-.074	-.646	.524

	Total	36161.507	36			

Dependent Variable: Profit margin (%)
Predictors (Constant), Number of stars (#), Net Promoter Score (%), Financial leverage (#), Accommodation capacity (%), Average distance (km), Market share (%), Net margin (%), No of Facebook likes (#), LN(assets) (#), Avg.scr. on booking.com (#)

Regression model is validated through F-test. Null hypothesis implies that linear regression model is not statistically significant, and alternative hypothesis implies that this model is statistically significant. The result

of F-test $F = 7{,}362$ and indicates that null hypothesis is accepted, meaning that overall linear regression model is statistically significant.

Average distance. The initial hypothesis: There is a negative relationship between average distance and profit margin. Average distance variable should influence the decision of tourist/customer to choose particular hotel according to the amount of time needed to get to the city's most important focal points (city center, central bus station and airport). Hotels with smaller average distance have higher occupancy rates, which could lead to higher profit margin. The result of t-test $t = -0{,}646$ and $Sig = 0{,}524$ indicates that this variable is not statistically significant for profit margin.

Market share. The initial hypothesis: There is a positive relationship between market share and profit margin. The assumption is that hotels with higher market share are more recognizable by the tourists, which could increase their profit margins. However, the result of t-test $t = 0{,}784$ and $Sig = 0{,}440$ indicates that market share is not statistically significant for profit margin.

LN (assets). The initial hypothesis: There is a positive relationship between hotel size and profit margin. Hotels with higher value of LN(assets) achieve economies of scale and reduce expenses, which increases their profit margins. The result of t-test $t = -1{,}531$ uz $Sig = 0{,}138$ indicates that this variable is not statistically significant for profit margin.

Financial Leverage. The initial hypothesis: There is a negative relationship between financial leverage and profit margin. It is assumed that hotels with lower financial leverage are more efficient, which could lead to higher profit margins. The result of t-test $t = -0{,}814$ and $Sig = 0{,}423$ indicates that this variable is not statistically significant for profit margin.

Social media reach. The initial hypothesis: There is a positive relationship between number of Facebook likes and profit margin. The number of likes on social networks indicates how particular hotel is popular among customers. Higher number of likes and followers increases the potential of a hotel to be chosen by tourists as a place to stay. Consequently, this could lead to higher profit margins. The result of t-test uz $Sig = 0{,}524$ shows that this variable is not statistically significant for profit margin.

Aggregate hotel ranking. The initial hypothesis: There is a positive relationship between average score on booking.com and profit margin. Higher average score shows higher popularity among tourists and higher customer satisfaction and potentially attract more hotel guests, which can consequently increase profit margins. However, the result of t-test $t = 4{,}038$ uz $Sig = 0{,}000$ indicates that this variable is statistically significant for profit margin.

Net Promoter Score: The initial hypothesis: There is a positive relationship between Net Promoting Score and profit margin. Net Promoting Score is marketing metrics that indirectly shows word-of-mouth effect achieved by certain hotel. Higher score indicates significant difference between respondents who recommend certain hotel and those who would not recommend it. This could lead to higher profit margins, but the result of t-test $t = 0{,}484$ and $Sig = 0{,}632$ shows that Net Promoting Score is not statistically significant for profit margin.

Net margin. The initial hypothesis: There is a positive relationship between net margin and profit margin. According to the result of t-test $t = 1{,}639$ and $Sig = 0{,}113$, this variable is not statistically significant for profit margin.

Accommodation capacity: The initial hypothesis: There is a positive relationship between accommodation capacity and profit margin. Hotels with high accommodation capacity could take advantages of economies of scale and consequently increase profit margin. The result of t-test $t = 0{,}950$ uz $Sig = 0{,}351$ indicates that accommodation capacity is not statistically significant for profit margin.

Category of hotel. The initial hypothesis: There is a positive relationship between category of hotel and profit margin. Number of stars reflects hotel's ranking, reputation and luxury. Hotels with high ranking should attract more tourists and consequently increase profit margin. According to the result of t-test $t = 0{,}754$ and , this variable is not statistically significant for profit margin.

5. CONCLUSIONS

This paper aimed to determine the main drivers of profit margins of the Belgrade hotel sector. As the results indicate the main profit margin driver is the previous customer satisfaction with hotel services As for the

contribution to the theory and practice of hotel management, this study has twofold implications. Firstly, the study contributes to the practice of hotel management as it empirically confirms that consumers and their opinions is the utterly factor that adds financial value to a hotel sector. Accordingly, the efforts of decision makers in hotels should be placed to the online reputation creation. As the results of statistical analysis indicate, the only variable that is statistically significant for profit margin is average score on booking.com, so it is recommended to make the effort to increase the rankings on booking.com. The average score on booking.com is composed by the following elements: cleanliness, location, staff, free wi-fi, comfort, additional facilities, and price-quality relation. Hotels should strive to set higher hygiene standards, improve wireless network performance, and to employ HR training and development programs in the field of customer relationship management. Significant attention should be paid to tracking and in-depth analysis of customers comments on websites booking.com and tripadvisor.com, and official Facebook pages. This analysis provides the information on the level of customer satisfaction and necessity of additional facilities and services provision. Timely identification of negative customer feedback enables hotels to fix their internal processes in order to prevent negative impact on their image and reputation. This is why these comments should be carefully tracked and responded to by a professional, regardless whether they have a positive or negative connotation.

Secondly, the paper has implications to other researchers in the field. Although the study did not cover all possible drivers of profit margins, it is important to path the way for further research in the area of hospitability industry. The study has some major limitations, both fundamental and technical. Fundamental limitations are linked to the set of variables used in the study. Accordingly, a recommendation for further research is to encompass a wider set of variables and statistically tested and refined indicators. Technical limitations are based on the sample size, timeframe, and the techniques used for the analysis. The sample size is rather small, and this study should be viewed as an ongoing project. This study is cross-sectional and based on the data from 2014. Further studies should apply time series and capture the evolutionary features of the hotel profitability in Belgrade. Finally, as all the other quantitative studies, this study has some technical flaws. Further studies should conceptualize on qualitative aspects of the topic covered and include a mixed-method approach in the analysis. Accordingly, the success on this intensively competitive market in digital era should not and can not be based solely on improvements of offline aspects of hotel industry. Hotels must focus their efforts on improving online appearance and digital reputation management.

PROTECTION OF INTELLECTUAL PROPERTY RIGHTS - WHAT DO FINANCIAL REPORTS SAY?

Nikola Radovanović*[1], Veljko Dmitrović[2], Snežana Knežević[2]

[2]Faculty of Organizational Sciences, University of Belgrade
*e-mail: nradovanovic@zis.gov.rs

Abstract: *Given the increasing importance of non-material assets, or intangibles, and the limitations which make their recognition difficult, traditional financial statements often fail to capture the value drivers that determine the market value of the companies. Although patents, trademarks, industrial designs and other intellectual property rights belong to the intangible assets in financial reports, the reports often do not separate these rights and, therefore, they are not adequately valued as a part of the companies' market value. We suggest that the change in the number of filed intellectual property rights application by companies should reflect the alteration of the share of intangible assets in the financial reports of the same companies. The methodology included quantitative and qualitative research method based on a survey, while the data has been statistically analyzed with the use of analysis of variance and chi-square tests. The findings suggest that the increased filing of intellectual property rights does not significantly affect reporting on intangible assets in financial reports of companies from technology-intensive industries in Serbia.*

Keywords*: intellectual property, intangible assets, intellectual capital, patents, trademarks*

1. INTRODUCTION

Financial reporting of intangible assets of companies is under increased focus in the last decades. Intangible assets are considered to be among the key factors of success for any company, both at present and in future (Álvarez Villanueva, 2011). It is generally understood that the biggest share of the modern company's market value lies in its non-material property, or intangible assets. Hulten and Hao (2008) state that intangible assets stand as one of the possible contributors to the disparity between market and book values of companies, and that market capitalization should reflect the value of intangible assets. Therefore, any decision on merger or acquisition, or on any big transaction between companies, require serious and detailed analysis of the intangible side of the companies in stake. Also, the relatively recent growth of the service sector and of information technology-related businesses, along with the dramatic increase in the number and size of international mergers and acquisitions, has made accounting for intangible assets highly significant (Lev, 2001; Saudagaran, 2001). An intangible asset is a claim to future benefits that does not have a physical (e.g., building or equipment) or financial (e.g., stock or bond) embodiment (Lev, 2001). For example, patents, brand names, and unique organizational infrastructures that generate cost savings for companies can be defined as intangibles (Kang and Gray, 2011). Currently, there are few comprehensive guidelines for corporations in either International Financial Reporting Standards (IFRS) or in U.S. GAAP on how to report IA, other than for purchased goodwill and development costs, in company financial statements. In other words, while the importance and the necessity of intangible assets in creating and maintaining corporate value have been widely accepted, traditional financial reporting frameworks unfortunately do not capture many of these value drivers (Jenkins and Upton, 2001; Upton, 2001; Lev and Zarowin, 1999). The reasons for that are "non-physical" nature of intangible assets and the uncertainties associated with their future benefits. However, it is clear that intangible assets in financial reports should include all intellectual property types which company possesses (as stipulated in the *International Accounting Standard 38 - Intangible Assets*). In this paper, we analyze how the applications for patents, trademarks and industrial designs, which are among the most commonly used intellectual property rights for achieving market competitiveness, are related to the reported intangible assets section of companies' financial reports.

A patent protects an invention which is new, involves an inventive step and is susceptible of industrial application. Patent applications have been frequently used as an innovation indicator on both micro and macro level. On the micro level, patenting is not carried out only for the reason of profiting from a patented

innovation through either its commercialization or licensing, but also for strategic reasons, one of which is the increase if negotiation power through increasing the value of intangible assets (Cohen et al., 2000). Evidence shows that patents very often play a critical role in creating competitive advantage of companies (Kollmer and Dowling, 2004; Giuri et al., 2005). Therefore, patents are considered to positively affect how owners and a stock market value the potential of companies through intangible assets (Fukugawa, 2012).

Trademark is the right that protects a mark used in the course of trade to distinguish goods and/or services of one natural or legal person from identical or similar goods and/or services of another natural or legal person. Regarding trademarks, Block et al., (2015) suggests that seeking trademark protection is of significant importance to small and medium-sized enterprises (SMEs) with orientation towards innovation, especially due to scarce resources which are usually a burden for smaller companies. Trademark registration is characterized as inexpensive and less complexed than patenting and, as such, serves as important appropriation function for SMEs which are interested in using intellectual property rights (Block et al, 2015). Furthermore, trademarks are seen as supplementary tools in negotiations for licensing and other means of product or service commercialization. They can strengthen the negotiating position of companies and they also have the ability to provide assurances on quality (Srinivasan et al., 2008; Block et al., 2014). The literature also suggests that trademarks are complementary to patents and that the two are used in conjunction with each other to offer more complete protection of IP assets (Blind et al., 2006; Thomä and Bizer, 2013). Trademarks may also play an important role in the appropriation of innovation rents by SMEs (e.g., Helmers and Rogers, 2010; Flikkema et al., 2014). The effects of trademarks on firms' market values has been analyzed by Sandner and Block (2011), who observed that trademarks have a positive effect on firm market value. Similar results are reported by Fosfuri and Giarratana (2009). Greenhalgh and Rogers (2012) studied the relationship between trademarks and market values of service and manufacturing firms and concluded that trademarks have a greater effect on the market values of the former that of the latter.

Finally, industrial designs are the third most common industrial property right, which provide their holders with the 25-year long monopoly (in most countries) for commercialization and prevention of use by third parties. Industrial designs are also considered an indicator of innovativeness, as they have to fulfill the requirement of global novelty as the most important requirement. Also, in some sectors, such as lightning, industrial designs are more frequently used as the IPR protection strategy that, for example, patents, due to their aesthetic characteristics. Therefore, industrial designs application are also considered as the driver of the value of intangible assets of companies.

Based on these findings, we suggest that increased orientation to patent, trademark and industrial design protection should lead to higher shares of intangible assets in companies' financial statements. We used indicators of patent applications, trademark applications and industrial design applications as variables in the analysis.

2. METHODOLOGY

In order to analyze the relationship between the filing of intellectual property rights and the reporting of intangible assets as the share of the value of total assets of companies, we have selected 29 companies from technology-intensive industries in Serbia. The selected companies are operating in the pharmaceutical industry, chemical industry, civil engineering, IT and telecommunications, and electrical equipment manufacturing. The value of reported intangible assets of companies within their total assets value reported has been taken from the mandatory financial reports open for public and given in the database of enterprises by the Serbian Business Registers Agency (available at *www.apr.gov.rs*).

For the purpose of the analysis, the data had to be normalized. In this regard, companies where the share of intangible assets was below 5% of the total assets value, the intangible assets level attributed to these companies was 0. Where this share was between 6 and 15%, the given mark was 1, while for the range between 16 and 25%, the mark was 2. The threshold for the maximum mark of 3 was at least 25%. Normalization of application for intellectual property rights has been done in a similar way. The companies who applied for only one patent/trademark/industrial design, received the mark of 1 for that intellectual property right. Where the number of applications was between 2 and 5, the mark was 2, while the maximum mark of 3 was given to companies where the number of applications for a particular intellectual property right was at least 6. Where there were no intellectual property rights filing, the company received 0 mark for that intellectual property right. The reason behind this normalization of scores is that the company who filed more than 5 applications of a particular IP right can be identified as an entity which has elements of strategic IPR management in its business.

In the final step, the comparison of the level of filing of intellectual property rights with the indicator of intangible assets share of companies has been carried out, in order to determine if there a significant interdependence of the variables. The comparison was performed with the statistical test by using analysis of variance (ANOVA) and by cross tabulation with the Chi-Square tests statistical method by using the SPSS software. Such tests were carried out having in mind that the analysis of variance (ANOVA) is normally used to determine whether there are any significant differences between the means of independent groups, while crosstabulation generates information about bivariate relationships.

3. RESULTS

Based on the analysis regarding filing intellectual property rights, total of 27.59% of analyzed companies filed at least two types of intellectual property rights which are still under IPR protection, while slightly higher portion of 31% companies filed none. Only 13.79% of companies have all three types of intellectual property rights filed and valid. Concerning particular intellectual property rights, trademark applications are dominant with 62.07% of companies filing trademark applications, 27.59% of analyzed companies filed patent applications, and 20.69% filed industrial design applications. Regarding intangible assets value share, only 31% of companies had the portion of intangible assets within the total assets value higher than 5%.

The statistical analysis with the application of cross tabulation with the Chi-Square tests has been applied to the intangible assets value and the filing of all three types of intellectual property rights separately in order to describe the relationship between these variables. The following three tables provide results from the analysis.

Table 1: Chi-Square Tests – Trademark applications/Portion of IA in total assets

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	6,638a	6	,356
Likelihood Ratio	5,428	6	,490
Linear-by-Linear Association	3,268	1	,071
N of Valid Cases	29		

a. 10 cells (83,3%) have expected count less than 5. The minimum expected count is ,17.

Table 2: Chi-Square Tests – Industrial design applications/Portion of IA in total assets

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	15,671a	6	,016
Likelihood Ratio	7,788	6	,254
Linear-by-Linear Association	3,328	1	,068
N of Valid Cases	29		

a. 10 cells (83,3%) have expected count less than 5. The minimum expected count is ,07.

Table 3: Chi-Square Tests – Patent applications/Portion of IA in total assets

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	3,420a	6	,755
Likelihood Ratio	3,816	6	,702
Linear-by-Linear Association	,040	1	,841
N of Valid Cases	29		

a. 10 cells (83,3%) have expected count less than 5. The minimum expected count is ,07.

Based on the likelihood ratio values of 0.490, 0.254 and 0.702 respectivelly, the analysis revealed that no significant interdependence has been found between the applications for intellectual property rights and the portion of intangible assets reported as the share of the total assets value by companies. Therefore, we assume that the increased filing of intellectual property rights does not significantly affects the increase in the reporting on intangible assets share in financial statements of companies in technology-intensive industries in Serbia.

The same evidence could be found from the ANOVA analysis, as shown in the following table.

Table 4: ANOVA – Filing of IP rights

		Sum of Squares	df	Mean Square	F	Sig.
Trademarks	Between Groups	4,424	2	2,212	1,813	,183
	Within Groups	31,714	26	1,220		
	Total	36,138	28			
Designs	Between Groups	3,034	2	1,517	1,972	,159
	Within Groups	20,000	26	,769		
	Total	23,034	28			
Patents	Between Groups	1,589	2	,795	,622	,545
	Within Groups	33,238	26	1,278		
	Total	34,828	28			

The results of the ANOVA analysis show that there is no statistically significant difference between the group means, with the significance level standing above the usual cut-off point of 0.05. Thus we do not have enough evidence of interdependence between the variable representing filing of trademarks, patents and industrial designs, and the variable representing the portion of intangible assets in the value of total assets of companies.

4. CONCLUSION

The research has been carried out for the purpose of determining whether filing of intellectual property rights application significantly affects intangible assets value which is reported in the mandatory financial statements of companies coming from technology-intensive industries in Serbia. Not only that it has been shown that there is no significant interdependence between filing of intellectual property rights application and the reported share of intangible assets, but the analysis revealed that firms coming from technology-intensive industries generally report significantly small shares of intangible assets in their financial statements. Having in mind the nature of technology-intensive industries, both results were surprising. In addition, the analysis has shown that a trademark protection is highly sought by these companies, making this industrial property right dominant in comparison to both patents and industrial designs. Almost three times higher portion of companies from technology-intensive industries applied for trademark applications compared to patent applications.

The main limitation of this research is that, although it is a result of a creative activity with intangible assets involved, filing of patent, trademark or industrial design application do not necessarily lead to the granted intellectual property right. Therefore, non-granted intellectual property right may not provide monopolistic incentives for the company and may not be financially reported in the intangible assets part of the company's value. In addition, lack of ability or willingness to report separate intangible assets forms, such as patents or trademarks, in the financial reports, represents serious obstacle for detailed analysis of the effect of company's IPR protection orientation on the valuation of non-material assets of the company.

The findings of this study could be important to organizations from technology-intensive industries, which are active in filing intellectual property rights. The analysis of the relationship between filing particular intellectual property right and intangible assets value share can provide insight into the effect of IPR strength of companies to their market potential in terms of book value indicators. The results of this research may contribute to management of companies coming from technology-intensive industries, having in mind that these industries heavily rely on intellectual property rights for their competitiveness.

THE IMPORTANCE AND APPLICATION OF TRANSFER PRICING COMPLIANCE IN MODERN BUSINESS

PhD Maja Djurica*[1], MSc Marko Jovanović[1], PhD Miha Marič[2]
[1]Belgrade Business School, Simic and Partners LLC
[2]Faculty of organizational sciences, Kranj
*Corresponding author, e-mail: maja.djurica@bbs.edu.rs

Abstract: *In the modern business world it is very important that managers of international companies, which have businesses with cross-border intercompany transactions, understand the concept of transfer pricing. A transfer price is the price at which divisions of a company transact with each other. Transactions may include the trade of supplies or labor between departments. Transfer prices are used when individual entities of a larger multi-entity firm are treated and measured as separately run entities.In this paper the folowing issues wil be explained: the concept of transfer prices and their importance in tax regulations, both in Serbia, and intrantionally; who are the related parties from the point of accounting and other non-tax legislationas; what are the methods used for complience of the transfer prices, what are the arm`s- lenth trasaction and how the company could aviod them.The results and data given in this paper represents the problems seen through our clients` business and their transactions with related parties. Also, the most important and frequently asked questions about this topic are explained, and the practical answers were given. It was also necessary to justify why and how certain situations were measured. We also find that changes in exchange rates have differential effects on arm's-length and related-party prices; an appreciation of the Euro reduces the difference between the prices.*

Keywords*: transfer pricing, taxpayers, related entities, arm's length principle, methods for verifying transfer prices, Corporate Income Tax Law*

1. INTRODUCTION

The study on transfer pricing is based on the "arm's length principle" formulated in the OECD publication, entitled "OECD Transfer Pricing Guidelines for Multinational Enterprises and Tax Administrations 2010", originally published in 1995, and modified in July 2010. Adopting the principle of arm's length ensures the equal tax treatment of all taxpayers, regardless of whether it is a person who is considered to be related or not. Serbia is not a member of the Organization for Economic Cooperation and Development (OECD), but the Serbian legislation generally follows the OECD methodology and documentary requirements.
(*OECD Guidelines for the application of the rules on transfer pricing, 2010*, p. 25)

According to the "arm's length principle", internal (transfer) prices between related companies must be specified in the same way to do this unrelated parties in similar circumstances. OECD regulations require that the application of the "arm's length principle" mainly based on the comparison of the essential conditions of a controlled (related) transactions and uncontrolled conditions (between independent parties) transactions. According to the OECD Rules, transactions can be compared, if there is no difference in the conditions that may substantially affect the price, or if the differences can be removed by appropriate adjustments. To determine whether there are significant differences between the compared transactions and operations, the following five factors should be carefully considered:

- characteristics of goods or services
- functional analysis
- contractual terms
- market conditions
- business strategy

Controlled and uncontrolled transactions and entities are not comparable if there are significant differences in terms of the risk, which cannot make appropriate adjustments. If, after comparing these five factors, we conclude that the differences between the compared transactions or businesses substantially affect the price and that it cannot carry out any reasonable adjustments to eliminate these differences, transactions and operations, according to the OECD Code, cannot be considered comparable. However, the Regulation clearly states that it should not happen that useful information, that can be obtained from uncontrolled

transactions that are not identical controlled, are not taken into account because they do not meet the strict criteria of comparability. (Denčić Mihajlov, Trajčevski,, 2011, p. 397)

Permissible methods of establishing “arm’s-length” price in Serbia in 2013 (Article 61 of the Corporate Tax Law,” Official Gazette of RS", no. 25/2001 ... 108/2013) are:

- Comparable (uncontrolled) market price method
- Costs price plus usual earnings method (Costs plus gross margin method) - Cost-plus method
- Resale price method
- Transactional net margin method
- Profit split method

Denčić Mihajlov, and Trajčevski, (2011) explained that any other method by which it is possible to determine the price of a transaction on the “arm’s-length” principle, providing that the application of the method previously mentioned in this paragraph is not possible, or that the second method is more applicable to circumstances than the methods previously mentioned in this paragraph (p.399).

2. TRADITIONAL METHODS

Traditional methods are based on transactional analysis using direct and indirect methods (e.g., gross profit) in examining the nature of arm's length transactions between related companies. Traditional methods include method comparable (uncontrolled) prices in the market, the method of cost price plus usual earnings (cost plus gross margin method) and the resale price method.

- Comparable (uncontrolled) market price method "shall compare prices that will be charged with trade in goods and services in a controlled transaction with prices that are applied in the trade of goods and services in a comparable uncontrolled transaction under comparable conditions".

- Cost plus method "is based on the cost of supplier goods (or services) in a controlled transaction, which refers to the transfer of goods or services to the customer, a related party. These costs are then added to the appropriate margin to be achieved adequate earnings, according to the functions performed and the market conditions. What is obtained by adding the margin can be considered arm's length price of the original controlled transaction."

- Resale price method "is based on the price at which the product was purchased from a related party and resold to an unrelated party. This price ("resale price") shall be reduced by an appropriate gross margin ("resale price margin") representing the amount of which is expected to cover the reseller sales and other operating costs, and that, according to the functions performed (taking into account assets used and risks assumed), achieve adequate profits. What is left after deducting the gross margin and corrections based on other costs incurred in the acquisition of the good (e.g. costs of customs), can be regarded as the arm's length price for the initial transfer of assets between related parties." *(OECD Guidelines for the application of the rules on transfer pricing*, 2010, p.29)

2.1. Transactional profit methods

Transactional profit methods examine the profits resulting from transactions between related parties. Two basic methods are the transactional net margin method and profit split method. Profits arising from controlled transactions may be a relevant indicator of whether the transaction was affected by conditions that differ from those that would be incurred by third-party companies or other comparable terms. (Oosterhoff, 2014).

- Transactional net margin method examines the net profit compared to the appropriate base (e.g. costs, turnover, and assets) that a taxpayer realizes the controlled transaction. Transactional net margin realized by the taxpayer in a transaction with related parties is compared with the transactional net margin realized by unrelated parties predominantly engaged in similar transactions, and it is done by applying a statistical method that net margins in transactions between unrelated parties are spilt into the quartiles. The basic principle of this method is that the party is being tested its activity can achieve similar net profit (compared on the basis of the resulting analysis) as an independent party, then consequently prices of transactions between related parties had to be just as arm's length prices..

- Profit split method attempts to eliminate the effect on profits of a controlled transaction which is appeared due to created or imposed conditions by determining the distribution of the profit that an unrelated party expected to realize from engaging in a transaction or transactions. This method first identifies the profit from the controlled transactions in which they are related parties engaged,

which should be distributed between the parties ("combined profit"). The same goes when the company realized losses instead of profits. Then, this method distributes the combined profits between related parties, the economic-based basis which approximates the distribution of profits that would have been expected and agreed to an arrangement that is in accordance with the principle of arm's length.

When determining the price of transactions on the principle of "arm's length" is used the method that best suits the circumstances of the case, where it is possible to use multiple methods when necessary. The choice of method is based on analysis of the facts on which it is necessary to consider:

1. The nature of transactions which are the subject of analysis
2. Availability and reliability of data for analysis
3. Degree of comparability between transactions carried out on transfer pricing with transactions carried out with or between unrelated parties, if these transactions are used to verify the compliance of taxpayers transfer prices with prices determined by the principle of "arm's length"
4. The appropriateness of using financial data of unrelated parties to analyze the compliance of transfer prices for certain types of transactions that the taxpayer perform with related parties
5. The nature and reliability of assumptions (*OECD Guidelines for the application of the rules on transfer pricing, 2010, p. 45)*

Table 1: Reasons for rejection / acceptance the transfer price method from the company

Method	Reasons for rejection / acceptance from the company
Comparable (uncontrolled) market price method	Intern comparable price is not applicable as the most of the given companies have only transaction with a related parties in Serbia -The application of Externally comparable prices is also not possible because there are no publicly available data for this type of transactions (external comparable price in the country as well as the prices of such transactions abroad are not available)
Cost plus method	- there is not a possibility of establishing an internal comparable margins -There Are no publicly available data for determining externally comparable margins
Resale price method	- In order to achieve comparability of transactions and obtaining valid results, according to the OECD methodology and the Ordinance on transfer pricing, this method is primarily recommended for distributors
Transactional net margin method	- At this method the companies are comparing the net profit margin realized by the taxpayer in transactions with related parties, with net profit margins achieved in similar transactions with unrelated parties. Transactional net margin in Serbia resale is 0.53% and is significantly lower than the average transactional net margin in theEoropean resale industry, which is between 6:41% and 16.28%.
Profit split method	- This is a more optimal method because the activities of related parties so united in a way that makes it difficult to separate analysis of individual transactions between them.

3. TRANSFER PRICING - CORRECTION OF REVENUE AND EXPENDITURE IN TAX BALANCE

Popović (2013), explained that Transfer Pricing, respectively Corporate Income Tax Law, and the Ordinance on transfer pricing require Companies which have transactions with related parties that in the Tax Balance express the effects of the correction of expenditure and revenue and to increase the taxable tax base if needed. To calculate the required data, it is necessary to apply some of the previously explained methods for determining whether transactions between related prices are in line with market prices. When submitting the Tax Balance, companies should also submit a study / report on transfer pricing to the tax authorities. *(*p. 285)

In the business analysis, if the company determines that the price based on transactions with individual related party differs from the established market price, applying the principle of "arm's length", the company is required to incorporate in the tax base:

1) the amount of the positive difference between the revenues arising from the transaction at a price determined by applying the principle of "arm's length" and income arising from the transactions with transfer price, or
2) the amount of the positive difference between expenditures arising from the transactions with the transfer price and expenses arising from the transactions at a price determined by applying the principle of "arm's length".

In the conclusion of the Study of transfer pricing, it is first necessary to determine the proper amount of correction of transfer prices for each transaction associated with the related parties or for each type of transaction with individual related parties (Popović, 2013, *p.* 290).

Adding the precise amount of the correction, the company determines the total amount of the adjustment of transfer prices based on transactions with individual related parties. In accordance with Article 60, paragraph 8 of the Corporate Income Tax Law, the Company is entitled to decrease the total amount from the adjustment of transfer prices on the basis of individual transactions with related parties for:

1) the amount of the negative difference between the revenues arising from transactions with the individual related party at a price determined by applying the principle of "arm's length" and income arising from the transactions after the transfer price, or
2) the amount of the negative difference between the expenditures on the basis of individual transactions with the related party after the transfer price and expenses arising from these transactions at a price determined by applying the principle of "arm's length".

There is the necessity if the Company is not able to do internally compare the cost of transactions with related and unrelated parties, to make a comparison externally and to determine the quartiles, regarding the range of realized margins of other companies within the same Industry on the market. If the established range:

1) considers that the transfer price of the transaction does not differ from the price based on the principle of "arm's length" if the value of transfer prices is within that range;
2) the price according to the "arm's length" is equal to the central value of the specified range when the transfer price is outside the specified range.

After reducing the amount of correction, based on transfer pricing as the transactions with related party, referred to the paragraph 3 of this Article, the taxpayer determines the final amount of the adjustment of transfer prices on the basis of individual transactions with a related party. (*Law on Tax Procedure and Tax Administration (2014), paragraph 85)*

Example 1:

The taxpayer "X" during the tax sold its goods to related party "Y" on the transfer price of 10 million dinars. The price that would be achieved on this basis on the market (price - "arm's length") is 12,000,000 dinars. So, there is a positive difference between the price based on the "arm's length" and transfer price. So the taxpayer corrects its revenue for the amount of 2,000,000 dinars.

With the same related party the tax payer "X" had the expenses for lease of immovable property in the amount of 2,500,000 dinars. The rent which would be paid by the taxpayer on the market (rents on the "arm's length") is 3,000,000 dinars. So, on the expenditure side, the taxpayer, "X" on the transaction with the same related party, achieved a negative difference (transfer price is lower than the price of "arm's length") of the amount of 500,000 dinars.

The taxpayer "X" in the conclusion of the transfer pricing documentation makes a final correction of transfer prices to related party "Y" by the amount determined by the correction (2,000,000 dinars) reduced by the amount of the negative difference that is achieved on the expenditure side (500,000 dinars), so that the final correction of transfer prices to the taxpayer will be 1,500,000 dinars. 2. (Čubrić and Negovanović, 2013, p. 12)

Example 2:

The taxpayer "X" in the tax period for which the tax balance was generated, had the revenue by selling products to the related party "Y" on the transfer price of 15 million dinars. The price which the taxpayer "X" could get on the market (price "arm's length") is 18,000,000 dinars. Therefore, the correction by the taxpayer "X" on this basis is 3,000,000 dinars (positive difference between the price of "arm's length" and transfer price).

The taxpayer "X" is within the same tax period generated revenue by selling real estate to related party "Z" on the transfer price of 20 million dinars. The price which the taxpayer X would make on that basis on the market (price "arm's length") is 18,000,000 dinars. Thus, on the basis of this transaction, the taxpayer "X" has made a negative difference between the price of the "arm's length" principle and the transfer price in the amount of 2,000,000 dinars.

However, the taxpayer "X" in this case cannot be offset correction that is found in the first mentioned transaction on the basis of the positive difference between the price of the "arm's length" principle and the transfer price with negative difference that is generated in the second transaction with other related party. So that the amount of the final correction based on transfer prices to the taxpayer Y remains 3,000,000 dinars. (Čubrić and Negovanović, 2013, p. 15)

- In determining the correction based on the transactions with related parties, the company need to go through the following process:

- With individual related party transaction for each individual, and for each type of transaction, determines the amount of correction of transfer prices;

- Identifies the total amount of the adjustment of transfer prices with individual related persons on the basis of all transactions with this related party;

- The total amount of the adjustment of transfer prices with individual related persons reduced by the amount of negative differences arising in transactions with these related party;

- Reduction of the total amount of correction of transfer prices with individual related party may not exceed the amount of correction associated with that person;

- Finally, adds the total amount of correction of transfer prices established by each related party, as described above. The sum of total correction of the taxpayer needs to be stated in the tax balance position under number 50, and this amount increases the tax base of income tax.

4. TRANSACTIONS WITH RELATED PARTIES – INTERCOMAPNY LOANS

4.1. Types of transactions- intercompany financing

In accordance with Article 61, paragraph 3 of the Law on Corporate Income Tax Law ("Off. Gazette of RS", no. 25/2001, 80/2002, 80/2002 - Law, 43/2003, 84/2004, 18 / 2010, 101/2011, 119/2012, 47/2013 and 108/2013), which provides for purposes of determining the interest that would be based on the "arm's length" calculated on loans, or loans between related persons, the Minister of Finance may prescribe interest rates that will be considered in accordance with the principle of "arm's length", written in the Ordinance of interest rates which is considered to be in accordance with the principle of "arm's length". This Ordinance was published in "Off. Gazette of RS", no. 023/2015 of 02.03.2015. years and shall enter into force on the day following its publication, ie 03.03.2015. year. *(Law on Income Tax,2013, paragraph 66)*

The Law on Personal Income Tax (2013)
The Law on Enterprises (2011)

This regulation defines the interest rates that are considered to be in accordance with the principle of "arm's length".

For 2014 the interest rates that are considered to be in accordance with the principle of "arm's length" were:

- 13.82% for short-term loans in RSD;
- 11.12% on long-term loans in RSD.

The above rates apply to loans.
The taxpayer has the right to substitute the amount of the interest rate prescribed by the Minister of Finance, for the purposes of determining the amount of interest that would be based on the "arm's length" calculated

on a loan or credit with related parties, the application of general rules on determining the value of transactions on a "beyond arm's length "from the art. 60 and 61, 1 and 2 of the Law on Corporate Income Tax. (*The Law on Personal Income Tax, 2013, paragraph 52).*
A taxpayer who decides to exercise this right, shall general rules on determining the transaction price based on the "arm's length" from the art. 60 and 61 st. 1 and 2 of the Law on Corporate Income Tax Law is applied to all loans or loans with related parties.

If the taxpayer decides to exercise this right, the Tax Administration, for the purposes of determining the amount of interest that would be based on the "arm's length" and then calculated on loans, or loans between that taxpayer and related persons, is not related to the amounts of interest rates prescribed by the Minister of Finance .

In the our example The Company did not to use the opportunity given to the prescribed regulations on transfer pricing, and that it does not have to prove the level of market interest rate which should be applied to those loans in the current circumstances, but to apply the rates proposed by the Ministry of Finance of the Republic of Serbia. (Milićević and Malinic., 2013, p. 522)

During 2014 a subsidiary of the Company Ltd. gave-connected society ABC, Serbia, interest-free loans. Below is a table with an overview of current borrowings and accrued interest.

Table 2: An overview of current borrowings and accrued interest from the inter companies loans

AMOUNT OF LOANS	The date of returning	The Duration of loan in days	The period for calculation	Applied rate	Accrued interest
1.704.580,96	31.5.2014.	451	151	0,03046%	78.401,52

1.200.000,00	13.6.2014	256	164	0,03786%	74.508,48
600.000,00	13.6.2014	224	164	0,03786%	37.254,24
120.000,00	13.6.2014	193	164	0,03786%	7.450,85
2.250.000,00	13.6.2014	192	164	0,03786%	139.703,40
50.000,00	13.6.2014	185	164	0,03786%	3.104,52
50.000,00	13.6.2014	184	164	0,03786%	3.104,52
100.000,00	13.6.2014	183	164	0,03786%	6.209,40
300.000,00	13.6.2014	182	164	0,03786%	18.627,12
350.000,00	13.6.2014	178	164	0,03786%	21.731,64
220.000,00	13.6.2014	140	140	0,03786%	11.660,88
536.289,54	13.6.2014	133	133	0,03786%	27.004,21
1.000.000,00	13.6.2014	128	128	0,03786%	48.460,80
850.000,00	13.6.2014	127	127	0,03786%	40.869,87
700.000,00	13.6.2014	123	123	0,03786%	32.597,46
300.000,00	13.6.2014	122	122	0,03786%	13.856,76

300.000,00	13.6.2014	120	120	0,03786%	13.629,60
10.000,00	13.6.2014	86	86	0,03786%	325,59
50.000,00	13.6.2014	85	85	0,03786%	1.609,05
250.000,00	26.9.2014	9	9	0,03786%	851,85
					973.507,61

In the tax balance is necessary to make a correction at the company our company which is a lender, so the tax base will increase for the amount of 973,507.61 dinars.

In the company of the borrower ABC is not possible to reduce the tax base on this basis.

5. THE EXAMPLE OF TRANSACTIONAL NET MARGIN

Transaction net margin applied in this particular case has the form:

$$Net\ margin = \frac{Net\ profit}{\text{Operating costs}} \text{ x } 100\%$$

This form of net margin is recommended for transactions concerning the provision of services. In determining transactional net margin realized by the taxpayer in a transaction from which he emerged transfer price, as a rule, are taken into account only those operational revenues and expenses that are directly or indirectly related to the transaction, and to the extent that they contributed to achieving net profit in the transaction. (OECD Guidelines for the application of the rules on transfer pricing, paragraph 2.77)

Costs and revenues that are not related to a controlled transaction should be excluded because they significantly affect the comparison with uncontrolled transaction. (Garrison, R and Noreen, E, 2012, p. 61)

Non-business items such as interest income and expense and income taxes should be excluded from the determination of net profit indicators. (OECD Guidelines for the application of the rules on transfer pricing, paragraph 2.80). From the income statement of the company ABC it can be seen that the total financial expenses (negative exchange differences and interest expense) was 6,416,231.34 RSD and are not taken into the calculation when calculating the total operating costs. Although it appears in the numerator net income, it is in fact about a business operating profit (excluding financial, and other extraordinary expenses and revenues), which is placed in relation to operating expenses. This is stated in Article 25, paragraph 3 of the transfer pricing that in determining transactional net margin realized by the taxpayer in a transaction from which it is derived transfer price, as a rule, are taken into account only those operating revenues and operating expenses that are directly or indirectly related to the transaction, and to the extent that they contributed to achieving net profit in the transaction.

Table 3: the example of TNM calculations

Transaction of the internal trade	
The revenue of the GERMAN company in RSD	213.210.414,80
Relevant Expenses	212.335.751,77
EBIT	874.663,03
TNM	**0,41%**
TNM on the company level	
Total Business Revenues	217.927.397,10
Total Business Expenditures	212.876.484,01
EBIT	5.050.913,09
TNM	**2,37%**

5.1 External comparable data

Data which the independent company engaged in the same or most similar type of activity and the company has tested a range of margins between 6:41% and 16.98%. This applies only to the functions performed by an independent company and tested the company. To obtain the proper range margin the company had used publicly available database AMADEUS issued by the company Bureau van Dijk. Data obtained from studies of transfer pricing companies from similar activities.

By searching the data AMADEUS obtained a sample of several companies and for each of the selected companies account net margin for each year, then the average is calculated for the analyzed period 2009-2013. year. Based on the average values of gross margins were calculated minimum and maximum, as well as the first and third quartile and median. Since there was only one comparable company from Serbia, the company included in the analysis the European companies.

The choice of this method is based on analysis of the facts that were analyzed and according to the Regulations on transfer pricing:

- Nature of transactions that are the subject of analysis;
- the availability and reliability of data for analysis;
- the appropriateness of the use of financial information unrelated persons for the analysis of transfer pricing compliance by certain types of transactions that the taxpayer performs with related parties;
- The nature and reliability of assumptions.

Net margin is the most appropriate indicator of the rate of profit to evaluate the financial operations of selected comparable companies. Based on the average value of the indicator of profit, calculated the minimum and maximum value of the net margin, or the first / third quartile and median. In order to eliminate the influence of temporary or accidental factors on the financial results, we used the averaged data for the period from 2011 to 2013. This approach is in line with the OECD Guidelines, which confirm that the use of data from several years accepted approach, and in accordance with Art. 26, paragraph 3 of the Rules on transfer pricing.

Table 4: The comparison of the quartiles

Minimum	**2,37%**
The first quartile	**6,41%**
Median	**8,86%**
The third quartile	**16,98%**
Maximum	**20,43%**

According to these results when they reject the extremes (minimum values between the first quartile and third quartile and maximum) conclusion is that the usual net margin of companies engaged in this activity between 6:41% and 16.98%, a median of 8.86%.

Net margin of our company achieved by the financial reports for 2014 is 2:37%.

6. CONCLUSION

Transfer pricing represents a major international tax planning opportunity and risk for many Multinational Companies. With a global increase in the volume and complexity of transactions among related parties and with countries looking to increase in tax revenue, tax authorities around the world have increased their scrutiny of transfer prices. The OECD has stated that “In a global economy where MNEs play a prominent role; governments need to ensure that the MNEs are not artificially shifting taxable profits out of their jurisdiction; the taxable income reported by MNEs should reflects the economic activity undertaken in the countries in which they operate." Today, MNEs are encountering an increase in the number of transfer pricing related tax audits and tax adjustments. This has brought transfer pricing to the forefront of attention for MNEs.

MNEs can create sustainable tax efficient structures by layering transfer pricing and tax planning with their supply chain initiatives. As MNEs expand or streamline their supply chains, they can make tax smart decisions about where to locate the value drivers and the important functions within their supply chains. For instance, if it makes sense to create a regional headquarters or centralized services such as a strategic sourcing group, MNEs should consider the tax rates that their cash flows would be subjected to in the various jurisdictions. MNEs should keep in mind that there are significant differences in the tax rates levied by countries they are operating in. As they decide on locations of important supply chain functions, they should perform their cost benefit analyses on an after tax basis.

Abstract: *Attracting, sourcing and acquiring the right people are main challenges of human resource management. The value and the success of an organization are often connected to hers talent management and the growth of human capital. The new developments and new technologies brought the necessities to implement change in these processes as well, in order to be compatible in this fast changing workforce market. The purpose of this paper is to present e-recruitment as a part of the talent management system of an organization and to depict the current state in recruiting business taking into consideration all the possibilities that the use of social networks are enabling.*

Keywords: *human resources, talent management, technologies, social networks, e-recruitment*

1. INTRODUCTION

The most frequently asked question of modern Human resource management is how to find, attract, recruit and retain talents. In this sense, contemporary literature and research within this field deal with the issues of managing talents very often. It is not possible to avoid mentioning the application of modern technologies through all the functioning processes of an organization, as well as their application in the area of human resources. The influence of contemporary technologies could be seen in human resources management activities and their everyday performance. In this paper, the recruitment process as a first and very important step in talent management will specifically be explained. Focus will be on the influence and change in delivering recruitment using modern technologies and social networks.

The paper will start with the general explanation of the terms human resource management and the talent management, as well as a recruiting process. Following, the influence of the contemporary technologies on recruitment process will be explained, with the special focus on the component of social media and social networks and their use in recruiting and managing talents.

2. TALENT MANAGEMENT

Generally, the term human resource management refers to the policies, practices, and systems that influence employees' behavior, attitudes, and performance. Human resource management includes staffing (recruitment and selection), compensating employees, employee relations, designing work, health and safety, equal employment opportunity, human resource planning as well as employee training and development (Noe, 2010, p. 4).

Talent has become the most critical and significant factor of competitiveness, it must be managed at least as carefully as any physical asset and it should be implemented with contemporary talent management technologies. Talent management could be defined as the ability to expertly attract, recruit, motivate, develop and retain staff; it is the process that brings together all human resource management processes, administration and technologies (Shweyer, 2004). Similarly, CIPD (2015) has described talent management as the systematic attraction, identification, development, engagement, retention and deployment of those individuals who are of particular value to an organization, either in view of their 'high potential' for the future or because they are fulfilling certain critical roles in an organization (CIPD, 2015). The effective talent management is a means of ensuring the right talent at the right time. Effective talent management increases the value of a company; alleviate the risk and encourages workforce productivity and innovation. Talent management system is essential for increasing the value of human capital in organization (Shweyer, 2004)

CIPD (2015) in its Annual Survey Report Learning and Development presented that companies consider as the main objectives in their organization's following talent management activities:

1. Talent management activities are more common in larger organizations,
2. In 50% cases all staff is included in talent management activities,
3. Focus is on developing high-potentials and future leaders,
4. High-potential in-house development activities, coaching, mentoring and buddying schemes are among the most commonly used and most popular and effective talent management activities.

In order to accomplish these talent management activities and result with useful talents in an organization it is our opinion that the special attention should be given to the recruitment process. According to the results of SHRM's Employee Recognition Report (2015) recruitment is in the top four challenges faced by HR organizations today, with the turnover, employee engagement and succession planning (SHRM, 2015).

Tong (2009) explains that in human resource management context, recruitment is a process of sourcing and acquiring the right applicants to an organization. Mostly this process includes searching for and attracting a pool of qualified applicants using all possible recruitment methods. The use of conventional recruitment methods is no longer suffices and timely to attract adequate number of qualified applicants. Many organizations have turned to adopting sophisticated recruitment strategies or combining various recruitment methods to attract them (Tong, 2009). This is where the application of contemporary technologies becomes useful trough different tools of e-recruiting.

3. THE USE OF CONTEMPORATY TECHOLOGIES FOR RECRUITMENT

Nowadays, different Web sites, Internet in general, provide employees with self-assessment tools, salary information for jobs within the company, career management advice, and training resources. Similarly, many companies in the employee recruitment business (such as monster.com) provide similar resources for job seekers and employers (Noe, 2010). As Shweyer (2004) emphasized, today effective talent management is not possible without the right technologies. Web brought the technologies that help employers in finding and managing job candidates. That is when talent management is viewed as a talent management system. Today there are more that hundred talent management systems (TMS) solutions providers (Shweyer, 2004).

Web-based technology is what shapes the talent management system. It is the combination of browsers, search engines, e-mail and database technology that allows talent management data to be gathered, analyzed and measured. Talent management data includes job requirements, source information, workforce plans, resume data, assessment data, contact information, testing results, background/reference data, job application history, performance data, interview results, etc. The goal is to create a talent record that is collecting data across the talent management life cycle, thus creating a more complete picture or profilepf the person's talents, aspiration and performance. Today, nearly every major vendor of e-recruitment solutions and talent management systems advertises a Web-based toolset that users can access easily trough standard browsers (Shweyer, 2004).

As the internet technologies have progressed the conventional recruitment methods have transformed to online recruitment (e-recruitment). This e-recruitment business thrived to become the second most popular online business besides booking airline tickets, in United States and Europe (Tong, 2009).

3.1. Social networks

A specific field in e-recruitment which became the most popular nowadays is e-recruitment using social networks, especially LinkedIn. Social networks will be explained highlighting the ones that are typically used for e-recruiting.

Social networking refers to systems that allow people to be networked (linked) with each other and be able to share resources with each other (Clara & João, 2010). In other words, social networks are virtual or online networks of people or communities. Depending on their purpose they can be classified as sites that are oriented to leisure, entertainment and companionship (such as: MySpace, Facebook, Twitter, etc.) and professional networking sites that focus on business networking (such as: LinkedIn, Ecademy, Yammer, etc.). Applications for social networking sites allow users to create profiles to share information about them and to identify friends or contacts out of other users with whom they share an interest. Networks such as Facebook, LinkedIn, MySpace and Twitter enable users to find and maintain personal and professional relationships with each other (Shelly & Frydenberg, 2011).

Chaka (2010) has introduced multi utility of social networks, from which the features that are most important for e-recruitment will be listed below (Chaka, 2010):

1. The establishment of professional and private contacts (networking)
2. Connecting with experts,
3. The disclosure of commonly shared activities (eg, conferences, vebineri, writing papers / books) and participation in them,
4. Exchange of knowledge, attitudes and opinions,
5. Profiling institutions ans strengthening their image, reputation and identity,
6. Marketing, advertising and promotion of institutional products and services (programs, courses, modules ...)
7. Overall recruitment and consideration of potential candidates, students or partners.

As the basic functionality of social networking from the perspective of individual users are the following: the ability to get to know people online and the ability to share and update personal and professional data about themselves. From the companies perspective social networks are mostly used to contact with their employees internally as well as externally with customers. They create communication channels that allow employees to cooperate with each other but also the consumers to express their opinion about product and services. All applications for social networking have similar characteristics of such as the ability to create profiles, the ability to determine other members of friends or contacts, and the ability to find friends of their friends. You can ask the person that shares some interests to be friends (the term used in personal networks such as Facebook and Twitter) or to connect (the term used in the professional networks like LinkedIn). Your collection of friends or contacts forms your social network. Creating a profile is also a common feature of most social networks, with the difference such as for example that the profile on Facebook mostly contains information about you and your interests, while at LinkedIn the information about persons education, current and previous job - work experience and recommendations of colleagues are posted. (Shelly & Frydenberg, 2011). Nowadays, these differences are not so distinguished since the LinkedIn has evolved and have lot of Facebook characteristics such as status massages, like/dislike and commenting of different kind, and Facebook has in professional sense so that every acknowledged company has a Facebook company profile.

3.2. The use of social networks for e-recruitment

According to SHRM Survey Findings - Using Social Media for Talent Acquisition – Recruitment and Screening (2016) HR professionals with the job function of employment or recruitment have given their opinion regarding the use of social media for talent acquisition. It is shown that (SHRM, 2016):

- Two-thirds of organizations (66%) have taken steps to leverage mobile recruiting—to target smartphone users, meaning that in most cases companies have optimized their career websites (39%), job postings (36%) and application processes (36%) for mobile users. Most major job search websites, such as Indeed, LinkedIn and Monster, have free applications for mobile user.
- Recruiting via social media is growing with 84% of organizations using it currently and 9% planning to use it - 81% of organizations reported that social media is their one recruiting tool among others and 5% of organizations reported that it is their primary recruiting tool.
- The top reason that organizations use social media for recruitment is in order to recruit passive job candidates (82%) – persons that are not actively looking for a new employment.
- Overall, 43% of organizations confirmed that the use of social media or online search engines to screen job candidates.
- Over 36% of organizations have disqualified a job candidate in the past year because of concerning information found on a public social media profile or trough an online search.

Buhalis (2016) provides a basis for understanding the impact of online and social media recruitment trends and issues emphasizing that the relationship is changed based on multiple direction of communication and inclusion of others. Social networks afford opportunities for the long-term engagement of past, current and future employees in the development and sustainability of the organization and its reputation. Relationships with all of the categories of employees can be facilitated through social media, recognizing that at different times each may play the role of promoter, recruiter, customer or ambassador. Websites, Facebook, Blogs and Twitter can build a social and professional community that is a continuous loop which outlasts one particular role or place in time. The role of the human resources department in facilitating this loop is crucial and an important area for consideration. It may also require new skills related to information technology, and for online media communication strategies to be included as part of human resource management activities (Buhalis, 2016).

In latest years lot of surveys have been conducted in order to explore the use of social media for recruiting and mostly in order to find out what social network are precived as not just as mostly used but as mostly effective as well. Here are some of the results:

- The companies that are using social media for recruiting have answered that they are using LinedIn, Facebook and Twitter for e/recruitment but that they find LinkedIn (73%) as most effective (SHRM, 2016).
- Recruiters' research showed that over 90% of companies use social media to recruit and most of them are using LinkedIn. About two-thirds of recruiters use Facebook, and little more than half are using Twitter to recruit. In most cases different social media is used as a support to traditional hiring channels by searching for candidates, posting jobs, and vetting applicants (Parkins, 2015).
- Alexander Mann Solutions and Social Talent (2016) conducted an online Global Recruiting Survey of about 1,000 sources and recruiters around the world in order to find out how social media was being used in the recruitment space (Ferguson, 2016). The results show that the most used hiring tools were social media in 2015 as it is shown in figure 1.

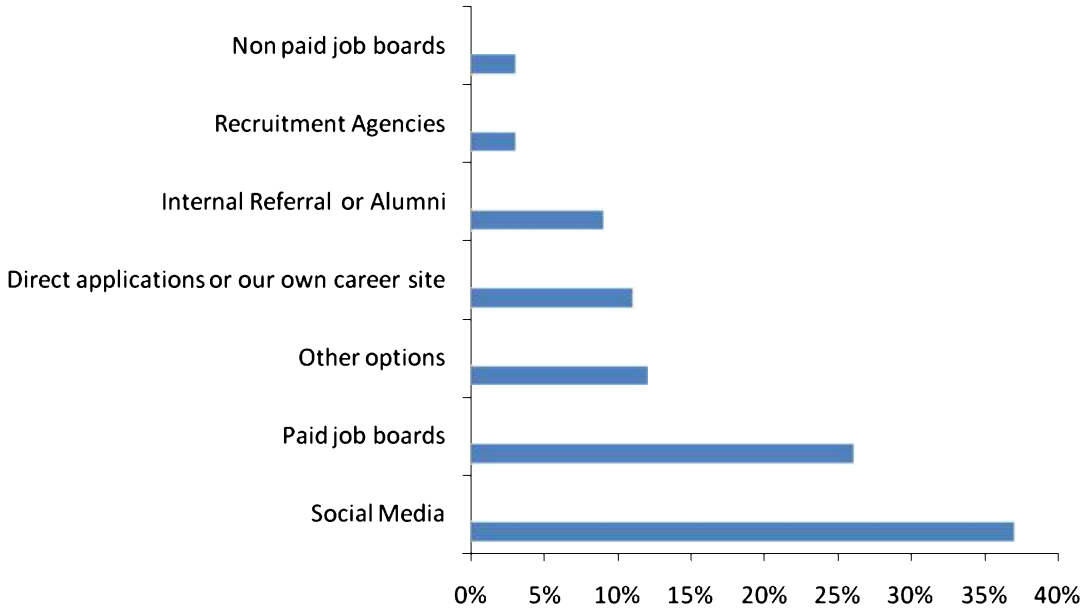

Figure 1: Where are successful hires ultimately found (Social Talent & Alexander Mann Solutions, 2016)?

As it was presented the platform becoming widely used for recruitment purposes is Web 2.0 and Social Networking Sites. Since these networks are mostly use for e-recruitment they will be presented with more details about their users in order to emphases the opportunities and the potential that they offer for finding talent in global market (Tabel 1).

Table 1: Social network characteristics: LinkedIn, Facebook and Twitter

Facebook (Facebook, 2015)	**LinkedIn** (LinkedIn, 2015)	**Twitter** (Twitter, 2015):
• 1.04 billion daily active users on average • 934 million mobile daily active users on average • 1.59 billion monthly active users • 1.44 billion mobile monthly active users • Approximately 83.6% of our daily active users are outside the US and Canada	• LinkedIn operates the world's largest professional network on the Internet with more than 400 million members in over 200 countries and territories. • Professionals are signing up to join LinkedIn at a rate of more than two new members per second. • There are more than 40 million students and recent college graduates on LinkedIn. They are LinkedIn's fastest-growing demographic.	• Twitter has around 320 million monthly active users. • 80% active users are mobile. • 3900 employees around the world, outh of what 40% are employees in technical role. • Professionals are signing up to join LinkedIn at a rate of more than two new members per second.

4. CONCLUSION

At the moment not all HR professionals are using social media for recruitment, although the presented results from a different Surveys conducted in last year has shown that are. Upon the results of SHRM (2016) Survey Findings on Using Social Media for Talent Acquisition it is recommended that HR professionals should use all options that would increase the online presence of their organizations as well as to incorporate the use of contemporary technologies into their talent acquisition strategies in order to broaden the pool of talents that they search for.

The use of social media for recruitment purposes are just beginning to be understood. It is clear that the use of social media for recruiting brought change in human resources with all of its possibilities and challenges. Human resource managers will mostly feel the consequences and they will have to be ready and willing to respond to the issues raised by these emerging practices (Buhalis, 2016). The question remains about the situation in Serbia? In our opinion, these social media tools are used in Serbia as in all other countries, since these are borderless and global trends that need to be followed in order to maintain the company's concurrency on today's market.

"JOHARI`S BEERGAME": THE EFFECT OF ALTERING COOPERATIVENESS IN SUPPLY CHAIN

Biljana Panić*, Ivana Kovačević, Mirko Vujošević
Faculty of Organizational Sciences, University in Belgrade
*Corresponding author, e-mail: panic.biljana@fon.bg.ac.rs

Abstract: *There are a lot of causes of bullwhip effect in supply chains and one of them is lack of cooperability as a personality trait. In this paper, the experiment conducted on students simulating beergame will be presented. The results of the experiment showed that the cooperativeness of participants in supply chain could be, at least partially, susceptible to situational conditions due to the fact that it is possible to change them. That conclusion is based on results showing differential effects of permitting and forbidding cooperativeness in supply chain during the beergame simulation. It was found that allowing cooperativeness during the beergame simulation, among cooperative participants leads to more self disclosure and feedback sensitivity which are similar but less pronounced within noncooperative participants in the same situation. On the other hand, lack of opportunity to cooperate in beergame situation leads to the restriction from self exposure and feedback sensitivity among inherently less cooperative group and less feedback sensitivity among participants with tendency to cooperate but with lack of opportunity to do that.*

Keywords*: supply chain, beergame, cooperability, Johari Window*

1. INTRODUCTION

Lack of information and coordination in the supply chains can cause the bullwhip effect, which implies a distortion of information within the supply chain because different stages in the supply chain have different demand forecasts, so that demand increasingly varies from retailer to manufacturer. Bullwhip effect was first identified by Forrester (1958). Later, the causes of the bullwhip effect were defined as "players' systematic irrational behavior" or as a "misperception of feedback" (Sterman, 1989, Goodwin 1994). Croson et al. (2004) have classified the causes of the bullwhip effect as operational and behavioral. Detailed review of those causes is given in paperworks of Panić et al. (2014) and Panić (2015). Behavioral causes are: coordination risk, distrust, cognitive limitations, underweight the supply line, and personality characteristic. Personality characteristic which causes bullwhip effect are risk taking, ambiguity, self-efficiency, locus of control and cooperability.

Majority of researches proved that collaboration improves performance in the supply chain (Anthony, 2000; Quinn, 2000; Mentzer, Roggin, and Golicic, 2000 according to Poirier, 2002; Chopra and Meindl, 2001; Lapide, Derome, and Radjou, 2002; Barratt, 2004; Nix et al., 2004; Vereecke, Muylle, 2006; Mangan, Lalwani, and Butcher, 2008; Deloitte, 2008; Van de Vijver, 2009; Luo, Jiang, and Hu, 2010; Hudnurkar, Jakhar, and Rathod, 2014). As different authors differently define collaboration within this context, we specify collaboration as cooperative strategy of supply chain partners. Nyaga, Whipple, and Lynch (2010) in their endeavors to find factors that promote collaboration, emphasized trust, dependence, long term relationship, information and resource sharing. In one study (Panić, 2015) it is found that the more cooperative participants in supply chain achieve cost reduction. Also, it was shown that it was possible to organize supply chain consisting of more cooperative participants. In this study we try to prove that it is possible to change cooperability of the participants in the supply chain. For that purpose we use Johari Window model.

2. THE JOHARI WINDOW MODEL

The Johari Window model is a tool for illustrating and improving self-awareness, and mutual understanding between individuals within a group but it can also be used to assess and improve a group's relationship with other groups. The model was invented by psychologists Joseph Luft and Harry Ingham in 1955, while researching group dynamics at the University of California Los Angeles (Johari). Autors called their model 'Johari' after combining their first names, Joe and Harry. Johari Window model is used for understanding and training self-awareness, personal development, behaviour, interpersonal relationships, group dynamics and inter-group development, empathy, cooperation, improving communications, team development and similar 'soft' skills. The Johari Window actually represents feelings, experience, views, attitudes, skills, intentions, motivation, etc - within or about a person - in relation to their group or to represent the same information for a group in relation to other groups.

The Johari Window consists of four perspectives, regions, areas or quadrants (Figure 1) (Johari). Each quadrant represents the information about the person, in terms of whether the information is known or unknown by the person, and whether the information is known or unknown by others in the group. Standard representation of the Johari Window model shows each quadrant the same size. The Johari Window quadrants can be changed - in new groups the open space for each team member is small because shared awareness is relatively small (Figure 1a). As the team member becomes better known the size of the team member's open free area quadrant increases (Figure 1b).

Figure 1: The Johari Window

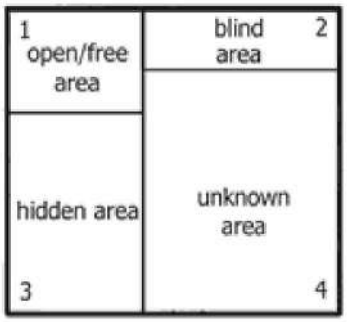

Figure 1.a: The Johari Window of a member of a new team or a person who is new to an existing team

Figure 1.b: The Johari Window of an established member of a team

The Johari window four regions are (Johari; Jalom, 2002):

- what is known by the person about him/herself and is also known by others - open area, open self, free area, free self, or 'the arena'
- what is unknown by the person about him/herself but which others know - blind area, blind self, or 'blindspot'
- what the person knows about him/herself that others do not know - hidden area, hidden self, avoided area, avoided self or 'facade'
- what is unknown by the person about him/herself and is also unknown by others - unknown area or unknown self

2.1. Johari quadrant 1 - 'open/free self/area' or 'public area', or 'arena'

Johari region 1 is also known as the 'area of free activity'. This is the information about the person - behaviour, attitude, feelings, emotion, knowledge, experience, skills, views, etc - known by the person ('the self') and known by the group ('others') (Johari; Jalom, 2002).

The aim in any group should always be to develop the 'open area' for every person, because when we work in this area with others we are at our most effective and productive, and the group is at its most productive too. This is the space of good communications and cooperation.

New team member starts with small open area because relatively little knowledge about the new team member is shared. The size of the open area can be expanded horizontally into the blind space, by seeking and actively listening to feedback from other group members - 'feedback solicitation'. Other group members can help a team member expand their open area by sensitively offering feedback. The size of the open area can also be expanded vertically into the hidden area by the person's disclosure of information, feelings, etc about him/herself to the group and group members. Group members can help a person expand their open area into the hidden area by asking the person about him/herself. Managers and team leaders can facilitate feedback and disclosure among group members or in directly giving feedback to individuals about their own blind areas. Leaders also have a responsibility to promote a culture and expectation for open, honest, positive, constructive communications, and the sharing of knowledge.

2.2. Johari quadrant 2 - 'blind self/area' or 'blindspot'

Johari region 2 is what is known about a person by others in the group, but is unknown by the person him/herself. By seeking or soliciting feedback from others, the aim should be to reduce this area and thereby to increase the self-awareness. This blind area could also be referred to as ignorance about oneself, issues in which one is deluded or issues that others are deliberately withholding from a person (Johari; Jalom, 2002).

Group members and managers can take some responsibility for helping an individual to reduce their blind area - in turn increasing the open area - by giving sensitive feedback and encouraging disclosure. Managers should promote a climate of non-judgemental feedback. The extent to which an individual seeks feedback, and the issues on which feedback is sought, must always be at the individual's own discretion.

2.3. Johari quadrant 3 - 'hidden/avoided self/area' or 'facade'

Johari region 3 is what is known to ourselves but kept hidden from others, and therefore unknown. This self represents anything that a person knows about him/herself, but which is not revealed for whatever reason. The hidden area could include fears, hidden agendas, manipulative intentions... It's natural for very personal information and feelings to remain hidden, but a lot of hidden information is related with work and so is better positioned in the open area. The aim should be to disclose and expose relevant information. By telling others how we feel and other information about ourselves we enable better understanding and cooperation. The extent to which an individual discloses personal feelings and information must be at the individual's own discretion (Johari; Jalom, 2002).

2.4. Johari quadrant - 'unknown self/area' or 'area of unknown activity'

Johari region 4 contains information unknown to the person and to others in the group. Large unknown areas would be expected in younger people, and people who lack experience or self-belief. Examples of unknown factors are as follows, and the first example is particularly relevant and common, especially in typical organizations and teams: an ability that is under-estimated or un-tried through lack of opportunity, encouragement, confidence or training; a natural ability or aptitude that a person doesn't realise they possess; a fear or aversion that a person does not know they have; an unknown illness; repressed or subconscious feelings; conditioned behaviour or attitudes from childhood (Johari; Jalom, 2002).

This information can be uncovered through self-discovery or observation by others. Counselling can also uncover unknown issues, but this would be known to the person. Whether unknown discovered knowledge moves into the hidden, blind or open area depends on who discovers it and what they do with the knowledge. The unknown area could also include repressed or subconscious feelings rooted in formative events and traumatic past experiences, which can stay unknown for a lifetime. In a work or organizational context the Johari Window should not be used to address issues of a clinical nature.

A team which understands itself - that is, each person having a strong mutual understanding with the team - is far more effective than a team which does not understand each other- that is, whose members have large hidden, blind, and/or unknown areas. Team members and leaders should always try to increase open areas and to reduce blind, hidden and unknown areas.

3. BEERGAME

Beer game was created as a part of the research of industrial dynamics in early sixties, by Sloan School of Management in Massachusetts Institute of Technology, to simulate performance of supply chain with one participant in each phase (Sterman, 1992).

Game is built up on the table representing beer manufacturing and distribution. Teams are formed to play game with the objective to minimize the expenses of whole supply chain. The winner is the team that finishes the game with minimal costs. Teams are divided into four sections: Retailer, Wholesaler, Distributor and Factory. Retailer comes to the wholesaler to buy beer. Wholesaler strives to satisfy the retailer`s demands from his supplies. Every unsatisfied order remains for subsequent period of time as backlog. Retailer asks from Wholesaler who orders from distributor, who refers to Manufacturer. Two time units (two iteration of simulation) are required for the product to pass from one participant to the other. Inventory holding costs are 0,50$ per case weekly, and backlog costs are 1$ per case weekly. Game starts from the state of equilibrium, which means that every participant has 12 cases of beer on stock, and initial demand is 4 crates in every phase. In first few weeks, participants learns about mechanisms of fill in the purchase order, creating backlogs and so on, and during that period of time demand is constant – 4 cases weekly. In first three weeks, participants can order only 4 cases per week, which is logical due to the fact that the demand is also 4 cases. At the beginning of the fourth week, participant can obtain unlimited amount of supplies, though it is pointed out that the demand of buyer could vary. One of his tasks is to anticipate the demand and to purchase accordingly. The total duration of the game is 50 weeks of simulation, but the desired effects are evident much earlier. Every participant has correct local information (about his inventory, backlogs, amount of supplies placed from his direct supplier each week and the amount of supplies he provided to other participant), but he has no insight into global information. Furthermore, communication between participants is not allowed.

Two groups (UN, CN) played according to the traditional beer game rule that each participant possesses only local information. Two other groups (UI, CI) were allowed to exchange whatever information they want. Game duration was 23 simulated weeks.

4. JOHARI`S BEERGAME: THE EXPERIMENTAL PROCEDURE

We simulated functioning of supply chain by playing partly modified beer game (Sterman, 1992). Participants in supply chain were 21 students of 3th year of Faculty of Organizational Sciences, voluntarily apply to take part in experiment. Firstly, they filled Social Value Orientation (SVO) questionnaire (Murphy et al., 2011; Murphy and Ackermann, 2012) and they were classified into cooperative or uncooperative subsample. Then, both groups were randomly divided into two subgroups, subjected to two different situational conditions. Consequently, we got four subsamples consisted from two different categories of participants, according to their individual proclivity toward cooperation, submitted to two different game rules, considering the interactional (communicational) circumstances. Those groups were:

- Uncooperative with information exchange not allowed (UN) – 4 participants
- Cooperative with information exchange not allowed (CN) – 5 participants
- Uncooperative with information exchange allowed (UI) – 7 participants
- Cooperative with information exchange allowed (CI) – 5 five participants

Each group represented one team who simulate one supply chain according to the established rules. Due to the fact that sample were students, game was renamed into a water supply game.

Due to the fact that the positions in Johari`s windows are different according to the level of mutual awareneess and familiarity developed during their common activities, there is an idea that it might indicate the behavioral change. So, we tested participants, before and after the experience of game simulation, by Johari`s methodology to see if there were any difference between their position.

In order to verify the hypothesis of possiblity to influence on behavioral change of participants in supply chainDa bi se ispitala hipoteza da je moguće uticati na promenu ponašanja učesnika u lancu snabdevanja u cilju povećanja kooperativnosti studenti su popunjavali Johari Window upitnik pre i posle simulacije.

4.1. Johari`s Beergame: Results of Experiment

There were an idea that the participants would be more ready to open toward each other and to receive feedback information, after the beergame simulation. It should be expressed through enlargement of public (open) self on behalf of blind and hidden self. Nevertheless, results indicate that different groups have different results. Each participant could gain total score between 24 and 120 on questionnaire, from 12 till 60 for self opening, as well as for readiness to accept feedback. Means for self enclosure and feedback sensitivity are given in Table 1.

Table 1. Results of Johari questionnaires before and after the beergame simulation

		CI			CN			UI			UN		
		M	**SD**	**N**	**M**	**SD**	**N**	**M**	**SD**	**N**	**M**	**SD**	**N**
oppenes	pretest	48.71	3.9	7	46.00	6.48	4	42.20	7.86	5	45.50	7.85	4
	retest	49.14	2.67	7	48.50	4.8	4	46.20	7.3	5	44.25	8.4	4
feedback	pretest	51.00	1.16	7	49.75	2.5	4	48.00	6.96	5	53.25	2.63	4
	retest	52.57	2.76	7	47.50	4.36	4	50.20	4.82	5	48.00	8.29	4
total	pretest	99.71	4.68	7	95.75	5.06	4	90.20	13.55	5	98.75	9.74	4
	retest	101.00	5.94	7	94.50	6.66	4	96.40	11.33	5	92.25	16.21	4

Comparative analysis of pretest and posttest effects is also given in Figure 2, 3. and 4.

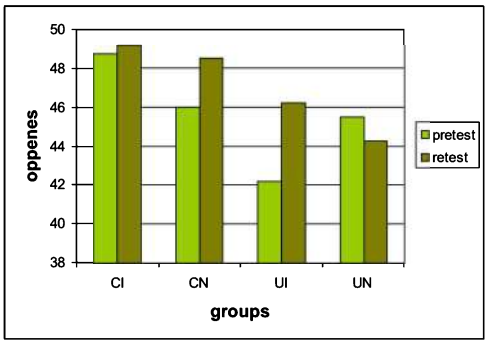

Figure 2: Enclosure before and after the simulation

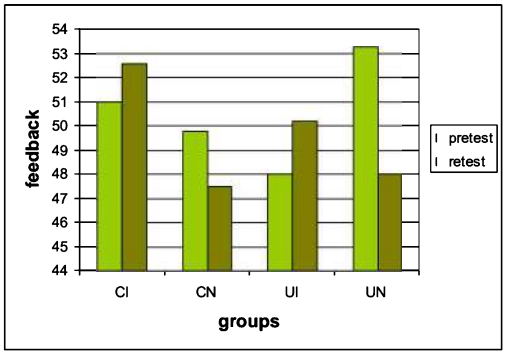

Figure 3: Feedback before and after the simulation

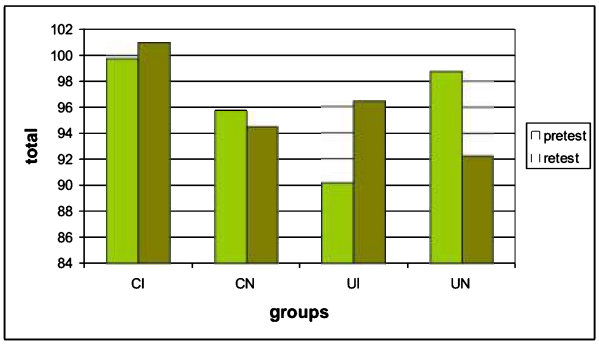

Figure 4: Total results before and after the simulation

Both cooperative groups (that were allowed to share information) (CI and UI), had expected results. That considered higher scores on self enclosure and feedback sensitivity after the simulation. CI group had heightened scores from 48.71 up to 49.14, while feedback sensitivity was increased from 51 to 52.57. UI group had higher self exposure, from 42.2 to 46.2, and more feedback sensitivity 46.2 instead of 42.2 before information sharing during the beergame simulation. Noncooperative group with no information sharing opportunity (UN) showed even reduced self disclosure tendencies (from 45.5. to 44.25), as well as the lack of readiness to receive feedback (from 53.25 to 48). Cooperative group with restriction of information sharing (CN) showed higher self enclosure, from 46, before to 48.5 after the simulation, but there were a lack of feedback sensitivity, that was 49.5 before and 47.5 after the experiment. Additionally, in this group sum of the results for self enclosure and feedback sensitivity after the game were lesser than before the game.

5. CONCLUSION

Significance of cooperativity for successful coordination in supply chain is well known fact. In the previous study of Panić (2015) less costs were found for more cooperative participants in supply chain and it was shown that it is possible to organize supply chain consisting of more cooperative participants. In this study we played beergame once again and we proved that it is possible to change cooperability of the participants in the supply chain. For that purpose Johari Window model were applied. This model gave us theoretical framework and methodological tool for indicating the level of openness and feedback sensitiveness of participants. Although we expected the overall amplification of the cooperative tendencies after the beergame simulation, i.e. after they familiarize with each other and spend some time together, results showed that there were different patterns of behavior among groups. It turned out that the results were dependent on conditions in which the game was played. Groups that were given the opportunity to share information enlarged their public self which is typical for members of well established teams. They also became more cooperative, compared to groups that had no chance to share information which is resulted in even more reduction of public self. There were possibilities that the circumstances in which information were hidden provoke distrust between participants with consequently reducing their willingness to cooperate.

As we could see from figures given in text, differences were rather small and no statistically significant, probably due to the short period of game duration. It might be assumed that the difference would increase and the results might gain on its reliability if only the simulation were last longer.

HUMAN RESOURCES AS THE INITIATOR OF HIGH VALUE ENVIRONMENTAL PERFORMANCES OF LOCAL GOVERNMENTS OF THE REPUBLIC OF SERBIA

Neda Nikolić[1], Vladan Paunović[1], Djordje Dabetić[2]
[1]Faculty of Technical Sciences Ĉaĉak, University of Kragujevac, Serbia

Abstract: *Human resources represent a significant potential for environmental improvement. Local governments of the Republic of Serbia face environmental problems and the problems of the potential and professional development of existing human resources. Studies in this field indicate that the organizational structure, ie.theimprovement of human resource management and environmental protection largely depends on the size of the local government. The discussed current HR architecture in local governments in the Republic of Serbia points to the necessity of a new strategic approach to environmental protection with human resources as a significant element of maximizing organizational performances in the field of environmental protection.*

Keywords: *human resources, environment, local government*

1. INTRODUCTION

Improving the quality of the environment in terms of local government of the Republic of Serbia is a permanent imperative and implies a strategic change and the necessity of its modeling in order to create an efficient, modern, professional, environmentally-oriented local government. No development-oriented organization can be imagined without quality human resources and their continuous improvement. "Performers of the overall activities of the organization, the people in charge, must be competent individuals with relevant working resources necessary to the organization or its individual businesses. The level of competence of individuals increases with the development of their abilities, skills and experience (Mihailović &Ristić, 2011)."Maximizing organizational and environmental performances involves directing human resources and is achieved by managing human resources.

"Human Resource Management in essence represents a new concept of relations between an organization and its employees and of managing their work and development. Its focus is no longer just employment jobs and labor relations, but also a whole series of activities created in the field of economy, organization and management using information obtained by the organizational sciences, psychology, sociology, communication science, technology, informatics... Human resource management is a subsystem of functioning of the organization, which includes the selection and implementation of goals and policies through planning, organization, management and control of activities related to human resources toward achieving the goals of the organization (Mihailović ,*Human Resource Management,* in press)."The impact of human resource management on organizational and environmental performances is important, but the mechanisms of influence are not sufficiently clear. This suggests additional research effort in the field of environmental protection to propose an operational model of HRM activities with the possibility of its successful implementation in local governmentsof the Republic of Serbia.

Strategic planning of human resource management involves the planning of organizational personnel, their knowledge and skills, training in the field of environmental protection in order to conduct human resources of the organization through a network of social relations, and transfer it into a common interest in protecting the environment and into improving the performances of local government. Strategic management is a broader concept than the strategy itself. This is the process of implementation of the strategic plan by aligning theorganizational opportunities with changes in the environment. The process of

strategic management is closely linked with human resources. On the basis of strategic choices, the necessary human resources are defined,the capabilities and actions of which will define the implementation of the strategy and, ultimately, the outcome itself. The importance of human resources strategy for the European Union is clearly seen in the fact that at the request of the French Presidency Ernst & Young conducted a survey that provides the European Union with an overview of current changes in the world of human resources, giving hints about what we might expect in the future. The results are based on replies in a questionnaire issued in September 2008, in which more than 300 executives from 26 countries were surveyed. The research for this report assessedthe contribution to the strategic processes. The results indicate that 3/4 of respondents believe that the management of human resources is associated with the strategic goals of public administration (Student Assessment in Human Resources Management, 2008).

Local governments in Serbia have no clearly defined human resources management strategy and have their compliance with environmental protection at an even lesser degree. Differences in approaches and strategic orientation thereof stem from the size of local governments. The notion that human potential of a local governmentis an integral part to successful strategy of preservingthe environment leads to the necessity of reviewing the general strategy of each local government in terms of its uniqueness and specificity. "Our instructive consideration includes the relationship between the overall organization development strategy,its human resource management subsystem (the intervening variable) and the performance achieved by the organization. This series is already known in theory and current research in this area asthe RBV model (Resource-based view), which is supported by most current and recent research projects. Many researchers (Pertusa-Ortega et al., 2010; Collins and Clark, 2003; Hayton, 2003; Kim and Gong, 2009) have tried to discover a number of specific configurations between strategy, HRM and performances, but the notion pervades that this goal is currently unattainable. The optimal position is that any data configuration of a model has its topicality and is unique at the time of conception, but also that it should be constantly changed and adapted over time. (Mihailović, *Human Resource Management*, in press)."

"Management of human resources in environmental protection, in addition to a direct impact on the improvement of the environment, has significant impact on overall performances of the organization. Studying the cause-and-effect relationships between strategy, HRM and performances (Boseliea, 2001, Combs, 2006; Huselid, 1995), it can be concluded that a HRM unit via influence of human and social capital positively affects the performances of a local government. For this reason, the process of human resource management in environmental protection of the local governments involves the maximization of human capacities with a central tendency of enlarging the capabilities of a local government by strengthening human and social capital. It is important to emphasize that the local governmentsof the Republic of Serbia are to a large extent dormant and sluggish organizations with a significant proportion of unused human resource capacity, which requires revision of human resources. "Harington (2003) brought evidence that many organizations in their functioning only use 20% of the capacity of human resources. This means that in many companies there is 80% of formal potential burdening companies with costs, making them inactive or insufficiently active in the realization of strategic objectives. The implication that we can consider current and topical is that there is significant room for improving human resources. Using a series of derived data, Huselid (1995) argued that improving human resources can positively influence organizational performances. Human Resources (HR) and Human Resource Management (HRM) have a strategic importance being a potential value and having a central position in the creation of an entity's capabilities (organizational capabilities) responsible for their competitive advantage in market competition (Ulrich and Lake, 1999, Tuan and Takahashi, 2009).(Mihailović, *Human Resource Management*, in preparation)."

Bearing in mind human resources as drivers of high environmental performance of local government in Serbia, we have designed research and determined the relationship between variables and influence factors on the organizational peculiarities of local governments in the field of environmental protection.

The subject of the research is to analyze the relationship between organizational characteristics of human resource management and protection of living and working environment in the local self-governments in

Serbia. Key factors of the subjects of investigation are characteristic organizational forms and their dependence on the size on local government.
The aim was to determine the factors and how they affect the processes in living and working environment, human resources and their development in local governments. Based on the set of objects and the research objectives and in compliance with current theoretical platform, a hypothesis was formulated:

H. - 1. Organization of human resources engaged in theoretical conducting of environmental and labor protection in local governments depends on the size of the local communities.

2. RESEARCH PROCEDURE

The research problem is related to a very current area of environmental management at the regional level and its narrower segments - local government units (JLS). Problem focus of the research is oriented towards the respect of key resources - human resources whitch are involved in the environmental management of local self-governments depending on their size.

The collection of data required for checking the hypotheses put forward in the research project, was conducted by the method of testing as the basic method of research, which is a common phenomena of this nature. In this study, such a method was applied as a most commonly used and most effective techniques - interviewing. The research process was conducted is appropriate by an specially designed instrument-questionnaire technique implemented individual interviews respondents. Attitude management of local governments on the issue of internal characteristics and factors of human resource management JLS, was realized using specially designed indoor electronic questionnaire. Questions are classified into groups and administered in the form of „Likert-type scales“, with five offered answers to every question.

The procedure of processing the obtained data was performed using standard procedures and parameters of descriptive statistics and inference. The data are classified and processed using the software package SPSS. For the establishment of the level were used of tested characteristics and their description, descriptive statistical indicators, such as measures of central tendency (mean, median, mode) and measures deviation (standard deviation, and skjunis kurtozis), and frequency response. For testing the connection between the variables, the data in the further processing of the correlation parameters are derived (c coefficient), and tested by standard method of application $\chi 2$ test and its significance DF (with specified threshold of significance, α - usually 0.01 or 0.05).

A research conducted in the Republic of Serbia in the period from March to June 2015, on a sample of the predicted **N = 145** respondents - local governments, reduced to **n = 105** respondents (number of returned questionnaires was 108; the number of respondents who responded to the questionnaire in a very appropriate way was 105; the number of invalid questionnaires was 3). 105 respondents,a number which makes 72.41% of the total number of respondents (N = 145), is sufficient enoughfor processing and drawing valid conclusions of the research process according to statistical postulates. Testing internal factors of human resource management in the units of local governments was realized by using an instrument for data collection in the form of a closed electronic questionnaire, divided by groups of questions.

3. RESEARCH RESULTS

Local governments were classified into five net indicators by numbers of inhabitants a) in municipalities with less than 20 000 inhabitants (the first indicator); b) municipalities with over 20 000 and less than 60 000 inhabitants (the second indicator); c) municipalities with morethan 60 000 and less than 100 000 inhabitants (the third indicator); g) municipalities with more than 100 000 and less than 150 000 inhabitants (the fourth indicator) and d) municipalities with more than 150 000 inhabitants (the fifth indicator). A tabular presentation of the sample is found inTable 1.

Table 1: Overview of the sample-to-population units of local government / municipality

Size of municipality		
	f	**%**
Less than 20 000 inhabitants	47	44,8
From 20 000 to 60 000 inhabitants	36	34,3
From 60 000 to 100 000 inhabitants	7	6,7
From 100 000 to 150 000 inhabitants	10	9,5
More than 150 000 inhabitants	5	4,8
Total	105	100,0

Starting from the assumption that the organizational structure of human resources and environmental protection depends on the size of the local government, by using the χ^2 test we will check the set statement (Table 2).

Table 2: Frequency of responses and the χ^2 local government size and organizational structure of local government test

		Local government size In number of inhabitants								
		Less than 20 000 inhabitants	From 20 000 to 60 000 inhabitants	From 60 000 to 100 000 inhabitants	From 100 000 to 150 000 inhabitants	More than 150 000 inhabitants	Σ Φ	χ^2	df	p
Whether a service for the development of human resources exists at the local level	fyes	3	5	0	3	3	14	15,245	4	0,004*
	fno	44	29	7	6	2	88			
Whether there is a service for planning, development and environmental protection at the local level	fyes	18	16	7	9	5	55	20,955	4	0,000*
	fno	29	19	0	1	0	49			

*significant at the level of significance 0,01 ($p < 0,01$)

The results show that the χ^2 test is statistically significant for the existing organizational structure of the local government ($p < 0.01$) in functional areas of the existence of services for the development of human resources and the services for planning, development and environmental protection. For these reasons we reject the zero hypothesis stating that there are in no way connected with the size of the local government.

Due to this claim, further analyses have been made to determine the correlation between the size of the municipality and the stated characteristics of the organization for which the χ^2 test is statistically significant, whereby the coefficient of contingency (C- coefficient) was used. In Table 3 the χ^2 values and the contingency coefficient values are isolated.

Table 3: χ^2 size contingency coefficient of local government and of the organizational structure of local government

	χ^2	df	p	c
Department of Human Resource Development	15,245	4	0,004	0,36
Department for Planning, Development and Environmental Protection	20,955	4	0,000	0,41

As it is known, the contingency coefficient "moves" ranging from 0 to 1 (the closer to 1 the coefficient value is, the higher the correlation of variables). Since the values of obtained contingency coefficients, the statistical significance of is determined, range from 0.36 to 0.41, one can conclude that the correlation they refer to is moderate.

For a better understanding it is useful to look at the following picture derived from performed analyses.

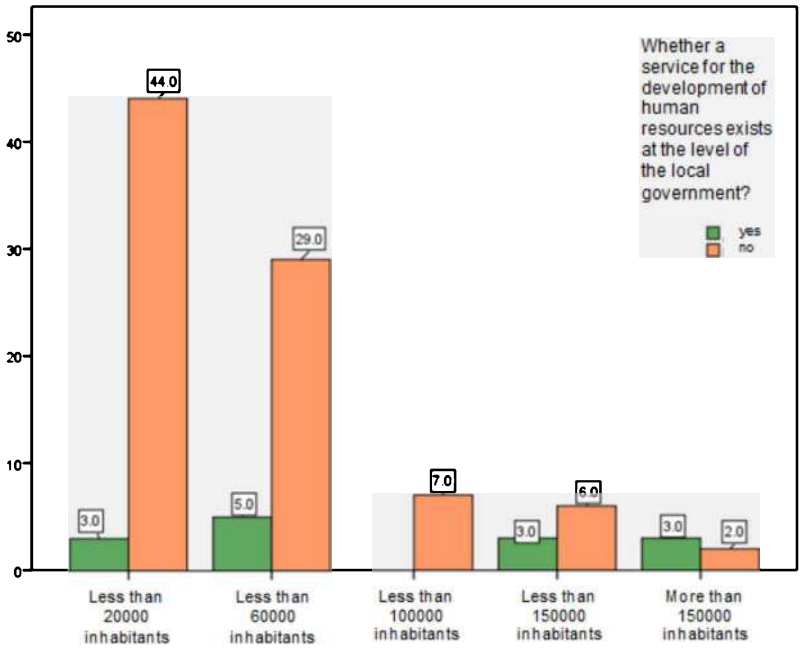

Figure 1: Correlation between the size of local government and the existence of services for human resource development

We see that the lack of services for the development of human resources is more prominent the smaller local governments are. It is necessary to bear in mind that in a total of 73% of local governments in the category of up to 60 000 inhabitants there is no human resource development service. It is interesting to note that none of the local government of 60 000 to 100 000 inhabitants there is no service for the development of human resources. Among local governments of over 150 000 inhabitants there is a higher percentage of those who have established a service for the improvement of human resources.

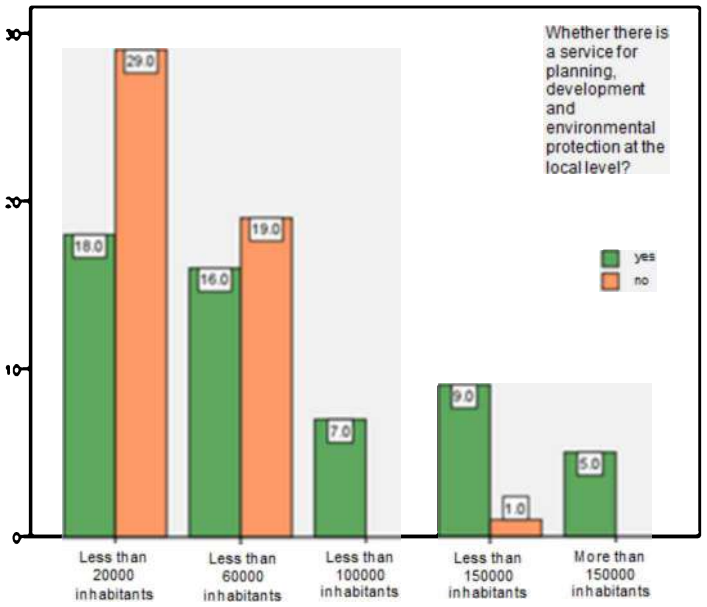

Figure 2: The correlation between the size of local government and the existence of services for planning, development and environmental protection

From the attached graphic it can be seen that in local governments with 60 000 inhabitants or less, a higher percentage of them has no established service which deals with planning, development and environmental protection. It is significant that all local governments of more than 150 000 inhabitants have a service for improving the environment in its organizational structure.

4. CONCLUSION

Human resource management in environmental protection applied with a view to mitigating or eliminating environmental externalities and to supporting the creation of sustainable development with people as the most important factor is the current strategic approach of local governments of the Republic of Serbia. Crucial support of strategic performances that are marked as successful consists of internal analysis and constant review of human resources management in the key success factors of functioning of local government, of which *the factor of environmental protection stands out in its importance*. The size of local government is one of the factors that determine the introduction of the new strategy, organizational structure modeling and business process improvement. The analysis of the results obtained during the verification and inductive set hypotheses implies that the involvement of human resources to preserve and improve the quality of life and working environment within the units of local sef governments depends on the size of local government. For this reason, we conclude that the organization of human resources engaged in the preservation and improvement of living and working environment must be adapted to the size and uniqueness of each local government.

FORMER SOLDIERS' ATTITUDES TOWARDS ACTIVE RESERVE SERVICE

Nebojsa Nikolic[1]
[1]Strategic Research Institute, Ministry of Defence
*nebojsa2008_g@yahoo.com

Abstract: *Personnel recruitment for armed forces is based on voluntary principle and contractual regulations of mutual obligations between the military organization and citizen who willingly decide to become a member of armed forces. This recruitment approach brings respective level of unpredictability and randomness in the process of man-powering of military units. Concept of Active Reserve is an answer to the challenge of sustainment of military units' readiness. The most desired candidates for Active Reserve positions in military units are former soldiers. That is, those people are already trained and have personal experience of how the military works. One of the most important questions is related to the motivations and propensity to serve in the military. This paper presents some results from conducted empirical research on the issues of motivations and propensity of potential candidates to apply for temporary military service through the mechanism of the Active Reserve.*

Keywords: *military, manpower, organization, motivation, reserve forces, management*

1. INTRODUCTION

Manpower structure of modern armed forces assumes two general categories: active and reserve personnel. Active personnel are those in military service who actually works for the military organization. Reserve personnel are all others who are in the evidence of the appropriate military recruitment bodies. However, they are not in military service at the moment. Military reserve personnel are called to duty only in cases of war, emergency situations or for training purposes. With suspension of conscript recruitment system and transition towards all-volunteer-force concept, military organizations have been faced with the need for additional tools for quick, efficient and effective fulfilment of empty posts in some military units. In order to manage that challenge, military organizations "invented" a specific kind of reserve soldiering status that assumes higher level of readiness, ability and will to respond to the call of duty in a short term. This mode of engagement is called the Active Reserve (in Serbia), while there are another terms in other countries.

Issues of reserve forces are actually in other countries too, particularly in the Europe. The reason for that is fact that majority of European states have made transition from conscript system and mandatory military service towards professional military forces based on voluntary system. It was happened in relatively short period of last decade of 20th century and up to now, Szvircsev (2014). To mention some of that states and date (year) when suspension of mandatory military service was put in charge: Belgium (1993), France (1996), Holland (1996), Slovenia (2002), Hungary (2004), Macedonia (2006), Bosnia and Herzegovina (2006), Romania (2007), Croatia (2007), Bulgaria (2008), Serbia (2010). Few countries which made this conversion of recruitment system much earlier than others and lead the change are the United Kingdom (1960) and the United States of America (1973). Fortunately, they have gained respective experience in dealing with various new challenges related to problems of manning an professional army and made data available, Keene (2015). Lessons learned and experience on the topic from those countries that have started earlier with professionalization and conducted new recruitment methods are very valuable and useful for many newcomers in the problem.

Reserve components itself have respectable importance, particularly when armed forces are engaged in large scale operations, for example USA armed forces in the First Gulf War, Pagonis (1992), or in a long period under high tempo of activity like Israeli Defence Forces, Catignani (2004). Reserve component is inevitable when so called "war army" structure and composition is considered Petrovic (2007); or when armed forces got the pressure from the side of engagements in international mission Sedivy (2013). Besides concept of Active Reserve seams as an efficient solution it also comes under testing towards the cost-benefit analysis Alock et all (2014). Issues about indicating the level of propensity and motivations to serve are of particular importance: Taylor et all (2015), Wiggins et all (2014), Griffit et al (1991), Nikolic (2015).

Concept of the Active Reserve could be perceived as an agility shift of the modern military organization who tend to obtain reliable mechanisms for sustaining manpower strength in a given external circumstances, limitations and available resources. Concept of agility is recognized among researchers in the military but is

also popular in the business area. Definition of the Agility Shift as it is proposed by Meyer (2015) is as follows: “The Agility Shift is the intentional development of the competence, capacity, and confidence to learn, adapt, and innovate in changing context for sustainable success.”

This definitional perception of agility fits well in the context of concept of the Active Reserve (AR). The AR concept comes from clear intention of the military organization to create additional channel for sustainment of its manpower strength level at desired level. It is adaptation of organization towards ambivalent issues of higher readiness level and limiting costs of it. Also, concept of AR is innovative one in comparison with traditional way of obtaining professional soldiers. It is innovative as well, particularly in changing context of contemporary security threats and challenges and corresponding new roles and missions for the military organizations.

2. ESTABLISHING ACTIVE RESERVE CONCEPT

Concept of Active Reserve is known in domestic defence context for almost a decade, but its full implementation in practice started in the middle of 2014, while during the 2015 started the process of selection of candidates for first contingent of one hundred future active reservists. Also, in the second part of 2014 started an empirical research on the topics of motivation and propensity of the population to serve in the status of Active Reserve. Part of that empirical research was dedicated and oriented towards the population of “former soldiers”.

Under term “former soldiers”, here we consider those people which already have experienced military organization and military life through the mechanism of mandatory military service that existed in the past before canceling conscription and introducing voluntary principle for military service. In the past, all male citizens have to serve obligatory term in the military organization and after that all of them are considered as potential candidates (reservists, passive reserve) for manning various military units in case of war. Some of those reservists are drafted and scheduled for duties in a so called “war units” that are in their essence reserve military units (“war units” or reserve military units are additional military forces that are formed in a case of war), and they are used to be called from time to time for training purposes and checks.

This kind of reserve personnel is the most desirable to be seen as applicants for the Active Reserve group. The reason is evidently based on perception about their experience in dealing with military organization: they have got basic and advanced military training through mandatory military service, and after that they gained additional experience from their temporary engagement in reserve military units where they are supposed to be called periodically for training and evidence updating. Also, they are expected to be more qualified for some jobs due to their professions and working experience in civilian life. This category will be further marked as: RSDSRU, which stands for: Reserve Soldiers Drafted and Scheduled for Reserve Units. The second group that is considered in this research presents former soldiers who just finished their mandatory military service, but have not been engaged in reserve units. This category will be further marked as: RSWSRU, which stands for: Reserve Soldiers Without Schedule in Reserve Units.

3. RESULTS OF EMPIRICAL RESEARCH

Empirical research has been conducted by researchers of Strategic Research Institute of the Ministry of Defence of the Republic of Serbia (MoD) with grateful support of other parts of MoD. Media support has been offered by Department for Public Relations, while main support in the field came from the Military Duties Department (MDD) which is responsible for tasks related to: defining measures and plans for engagement of citizens, companies, government authorities in a case of emergency and war; as well as to issues of military obligations, work and material obligations, and other tasks (for more see: http://www.mod.gov.rs/). In fact, MDD network of offices across the country were essential for successful interviewing respective number of participants in a very short time.

Questionnaire itself was created under influence of at least three factors. First, it is designed in a way to enable collection of appropriate data that could satisfy requirements that have been given at the very beginning. Second, findings and lessons learned from other similar research have been used and that contribute to efficiency of our efforts. And third, internal revisions of the draft version of the questionnaire have been used in iterative way in order to improve final document. Final form of the questionnaire contains questions grouped as follows: General data -ten questions; Information sources –four questions; Propensity to join the Active Reserve –two questions; Motivations to join the AR –fourteen questions; and Self-assessment -four questions.

Planning and realization of this empirical research was performed with full respect of the following principles: unconditional voluntarily participation and full anonymity of participants. Those two principles are fundamental because they are preconditions for frankly responds of participants. Randomness of the sample is achieved by random choice of time (period of performing empirical research) and territorial determinants (whole territory of the country).

Empirical research was realized and we have got results from 403 participants in total. In this sample there were 113 persons from RSDSRU category (Reserve Soldiers Drafted and Scheduled for Reserve Units), who were willing to fulfill the questionnaire. In conducted empirical research there were 290 persons from RSDSRU category (Reserve Soldiers Without Schedule in Reserve Units), who were willing to fulfill the questionnaire. Comparative views of findings from empirical research for both categories of former soldiers are arranged in the following tables.

Table 1: Age structure of respondents (%)

Category Age	RSDSRU (%)	RSWSRU (%)
Up to 25 years	2	9
26 to 32 years	19	38
33 to 40 years	25	34
41 and above	48	13
Not declare	6	6

Table 1 presents age structure of participants and differences between the two groups are evident. The most frequent age for the RSDSRU is 41 years and older (48%), while in the RSWSRU dominate age from 26 up to 32 years (38%). From data in Table 1, few things are evident. Age structure in category RSDSRU is not promising, because almost half of responders are too old to join the Active Reserve (there is an age limitation for joining the AR), however, their view, motivation and propensity are valuable indicator for some broader analysis because of the most valuable experience they are possessing in comparison to other category. Situation is much better with other category, RSWSRU.

Table 2: Educational level structure of respondents (%)

Category Ed.level	RSDSRU (%)	RSWSRU (%)
Elementary school	2	14
High school	66	68
Higher School (BA)	11	7
Faculty (Graduated)	21	10
Not declare		1

Table 2 gives insight into educational structure of participants. In both categories persons with high school level dominate (66% and 68%), while faculty graduates in the RSDSRU are to times better (21%) then the RSWSRU (10%). However, it is sad that in younger category of RSWSRD there are seven times more people with the elementary school than it is a case in the older one (2% against 14%). Educational indicators are in concordance with findings about employment status: the RSDSRU a group of older, but better educated population (67% employed) wins the RSWSRU a group of younger, but lower educated group (40% employed), Table 3.

Table 3: Employment status of respondents (%)

Category Age	RSDSRU (%)	RSWSRU (%)
Un-employed	31	53
Employed	67	40
Not declare	2	7

Table 4 gives answers on direct questions about propensity to serve in the Active Reserve status for two cases: service in the country, and, service in missions outside the country. Both groups showed relatively low level of interest for joining the Active Reserve military service. Average marks as estimations about level of propensity to join the Active Reserve, on the scale from 1 (absolutely not interested for joining AR) up to 5 (very interested to join), are not encouraging at all (2,83 and 3,47), particularly for the second question ("missions abroad") where results were only 2,48 for older, more educated and more employed population (RSDSRU), while results for the other group are something better but is still far from very good.

Table 4: Propensity to serve in AR

Category Mission	RSDSRU (on the scale 1-no to 5-yes)	RSWSRU (on the scale 1-no to 5- yes)
In the country	2,83	3,47
In missions abroad	2,48	3,20

Finally, empirical findings related to the possible motivational factors for joining the Active Reserve are presented in Table 5. In some sense this findings are expected particularly for the more experienced, more educated and more employed group (RSDSRU). This category of population is more realistic and objective, illusion-free, more informed and so on. The first motive is patriotism, than follows: money, getting new knowledge and earning new qualifications. This motivational constellation is not strange as it look like at the first impression. Possible explanation (at least for the author) could be as follows: this mature group is not too much interested in military service at all (Table 4 results), they realize practical benefits from potential engagement (money, knowledge, qualifications) however, primary factor for potential joining, would be patriotism. In any case, those findings are in favor of the Serbian Army as an entity closely perceived with patriotism, but also as a good employer which is able to offer good knowledge and additional qualifications, as well as to give fair money for work and engagement.

Table 5: Motivations ranks to join the AR

	MOTIVES	RSDSRU	RSWSRU
1.	Patriotism	1	1
2.	Money	2	2
3.	Getting new knowledge	3	5
4.	Earning new qualifications	4	4
5.	Care for peace	5	3
6.	Getting to know new people	6	8
7.	Family tradition	7	6
8.	Arms fan	8	9
9.	Military life fan	9	7
10.	Curiosity	10	11
11.	Oportunity to travel	11	10
12.	Adventurism	12	12
13.	Health insurance	13	13
14.	Opportunity to give orders	14	14

4. CONCLUSION

Modern armed forces are deeply dependent on its reserve personnel. This is particularly true for professional armies whose manpowering is based on the voluntary principle. Motivational issues of the population to join military service, in this case Active Reserve, have very high importance for overall process of obtaining personnel for military units with principle of voluntary recruitment.

Conducted empirical research offers results for one of the most desirable group for recruitment for military Active Reserve and those are former soldiers with more or less additional military experience. Findings on motivation to join the Active Reserve are in favour of the Serbian Army as an entity closely perceived with patriotism, but also as a good employer which is able to offer good knowledge and additional qualifications, as well as to give fair money for work and engagement. Level of propensity to join Active Reserve is better for younger population of the sample, than for the older one.

THE MAIN MOTIVATING FACTORS FOR SOMEONE TO TAKE UP ENTREPRENEURSHIP

Ivana Milinković[1], Ivana Kovačević[1], Dobrivoje Mihailović[1]
[1]Faculty of Organizational Sciences
Corresponding author, e-mail: i.milinkovic93@gmail.com

Abstract: *Managers and entrepreneurs both play an important role in the business community. Many of them share some of the same characteristics, but some differences exist when it comes to the basic traits of each. One of the differences is in the way of their motivation which we try to explaine in this paper through Self-determination theory that include autonomous motivation and controlled motivation.*
The purpose of this paper is also to present relationship between entrepreneurship and motivation and how human motivation might influence the entrepreneurial process. Study of the entrepreneurial process and entrepreneurs motivation is important because it drives innovation and technical change, and therefore generates economic growth. The main point of discussion is motivational differences, variations across people in their perceptions of risk and opportunity which influence entrepreneurial decisions.

Keywords*: Motivation, autonomous motivation, controlled motivation, managers, entrepreneurs, motivating factors*

1. INTRODUCTION

How and why entrepreneurs formulate business ideas and choose their business ventures is a subject of continuing study. We can observe motivation ~~-as~~ the inner state that energizes activities or action and directs or channels behavior towards the goal" (Asagwara, 2000). The main question is where do entrepreneurs get so much motivation, where does it come from? What is the difference between people who always seem to have so much motivation and energy, and others who struggle with just getting the first page of a business plan written?

Newly created enterprises increase the dynamism of economies and generate employment. The SME sector in Serbia recruits 53.3 percent of total employment, 60.7 percent of total investments, realizes 77 of exportation and participates with around 61.6 percent of the GDP (Chamber of Commerce and Industry of Serbia). Since they have such a big impact on the economy, they are the object of growing research interest. Focus is on entrepreneurs who form a new company. The first step is to make a decision about forming a new company, which is based on both personal and subjective motives. Founder's motivation represents a commitment to a project or business idea, and affects the development and success of the company in the future (Sánchez, Sahuquillo, 2012).

In this paper, we suggest how human motivation might influence the entrepreneurial process. Through self-determination theory we would like to explain the differences between autonomous motivation and controlled motivation. Our assumption is that autonomous motivation is more pronounced among entrepreneurs and controlled motivation among managers. With this assumption we do not want to exclude the fact that all human actions are the result of both motivational and cognitive factors, and that also includes ability, intelligence, and skills (Locke,2000).

2. SELF-DETERMINATION THEORY (SDT) – AUTONOMOUS AND CONTROLLED MOTIVATION

As a macro theory of human motivation, self-determination theory (SDT) suggests that people are motivated by a need to grow and gain fulfillment. Their activities are directed toward personal development, life goals and aspirations, self-regulation, energy and vitality and need to gain knowledge or independence (Deci, Ryan, 2008).
The self-determination theory identifies three key psychological needs that should be satisfied to raise well-being and health. Also, according to the theory, people need to feel the following in order to achieve psychological growth, but some of these needs may be more salient than others at certain times or expressed differently based on time, experience or culture. These needs can be universally applied.

- **Competence** - Seek to control the outcome and experience Master (White, 1959).
- **Relatedness** - Universal want to interact, be connected to, and experience caring for others

(Baumeister, Leary, 1995).

- **Autonomy** - Need to feel in control of own behaviors and goals. This does not mean to be independent of others (Deci, Vansteenkiste, 2004).

The most important difference in self-determination theory is between autonomous motivation and controlled motivation. Our assumption is that the autonomous motivation is more common with entrepreneurs while controlled motivation is typical for managers.

2.1. Autonomous motivation

Autonomous motivation can be defined as a set of intrinsic motivation and some types of extrinsic motivation in which people integrated a value of an activity into their sense of self (Deci, Ryan, 2008), more specifically as the motivation to work on something because it is interesting and personally challenging. An entrepreneur is a starter, an individual whose main goal is to start a business by setting up an enterprise. He starts the business for his personal gratification, and become the leader responsible for the destiny of the venture.
Intrinsic motivation is form of autonomous motivation. Intrinsically motivated peoples work for passion, pleasure, and interest. Intrinsic motivation correlates with proactive engagement in work (Gagne, Deci, 2005) and high levels of psychological health (Baard, 2004; Deci, 2001).

An entrepreneur is a person in charge with direct financial benefits, but also assumes all risks involved in running the enterprise. One of the most frequently asked questions is ~~-w~~what motivates an entrepreneur to take all the risks and start a new business?" In the most cases, the answer is an ~~-e~~ntrepreneurial obsession". The most successful entrepreneurs are not also the most talented, but the one who have ideas, see an opportunity, and find out what customers want. They have conviction and believe in their ideas. The main reason for an entrepreneur to start a business enterprise is his individual satisfaction and opportunity to create a new environment, create something from scratch, meet new people, build a team and create a jobs.

This theoretical approach of understanding the motivation that drives entrepreneurs can be confirmed through numerous examples from practice. One of the successful entrepreneurs is Robert Mondavi, who felt ~~-r~~eborn" after starting the winery that bears his name. ~~-I~~was like a kid again, bursting with energy, ready to climb the mountain, conquer the world, go for the gold. Yes, at the unlikely age of fifty-two, the great adventure of my life had finally begun" (GCASE – Global Community for Advancing Studies on Entrepreneurship). This approach and the type of motivation is the opposite of being extrinsically motivated. Extrinsic motivation means being motivated by expected evaluation, external rewards such as money, fame, and praise, and it leads to a decrease in intrinsic motivation. Entrepreneurs do what they love, and they love what they do (GCASE).

2.2. Controlled motivation

Deci and Ryan (2008) defined controlled motivation as a function of external contingencies of reward or punishment. Regulation of action is energized by factors such as an approval motive, avoidance of shame, contingent self-esteem, and ego-involvements (Deci, Ryan, 2008). In cases when people are controlled, they might to feel pressure to think or behave in particular ways. Controlled motivation can also be defined as a desire to transfer learning that is not initiated and governed by the self (i.e. regulated by external rewards or sanctions) (Deci, Ryan, 2008).

A manager is a person who is a servant in the enterprise owned by the entrepreneur, but he or she does not bear any risk involved in the enterprise. Every month a manager gets fixed salary as the reward for the services rendered by him in the enterprise. A manager is a part of controlled work environment which diminish employees experiences of autonomy, competence, and relatedness. Externally regulated managers see workplace rules as externally imposed, what limits their passion and desire for change, and their only motivation is to obtain rewards such as praise, promotions, and financial benefits. Typically top managers instead of using motivation in the workplace to inspire people to work better, they believe in the idea that ~~-p~~ressure makes diamonds". There is also a believe that if you want exceptional performance, you align employee objectives with end-of-year bonuses for hitting certain milestones and then employees will turn up their work ethic to reach them (Tim Olson, Olson group).

Regarding points of distinctions, we can conclude that an entrepreneur differs from a manager and that different thing motivates them. A manager is someone good at execution. Typically managers follow a business plan, or strategic plan, which they may or may not have had any say in developing. The entrepreneur has an idea for a new business. Entrepreneurs are independent thinkers, brave enough to take risks and put ideas into action. All this differences influence on their motivation and goals. In this paper, we

would like to put the focus on entrepreneur motivation and entrepreneurship because newly created enterprises increase the dynamism of economy and generate employment, and that could be one of the way of reshaping the future- through entrepreneurship.

3. MOTIVATIONAL CONCEPTS THAT DRIVES ENTREPRENEURS

No two entrepreneurs are alike and there is a range of factors which could inspired them to take the leap and start a business. One of a judge for Ernst and Young's Entrepreneur of the Year (EOY) Award Program, Jack Stack, said that their inspiration and motivation is evident in their appearance and behavior - "You can see it in their eyes. You can see it in their confidence. You can see it in the way they talk" (GCASE). Entrepreneurs are creative and willing to take risks especially if they know they can influence the outcome of the event. They have great vision of commitment, vision, and passion. They are idealistic and optimistic, innovative, aggressive, and intensely focused.

Study of the entrepreneurial process and entrepreneurs' motivation is important because it drives innovation and technical change, and that leads to economic growth (Schumpeter, 1934). Entrepreneurial action is the process through which supply and demand are equilibrated (Kirzner, 1997). Also, we can observe entrepreneurship as an important process by which new knowledge is converted into products and services (Shane & Venkataraman, 2000). It has become an important vocation, and has important role in the development of human and intellectual capital (Zahra & Dess, 2001).

Motivational differences in many ways influence on entrepreneurial process. One of the things that have an effect on entrepreneurial process is variation across people in their perceptions of risk and opportunity (Shane & Venkataraman, 2000). People vary in how they view the risk of expending resources before knowing the distribution of outcomes (Palich & Bagby, 1995). At the entrepreneurial process the probability of success is low. Only those people who are willing to precede despite these odds might be more optimistic or higher in self-efficacy than people deterred by these odds.

Through the example of an entrepreneurial process and motivational concepts that are defined by Scott Shane, Edwin A. Locke and Christopher J. Collins in the paper "Entrepreneurial motivation", we will try to explain motivational concepts that drive entrepreneurs. Also, Ivan Bjelajac COO at Devana and one of the most successful Serbian entrepreneur explained on his example how he see the different motivational factors, and what drives him through his entrepreneurial career.
There is a set of human motivations that psychologists have shown to influence many aspects of human behavior. These include the motivations, nAch, and the locus of control, desire for independence, passion, and drive.

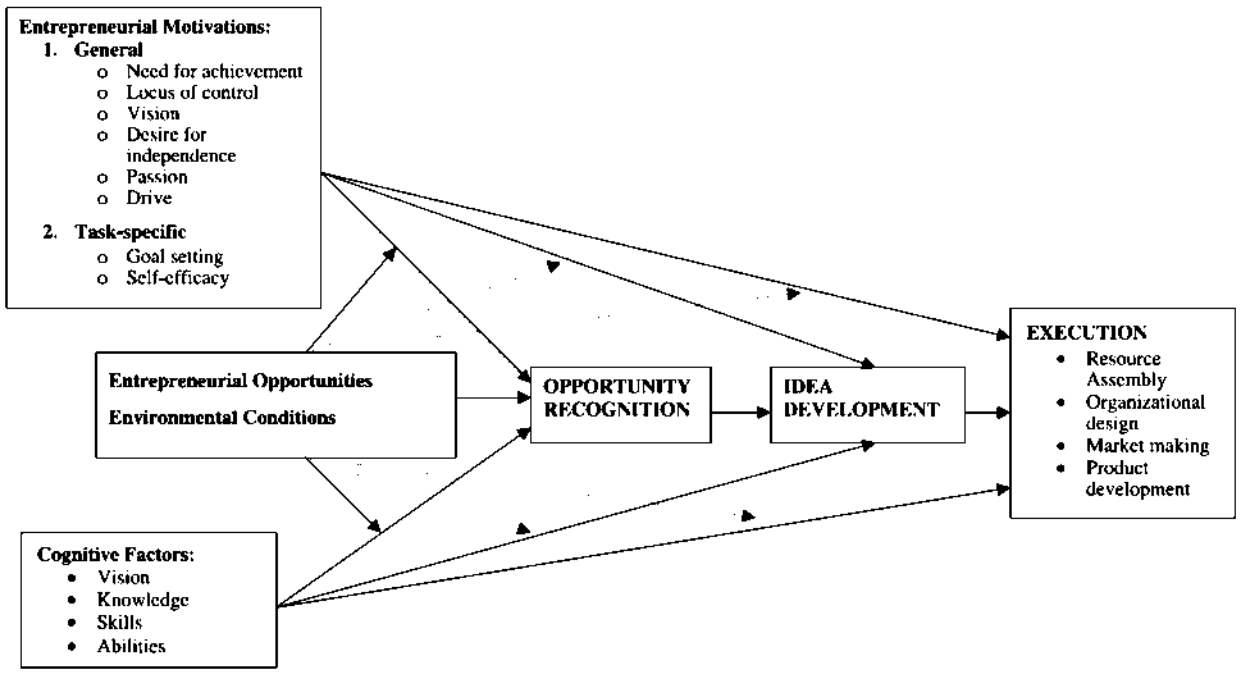

Figure 1: Model of entrepreneurial motivation and the entrepreneurship process (according to Shane, Locke & Collins, 2003).

Need for change and achievement

The need for achievement is driven by the need for a sense of control and in particular it is evidence that we can influence what happens around us. Achievement can also boost our sense of identity as our achievements help define our self-image. Individuals who are high in nAch are engage in activities or tasks that have a high degree of individual responsibility for outcomes, require individual skill and effort, have a moderate degree of risk, and include clear feedback (McClelland, 1961). Maslow (1943) effectively includes achievement as a part of self-actualization, where we seek to achieve what we are capable of achieving.

Balaji Viswanathan, Product Manager at a VC Funded Startup, from his experience, said that entrepreneurs constantly want change; they have a wish to be the bearers of the change and constantly achieve more. They are problem solvers, but also motivated to create something new. Every entrepreneur has a vision ("I want to aggregate the world's information" or "I want to put a PC on every desk") and always find a way to realize the same.

Ivan Bjelajac, COO at Devana and one of the most successful Serbian entrepreneurs, said that everyone likes to give his life some meaning, you can do it in many ways, but building stuff is a great way to do it. He thinks that all people love to see something they created being used by other people. When someone compliments your product, it feels very special.

Risk-taking

Entrepreneurship means risk, the risk of walking away from security and career path to create something new. Most business types that thrive on innovation will encourage risk takers. Individuals who have higher achievement motivation should prefer activities of intermediate risk because these types of activities will provide a challenge (Atkinson,1957). On the other hand, individuals who score high on the motive to avoid failure will avoid intermediate risks. Begley (2000) defined risk-taking propensity as the willingness to take moderate risks.

Balaji Viswanathan, Product Manager at a VC Funded Startup said that many people who like to start-up, want it for the challenge and want to handle big problems. Also, he said that successful entrepreneurs are always curious and ask - what if we implement a new way of working, and remove existing. They endeavor to understand the customer's minds, markets and competitors. They almost always include huge risk while making decisions. Balaji Viswanathan concludes that an entrepreneur in no different from a researcher who is searching for the truth.

On the other hand, Ivan has an opinion that whole life is filled with taking risks. We take risks every day, but most people are not even aware of them. Entrepreneurship can mean that you are aware of the risks and want to influence the outcome. Not influencing the outcome could be considered more dangerous. Actually, Ivan thinks that entrepreneurship is not so much about risks.

Tolerance for ambiguity

Ambiguity refers to the situation which is doubtful or uncertain. Tolerance for ambiguity can be understood as an important trait for entrepreneurs. The challenges and potential for success associated with business start-ups are unpredictable (Schere, 1982). It involves tolerance for ambiguity as the propensity to view situations without clear outcomes as attractive rather than threatening for entrepreneurs (Budner, 1982). Entrepreneurs continually meet more and more uncertainty in their everyday life, but the business owners with a high tolerance for ambiguity can normally handle new and unpredictable situations.

Many entrepreneurs do not like ambiguity. They want to influence the outcome. However embracing ambiguity can sometimes be mind opening and can lead to some amazing results (Ivan Bjelajac).

Locus of control

There are two types of individuals - ones who have an external locus of control, and others who have an internal locus of control. People with an external locus of control believe that the outcome of an extent is out of their control, and attribute their success or failure to outside influences. The others, with an internal locus of control, are the ones who base their success on the own work and completely control their lives. They also believe personal actions directly affect the outcome of an event (Rotter, 1966). That is why an internal locus of control would be likely to seek entrepreneurial roles. They desire positions in which their actions have a direct impact on results (Durand, 1975).

So, we can conclude that entrepreneurial actions affect the outcome of an event. Individuals have the opportunity to be more creative when running own business. They can experiment with a new website design, develop new marketing strategy, create something innovative, design new packaging and new advertising campaigns.

People, especially entrepreneurs, do stuff because they want autonomy, purpose, and mastery (Ivan Bjelajac).

Self-efficacy

Self-efficacy is the belief in one's ability to muster and implement the necessary personal resources, skills, and competencies to attain a certain level of achievement on a given task (Bandura, 1997). Regarding self-efficacy, or confidence as it is commonly known, we can explain why people of equal ability and knowledge can have different results and successes.
An important role in determining chances for success is self-efficacy. Individuals with high efficacy have a positive attitude towards new situations and difficult tasks see as a challenges rather then the limitations. This approach leads in intrinsic interest in activities. For entrepreneurs it is characteristic to have high efficacy, which is reflected through the continuous setting of challenging goals. Entrepreneurs always have a strong commitment to accomplish those goals.

Goal setting

Edwin Locke, in 1960's, put forward the Goal-setting theory of motivation. This theory predicts that people will channel effort toward accomplishing their goals, which will in turn affect performance (Locke & Latham, 1990). Locke and Latham (2002) found a direct linear relationship between goal difficulty, level of performance, and effort involved. This relationship will stay positive, as long as the person is committed to the goal, has the requisite ability to attain it, and doesn't have conflicting goals (Locke & Latham, 2006).
If an individual has a challenging, specific, and concrete goal, that is also measurable, he or she will setting a structure which directs actions to achieve the same.

One of the MIT professors, Edward Roberts, has also addressed this topic. He has studied MIT graduates who had gone on to start technology-related businesses. Through its research he discovered that the most successful ones did not seek ~~s~~ome intangible objective." Instead, they want to create something ~~s~~ignificant and tangible", and it was a challenge for them.

Many people are able to make a onetime success without setting a clear goal. Goals are key to understanding failure and success and repeating it (Ivan Bjelajac).

Independence

For all entrepreneurs, starting a business is the route to ~~l~~life, liberty, and the pursuit of happiness," no matter how risky. Independence makes people more capable, more prepared and a little more confident on handling issues that are a part of their lives. They are more prepared to make decisions and take actions without having to wait for support or permission.
Independence is leading motivation for entrepreneurs. That assumption is proved by Hornaday and Aboud (1973) who were interviewed 60 founders. All the founders were significantly higher than the general population on measures of independence.

Balaji Viswanathan, Product Manager at a VC Funded Startup, also conclude from his experience that independence is one of the key factors that drives entrepreneurs. Many guys who start-up a business, do that don`t wanting to be a part of a company in which they have no way to shape the destiny. They wish to create work their own time, own place, own tasks and goals.

Ivan Bjelajac, COO at Devana agrees that for many entrepreneurs, starting a business is the route to ~~l~~life, liberty, and the pursuit of happiness". Running your own business gives you a sense of freedom.

Drive

The drive is a willingness to put forth effort— both the effort of thinking and the effort involved in bringing one's ideas into reality (Shanea, Locke, Collins, 2003). When entrepreneurs pursue the opportunity, they must take action to make it real. There are the four aspects of the drive: ambition, goals, energy and stamina, and persistence (Shanea, Locke, Collins, 2003).

–Because an entrepreneur can never be sure of a return on his investment, starting up a business is like offering a gift to the world, in the hope, but never the certainty, that the gift will be reciprocated" (George Gilder). Through this sentence, technology guru George Gilder described how he see importance of drive in entrepreneurship.

Ivan also explained this from his experience –The key to success is that when you fail, you must fail quickly and inexpensively. Test, analyze, figure out why you failed, evolve, and iterate. Focus and energy are two key attributes of the drive. That is the meaning of having the drive because there is no way to do that without being self-driven."

Egoistic passion

For the most of the entrepreneurs, ego is a central motive to take up entrepreneurship. After they took the first step in starting business, they passionately start the process of building an organization and making it profitable. They are lying an effort to do what is actually in their interest.

Amar Bhide, after a ten-year period of teaching and studying entrepreneurship at Harvard Business School, concluded that –it takes an extraordinary individual to build a promising company - extraordinary regarding someone who has an almost maniacal level of ambition. Not just an ambition to make a comfortable living, to make a few million dollars, but someone who wants to leave a significant mark on the world" (GCASE).

Entrepreneurs choose to "live a few years of your life like most people won't so that you can spend the rest of your life like most people can't." Ivan said: –I do not necessarily agree with this presumption, but it is true that money is a big motivator. I always felt like ownership devoid of work is a bit parasitic, so I think that entrepreneurship is a great way to build assets you can play with later" (Ivan Bjelajac).

4. CONCLUSION

Entrepreneurs do not only produce revolutionary technology, they also change human habits and lifestyle, and become cultural phenomena. Bill Gates was a major figure and successful entrepreneur in the 1990s. In the 2000s, it was the late Steve Jobs and the Google boys, Larry Page and Sergey Brin. And now, in 2010s, we have a Facebook founder Mark Zuckerberg.

These people and more other entrepreneurs are motivated by a range of factors that are different for everyone. When we talk about motivation we should considered both personality and the environment. For example, Need achievement theory explains why high achievers (entrepreneurs) choose challenging tasks and why low achievers (managers) choose easier tasks. And each of the above-mentioned motivation theories has some valid points. But, in general, the most important issue is to recognize the small number of bio-behavioral wants as the basis of all motivation.

When we talk about entrepreneur's motivation, about –entrepreneurial obsession", we talk about intrinsic motivation. Intrinsic motivation is a term that explains one's desire to work on something that is stimulating satisfying or challenging on a personal level. On the other side, there are the people who are extrinsically motivated, driven by expected evaluation and rewards. Almost all entrepreneurs enjoy their work, have clearly set goals, and strive to create something that is tangible and significant.

Regarding motivational factors in this paper, we try to explain how an entrepreneur differs from a manager and how different things motivate them. A manager is someone good at execution. Typically managers follow a business plan, or strategic plan, which they may or may not have had any say in developing, while entrepreneurs have ideas for a new business. Entrepreneurs are independent thinkers, brave enough to take risks and put ideas into action.

Through the road map of an entrepreneurial process, our attention was to review the major motivations that prior researchers have suggested should influence the entrepreneurial process, as well as to give examples of entrepreneurs who use their experience to explain all of those motivations. Also, this paper providing specific recommendations how motivations might influence the entrepreneurial process at each of its stages and main conclusion in this paper is that motivated entrepreneurs are the most important factor to the entrepreneurial process, human motivation in all theories of the entrepreneurial process is crucial.

IMPACT OF HUMAN RESOURCE MANAGEMENT ON ORGANIZATIONAL PERFORMANCE

Dražena Stanojević,
Gradska uprava Subotica
Corresponding author, e-mail stdasha@eunet.rs

Abstract: *Modern organizations are faced with numerous challenges imposed on them by changing and dynamic environment. Among the many activities undertaken, special attention should be paid to proper management of human resources. Human resources are the most important resource in the organization and a source of competitive advantage. Employees with their knowledge, skills and abilities contribute to business success and improving the performance of organizations. In the scientific theory and practice is increasingly emphasizes the importance of human resource management and its impact on organizational performance. The aim of this paper is to explain the connection between human resource management with the performance of the organization through appropriate theoretical models, as well as to show the individual results of relevant research in this area. In the case of Spanish companies will show how the training of employees as a human resources activity has positive influence on individual and organizational performance and growth of the company.*

Keywords*: human resource, human resource management, organizational performance, training*

1. INTRODUCTION

Organizations should recognize importance of human resource as a source competitive advantage. People with their skills, knowledge and abilities represents critical factor for business success. Human resource become more important as business environment become more competitive. Globalization, permanent growth of inovation, and technology, knowledge-based economy are contemporary trends that impact on individual and organizational performance. This paper will explain the concept of organizational performance, the importance of human resource management to improve organizational performance, and consequently business performance of organizations. You will examine theoretical models explaining the link between human resource management and organizational performance. With regard to the training of employees is an important activity human resource management, the research results show the Spanish authors explaining the positive effects of training employees on organizational performance.

2. HUMAN RESOURCE MANAGEMENT AND ORGANIZATIONAL PERFORMANCE

Performance management is a “continuous process of identifying, measuring, and developing the performance of individuals and teams and aligning performance with the strategic goals of the organization ”. (Aguinis, 2009 , p. 3). The key components of this definition are that this is a continuous process and that there is an alignment with strategic goals.

2.1. Term and definition of organizational performance

According to Enos (2007), organizational performance is related to defining and achieving specific goals, although different definitions can be found in literature.

Table 1: Definitions of organizacional performance (source Enos, 2007.)

Author	Definition	Contribution
Enos (2007)	Organization performance are indicators and progressive achievement of tangible, specific, measurable,worthwhile and personally meaningful goals.	Definition and selection of quantitative indicators.
Parmenter (2010)		

	The organizational performance is marked and classified by success indicators, performance indicators and key performance indicators as key success indicators. The fundamental success factors are the list of problems or aspects of organizational performance that indicate the vitality of the organization, its state and success.	Key indicators of organizational performance
Franceschini, Galetto and Maisano (2007)	Measuring organizational performance reports on the long-term process of continuous monitoring and reporting on achievements, especially of the pre-defined aims. The measures of organizational performance can be related to the type or level of process, direct output results.	Observation of everything that the measures of organizational performance can relate to.
Buble (2006)	Taking into consideration the effects of performance represents the beginning of the business process transformation. One of the aims of improving business processes is to determine economic sense that the changes will bring, which is not possible without measuring performance.	Quantifying the economic sense of changes.
Jeston i Nelis (2008)	If business performance is not measured, you cannot manage your business. To measure performance means to know and to be able to make a decision in certain circumstances.	The importance of measuring performance in the context of making good business decisions.
Davenport (1993)	Actions are important, but they will not be taken unless everything is directed towards improving the process.	Discusses performance problems.

2.2. Linkage between human resource management and organizational performance

In recent years, scientists have devoted great attention to examination of the relationship between human resource practices and organizational performance. Based on previous research until today, it becomes increasingly clear that the system of human resources is an important component that helps the organization to be more efficient and achieve competive advantage.

Develop organizational skills by learning from the past, present and adaptation to create the future on the basis of predictions. The competitive advantage of the company is that these features needed to create recombine and transform the organization in the context of a dynamic competitive environment. Problem creating a model from strategy HRM-firm-performance is difficult because of the dynamics that exists in environment and affects organizational skills.

In the scientific theory and practice, there is a growing interest in understanding connection between HRM and organizational performance. In analysing the impact of HRM on organisational performance, each of the HRM-performance linkage models developed complements the others by adding constructs, variables or relationships (Alcazar, Fernandez, & Gardey, 2005).

Resource based view is an appropriate theoretical framework that describes the proper relationship model relationships between strategy, HRM and performance. Given the complexity of the relationship, this relation has been recognized as the "black box".

According to Guest (1997), there is a need for theory on performance, theory on HRM and theory how the two are linked. The theory proposes that performance at individual level depends on high motivation, possession of the necessary skills and abilities and an appropriate role and understanding of that role. Only HRM practices that encourage skills,motivation and appropriate role structure impact HRM outcomes. These factors influence behaviour outcomes, which translate into performance outcomes, which result in financial outcomes (see the next figure).

HRM strategy (differentiation, focus, cost) ➔ HRM practices (selection, training, appraisal, rewards, job design, involment,status and security) ➔ HRM outcomes (commitment, quality,flexibility) ➔ Behaviuor outcomes(effort/motivation, cooperation,involvement, organizational citizenship)➔ Performance outcomes(high: productivity, quality, innovation; low: absence, turnover,conflict, customer complaints)➔ Financial outcomes (profits,ROI)

Figure 1: Guest model HRM- performance

This model suggests that business strategies drive the design of the HR system. HRM practices directly impact employee skills, employee motivation and work design which consequently influence employee's creativity, productivity and discretionary behaviour. These variables, in turn, result in operational performance, which relates to profitability and growth, ultimately determining firm market value (Gardner *et al.*, 2001).

Model of Becker (1997) suggests that business strategies drive the design of the HR system. HRM practices directly impact employee skills, employee motivation and work design which consequently influence employee'screativity, productivity and discretionary behaviour. These variables result in operational performance.

Business and Strategic Initiatives ➔Design of HRM System ➔Employee skills, Employee motivation, Job design and Work structures ➔Creativity, Productivity, Discretionary Effort ➔Improved Operating Performance ➔Profits andGrowth ➔Market Value

Figure 2: model HRM- performance by Becker

The People-Performance framework (Purcell *et al.,* 2003) is built on two assumptions:
1) the framework advances the concept of discretionary behaviour by suggesting that virtually all employees have the capacity to engage in discretionary behaviour;
2) the critical role of line managers because they have discretion in the way that they apply HRM and the way they behave towards employees.

These model also focus on abilities, skills and motivation of employess and opportunities to participate (Boselie, 2010).

Wright and Nishii (2006) examined some of the mediating processes that might occur in HRM-Performance relationship by examining the relationship at multiple levels of analysis. They present the model that includes intended HR practices, actual HR practices, perceived HR practices, employee reactions and performance (see Figure 3).

Intended HR practices ➔Actual HR practices Perceived HR practices ➔Employee reactions (affective, cognitive behaviour) ➔ Organization performance

Figure 3: HRM- performance link model by Wright and Nishi

3. HRM-ORGANIZATIONAL PERFORMANCE RESEARCH BASED ON SPANISH FIRMS

Among the many activities of human resource management that have a critical impact on organizational performance highlights staff training. In changeable conditions imposed by a dynamic environment, organizations need to pay special attention to the development of intellectual capital. Training is an essential activity of human resource management. Expansion of training in organizations reflects its potential use as a means to improve the development of human capital and the enterprise. However, research regarding the

effects of training in the practice of late in some way and it is necessary to establish a theoretical framework to explain the training process and its results.

Spanish authors Núńez-Cacho P., Grande F., Lorenzo D. (2015) have conducted research on the effects of training on organizational performance. The main contribution of this research is to improve the training and knowledge of its basic characteristics.In addition, analyzes its impact on employees and organizations and identify factors that can affect the efficiency of this type of training. As for the implications, this study provides valuable guidance to help managers in the assessment of investment in training and orientation in human resources planning strategies in their organizations.

The questionnaire was sent to managers of human resources in the 2,303 Spanish companies. In order to collect the information needed for research, companies are selected from the Spanish business register.The response rate was 21.6% and in the stydy participated 498 companies. The confidence level of the sample is 95% and the margin of error is 3.96%. As a control varijebile were used medium-sized companies (in terms of number of workers whose average is 174), and the average age of the company (35 years). The study companies from the following sectors: industry (39%), trade and services (37%) and the primary sector (24%). Even 91% of the companies surveyed fully implement training programs.

The questionnaire was developed based on a review of existing literature in order to obtain information necessary for solving research problems. The variables that were used in the study are:

- Organizational support and precondition
- Training
- Individual performance oh human resource
- Organizational performance
- Sales growth and productivity.

As a control variable were used medium-sized companies (in terms of number of workers whose average is 174), and the average age of the company (35 years). The study companies from the following sectors: industry (39%), trade and services (37%) and the primary sector (24%). Even 91% of the companies surveyed fully implement training programs.

Given that in the scientific literature there is no consensus around considerations of training effectiveness, the authors define it in the study tested four hypotheses:
1) Hypothesis 1: Organizational Support improves individual performance human resources in the company;
2) Hypothesis 2: training improves individual performance of the human enterprise resource;
3) hypothesis 3: Improvements in individual performance as a result of the training has a positive effect on organizational performance;
4) Hypothesis 4: Improvements in individual performance as a result of the training has a positive effect on the growth of the company.

Table 2: Corelation and Cronbach alpha (diagonal) for measurements scale

	Organizational support	**Training**	**Individual performance**	**Organizational performance**	**Sales growth and productivity**
Organizational support	**0.77**	-	-	-	
Training	0.49	**0.94**	-	-	
Individual erformgance	0.41	0.40	**0.71**	-	
Organizational performance	0.36	0.44	0.31	**0.81**	
Sales growth and productivity	0.26	0.38	0.38	0.33	**0.77**
Varians	0.55	0.67	0.52	0.71	0.81

Source : Núńez-Cacho P., Grande F., Lorenzo D.,(2015), „*The effects of coaching in employees and organizatinal performance*“, Intagible capital, 11 (2), p. 166-189, downloaded 15.01.2016.ca http://www.intangiblecapital.org/index.php/ic/article/view/586/464

Overall, scala has realibility α = 0,711 and r = 0,728 which is acceptable for investigative srudy, a composite index of reliability in accordance with the recommendations.All relations are recognizable. Therefore, the assessment index indicates good agreement on the basis of accepted criteria.

The research results make it possible to infer that the processes have become the medium of training is useful for the development of professionals in the organization, as found effect on the performance of human capital. Training helps organizations to improve their competitive position through the impact on organizational performance, increase sales and productivity growth. On the one hand, managers can benefit from the training process, and to exploit the potential of human resources of the company. On the other hand, a relevant contribution of this research is the positive effect of the training process in the organization, which can be measured in terms of the results of the company and its growth.

4. CONCLUSION

As organizations strive to compete in the global economy, differentiation on the basis of the skills, knowledge, and motivation of their workforce takes on increasing importance. In theory and practice of management, is increasingly emphasizes the importance and impact of certain activities of human resource management on the performance of the organization. According to the modern understanding of "strategic partnership" human resources function needs to have both strategic and operational focus and at the same time takes into account the systems and people. Then human resource management is not only a link between the strategy and the expected performance of the organization on the one hand and the needs of employees and their individual performance on the other hand, it is an integral part of the formulation and implementation of business strategy. Adequate training programs and the development of human resources lead not only to changes in reaction, attitudes, knowledge and behavior, but also to improve the results of the work of individuals and beyond that to the better performance of the organization expressed a variety of key performance indicators such as productivity growth and / or reducing absenteeism or staff turnover, improve the quality of products or services, reduce costs and / or increase the profits of the company. Organizations need to understand that human resources management is an important segment of business strategy and a source of competitive advantage. Numerous studies in theory and practice have shown that there is a correlation between the practice of human resources and organizational performance. Research conducted by Spanish autors show that exists positive relations between training (as an important part of HRM) and organizational performance. In the opinion of the author of this work in the future is even more expected expansion of research on the impact of HRM on organizational performance.

SPIRAL DYNAMICS AS VALUE SYSTEM AND COMPETITIVE ADVANTAGE OF AN ORGANIZATION

Dusanka Rodic *[1],
[1] University of Belgrade, Faculty of Organizational Sciences
Corresponding author, e-mail: dushka_rodic@hotmail.com

Abstract: *This paper aims to discuss the Spiral Dynamics as both theory of value system and usable tool for organizational competitive advantage. Spiral Dynamics is a framework for understanding the dynamic forces that drive people to action in personal lives, business relationships, education, and even geopolitics. The theory of spiral dynamics can be seen as a model for understanding complex values and beliefs that encourage people to different behaviours, but t can also be considered as a tool for managing differences between people and differences between people's value systems and organizational value system. The theory of Spiral dynamics is very wide and complex subject to discuss, but in this paper it will be described just essentials for understanding the whole concept, what is Spiral Dynamics about, some main principles of it, how is could be applied to organizational efficiency and effectiveness and make a competitive advantage of it.*

Keywords*: values, beliefs, vMEME, value system, organizational value system, motivators on spiral, value fit as competitive advantage*

1. INTRODUCTION

The person who is responsible for the foundations of Spiral Dynamics is professor Clare W. Graves. He was professor of psychology of Union Colleague, New York. Professor Graves was disappointed with psychology as science back then. He had found lots of mess and inconsistency and even contradictories in psychological data and theories, and it led him to go to adventure of researching. Professor Graves initiated research project, wanting to find out which is prevailing worldview among people. The main question he asked was: "What is that characteristic that makes mature, grown-up human personality". His research lasted for thirty years. Data he got in his research, Graves benchmarked with the date of other scientists. After thousands of interviews worldwide, Graves developed a theory which he called: "The Emergent, Cyclical, Double-Helix Model of Adult Biopsychosocial Systems Development." He later modified the name as "The Theory of Levels of Human Existence." Graves (1973) summarized his theory in this manner: "Briefly, what I am proposing is that the psychology of the mature human being is an unfolding, emergent, oscillating spiralling process marked by progressive subordination of older, lower-order behaviour systems to newer, higher-order systems as man's existential problems change." Even today, his opinion and theory are considered advanced and it is more and more accepted.
After Graves, there are other people who contributed to the development of todays Spiral Dynamics theory, and its practical application on ordinary life situations. To develop the version of today's theory after Graves, many other achievements from other sciences and science disciplines are used, such as are: neurobiological science and achievements of organizational science, which no gives to Spiral Dynamics an interdisciplinary characteristic. Some of the well-known names are: Don Beck, Christopher C. Cowan, Nataša Todorović and Ken Wilber.

The name itself tells about Spiral Dynamics as non static theory, it is not determined, but evolves with the evolution of human consciousness. Humanity has the power to establish new levels of consciousness that carry withinthem the characteristic values within itself, beliefs and artifacts that together create totaly new value systems.

2. SPIRAL DYNAMICS THEORY

2.1. Definition

Spiral Dynamics is the most modern, most comprehensive and most respected psychological theories, which combines the 'bio', 'psycho' and 'socio' aspects of human functioning. (Beck and Cowan, 1996) stated that It

gives us a scientifically based way of thinking about the complexity of human existence and understanding of order and chaos in human relationships. Explains the deep forces in human nature that shape our values and representing the form and trajectory of effective change. Spiral Dynamics provides a greater understanding of how people, organizations and entire cultures work from the inside out or herself is a very versatile tool that allows people to work, study and live with better quality of life and to be more successful.

Spiral Dynamics is:
• a way of understanding and predicting changes in response to these changes,
• also a way of understanding the 'why' people think the way they do,
• a model of development of human value system,
• a framework for understanding organizational development,
• a mechanism for assessing the appropriateness of changes
• a human factor that is missing in the process of business restructuring,
• an effective framework for guidance - for understanding complex situations and create new relationships,
• a framework that the best way fits other systems, models, approaches or interventions
• the development model of human nature, not just out of where it comes what we think is worth, but also out of where our values and thinking come and which directions they go.

2.2. Six dimensions of value system

Six dimensions of value system are: semes, themes, mindsets, world views, ᵛMEME and gens.

1. Semes - words, symbols, icons (pictures) and objects that are related to ᵛMEME.

Schemes are what is tangible. These are: words, music, literary metaphors, icons, paintings, artifacts, and other "concrete" objects that are the final products and specific packages of stored ᵛMEMEs. It can be, for example: symbols such as Christian Cross or the Star of David; political campaign slogans or props; flags, logos and markings; fashion and dress codes; colored gangs and their behavior; musical styles, the lyrics, melodies and rhythms; Personal possession (cars, houses, collectors' items and status symbols); architectural styles and living spaces; Technology and gadgets in all forms.

2. Themes - Questions (outcomes) causes and events that formed around the meme energy field

Topics are what is intangible. The idea, cause, reason, question, position or event that is attracted by the ᵛMEME and the one where ᵛMEME also put its core intelligence in. This then becomes the theme of a representative or transferor for that specific Meme, for example: religion, political affiliation, socio-cultural movement, a philosophy, a symbolic event, a celebration, etc.

Together, Schemes and Themes are called “memes” according to Richard Dawkins (1976) and other in “memetic” literature. The idea behind the” Meme” is self-repeating package of information that is propagated through the ecology of the mind in the forms of reproduction similar to viruses. Parallel structure in biology is gen. In chaos theory, the parallel structure of the fractal. In the language of Spiral Dynamics, "a great meme" - value MEME or we will call it ᵛMEME - the process by which people become closer to it, drawn to it, and then eventually take them away from Themes and Schemes category so called "Little memes".

3. Mindsets - online, constantly present active, dominant ᵛMEME(s) in certain situation

Activated ᵛMEME(s) and "on-line" world view are employed in a particular moment of judgment. It will be shaped by previous experiences, the relative priority clusters of ᵛMEMEs of that person and the unique properties of the message or stimulus that activates and focuses the mind. Think of memes as "hot" and "cold" buttons that can be artificially manipulated (to some extent) with the agents of change that would affect on which of the ᵛMEME to use in the act of interpretation and judgment. How can ᵛMEME(s) come and go, to shine and to fade out in terms of priorities, the persons ways of thinking are designed with a special ᵛMEME which is activated at a specific time and a specific place and will reply on specific living conditions.

4. World views - repertoire range of all awakened, available ᵛMEMEs
   - Cluster all available memes that recognizes the mind (that are in it)

   View of the world is made up of the repertoire meme (that had been awakened) with their relative strengths and significance. Find itself in a view of the world:
   - epistemology-way knowledge.
   - Community FILTER AND EDITORS (both conscious and unconscious) that sieved and sorted input.
   - Sets of evaluative filters and editors (both conscious and unconscious) to sift and sort input
   - Built in priority stack or cluster that exists in varying degrees of strength and relevance when a person/organization/society is in a “idle” position (before a mindset-focusing stimulus) and which orders inputs.

- Ways of interpreting themes and connecting with Shemes
- Lenses that magnify or minimize events in the perceptual world.

- Process of pattern recognition and scanning for relationships.
- Structures of like/dislike, approach/avoidance, and live-for/die-for causes.

5. ᵛMEME(s) - the Core Intelligence within the Biopsychosocial System's "DNA", are:
   - A "bottom line" for human existence.
   - A rationale for why thing happen.
   - A Level of complexity of functioning.
   - A Neurological capacity to detect and deal with a specific set of life conditions.
   - A range of development from low to high elaboration.
   - A Closed, Open, and Arrested condition (within the situation and context).
   - A specific package of approaches to emotions and feelings.
   - A concept of time and place.
   - A locus of control (from inside or outside).
   - A degree of predation or proliferation (how driven to spread outward like a virus or consolidate. inwardly; how much to move beyond boundaries or to operate within the boundaries).
   - A particle-field focus between concentration on individual particles *(elites)* or the entire field *(collectives).*

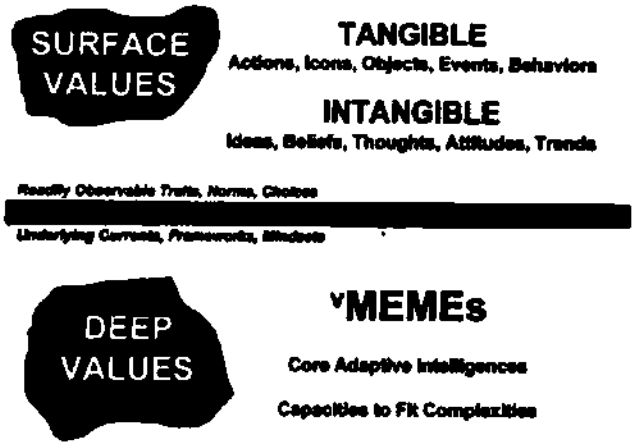

Figure 1: Structure of ᵛMEME, Adopted from: National -Value Center, Inc. Denton TX, Spiral Dynamics Integral Level I Certification course materials

6. Gens - The individual and collective biological genetic pools
   - A Closed, Open, and Arrested condition/capacity (within the person)
   - Personality - temperament and texture attributes
   - Physiological characteristics and traits
   - Propensities toward intelligences and capacities

2.3. Five deep strata which shape value system

Five deep strata of value system consists of, on the first place: Life conditions (internal and external), which when any change occur in them, it effect on Genetic and Memetic codes (in people), than as chain reaction it affect on Minds and ways of thinking, than it again has effect on Systems and structures, and finally it is noticeable in change of our actions and behaviors.

Different life conditions activate different value system ᵛMEMEs. According to professor Graves (1970) life conditions are the real activators of ᵛMEMEs and his research suggests eight main value systems which evaluated until today. They are reactive, traditionalistic, exploitive, scarifying, materialistic, sociocratic, existential and experimental.

Table 1: Existential states, associated motivational systems and end values;
Adopted according to table from the article: Graves, Clare W.,"Levels of existence: An open System Theory of Values", Journal of Humanistic Psychology, November 1970, Vol. 10, No.2

Existential state*	**Motivational system**	**Means values****	**End value****
H-U	Experience	*Experiencing*	Communion
G-T	Existence	Accepting	*Existence*
F-S	Affiliation	*Sociocentricity*	Community
E-R	Independence	Scientism	*Materialism*
D-Q	Security	*Sacrifice*	Salvation
C-P	Survival	Exploitation	*Power*
B-O	Assurance	*Traditionalism*	Safety
A-N	Physiological	No conscious value system; values purely reactive	

*A-N: a psychological system: B-O/H-U: psychological systems.
**Italicized values: primary orientation on each value system.

[v]MEMEs awakened with certain life conditions are found in: people, organizations and entire societies.

2.4. Spiral with characteristics

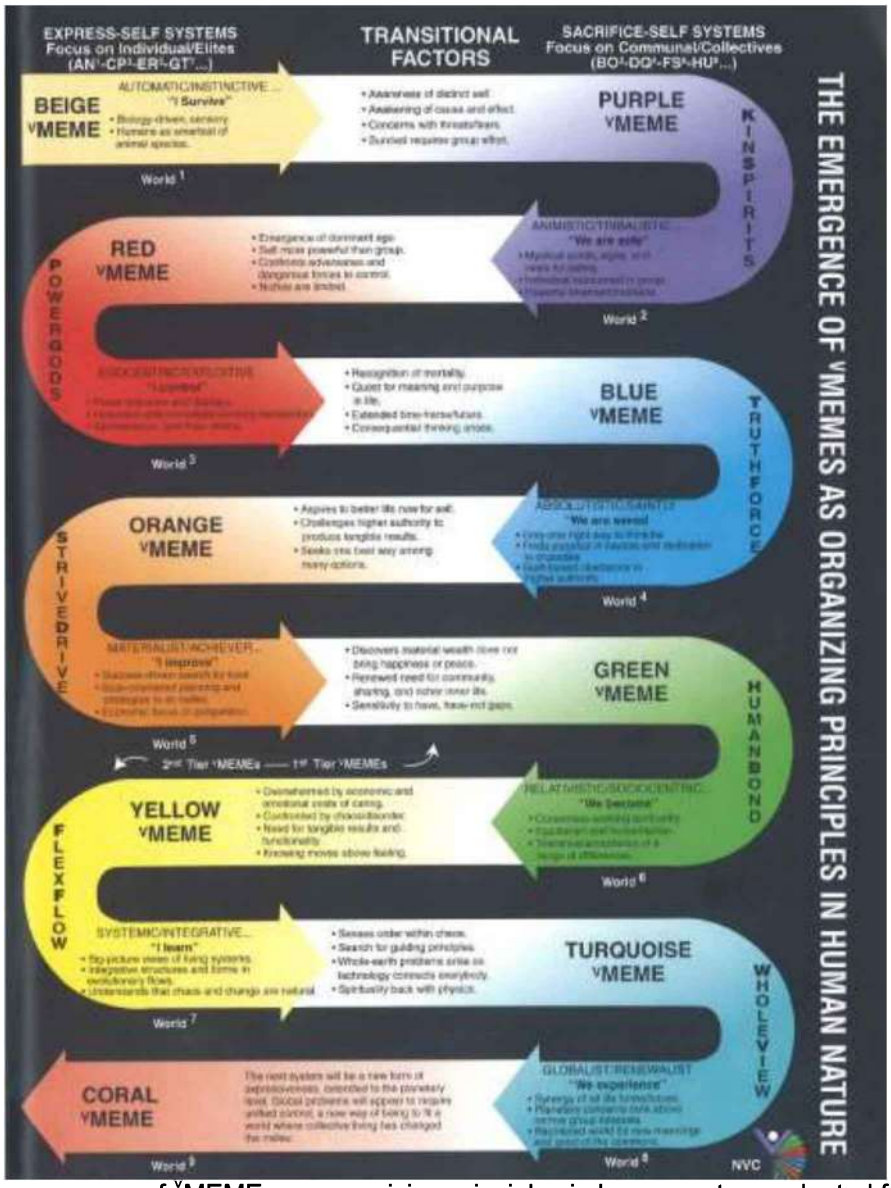

Figure 2: The emergence of [v]MEMEs as organizing principles in human nature, adopted from: National - Value Center, Inc. Denton TX, Spiral Dynamics Integral Level I Certification course materials

3. SPIRAL DYNAMICS AND ORGANIZATION

According to (Beck and Cowan, 1996) organizations are structures in our mind. The words printed on the charts projected onto the walls, symbols and actions around the neck, and areas occupied as a manifestation of power are nothing else but the artifacts and icons. Really genuine, real connections are within the ˅MEMEs in profile of people who are part of this organization, this invisible network that command ordered society and relationships. We carry them around in our heads at any moment. Each location along the Spiral has its own mental configuration as the range of radar, where the contours are drawn being ideal life. Which circle on the radar scope is the most important depends on which meme active. Then our radar screen looks like this:

BEIGE ˅MEME: to care about bread and butter issues of survival at its most basic level.
PURPLE˅MEME: as a magical circle that makes everyone feel safe within it.
RED ˅MEME: self-centered as an empire where one feels powerful and controls weak and subordinate.
BLUE ˅MEME: as a fixed pyramid, which provides stability, durability and assigns each place.
ORANGE ˅MEME: as a matrix of the playing field that promotes opportunities and rewards capabilities.
GREEN ˅MEME: a warm supportive community of equal who care about each other.
YELLOW ˅MEME: as a floating network that transfer functions above, below and between natural layers.
TURQUOISE ˅MEME: as a living organism that brings order internally (within the chaos).

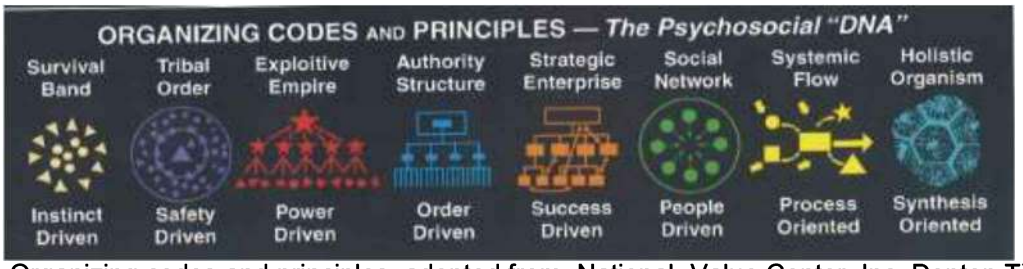

Figure 3: Organizing codes and principles, adopted from: National -Value Center, Inc. Denton TX, Spiral Dynamics Integral Level I Certification course materials

3.1. Spiral Dynamics and leadership

Leadership as the ability to translate vision into reality according to (Bennis, 1961). If just the leadership based on the results, is taken into consideration, than the highest quality is selected from short-term and long-term results achieved "leaders with clearly articulated set of values" (Ulrich, Zenger and Smallwood,2013). Leaders who understand their personal values, their organization achieve lasting results. In the absence of clearly defined values, leader with no real vision is constantly changing his goals, so the direction for the organization is not clear as well.

Some principles of Spiral leadership:
1. Different organizations have different positions on the Spirals, therefore, need to develop management strategies that align people, the vision of the future and the work currently performed.
2. Managers should develop a consistent, comprehensive approach to every issue within the Organization - the selection, hiring, positioning, training, internal management and external marketing - so that all these elements are balanced, integrated and unified in its effect.
3. Organizations should be designed in such a way from "top to bottom and from the bottom up" to link the functions, logistics and decision-making structure so as to prepare for the new complex problems.
4. Successful organizations may be at risk of failure if they continue to lead the people in a way that made them successful in the past.
5. Many people today should lead and manage differently, because they can be placed at different levels on Spiral and can move faster than most of their bosses, teachers or parents.
6. Marketing strategies often fail because the designers transfer their value systems on the public assuming that these people have the same values as they do.
7. It is not a question of 'how to motivate people?' but how you treat what you are doing in relation to their natural motivational currents. A person has a right to be who he/she is.
8. Today's problems with productivity, quality, political instability and restructuring are signs of growth, not decline. This will force us to find new and innovative ways of managing people, based on what these people have now already become.

3.2. Motivators according to the Spiral levels

vMEMEs	HOT BUTTONS	COLD BUTTONS
BEIGE	offer food, water; sex; input through basic senses; touch {if safe); caress to give reassurance; recognize the intelligences which are there	withdraw food or make threatening moves; cause physical pain or discomfort through temperature: .' thirst; treat as animal-like being
PURPLE	rituals; respect for powerful figures; appeals to safety, magic, mysticism; traditional ways and customs; home and hearth; desires of spirit beings, signs and omens; give tokens & tangible goods; respect elders; show honor to ancestors	speak ill of the chief or tribe; step on or desecrate sacred grounds; violate taboos or ritual ways; introduce ambiguity; isolate and force accelerated change and uncertainty; threaten family; disrespect eiders or ancestors; don't try to understand
RED	immediate payoffs; macho appeals, challenges, and dares; heroic images; more clout and personal power; looking good and getting due respect; gaining control over nature and other people; getting by with something; prizes and rewards—NOW	challenge power or courage; shame or put down person/group; move onto turf uninvited; display more powerful weapons; make gestures and name- call; be derisive and laugh; make to lose face; taunt as an outsider; appear or talk weak; make excuses
BLUE	duty, honor, country; *semper fr,* righteousness; obedience to. higher authority; being prepared; sacrifice and discipline; rewards for dedication to come in the afterlife; stability/order; purpose; standards & norms; finding greater meaning; being a good citizen; punctuality	attack religion, country, or ethnic heritage; desecrate symbols or Holy Books; put down the One-True-Way or make fun of it; violate chain-of-command; disregard rules and directives; appear unfair or sleazy; be wishy-washy; use bad" language; demean the standards; be late
vMEMEs	HOT BUTTONS	COLD BUTTONS
ORANGE	opportunities to succeed; progress, growth, winning, achievement, making things better; competitive edge & advantages; bigger-and- better, new-and-improved; state-of-the-art; fashionable; prevailing through experience, calculated risks & good science; cutting-edge; make deals & bargains; treat like VIP	put down profit or entrepreneurism; talk about collectivization accuse of games and demean .outcomes;challenge compulsive drives; deny rewards for good performance; force sameness; cost prestige; trap with rules and procedures; fail to bargain or negotiate; seem inflexible; treat as one of the herd; seem ordinary
GREEN	participation and involvement; consensus decisions; teamwork; liberation of the oppressed; sharing; acceptance of human weakness and foibles; openness; environmental sensitivity; tolerance; political correctness; inclusion; social responsibility and awareness; participation; corporate citizenship; community involvement	assault the group's goals and ideals; try to get centralized control; divide the group; reject collective for individual accountability; support aggressive competition; deny affect and feelings; degrade quality of life or environment; appear cold-blooded; appear mercenary; rely on "hard facts" to the exclusion of people factors; act elitist or exclusive
YELLOW	liberate to be and do as one chooses; learning interesting things to enhance quality of being; access to diversity in people, choices, and big- picture views; enhancing competency and functionality; principles and "what's right" tries to produce in appropriate and sustainable ways; demonstrate linkages & interconnections	force rules without reasons; impose dysfunctional structure; focus on minor details; be punitive; deny individual control of time; make work repetitive; close access to varied information or learning resources: try to homogenize; knowingly harm people or the environment; pass the buck to the future; force groupness; ignore diversity of thinking
TURQUOISE	experience *of* being above self-interests and even group pressures; to find unity in ideas and goals of whole-Earth impact; responsible to the overall good; complex, multidimensional thinking; survival of life on the planet; interactive holism; interdependence; to form groups of individuals; appreciates the spiritual side of things	hide reality; set short-term goals at expense of living system in the long-term; enforce narrow views about ethnicities, ideologies, and political conflict, deny spirituality; make self-serving excuses; leave residues; seek advantages through deception; appear mundane; take a narrow view; put up with destructive forces; take the easy course; be too earthbound

Figure 4: Motivatos and "cold buttons" for each Spiral level, adopted from: National -Value Center, Inc. Denton TX, Spiral Dynamics Integral Level I Certification course materials

3.3. The example of application of Spiral Dynamics on organization as its possible competitive advantage

It is known that the corporate culture can affect company's success both in a positive and negative way. Clearly defined values shared with the employees that are followed within the company have proven decisive factors the level of success of the company (Krumm and Rainer, 2012).

This is 5 years old practical example from my working experience. Client's one branch office of one well known pharmaceutical company - leader in pharmaceutical innovations and development of new technologies – Abbott , had to choose candidate for marketing manager position for that branch office and that country. In the pictures below is shown final check of just one candidate C2 (because of the privacy of people and company).

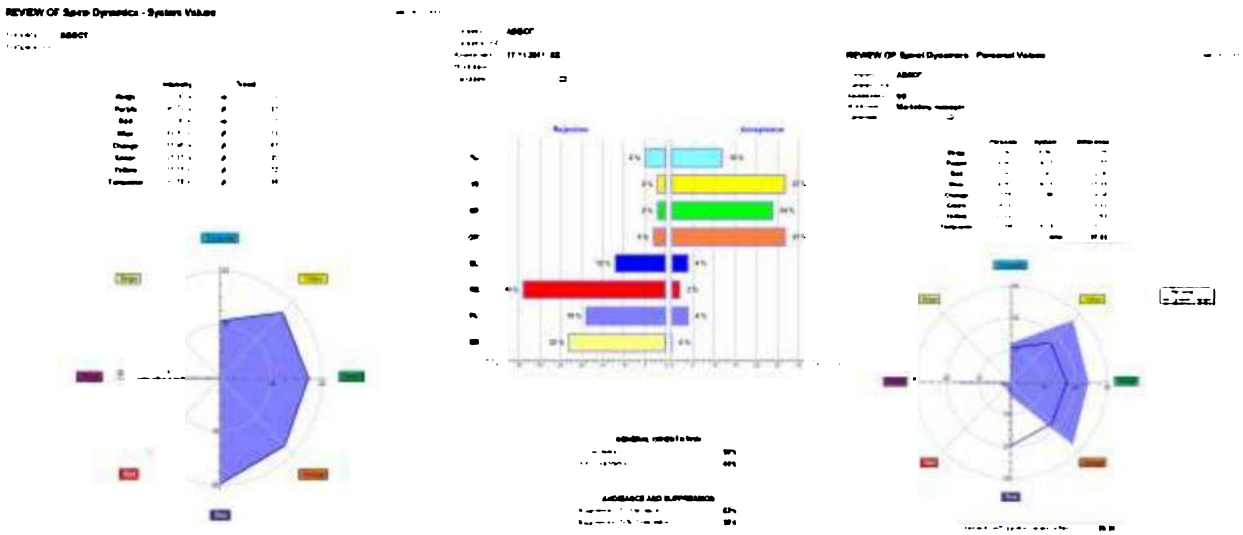

Figure 5: (from left to right) Company's value system; Candidate's value system; Candidate-organization fit

As we could see on Picture 5, last diagram shows us value fit between organization and candidate C2. What we can see from it is that similarity of value pattern of candidate with the value system of company is 86.36 %, which is high score. We can also see that with 10% candidate differentiate from the pattern of organizational value system. When we look at the diagram, we clearly see that the candidate has a greater presence of orange, yellow and green ^{V}MEMEs comparing to the organization. Then let's see the workplace, the position of the Marketing Manager. If we remember that if person should be a manager, it is good to take care of people, considering all people to have same rights and starting points, social care and etc., and it can all be found in green ^{V}MEME, and because of that it actually leads to the conclusion that this is not the perfect fit but this is preferable for candidate, to have more green than organization. If we now remember that marketing is an eternal struggle that by marketing research activities organizations are trying to ensure competitiveness in the market and that our orange ^{V}MEME gives us competitive spirit, ambition, initiative, relying on knowledge and science, we can here conclude that it is good if the marketing manager for its function and requirements of workplace to has more orange in the present value system rather than a company, because he/she is the one who pulls the company to continue to develop value system and be more competitive in the market. The last one, yellow ^{V}MEME where a candidate has more developed and present than the organization. Yellow ^{V}MEME -system flows, saving resources, continuous improvement, and the ability to look at all previous levels to spiral in the organization and the people, again impose the conclusion that if candidate or employee does not match 100% with the organizational value system , this exactly could be the competitive advantage of this organization.

4. CONCLUSION

This paper aimed to introduce to the reader the theory of Spiral Dynamics from the roots of its origin to its application to individuals and organizations or organizational development, as well as to show the adjustment of employees to the organizational value system and vice versa. In case of adapting the organizational value system to the employee's is more in the case of adjusting the value system of individuals who are the initiators of further organizational development, such as organizational leaders, or change leaders for example.

Throughout this paper is tried to make closer the development of the Spiral Dynamics theory, but also its dynamic character, its specific "never-ending" characteristic, because of the constant evolution of living beings on Earth and evolution of individual, social and collective consciousness .Value systems typical for any period of human development from the very beginning until now, are codes engraved in human bio-psycho-social "DNA" , and in every moment of changing living conditions they are adapting to the constant social changes and changes in information technology. Those value system changes and adapt to new era phenomenon are deeply affecting behavioral patterns and forming the new ways of social interaction, but also new forms of existence and personal development of individuals.

Thus, four-dimensional, powerful, this theory of Spiral Dynamics justifies its emergence from numerous psychological theories unified with the other sciences research, giving us the most complete picture of how deeply engraved artefacts, symbols, traditions, ways of thinking, systems and structures can respond to changes in living conditions and circumstances surrounding triggering an avalanche of predicted behavior patterns characteristic to the dominant value system.

Knowing the dominant value system of the individual, we can predict his/her reactions in certain circumstances, as well as its drivers but also what discourages him/her. Also, knowing the dominant value system of an organization, we can assume or even we can easily describe the organizational culture, both visible symbols on eyesight and also the deep beliefs which are shaping organizational culture to be as it is.knowing then, both the value system of the individual and the organization, it could be possible to predict the chances of developing the organization and the individual, as well as to predict possible conflicts, motivation and reward systems.the other things we could do knowing both organizational and employees' value systems, we can do strategical planning, we can successfully do the alignment of the organization's vision with the vision of the individuals (employees), and we can certainly predict some of the problems that affect today's organizations.

These are mainly problems affecting domain of human resources departments in the organizations, they can be manifested in the form of employee fluctuations and absenteeism phenomena for example. Value system fit between organization and new employee could be beneficial in a way that if the fit is positive, it could help avoiding the costs of introducing new employees in workplace. From the other hand if employee does not fit well into the value system of the organization and the organizational unit to which it should belong, it could be cost for organization in a way of need for finding new candidate for this workplace and there are cost for hiring an cost for introduction to work of new employees plus cost of loosing time and money on previosu employee and its introduction to workplace.
Here in conclusion of this paper, are mentioned just a few of the possible applications and benefits of the Spiral Dynamics theory, as useful tool for predicting organizational change, its competitive advantage in the market, and also as tool to avoid major problems in the field of human resources which are nowadays increasingly affecting organizations operating in modern business environment. As the theory is dynamic, its application will never be "out of fashion" because it is closely follow human society and all the changes it faces, and then Spiral Dyanmics again develops and evolve from all the changes and leaps of human society, it is never ending circle.

MILLENNIALS IN THE WORKPLACE

Sonja Ivancevic *[1], Tatjana Ratkovic[1]
[1] Faculty of Organizational Sciences, University of Belgrade
*Corresponding author, e-mail: sonja.ivancevic@yahoo.com

Abstract: *Each generation has its own distinct characteristics, values and attitudes toward work. Companies need to adapt processes and procedures in order to successfully integrate diverse generations into the modern workplace. The aim of the paper is to reveal the key characteristics of Millennials in the workplace as well as main challenges they face in organizations nowadays. There is a big difference between what Generation Y expects and demands of a job and what it actually gets. In this regard, it is necessary to change the modern organizations and adjust them to meet the needs of Millennial workers which will soon dominate the workplace in numbers.*

Keywords*: workplace, human resources, Millennials, generations, employees*

1. INTRODUCTION

Members of each generation resemble each other having a number of common characteristics due to the influence of different social, economic and political events that shaped their childhood and adolescence. This usually results in the fact that each generation adopts a system of values, beliefs, expectations, and behavioral patterns that are different from previous generations' and form a recognizable generational identity (Inglehart, 1997).

However, many analysts emphasize that numerous organizations around the world have no proper understanding and knowledge of the employees who work for them, nor make serious attempts to identify the profiles of the employees. For this reason, organizations are failing to align the needs, attitudes, values and behavior of their employees with organizational requirements (Singh, Raj and Bhandaker, 2012). In the absence of such a strategy and the necessary knowledge, workers are assigned tasks, schedules and work principles which do not suit them, and for which they are, by their preferences and characteristics, in some way incompetent. Thus, managers' discontent grows and companies' objectives are not achieved while motivation of workers decreases gradually, which eventually leads to increased absenteeism and unavoidable lay-offs or resigns.

2. DIFFERENT GENERATIONS IN THE WORKPLACE

Generation Y or the Millennial Generation, is a demographic cohort that follows Generation X (1966-1979). There are no clearly defined years that determine this generation's span, but most researchers and authors use a range between 1980 and 2000 to mark the birth years of the members of this generation. Several authors use other names for this generation, such as 'Nexters ' or 'Nextus Generation' (Barnard, 1998; Burke, Cooper and Antoniuou 2015; Zemke, Raines, and Filipczak, 2013), 'Boomerang ' or 'Peter Pan' generation, as they are called by American sociologist Kathleen Shaputis (2004), because of the characteristics they have. According to the Pew research center, in 2015, Millennials made up 34 percent of the US labour force, and the same source anticipates that by 2020 they will make almost half (46 percent) of the workforce. Even more dramatic are the Brookings' numbers which claim that by 2025 Millennials will become 75 percent of the global workforce. It's worth noting that the Millennial population as a whole (not just its workforce) surpassed that of Baby Boomer generation (1946-1965) in 2015 as the nation's largest living generation.

In this regard, it is necessary to deal with the generation Y thoroughly at both global and regional levels, and make the necessary changes in the approach and motivation of employees in order for the business world in every industry to continue to operate at an optimal level.

Organizations expect employees to obediently adapt to work, their work roles and the existing organizational culture, rather than to adjust organizational processes to the expectations and needs of the people who work there. This would not be the biggest of a problem if it was not for one of the main characteristics of the youngest working cohort, which is ''disobedience''. Or at least it is perceived as such.

They are perceived as outrageous, lazy, spoiled and egoistic. They are considered to have no work ethic and are not loyal to the organization they work for. In the eyes of their predecessors they have no respect for authority, are unprofessional, too relaxed and have poor communication skills on one hand, and on the other hand are very demanding with a lot of unrealistic expectations (Tulgan 2015). Nevertheless, this infamous generation is spreading its wings in the workplace, outnumbering Gen X and Baby Boomers in the business world and outside of it. And who are they? They are Millennials! They do not ask for permission, they are blind to hierarchy and, avoiding false modesty, they claim what they want from scratch. And, what do they want? They want answers, flexibility, continual feedback and mentorship. They want meaningfulness, team work and to be heard. Most importantly, they want their life and they do not compromise about it. Unlike their parents. Unlike their grandparents. How bold is that? Should their managers let them get away with it? Well, if they want their companies to work after they have retired, if they want to boost their business and stay competitive in a global market, and, if they want to create a survivable, let alone positive work environment, then the answer is yes, they probably should.

Those companies that find a way to work with Millennials without diminishing performance standards and the quality of work will have a strategic advantage on the market. Having acknowledged that the problem exist, business experts around the globe have started to bust the ongoing myths about Millennials and to take a different, more positive approach to them, in order to bridge the gap between the cohorts and find a constructive way to work with Millennials and ensure the future of their own business.

During the last two decades, a large number of researches and studies on Generation Y have been conducted, especially on the western hemisphere. Different authors rely on the data from numerous works on this topic (Singh, Raj and Bhandaker, 2012; Barkin et al. 2010; Deal, Altman & Rogelberg, 2010; De Hauw & De Vos, 2010) in order to show that this generation differs from the previous by its system of values, aspirations, goals, priorities in life and lifestyles. Taking it into account, the integration of Millennial generation into the business culture created by the baby-boomer generation (Baby Boomers) is not an easy thing.

First of all, in order to better understand this generation, we need to consider the main factors that shaped their childhood and growing up, namely: globalization, technology, uncertainty of institutions, digital environment and diversity. Also, two micro trends that have formed them, particularly stand out, and these are: helicopter parenting and virtual reality (Tulgan 2015).
Let's start from the last.

Helicopter parents usually do everything for their children. They organize or structure their time from the morning to the time they go to sleep, carefully planning their activities, leaving them no much space for free play and the like. They also resolve conflicts for them, either because 'they are trying to help or don't have time for their children to take up their time to work it out' (Caraher 2015). Even though or because of the fact that they are raised in completely opposite way, most of the parents, who belong to Baby Boomer or Generation X, are overprotective, stroking egos of their children for participating, and not for accomplishing tasks properly, let alone winning, which is one of the biggest differences. Older generations weren't commended until they have won something, got all the best grades, completed any of the tasks really well and were exceptional. They were also strongly criticized for not behaving properly, not doing their best, not putting enough effort into what they did, etc. The same goes for the patronizing behaviour of Millennials' teachers and professors. The bottom line is that they are expected to behave in the same way as their parents only when they start working. In the workplace, once they make big mistakes, they get fired, and are not praised only for showing up. They are not encouraged and guided anymore, and they become disillusioned.

In spite of that, parents continue to be extremely involved in their Millennial children's careers and lives (and the case is mostly the opposite with previous generations), and many HR managers consider it a secret weapon to talk to or involve parents in some way in order to convince the Millennials to join or stay in a company. Several studies show that Millennials' parents are more influential than any other input. "Let's summarize these astounding statistics once more. Nearly nine out of ten (88 percent) of the Millennials look to their parents as a positive influence, and only 3 percent view the parents negatively. Also, 85 percent of the Millennials look to their parents as their primary source of advice and guidance." And here's the irony- Baby Boomer and Xers complain the most about Millennials and they do not realize they are products of their own parenting style.

3. MILLENNIALS AS DIGITAL NATIVES

Millennials are the first generation born after computers and technology have been invented. They are part and parcel of their lives, just like the radio or TV was of previous generation. They are called digital natives because they are native speakers of the digital language of computers, the Internet and other virtual reality media. That's why their attitude towards it is significantly different from that of digital immigrants who have only partially adopted technology as part of their work and life. Millennials, called by some Generation Txt, are always connected, either by email, smartphones or social networking sites, and they always communicate. They want this kind of communication in their workplace as well, they are used to it and feel more comfortable with than with face-to-face communication. They also want access to anyone and anything at any time. 'Just as access to any information is taken for granted, so is access to anybody' (Caraher, 2015). In addition, their informality present in virtual world, is usually transmitted to the workplace, where, accompanied with the crave for an unrestricted accessibility, makes this generation blind to hierarchy.

Apart from being always available as well as connected to everyone, digital world has also conditioned them to fast responses depriving them of patience (once an extremely valued characteristic). Now they want immediacy at work as well as in their private lives.
Blogging and gaming on the Internet, chatting on social networking sites, made them prone to team work, diverse surrounding and peer collaboration both in real and virtual world, since they simultaneously live in both. Due to the virtual world they prefer an interactive, engaging and fun environment, including the workplace as well.

The Generation Y is defined by uncertainty, uncertainty of their safety, uncertainty of their future, and uncertainty of what is to come next. Terrorism, global economic crisis, recession, lay-offs have been their reality emphasizing the unpredictability of tomorrow. The only sure thing about the future of the Millennials is that everything can change, and that the change is the only predictable thing in their lives. And they have trained themselves to expect it. The whole concept of their career perspective has changed in comparison to the one of the former generations. Lifelong learning, perpetual professional development and acquisition of new skills have strengthen and equipped them for the time of the utmost uncertainty. They have learned how to rely on themselves rather than the institutions and not to have great expectations, but start from scratch easily every time the country or an institution lets them down. Moreover, they are not prone to making permanent connections with companies, but rather voluntarily change them in search for a better job which will give them more satisfaction on a daily basis.

The advance of technology, rapid communication and transportation, has made the world a 'global village'. Relationships are built via social networks, and video conferencing has allowed for the deepening of relationships among people who have not met in real life. Many companies are founded by partners whose relations are digital. The quality of somebody's work, not their geography, has become many headhunters' priority. Diverse workforce is becoming commonplace both in virtual and in real world. The awareness of global issues is also expanding. Meeting people virtually, travelling more internationally and connecting globally is what Millennials expect in their workplace as well, making diversity a must in their professional lives.

4. THE MILLENNIAL MIND-SET

In her book 'Millennials & Management: The Essential Guide to Making It Work at Work', Lee Caraher (2015) points out that contrary to how they are generally perceived by others, Millennials see themselves as confident, contributors, change makers and capable:

- Confident. They are confident that they can contribute, that they can learn, that they can make a difference, that they matter and that they can be fulfilled in their work as part of a meaningful life. On one hand, they are raised to believe in themselves, on the other hand, they don't want to spend their lives at miserable jobs just because they have to pay the rent, like some of their parents did or do. They want it all and they believe they can get it. There's just this problem that they want it now, sometimes with no hard work, hence the feeling of entitlement.
- Contributors. They want to contribute to the 'real' work from day one (which is why the direct access to leadership is at the top of the list of job satisfaction priorities for them). They want to do important work and do not want to wait for years to get an opportunity to do it. What is also connected to this is that hierarchy and structure of the company is an outdated concept for them, and something that stands in the way of their hopes, dreams and fulfillment. So, even though, according to Lee, 91% of Millennials expect to stay in their jobs for less than three years, they stay longer when they understand how they fit in, and how their work contributes. They want to feel that they are important for the company, and they want to be told so. They need feedback, support, and the thorough understanding of the entire work process of their company and how exactly they fit in and why their work and their job position is important.

- Change makers. They want and feel that they can make a difference (to change the world or their part of it), the way the business works, the way it contributes to the community (that's why their dedication to community service and volunteerism can be found in most of the researches on the topic). If their job makes a direct environmental or social change, they are more satisfied.
- Capable. They believe in themselves so much, that they can do anything, they feel they have so much to offer and that they are full of potential, and they question whether the job is right for them and not if they are right for the job (such a different attitude to that of Boomers or Xers at their age).

These Millennials' traits strongly influence the characteristics they desire from the workplace. The research conducted by Singh, Raj and Bhandaker (2012) and presented in their book 'Millennials and the Workplace: Challenges for Architecting the Organizations of Tomorrow' lists the following characteristics of the workplace as Millennials' priorities:

1. The Millennial generation craves for a work environment that provides its members with the freedom to experiment, offers opportunities for taking initiatives and encourages innovation and generating ideas.
2. The Millennial generation also wants to work in an environment where their work and contribution are recognized and rewarded.
3. Fairness and transparency are important factors that attract representatives of the Millennial generation to join the organization.
4. The members of the Millennial generation would like to work in the workplace which offers many opportunities for learning, growth and development.

Other important attributes of a desired job for Millennials are: the possibility of teamwork, frequent, constructive feedback, work-life balance, openness to suggestions and expressing opinions, opportunities for leadership development, participation in charity and volunteering, care for physical and mental health of the employees, and only after these come meeting their financial needs and job security.

5. CONCLUSION

In the past the workplace functioned in such a way that employees would simply follow orders given by the supervisor – they didn't ask questions. However, Millennials don't typically respond well to this type of management style. There is a big difference between what Generation Y expects and demands of a job and what it actually gets. In this regard, it is necessary to change the modern organizations and adjust them to meet the needs of Millennial workers which will soon dominate the workplace in numbers. Modern workplaces have become more flexible and respectful of the needs of their employees. The most important segments of management to work on while building a Millennial-friendly organization include: making work meaningful, giving clear directions, providing constant feedback, provide meaningful acknowledgement and appreciation, ensuring transparency, providing full-life approach to work, providing access to management/leadership as well as mutual mentorship.

WHAT EVER HAPPENED TO THE CONCEPT OF HR BUSINESS PARTNERSHIP? SOME EVIDENCE ON FIRMS OPERATING IN SERBIA

Ivan Stefanović[1]
[1]Business Processes and Procedures Department Head, Vojvodjanska Bank ad Novi Sad
e-mail: ivan.stefanovic@voban.groupnbg.com

Abstract: *The concept of HR business partnership has not been understood appropriately by the majority of HR professionals in Serbia, which is why this paper seeks to remedy this situation. It starts with a theoretical concept of HR business partnership and accompanying Ulrich's model. After that, some insights about the current situation of HR business partnership concept in Serbia are given based on the author's investigation within three firms operating in different industries. In the end, a set of guidelines for HR professionals is provided. They refer to the need of acquiring better understanding of the HR business partnership concepts and Ulrich's model, after which they provide several useful steps for implanting them within a firm. The premise of the whole paper is that, if HR professionals want to take a sit at the executive table, they have to position themselves as strategic partners that add value to the entire organization.*

Keywords*: HR, business partnership, Ulrich's model, HR excellence, HR service center*

1. INTRODUCTION

Some critics argue that HR has not yet proved to be worthy to take this place because it acts more as an administrative service or compliance function than business partner (Ulrich & Dulebohn, 2015). Even some critics in US, where the field of HR has its roots, say that HR managers focus too much on administrative side of their work and lack vision and strategic insight (Cappelli, 2015). They claim that HR function is more focused on details within its scope of authority than the big picture and it is more concerned with its specific activities than the end-to-end value creation for the external customer. In other words, there is too much concentration on being expert in particular areas, such as: recruitment, staffing, rewarding, communication, training, employee relations, and so on (Hird, Marsh & Sparrow, 2009). What is needed instead is orientation on results and overall firm performance.

The concept built during 1990s as a result of inability of HR to make a significant contribution to the strategic agenda came to be known as "HR Business Partnership" (Ulrich et al., 1995; Ulrich, 1997; Losey, 1999; Ramlall, 2006). Intent of the HR Business Partnership (HRBP) was to help HR professionals integrate more thoroughly into business processes and align their day-to-day work with business outcomes (Ulrich & Brockbank 2009). With this concept, HR professionals have tried to provide a seemingly profound answer to the challenges business has been imposing on them. Even though HRBP has resulted in increasing the perceived value of HR, it is still hard to say whether it is close to deliver value to the business on a constant basis as promised.

2. THEORETICAL BACKGROUND

HRBP concept has not evolved over night, but rather resulted as a response to the shifting demands of business through the years of HR discipline development. Therefore, a very short look back down the HR history lane seems to be appropriate, after which we will explaine the model that enables HRBP concept operationalization.

2.1. A Short Look Back at the HR History

The need for HR and the emergence of this field as a profession in U.S. were results of World War I. In 1914 a widespread labor shortage began, especially for skilled workers, resulting in wage increases. This situation created a need for employers to utilize their workforce as much efficiently as possible, while trying to minimize the turnover rate. The epilogue was seen in establishing personnel departments between 1915 and 1920 to centralize employment related activities directed toward meeting business needs (Ulrich & Dulebohn, 2015).

In the following period, the priority of HR has been on dealing with unions due to their growth in power, while most other activities came to be viewed as low level and purely transactional. Thus, business has started to perceive HR as a necessary function that focused on administrative activities and cost control.

Another leap in viewing HR as a function that adds value to the entire organization happened in 1980s. This happened due to several factors occurring simultaneously: increased internationalization of business operations, deregulation in many industries, decreased unionization, changes in employment legislation, and the start of the shift from industrial to knowledge-based economy (Ulrich & Dulebohn, 2015). This situation led to rethinking the way in which business perceived its employees. All the sudden, they were no longer treated as mere expense, but became the most valued "resource" for gaining advantage over competitors (Prewitt, 1982). This approach was based on so-called "inside-out" view (Baden-Fuller & Stopford, 1994), in which internal resources constitute the starting point for understanding what organizational success means.

The massive restructuring of firms that took place in subsequent years starting from the 1990s, saw the first large scale outsourcing, including a large portion of transactional HR activities, such as payroll and benefits processing, as well as some types of training. At the same time, information technology proliferation has enabled the use of employee self-service with respect to a wide variety of HR activities. All the sudden, it has become obvious that a radical shift in perception of HR has to happen again in order for HR field and profession to remain viable in the long run.

2.2. The Contemporary HR Paradigm

Pressed with increasing demand to produce more value to the bottom-line, HR professionals had to rethink its role within a firm. The line of work that sparked the new wave of thinking about HR has been provided by various authors who argued that overall firm performance is maximized when HR policies and practices are consistent with the business strategy (cf. Schuler & Jackson, 1987; Miles and Snow, 1984, Ulrich, 1997, Becker and Huselid, 1998). In the exact words of Lawler and Mohrman (2003): "HR's greatest opportunity to add value may well be to play a role in the development and implementation of corporate strategy." (p. 2) This wave led to HRBP concept in the form we know today.

HRBP concept focuses on HR's role in the creation and maintenance of the capabilities that a firm must possess in order to deliver value to its customers, shareholders, employees and communities (Ulrich & Brockbank 2009). In order to be viable in everyday life of a firm, HRBP work ought to be divided into at least three, but in more complex organizations – five components, each with its own roles and responsibilities (Joinson, 1999; Kates, 2006; Ulrich, Younger & Brockbank, 2008; Ulrich & Dulebohn, 2015). Three basic components and their interactions came to be known as "Ulrich model", "3 Box model" or "Three Legged Stool". These components are as follows:

(1) HR business partners (a customer-facing front end). These are generalists who are matrixed in some form between line managers and HR. They act as consultants and planners, linking the business with appropriate HR programs. In other words, they are client relations managers whose job it is to diagnose client's wants and needs and then pull knowledge together to meet those client's expectations.
(2) Centers of excellence/knowledge (a product-focused back end). These are small specialist groups that produce programs and policies and provide decision support. They are populated with individuals who have deep expertise in the HR core areas of staffing, learning, compensation, organization development, and so forth. These employees depend upon the business partners to roll out the programs they create to the business.
(3) Operational/administrative service center. This center is intended to reduce costs and improve both efficiency and quality by systematizing and reducing transactional work, such as: payroll and benefits processing, employee assistance programs, relocation administration, pension plan enrollment and administration, applicant tracking, queries answering, resolving low-intensity employee relations issues, and the like. In addition, by taking employee-centered work away from the generalists, it theoretically frees up their time to concentrate on higher-value, management-focused work. HR service center enjoys economies of scale, meeting employee needs and resolving concerns by fewer dedicated HR resources based on highly standardized processes. Due to maturation of information technology, it may be located anywhere (usually, the choice is some lower-cost location, such as Eastern Europe or India). Also, the center may be centralized internally, outsourced, or provided through multiple vendors.

Even though the model just depicted proved to be worthy in terms of adding value to the overall business, some HR work continued to fall through the cracks (Reilly & Williams, 2006). Thus, the work on

operationalizing HRBP had to be continued. Besides these three basic components, two additional components were brought to light in order to strengthen the weaknesses perceived in the "Three Legged Stool" model (Ulrich, Younger & Brockbank, 2008). These are:

(4) Operational executor. What has been missing in some HR endeavours is the capacity to deliver and implement the ideas from the excellence center, while maintaining focus on the business and its customers. While this work ideally occurs through an integrated team made from experts pulled from various components of the excellence center, a designated person ought to be charged with this team and how it works. Thus, operational executor is usually assigned to a business in order to help turn the strategy into action. This position is focused on implementing specific projects within the business.
(5) Corporate HR. Since operationalization of HRBP concept obviously disperses HR activities, it is necessary to have one instance to integrate the remaining four. Therefore, corporate HR is established. Its primary concerns are the relations with CEO and the rest of top management, alignment of all HR work to be done with business goals, arbitration of disputes between centers of excellence and business partners, ensuring HR professional development and creating a consistent organizational culture.

As Ulrich's HRBP model has grown in popularity, numerous questions have been raised. For example: (1) Is this model suitable for firms no matter what their context or industry is, (2) What specific competencies does each role require, (3) how should differentiated roles be integrated in order to achieve the necessary level of coordination, (4) is this model really effective in selecting and developing business partners or linking HR strategy and business strategy, etc. Some of these questions have been answered and others are still waiting for appropriate response based on empirical evidence.

However, the fact remains that the benefits gained from Ulrich's model implementation have been mixed. While HR in some firms has made progress down the road of becoming a true business partner, many other firms claimed not to be able to experience the results anticipated by the use of this model. It has become obvious that the depth of HR talent capable of taking on an HR business partner role varies markedly between countries and firms. On the other hand, cultural differences reflected in the relationship between line managers and employees, and employees and HR have all impacted the ease with which this model can be implemented.

The results of a year-long ethnographic study considering the themes of becoming strategic, becoming a partner and remaining a generalist, showed that various tensions emerge as HR practitioners attempt to become strategic partners (Pritchard, 2010). Caldwell (2003) argues that converting HR practitioners to strategic partners will always be an overly ambitious transformation given the intrinsic role of ambiguities in the HR profession, which derived from its shifting cross-functional boundaries, substitutable expertise, unclear accountabilities and performance measures, and invariably problematic dependence on line managers for HR delivery (Caldwell, 2003).

Nevertheless, HRBP concept and Ulrich's model have proven their usefulness in different contexts, especially in firms with product portfolio diversified in related, as well as in non-related manner (Ulrich, Younger & Brockbank, 2008).

3. HR BUSINESS PARTNERSHIP CONCEPT IN FIRMS OPERATING IN SERBIA

The critique presented by magazine Fast Company's deputy editor, Keith Hammonds, in August 2005 has brought to light many negative aspects of HR work (Hammond, 2005). Hammond argued that HR managers contributed very little to organizational performance and remained fixated to bureaucratic procedures and administrative tasks. He also noted that the few things HR was good at could be outsourced, and that the strategic contribution HR managers were trying to achieve was beyond their capabilities. As much harsh as this critique may sound, it perfectly paints the picture of HR work in majority of firms operating in Serbia today, 10 years after this article was published.

Even though there is a general agreement that: (1) human capital can be a source of competitive advantage, (2) HR practices have the most direct influence of human capital of a firm, and (3) the complex nature of HRM systems of practice can enhance the inimitability of the firm (Delerey and Shaw, 2001), there is still an urge to thoroughly define how HR is going to add value to the firm and enhance its overall performance. This is especially true for firms doing business in Serbia. In those firms, it seems that an "inside-out" approach (Baden-Fuller & Stopford, 1994) still dominates. Under this approach, HR creates value just by serving employees, redesigning HR practices or making them more efficient.

So what ever happened to the HRBP concept in Serbia? The simplest answer would be that it has been misunderstood by majority of firms that attempted to implement it. This conclusion is made based on more than dozen unstructured interviews in the previous four years author has had with HR representatives working in various industries. However, since information gathered this way is not first-hand, i.e. not experienced directly, it has been treated only as a spark for further investigation on this topic. As a result, three large firms operating in Serbia, each of them with a long tradition but within different industries, were chosen for examination of HR practices. Their names will not be revealed due to confidentiality reasons.

3.1. Chemical Exporter

The first firm operates in chemical industry. It was founded in 1970s and now employs more than 1,500 people. Even though its technology is very old and needs to be renewed, it has a wide range of products with more than two-thirds of revenues coming from the export.

As for the HR concerns, it does not have a business partnership concept implemented. Instead, it relies on classic functional support to the business based mainly on transactional activities, which is the result of several factors (analysis of these factors is out of scope of this paper and will not be discussed any further). In other words, the work is more focused on administrative tasks, rather than on talent issues. Nevertheless, HR is divided in the following areas of expertise: recruitment and staffing, training and development, administration, employee relations, and internal communications. These areas of expertise are being coordinated at the level of HR director. This person is responsible for integrating the efforts of HR employees and delivering services to the business. The following figure illustrates the relations between HR and business (Figure 1).

Nevertheless, even a highly capable HR director cannot replace the business partnership concept, no matter how hard he or she tries. In the case of the Chemical Exporter, HR is acting completely reactively. It is mainly focused on administrative and employee relations tasks, while often seeks outside help from various consultants for HR activities that may influence the strategic agenda of the firm. Even though there is awareness about the lack of HR competences, nothing is being done in order to develop the knowledge, skills and abilities that might help the business to achieve its goals and add value to the organizational performances.

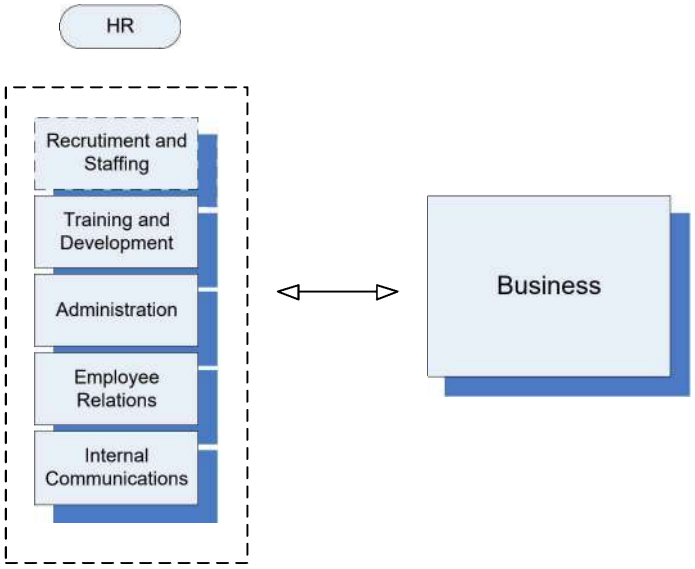

Figure 1: Relationship between HR and business in Chemical Exporter

3.2. Financial Traditionalist

The second firm operates in financial industry. It was established in 1860s with the aim of providing loans to the farmers. In the following decades, it has significantly broadened its scope of services resulting in a complete strategic repositioning. These changes in its business policy, even though seem large when perceived cumulatively, have been made in a slow and conservative fashion during a long time period. On the other hand, exceptionally long history of this firm has allowed it to play a very important role in the

development of Serbian economy, thus creating its image in a public as a very reliable business partner with traditionalist values. It now provides jobs to approximately 1,500 people.

In this firm, HR has recognized the concept of business partnership as a valuable asset and started its implementation. Nevertheless, the model currently implemented represents some sort of a hybrid somewhere between functional and HRBP models. As may be seen in Figure 2, HR Business Partner is actually a liaison between business on one side, and recruitment and staffing, as well as training and development on the other. In other words, if the business needs some services related to internal or external staffing, or perhaps increasing the competences of employees, it will approach HR Business Partner. On the other hand, services related to employee administration or relations, job descriptions, internal communication, and so on, will be provided directly, without HR Business Partner in between.

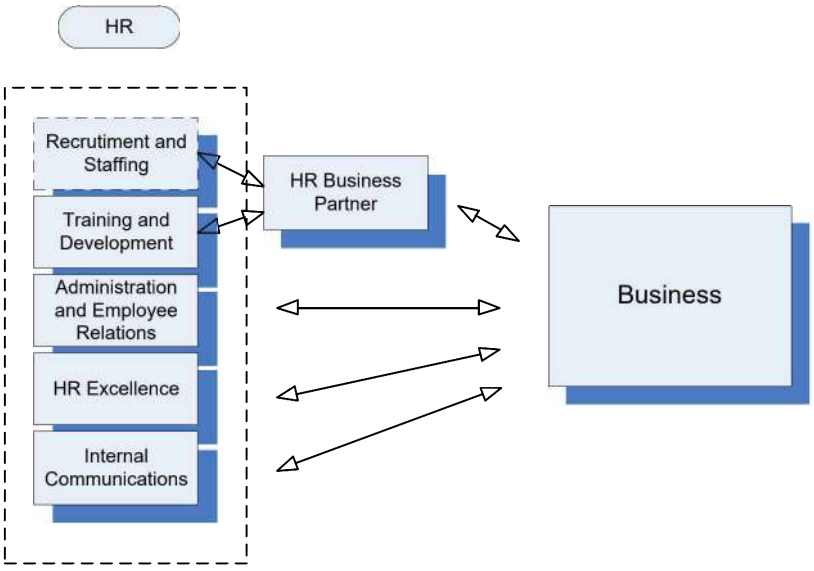

Figure 2: Relationship between HR and business in Financial Traditionalist

Even though HR Business Partner role in this case somewhat decreases the complexity for the business by creating a single point of contact for staffing and development services, it does not add true value to the strategic agenda. HR is still acting reactively by providing mainly transactional services on demand (even talent management services, if done purely according to the request when requested, may be seen as transactional), mainly due to the fact that there is still a wide gap to bridge in terms of competences needed to become a value added business partner.

3.3. Oil Major

The third firm operates in oil and gas industry. It was founded in 1940s in order to perform oil and oil derivatives trading. Due to its long history, it has gone through several periods of profound ownership and organizational restructurings, resulting in significant growth and business development. Now, it has become a vertically integrated firm with various products, supplying a major part of Serbian oil market. It has also become a highly successful competitor in the regional market that employs more than 10,000 people and provides a significant contribution to the Serbian GDP and budget increase.

Oil Major is organized into several divisions, each one being semi-autonomous and in charge for one particular part of the integrated value chain. Due to the complexity of the business coming from several lines of operations, it had been decided that HR needs would have been best served by adopting the HRBP concept. Therefore, each division has been granted a designated HR Business Partner in charge for all of its HR challenges. At the same time, administrative tasks have been kept centralized. They have been automated and organized based on a self-service principle. The HRBP model implemented in this firm is depicted in Figure 3,

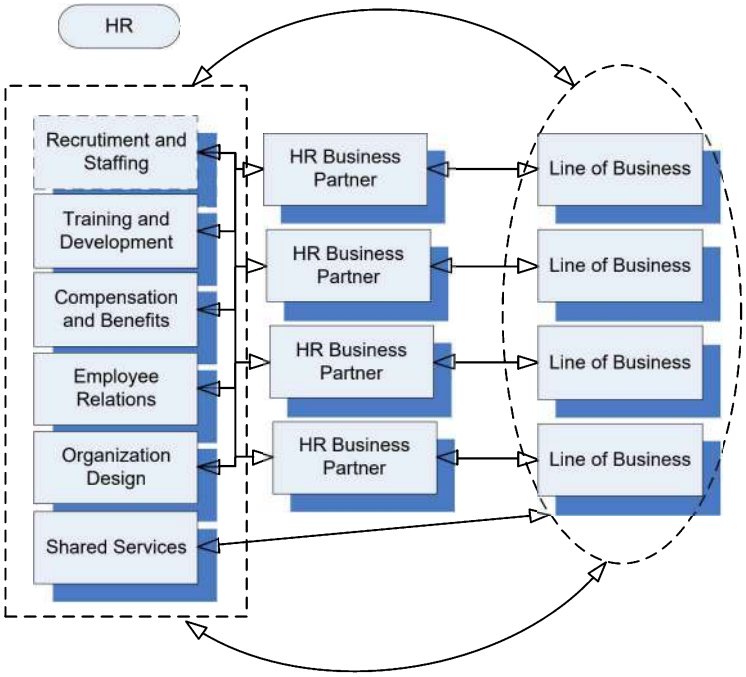

Figure 3: Relationship between HR and business in Oil Major

However, due to the lack of a proper communication about the business partnership concept and critical competences needed for this model to be adopted throughout the firm, as well as a strong organizational heritage that created inertia, the result of the entire endeavour has not been a true HRBP model. Rather, it has been a sort of a hybrid that, on one hand, provides the interface for all HR services toward the lines of business in the form of a designated HR Business Partner. Here, a business partner is an HR generalist and acts as a broker by providing the services to the business that he or she integrates after pulling them from HR centers of knowledge (Recruitments and Staffing, Training and Development, Organization Design, etc). On the other hand, the relationships between the business lines and HR centers of knowledge are still being maintained, which very often results in HR Business Partners being skipped. In those cases, business lines communicate with HR lines directly.

This situation creates a lot of difficulties and confusion. Roles are not well defined, activities are being duplicated, and communication channels are not straightforward. This usually leads to procedure breaches, not meeting the deadlines and overhead costs increase. Thus, implementation of this kind of HRPB model may have led this Oil Major into more unnecessary complexity, resulting in higher costs than benefits.

Regardless of the fact that some level of awareness about the importance of HRBP concept in Serbia does exist, after seeing these three examples, one might conclude that the attempts of implementing it somehow do not achieve the desired end result. Even though findings in these three organizations certainly may not be generalized on the whole population of firms operating in Serbia, they may serve as a signal that the HRBP concept has not been understood correctly in the HR community and that it is necessary to remedy this situation. Therefore, some recommendations seem appropriate.

4. RECOMMENDATIONS FOR HR PROFESSIONALS IN SERBIA

If firms operating in Serbia want to increase the value they add to the business, their perception of the business ought to switch. Instead of “inside-out”, they need to adopt an “outside-in” view. This approach starts with the environment in which the firm operates, after that it moves to the strategy by which the firm seeks its alignment with the environment, and finally considers HR policies and practices customized to meet the strategy and add value to it. According to Ulrich and Dulebohn (2015), in “outside-in” approach, HR creates value by making sure that services HR offers inside the firm are aligned to expectations outside the firm. Therefore, HR professionals ought to “… shift their attention from the organizational level and internal regulation to a more interactive level between the organization and the environment…” (Paauwe & Boselie, 2003, p. 67)

So, what is needed in order for HR in firms operating in Serbia to become a strategic partner? It seems that the proposal provided by Lawler and Mohrman (2003) for the firms operating in developed country equally applies to the situation currently found in Serbia. "The consensus seems to be that change is required both in the skills of individuals in the HR function and the way the HR function is organized and carries out its activities. HR not only needs to have competencies having to do with the business issues involved in strategy and strategy development, it needs to be able to contribute to organization design and change management. As far as its own organization concerns, it needs to be organized to carry out the basic administrative functions as well as being a strategic partner." (Lawler & Mohrman, 2003, pp. 4-5)

If this becomes a case, the business will finally start perceiving HR as a true strategic partner. According to Ulrich, Brockbank & Johnson (2009), HR professionals can ensure HR takes a true leap toward becoming a strategic partner by doing the following:

(1) Facilitate the strategy creation process by ensuring that right people are engaged in communication about strategic agenda and streamlining this discussion.
(2) Help clarify and articulate the strategy by making substantive contribution in communicating strategy to all employees and other stakeholders.
(3) Ensure execution of strategy by aligning HR practices in all its activities (recruitment, staffing, rewarding, communication, training, etc).
(4) Align leadership behaviour to strategy by clearly articulating what leadership knowledge and behaviours align with strategy and then turning these expectations into clear competencies and performance standards.
(5) Bring the view of the outside customer in by getting to know the motives, drives, and needs of external customers, and then translating this knowledge into relevant actions.

It should be mentioned that, in practice, the implementation of HRBP has rarely followed a single model, and there is growing concern regarding the efficacy of the more generic and context-independent competency frameworks propounded by advocates of business partnering (Ulrich and Brockbank, 2005). In other words, HR professionals in Serbia must undertake a broad multidimensional analysis of the current situation in their firms. Only after they are fully aware of the strengths and weaknesses within them, they may start designing the HRBP model to be implemented, as well as the process of implementation. The contingency approach should be entirely taken into account (cf. Pugh et al, 1963; Lawrence and Lorsch, 1967; Mintzberg, 1979).

5. CONCLUSION

HRBP concept and accompanying Ulrich's model have presented a tremendous revelation within the field of HR development. They have paved the way toward increased significance of HR as a true business partner that influences the performance of an entire firm.

Nevertheless, experience in Serbia has shown that implementation of HRBP concept is not an easy task to master. HR professionals must understand what this concept is really about and start working on elevating their competences in order to meet the requirements of becoming strategic partners. On the other hand, simply pursuing the structural solution implied by the Ulrich's model is not a sufficient condition for HR to deliver high perceived value (cf. Hird, Marsh & Sparrow, 2009). Becoming true strategic partners that add value to the entire organization require from HR professionals to understand the business context and key stakeholders, as well as how they interact with each other. They also need to rethink their role within the firm and find a way in which they may add value to the entire firm. These findings will help them acquire the knowledge that will enable them to participate in strategy formulation and execution on a sustainable basis.

HR has traveled a long way since it first emerged as a profession, but it seems that somewhere down the road it took a wrong turn, especially in case of Serbia. In order to continue this journey toward increasing the significance of HR as a true business partner, HR professionals must rethink their purpose and role in firms and start developing HR as a contributor of value to the strategic agenda. They must embrace the fact that if they wish to be recognized and take a sit at the executive table, they will have to be able to bring their share of value to the performance of an entire organization.

WFMS AS THE FOUNDATION OF BUSINESS PROCESS IMPROVEMENT: HUMAN RESOURCE MANAGEMENT PERSPECTIVE

Nemanja Minić[1], Marija Lukić[1], Milica Savić*[1]
[1] University of Belgrade, Faculty of organizational sciences
*Corresponding author, e-mail: savic1414@gmail.com

Abstract: *The optimization of business processes is a modern approach to implementation of organizational changes of different scope. This paper is closely related to business processes improvement through their automation and informatization. The aim of this paper is to explore the effects of the application of Omega Workflow Manager in the process of recruitment and selection of human resources. The basic characteristics of the process, its role in the organization, the impact on the efficiency and effectiveness are presented, as well as the description of an Omega Workflow Manager. The results of the analysis indicate that the implementation of this system leads to savings in terms of time, material resources and allows for a better control and coordination with the processes related to human resources.*

Keywords*: organizational change, process improvement, process optimization, workflow management, human resources*

1. INTRODUCTION

The term "process" may have various interpretations. Lindsay, Downs and Lunn (2003) cite the definition of Hammer and Champy from their well-known book *„Re-engineering the Corporation",* in which they define it as "a collection of activities that takes one or more kinds of input and creates an output that is of value to the customer. A business process has a goal and is affected by events occurring in the external world or in other processes" (p. 1015). Radović, Tomašević, Stojanović and Simeunović (2012) cite Davenport's definition of business processes as "a structured set of activities that can be measured, and which is designed to produce a specific output for a particular customer in the market" (p. 4). These definitions are sufficiently compressed, but at the same time they provide sufficient information to understand the processes and their importance.

Lin, Yang, and Pai (2002), after analyzing the work of well-known authors in this area like Davenport, Hammer, and Champy, suggest that business processes consist of five elements (p. 20-21):

- *Users* - each process serves a particular user with its output
- *Activities* - parts of the process which can be regarded as sub-processes
- *Related activities* – the identified activities are not isolated but are a part of the chain of activities directed towards the creation of value for the end user
- *People and technology* - the identified activities performed by humans or machines, or a combination thereof
- *Organizational units* - processes often span across multiple organizational units, but also there are processes that ocur in only one of them

Aguilar-Saven (2004) emphasizes that the processes go through different phases of development within an organization. These are (p. 131):

- The initial phase which leads to the establishment of the process
- The stage with an increasing number of repetitions of certain processes
- The defining phase that leads to the standardization and documentation of the process
- The stage where the processes can be managed, where you can measure and control their performance, and
- The optimization phase wherein the processes are being improved continuously

Hammer (2007) points out that for successful functioning, it is essential that the process is well designed and that the people who participate in its implementation have appropriate skills and knowledge. Furthermore, the owner of the process (a person who has authority and responsibility for providing the results of the process) needs to be identified and the infrastructure needs to support the progress of the process. Lastly, it is necessary for the system measuring the process results to be precisely developed. All these elements correlate with each other and they cannot separately lead to the proper operation of the process. Although all these elements are prerequisite and obligatory, the existence of each one of them is no guarantee for the progress of the process. In addition, so as to successfully realize the process, the existence of certain

organizational elements is critical. The most significant among them are leadership, culture, expertise, and management (p. 3).
When the process does not work properly, the certain changes must be taken. Draheim (2010, p. 16-17) and Mansar and Reijers (2007, p. 199) suggest that improvements of the process can be achieved in different ways: by defining a new job by combining several existing ones (elimination, recombination or introduction of new activities), performing work in the context where it arises, balancing centralization versus decentralization, allowing decision making at the operational level, allowing process steps to be performed parallelly wherever possible, identifying efficient versions of business processes, reducing control etc. These activities are performed in order to achive the process standardization. As Davenport (2005) points out, this term may refer to the standardization of activities and the process flow, standardization of process performance (when companies determine the activities that make up a process, they can start measuring its results and comparing it with external companies), standardization of process management (which shows how well the processes are managed and how to measure their success). This type of standardization is now the most widely used (p. 102-104).

There are various types of business processes; however, taking into account the aim of this paper we will highlight Porter's (2008) classification of activities: *primary activities* (inbound logistics, operations, outbound logistics, marketing & sales, and service) and *support activities* (firm infrastructure, human resource management, technology development and procurement) (p. 37). The following sections of this paper shall focus on dealing with the support processes, since their automation is rather applicable.

Once we have identified the basic elements and main characteristics of business processes, we shall analyze the concept of automation and informatization of business processes, as well as *Omega Workflow Manager*.

2. WORKFLOW MANAGEMENT SYSTEMS (WFMS)

Informatization and automation of business processes create the opportunity for "consideration of the organization on the entirely new way" (Jaško, Čudanov, Jevtić, & Krivokapić, 2013, p. 34). Permanent development of information and communication technologies on a global scale has caused an expansive growth of automation and informatization of business processes. Enterprise Resource Planning (ERP) and Workflow Management System (WfMS) are some of the most commonly used software solutions that represent the integration of IT-domain and business process management (BPM). Ravesteyn and Batenburg (2010) point out that implementation of such a solution is very often understood as "just another software application" and from this perspective it usually leads to a lack of coordination with social and organizational aspects of business (p. 493). Therefore, to prevent this kind of business misunderstanding, they suggest that "...organizations should realize that BPM-system implementation is not mainly an IT project, but should preferably be initiated by top management" (Ravesteyn & Batenburg, 2010, p. 492).

Petković and Lazarević (2012) define the workflow management as "…a technological support in redesigning work, business and information processes, as a technique of organizational change and a technique of process redesign" (p. 60). Also, Mentzas, Halaris and Kavadias (2001) describe the workflow management system as "…the most evolved of those applications providing consistent information flow between the participants in the process, smooth integration of the flow of work, timely sharing of data and information during the planning and implementation phases and harmonious support for the collaborative aspects of work" (p. 124). They highlight that development and implementation of this kind of application require precisely defined tasks, employees' roles, rules, and procedures. WfMS, as a business processes management tool, has three main perspectives: (1) control flow perspective - defining the sequence of activities in the process; (2) data perspective – the set of information that is transmitted, and (3) resource perspective - assigning responsibilities to employees for task realization (Stroppi, Chiotti, & Villarreal, 2015, p. 86).

Assigning a required number of people to carry out each business task, effective monitoring of its realization and control of the business task flow are the three main reasons why an increasing number of organizations all around the world have implemented WfMS (Tsai, Huang, Wang, & Chen, 2010, p. 1538). Besides that, WfMS allows employees to spend less time on delegation and coordination of work; process informatization leads to a decrease in time when a task comes to a standstill during its life cycle and also encourages the reduction of time when task is to be completed (Reijers, Vanderfeesten, & Van der Aa, 2016, p. 128). For successful application of WfMS, it is necessary to precisely define the process - all steps and activities that the process comprises. A great number of authors emphasize the importance of properly defined process flow. For instance, Van der Aa, Reijers and Vanderfeesten (2016) explain that properly defining activities is

crucial because their content and size affect model understandability, experienced meaningfulness and execution efficiency, as three crucial aspects of process design (p.162).

Replacement of manual labour with a process that is automated through information system, leads to improvement of the process efficiency (Vukicevic & Milosevic, 2012, p. 65). Reijers, Vanderfeesten and Van der Aa (2016) did a multi-case longitudinal study of the implementation of Workflow Management System (WfMS) to determine whether the use of this kind of system positively affects the process improvement. This process oriented analysis included over 25 processes across 10 organizations and showed that the business process automation had a positive effect on reducing the time needed for the realization of business activities. The results showed that performance improvements through implementation of WfMS in general were substantial (p. 130-139).

Based on the literature review, we can conclude that the WfMS is a modern, applicable and prospective concept, which could lead to significant improvements, as shall be explored and demostrated in the case of *Omega Workflow Manage*r.

2.1. Omega Workflow Manager

Omega Work Flow Manager is a web application created using a variety of Internet technologies in order to develop a software that will support process automation of the real system (organization). The authors have attempted to make this application user-friendly, so that the software can be quickly developed and implemented. A wide range of functionalities allow modeling of mainly medium-sized processes.

The software is based on logic and the basic elements of the existing process, as well as on the experience of WFM moderator. WFM primarily has been developed for moderators of the process, i.e. people who are studying, modeling and designing process to create software. Also, predefined processes help automation of new similar processes, which is great because clients require a simple and quick solution.

The form that represents the process has its own database – information, users, execution rules, restrictions, etc. It is divided into steps and each step has its own processor. The processor is actually the owner of the step. The step represents an ordered set of pages, wherein questions for the users are defined, recognized and adequately set up in order to follow the process in the right way.

In OWfM, participants from the real process are presented as software users and activities are presented as steps. The application is able to communicate with the database, so it is possible to retrieve useful information which is not directly presented on the form, but could be useful in the decision-making process when a user starts filling out the form. As regards the work with data, SQL operations are supported (select, insert, update, delete), as well as queries and complex queries. All this is implemented through actions, which is comparable with methods in programming languages. With regard to the used technology, the outputs from the process (documents, reports and results) can be exported to an Excel or a Word file that allow monitoring of all data that have passed through OWfM, or, more precisely, through a certain process.

Process automation through OWfM is performed in several steps:
- Determination of processes which are to be automated
- Modeling business processes
- Defining users, their roles and activities
- Defining the database
- Defining the input and output documents

The graph below shows the use of certain software solutions depending on the complexity of the process. For example, an increase in the complexity reduces the efficiency of the use of e-mails as a tool of managing the process. Also, the more complex the process is, the ERP is imposed as the optimal solution, but the major obstacle is the price. Obviously, the implementation of OWfM in the processes of medium complexity is the best solution, provided that it is used in the right way.

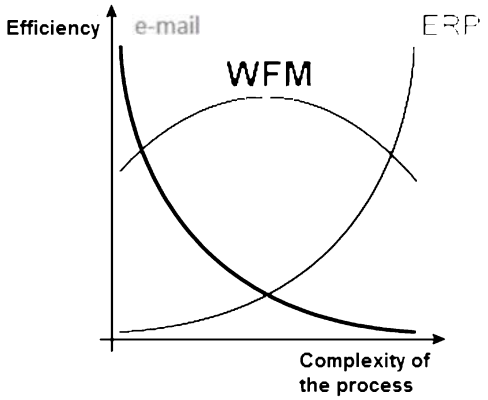

Figure 1: Relation between the process complexity and the software efficiency

These are the basic characteristics of Omega Workflow Manager. Moving on from the example of application in Organization M, we are going to present some of its implementation results, advantages, and limitations. The results of the following analysis are mainly quantitative, which is important for the comparison of the state before and after the introduction of OWfM.

3. THE EXAMPLE OF THE OMEGA WORKFLOW MANAGER IMPLEMENTATION

Organization M (hereinafter only *Organization*), measured by the number of employees (around 1,000) and financial performances, represents a large, successful and stable company. The organization does not have financial problems, but wants to improve the operational efficiency. The subject of the project was the improvement of HR processes, and the entire organizational unit (hereinafter only *Human Resources* or *HR*). Human resources consist of four departments: *Department for Norms of Labor Relations, Department for Employees Education and Training, Department for Labor Legal Affairs, and Department for Selection and Potentials Evaluation.* Each of these departments has employees in the central part of the organization, and in the four organizational depots. The analysis of the work volume in HR for the period of previous three years was conducted during the first phase of the project. The data on the main processes, their average duration as represented in hours, the number of repetitions on an annual basis, as well as the total annual work volume (average duration * number of repeats) for these organizational units and in total were obtained through the analysis and the relevant calculations. Some of the data are shown in the following table.

Table 1: List of HR processes, their annual duration and percentage share in total work volume

Process	Annual work volume (h)	Share in total work volume (%)
Department for Norms of Labor Relations	2,275	8.96%
Normatives of Labor Law Affairs	1,479	5.82%
Additional jobs	796	3.14%
Department for Employees Education and Training	8,059	31.74%
Employees education	1,633	6.43%
Training and professional development	2,839	11.18%
Additional jobs	3,588	14.13%
Department for Labor Legal Affairs	4,943	19.47%
Labor legal affairs during employment	3,519	13.86%
Labor legal affairs outside employment	172	0.68%
Labor legal affairs for employment	100	0.39%
Additional jobs	1,153	4.54%
Department for Selection and Potentials Evaluation	10,112	39.83%
Recruitment and selection of youth cooperatives	24	0.10%
Recruitment and selection for temporary jobs	415	1.63%
Recruitment and selection for intern	181	0.71%
Recruitment and selection of trainees	3,123	12.30%
Recruitment and selection for employment	5,280	20.80%
Additional jobs	1,091	4.30%
TOTAL	**25,390**	**100.00%**

It should be noted that not all of the business processes can be the subject of automation. For example, Hall and Johnson (2009) define so called "artistic processes" that use diversity environment to create variations of products or services that are highly valued by consumers (p. 58). These processes cannot be the subject of automation. Becker, Kugeler, and Rosemann (2003) suggest that the previous analysis should include structural characteristics of the process, organizational status and conditions, as well as the potential benefits of automation in order to allocate certain candidates (p. 268). Based on the results of the first phase, we can consider the type and the scope of work in human resources, and isolate the processes that can be modeled. This selection was based on the following criteria: the possibility of modeling, participation in total work volume, the possibility for the improvement of related processes in other organizational parts, and the number of participants in the process. In our case, the analysis showed that certain processes can be modeled (e.g. recruitment and selection, training and professional development, labor legal affairs), while others either cannot be modeled or are not so important for modeling (normative of labor law affairs and additional jobs by individual organizational units). For the purpose of this article, we will explain in detail modeling of the process of *Recruitment and selection*, while other processes were modeled in a similar way.

Recruitment and selection is one of the most important processes in organization M, as evidenced by the share of its organizational unit of 39.83% in total work volume. This can be seen as a direct consequence of the size of the organization and the constant need for new employees. There are several different forms of the process realization, depending on whether the subject is recruitment and selection for a full-time employment, for temporary jobs, for youth cooperatives or trainees. Essentially, the process encompasses the following activities: *initiation for declaration of needs for employees, identification of needs for employees, forming the Plan of employment, advertising the need for candidates, recruitment and selection of candidates, creation of the Employment Contract, and training on health and safety at work.* The process is carried out by three executors and passes through all previously mentioned services. The average number of repeats on an annual basis is around 1000 (including all different forms of recruitment and selection).

The process analysis revealed that there are some problems in the realization of most of these activities, and that there is a significant room for improvement. For example, during the activities of initiation for declaration of needs for employees, the identification of employees' needs, and forming the Plan of employment, there are problems of late delivery of the requested data, submission of data in a form that is not appropriate, unnecessary repetition of work (e.g. retyping the data) or frequent typing mistakes, and the like. These three activities are carried out for all of the above mentioned forms of recruitment and selection (full-time, temporary, youth cooperatives or trainees). In the part of advertising the needs for candidates and recruitment and selection of candidates, main problems are related to overworked (overburdened) employees at headquarters, since all received biographies are being analyzed in the central organizational unit, although in depots there are all the technical and human prerequisites for the performance of this activity, high costs of transport charges of candidates who are obliged to take all the selection tests in the central organizational unit, inefficient processing of received biographies in terms of their grouping in one place and inefficient comparison of one candidate with another. Then, in the part that refers to the creation *of the Employment Contract*, one of minor problems that may come up is that there are no document models that would be largely automatically filled, and therefore there is a possibility of making some minor mistakes. In relation to the abovementioned problems, this is the smallest one. Some common problems that exist in the whole process are related to the long duration that some routine tasks require, which results in a lack of time to deal with substantive matters; the fact that there is no process automation at all, and the data on employment are not integrated and available in one place. Thus, there is a large space for implementation of the system, not only for solving the current problems, but also for those that could arise in the future.

The implementation of the system was based on the previously presented analysis, the identification of the problems, and the needs of users. The largest portion of this phase was dedicated to a search for solutions to the identified problems, while the modeling was completed relatively quickly. Based on the analysis, it can be concluded that the long duration of the process is the main problem, or as a large part of it, and therefore, the focus was on its reduction. It should be noted that the system shortens the process duration in two basic ways: through the process optimization (e.g. elimination of unnecessary activities), and automation that the system allows (automatic creation of reports, documents, overview of the relevant data for the decision making, etc.). The improvements can be best examined by a comparative analysis of the obtained data presented in the table below. The table shows the situation before and after the system introduction.

Table 2: Comparative analysis of the process of recruitment and selection

Recruitment and selection	Duration time (before OWFM)	Duration time (after OWFM)	Change (%)
Initiation for declaration of needs for employees	5	3	40.00%
Identification of needs for employees	260	243	0.07%
Forming the Plan of employment	60	50	0.17%
Advertising the need for candidates	2.5	2.5	0.00%
Recruitment and selection of candidates	2	1	50.00%
Creation of the Employment Contract	5	3	40.00%
Training on health and safety at work	2	1	50.00%
TOTAL	**336.5**	**303.5**	**9.73%**

It is notable, based on the table, that a significant shortening of the duration of certain activities (from the minor ones by 0.07% to the large ones by 50.00%) has been achieved. This can be interpreted as a direct result of the transfer of particular manual activities to the system. What cannot be seen from the table is that the recruitment and selection activities were decentralized and partially transferred to depots, thereby achieving the savings in terms of the costs of transport charges. A very interesting fact is that this improvement was made without any other organizational change, which opens the space for redistribution of work within the framework of human resources, but also in relation to other organizational units (e.g. finance). Čudanov, Jaško, and Jevtić (2009), point out that "ICT itself does not point organization toward more or less decentralization, but widens possibilities for adjusting level of decentralization to other internal or external parameters characteristic to the organization. Development of ICT leaves much more freedom to the designers and consultants to accommodate organizations to other influences, both internal and external" (p. 106). Other processes in human resources were modeled in a similar way, and their obtained time savings are shown in the table below. By grouping the time reductions per processes and their organizational units, we made a comprehensive quantitative analysis of their improvements. Therefore, it can be noticed that the organizational unit of Human Resources achieved significant improvements in terms of time saving per organizational units (from 3.35% to 48.47%) and are huge in total. Besides these quantitative effects, there have been significant qualitative improvements, related to the main strenghts of the system listed in the following table.

Table 3: Effects of implementation of Omega Workflow Manager in HR

Process	Annual work volume (h)	Share in total work volume (%)	Annual work volume (h) after OWFM	Share in total work volume (%) after OWFM	Change after OWFM (%)
Department for Norms of Labor Relations	2,275	8.96%	2,199	12.20%	3.35%
Normatives of Labor Law Affairs	1,479	5.82%	1,479	8.21%	0.00%
Additional jobs	796	3.14%	769	4.27%	3.35%
Department for Employees Education and Training	8,059	31.74%	7,072	39.25%	12.25%
Employees education	1,633	6.43%	1,546	8.58%	5.33%
Training and professional development	2,839	11.18%	2,705	15.01%	4.71%
Additional jobs	3,588	14.13%	3,509	19.47%	2.21%
Department for Labor Legal Affairs	4,943	19.47%	3,537	19.63%	28.45%
Labor legal affairs during employment	3,519	13.86%	3,230	17.93%	8.21%
Labor legal affairs outside employment	172	0.68%	157	0.87%	8.57%
Labor legal affairs for employment	100	0.39%	92	0.51%	8.36%
Additional jobs	1,153	4.54%	1,115	6.19%	3.31%
Department for Selection and Potentials Evaluation	10,112	39.83%	5,211	28.92%	48.47%
Recruitment and selection of youth cooperatives	24	0.10%	22	0.12%	8.71%
Recruitment and selection for temporary jobs	415	1.63%	380	2.11%	8.36%
Recruitment and selection for intern	181	0.71%	165	0.91%	9.01%
Recruitment and selection of trainees	3,123	12.30%	2,834	15.73%	9.25%
Recruitment and selection for employment	5,280	20.80%	4,766	26.45%	9.73%
Additional jobs	1,091	4.30%	1,054	5.85%	3.41%
TOTAL	**25,390**	**100.00%**	**18,018**	**100.00%**	**92.52%**

The effects of the system implementation can be felt very quickly, especially for the processes which are often repeated. Having analyzed the improvements that the system has brought, we should shortly analyze the costs of implementation. In general, it can be said that they vary depending on the process complexity and the project duration (which again depends on the complexity), and that they are made of two components: the costs of process modeling, and the costs of license for using the software. The implementation costs can be roughly assessed at 40 Euros per hour, while the costs of license for using the

software could range from a few hundred Euros to several thousand Euros per month. However, as compared to other, more complicated softwares (e.g. SAP) the period of return is much shorter.

Based on the foregoing, we can point out that the system implementation leads to the improvement of coordination, simplification of the process through the elimination of some unnecessary activities, reduction of the process duration and costs, improvement of the process quality, unburdening employees and consequently to the increase in their satisfaction, a partial improvement of related organizational units, better data management, as well as to opening up opportunities for implementation of other un/related organizational improvements (e.g. optimization of the number of employees, better performance monitoring etc.). Considered in relation to other systems, the advantages of the system are: a shorter period of implementation, lower costs of implementation, faster return on investment, lower volume of change etc.

During the system implementation and use, certain problems of much smaller scale and significance compared with the more complex systems could also occur. They are mostly organizational in nature, and related to unclear needs of users (they usually do not know what are the real problems, for what purpose they want to use the software, what are the most suitable processes for modeling etc.), resistance of employees towards the use of the system (fear of some employees due to the system transparency, the possibilities of determining a halt holder, the increased degree of control) and the like.

4. CONCLUSION

The rapid development of technology has created challenges in the field of the optimization of business processes. New information technologies offer great opportunities for the improvement and optimization of business processes. The optimization can be incremental or radical and, depending on the current state of the organization, it may include the whole organization or just certain parts. It can be the part of a broad or narrow organizational change. Likewise, the optimization does not have to refer only to the elimination of process activities, but also to the reduction of time and other resources. Considering technology as one of the main factors that affect changes in Human Resource Management (HRM), some authors explained that changes in technology "…transformed the way that organizations recruit, select, motivate, and retain employees" (Stone, Deadrick, Lukaszewski, & Johnson, 2015, p. 1). According to them, the growing importance of these changes is a consequence of the contemporary business approach based on the knowledge and talents of employees.

However, if company decides to conduct the informatization of business processes, it would be good first to conduct the evaluation of optimal software solution. Čudanov, Jaško and Saviou (2010, p. 37) in their research showed that the highest level of information and communication technology adoption is recorded in large and medium-sized enterprises. In our country, the largest number of enterprises are medium-sized enterprises where ERP or SAP cannot be effective, due to the lack of complexity of the processes, and those systems also require excessive implementation costs. The practice has shown that the WfMS software is an excellent tool for modeling processes of medium complexity.

In practice, it has been proven that Omega Workflow Manager System gives good results in processes from different organizational units (finance, procurement, sales, marketing, etc.). The system has been successfully implemented in some of the leading companies in Serbia: SBB - sales channels management, Mercator-S – work performance evaluation, online tests, legal documents approval, Coca-Cola Hellenic - processing applications, work performance evaluation, Vinča Institute of Nuclear Sciences – public procurements.

In the case of organization M, we saw that in human resources department only one process automation can lead to significant improvements in efficiency and effectiveness. Moreover, if the number of modeled processes increases, the total effect also increases due to the synergy effect. This kind of project represents an ideal opportunity for the analysis of the current working modes, and solving some core problems and the implementation of new ideas.
In this paper, we focused on the organizational aspects of business processes optimization. The subject of further research could include a cost-benefit analysis and also it would be interesting to investigate the effects of joint realization of system implementation and implementation of major organizational changes, such as corporate restructuring.

Abstract: *Understanding of customer demands was always the weakest point in information systems development. Due to the inadequat understanding and defining business demands, numerous projects end up not being successfully finished. Being aware that client demands are changing, many companies decide to use agile methodologies which generally contribute to faster and more efficient information systems development. However, there are many tools and methodologies which are considered to be agile. Companies decide to use two or more methodologies for managing projects of information systems development, in order to use their advantages and adjust them to their business model. The goal of this paper is comparative analysis of Scrum and Kanban methodologies, as well as their tools, with the idea to integrate these two methodologies in order to use their best practices. The analysis shown in this paper is used for developing software tool called „ScrumbanTool", which presentation is going beyond this paper.*

Keywords*: agile methodologies, scrum, kanban, information systems development, project management*

1. INTRODUCTION

Information systems development consists of all activities related to analysis, design, development, and deployment. Considering the fact that technologies change with time, organisations need new systems or significant changes in the old ones, in order to fulfil their goals. This points out the fact that the information systems development is complex and continuous process.

Throughout software development, different methodologies developed that help information systems development. Numerous factors influence the choice of methodology, one of them being the support of methodology in managing the project of the information systems development. Project management is not only significant scientific discipline needed in every organization, but is also considered to be necessary for the survival of any company. Due to the changes in client's demands, many companies decide to use agile development methodologies which enable better focus on client's problems, shorter time for project realisation and faster and easier adjustment to changeable environment (Moniruzzaman & Hossain, 2013).

It is not so rare the companies decide to combine two or more methods for project managment, in order to use these methods in the best possible way and adjust them to their business model. With the development of agile methodologies, numerous software tools that enable easy survey of project and it's managing, are also developed. The goal of this paper is comparative analysis of Scrum and Kanban agile methodologies.

2. AGILE SOFTWARE DEVELOPMENT METHODOLOGIES

In the late 1990-ies, a group of designers (Ken Beck, Alstair Cockburn and others, founded Agile Alliance) was the creator of agile approach in the information systems development Supporters of agile software development methodologies bring in 2001 Agile Software Development Manifesto trying to emphasize the role the flexibility could have in more skilled and faster development of software product (Padavić, Velić, & Ljubobratović, 2011).

According to the Agile Manifesto (Fowler & Highsmith, 2001), some of the principles of agile methodologies are:

- The highest priority is to satisfy customer through early and continuous product delivery
- The change in demands is normal, even in the late project phases
- Software product that works, is delivered every few weeks or months
- The team periodically tests good and bad procedures, and tries to repair them for the next period

The principles represent conceptual framework which should be used during development of software product. Agile methodologies are subset of iterative and evolutional methods, and are based on iterative enhancement, while iterations (repetitions) are short in order to give correct information to project team.

Understanding of customer demands has always been the weakest point in the information systems development. Due to inadequate understanding and defining of business demands, some software development projects failed to fulfill customer expectations. Management of demands consists of activities which are dealing with detecting demands, following and controlling of versions and changes in demands. The change in demand is every change of the existing demand or new demand that can influence the existing demands.

Demand changes happen due to the changes in business environment or customer needs. Defining demands, according to the traditional methodologies, goes through phases of analysis, documentation and check. For many organizations, this is a process of few weeks or even months. Unlike traditional, agile practice deals with smaller parts of demands, which are developed and tested during one sprint (iteration) and, in the end, being presented to final customer, for demand validation. Identifying and development of agile demands is done during agile planning, development and delivery (Milanov & Njegus, 2012):

- Agile planning. Agile teams develop demands according to their business values, i.e.: profit increase, cost decrease, service improvement, harmonizing legislation, accomplishing market goals etc. Agility means focusing on the actual values and discarding everything that is not of great importance. Planning covers not only „current view“ (current iteration), but as well the review of the solutions and „big view“(the vision and the map of product development). Product owners are doing agile planning, by constantly reconsidering demand priorities and by validating risks and dependencies.
- Agile development. Agile development team estimates, develops, tests and demonstrates demands to final users. Before the beginning of Sprint, development team sketches data model, condition diagrams or interfaces, which also represents mini specification of the solution.
- Agile delivery. Demands are often dependent on one another. Agile teams analyze and optimize dependencies of the demands.

Predetermined length of the iteration is used as a time frame for the development team. According to the length of the iteration, the scope of the problems to be solved is being determined. The main difference between agile and iterative methodologies is the length of a single iteration. While the length of the iteration for iterative methodologies is three to six months, with agile approach the interval decreased to one to four weeks, and the most 30 days.

Some methodologies for information system product development based on agile principles are (Abrahamsson, Warsta, Siponen, Ronkainen, & Ronkanen, 2003), (Hiranabe, 2007):

- eXtreme Programming – XP
- Scrum
- Feature Driven Development – FDD
- Crystal family of methodologies
- Dynamic Systems Development Method – DSDM
- Adaptive Software Development – ASD
- Kanban

2.1. Scrum development methodology

The term „scrum“ originates from rugby and represents „throwing the ball back into the game“. This methodology is fast, adaptable and more and more popular among IT companies.

Initially, this agile methodology was developed as a set of management recommendations and suggestions for managing the information systems development project. Project development with Scrum methodology is done iteratively, and iteration is called Sprint. Sprint has to be predetermined and is recommended to last between two and four weeks (Pichler, 2010). After one Sprint, one draft version is ready for delivery, while the whole project can be done through three to eight sprints.

According to Scrum, complete system development is divided into three groups of activities: pregame, game and post-game (Gorakavi, 2009). Through pregame, demands and development priorities are being defined, and value of newly built increments is being estimated. Throughout the game, the development and functionality implementation are done iteratively, and in post-game period, testing and integration (Figure 1).

Scrum tools are making processes and activities of this methodology much easier. Many vendors are offering their versions of tools for project management that support Scrum, and some of them are with open code. Some of Scrum tools are: Agile Tracking Tool, Scrumwise, ScrumDo, Scrumy, Agilito, Agilo for Scrum, PangoScrum, Scrumpad, Rally Dev, Jira etc.

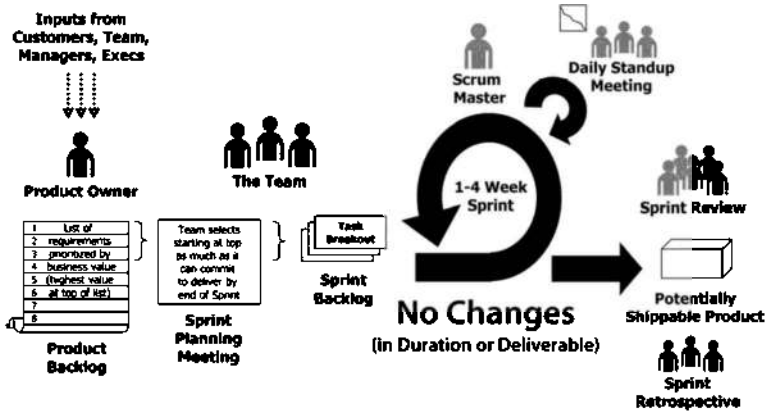

Figure 1: Scrum methodology through phases (Deemer & Benefield, 2010)

Jira is one of the best known Scrum tools. It is the product of Atlassian, and is used for project management. It is written in Java program language, and it also has its free version for projects with the open code (Atlassian, 2005). It is often used with systems for version control, such as SVNili Mercurial, and with Bamboo build server. The system enables communication within development team, as well as with a buyer or owner.

With very intuitive control board, it is possible to:
- Create, set projects
- Set schemes and workflow
- Work with tasks, as a main project unit
- Track task length and status
- Give priority and person in charge for every task
- Sort backlog etc.

2.2. Kanban development methodology

Kanban agile methodology of information systems development is following Lean software development. The term „lean" represents the motive to spend less amount of time, less human effort, less investment, less effort and less finances during development.

Kanban spread through production industry in the world, as the tool for Lean Manufacturing, and in agile information systems development, it is the way of project visualization by placing cards with assignments on the board, by which just in time – JIT development strategy is achieved (Wagener, Schmit, Mandal, & Vaishnavi, 2012). In Japanese vocabulary „kan" means „signal" while „ban" means „card" or „board".

Lean Kanban strategy is generally more focused on job being finished in time, instead of being focused on who did it. People work together, but they do not work with the same speed, they do not have the same knowledge and skills, so they have to synchronize (Anderson, 2010). In Kanban, the work is organized by tasks or processes, and allows team members to change on their own the workflow in the most productive way.

The rules of Kanban do not consider important demands that are not needed at the moment by anyone, do not write more specifications than can be programmed, codes are written in the amount that can be tested, and according to that, only what can be released is tested (Anderson, 2010). Kanban system in engineering is done in a way that all demands which are waiting in line are passing through few phases, until they are finished. When demand is in a phase „Finished" than it goes to the next phase.

The advantages of Kanban, compared to traditional „push" systems, are (Topić, 2012):
- Simple and understandable process
- Gives fast and precise information

- Low costs of transferring information
- Possible fast reply to changes
- Limited capacity in process
- Avoids hyper production
- Minimizes waist
- Easier control maintaining

Main Kanban principles which are continuously followed by the team are: visual control (Kanban board), Limit Work in Process – WIP, card pull, fix Kanban backlog. The usage of colored cards and their availability for different types of work, can enable development team too quickly:
- See what is currently being worked on (the cards give value to a certain job)
- Easily see blocker tasks
- Estimate how good was the analysis
- Do easy tracking (how many tasks exceeded time limit etc.)

If there is emergency case concerning support demands or mistake in software product (software bug) during production, than an empty space in Kanban board is used, under the name „Urgent". The tasks that are solved in this way are not being put into backlog, but the aim is to solve them as quickly as possible.

The advantage of Kanban board is visibility of the following (Hiranabe, 2008):
- The work of individual
- Is the individual overloaded with work
- Where is bottleneck
- Where problems in work occur
- What is being blocked

Some of the well-known web-based Kanban tools are: Lean Kit Kanban, Kanboard, Axosoft, Kanbanery, AgileZen, Flow, FogBugz Kanban, GreenHopper, Hansoft, LeanKit Kanban, Lino, Qanban, SilverCatalyst and others.

3. COMPARATIVE ANALYSIS OF SCRUM AND KANBAN METHODOLOGIES

- Comparison by the number of rules

These two methodologies can be compared by the number of rules they possess. If a certain methodology has more obligatory rules, that methodology is called prescriptive methodology. On the other hand, if methodology does not possess any rule, it is called adaptive methodology. Completely prescriptive methodology gives all the guidelines and rules, so everything organization needs to do is follow the rules, without any other efforts during project management, while completely adaptive methodology leaves everything to organization without any rule. Both extremes are very risky (Kniberg & Skarin, 2010).

Agile methodologies are generally referred to as light weight methodologies, because they are less prescriptive from traditional methodologies. Both Scrum and Kanban methodology are very adaptive, but compared to one another, Scrum is more prescriptive. Scrum possesses more limits and therefore has fewer options. For example, Scrum expects usage of time-limited iterations (sprints), while Kanban does not.

- Comparison by roles

There are three different types of roles in Scrum: Product owner, Development team and Scrum leader. There are no different roles for different members of team, in other words, there are no specific roles. This does not mean that the team organised around the project should not have its owner, but rather that it is not necessary.

On the other hand, both Scrum and Kanban are open to adding any other type of role if necessary. But there has to be precaution, in order to add new value to the product by adding new role, and not only conflicts with other elements of the process. Companies often add Project Manager to the team, who synchronises teams and product owner. However, since the global motto of both methodologies is „less is more", if organisation is having a dilemma, the recommendation is to start with less number of roles in a team.

- Comparison by meetings

Scrum team is having a short meeting every day at the same time and place. The goal of these daily meetings is to exchange information about development, plans for the next day and to point out any major problem if there is any.

Kanban does not imply daily meetings, but nevertheless most of Kanban teams have this habit. It is a great technique for any methodology.

Scrum form of meetings is mainly about people, since every person gives a report, one after another. Kanban teams use more Kanban board, and are focused on the problems that are visible on the board. The problem of this way occurs when many teams use the same board and have daily meeting together, because it is not always necessary to listen to other team's problems (Kniberg & Skarin, 2010).

- Comparison by time planning

Scrum is based on time-limited iterations. The team itself determines the length of iteration, but it is important that iteration always has the same length through the complete project development, or at least, one long period of time.

At the beginning of each iteration a plan is being formed, team plans certain and definite number of orders from backlog, based on the priorities of product owner. During iteration, team is focused on finishing orders that had been planned at the beginning of the iteration, while at the end of the iteration the team presents potentially finished product to stakeholders and gives a retrospective/discussion in order to improve complete process.

One Scrum iteration is time-limited sequence which combines three different activities (Kniberg & Skarin, 2010):

- Planning
- Continuous process improvement (retrospective)
- Releasing the product of iteration into production

When using Kanban methodology, the iterations are not predetermined. The team can decide at any moment when to plan, improve the process or release application into production. It can decide on one of the basic tactics, such as releasing application into production on Mondays, or when client demands, or i.e. only when application undergone significant changes or improvements (whenever something useful can be released).

- Comparison by boards (Scrum and Kanban board)

In Scrum, backlog of iteration shows everything that should be done during current iteration. This information is often shown by using cards on the wall, which is called Scrum or Task board.

Both Kanban and Scrum board follows numerous demands as an improvement or workflow. Let us say that both boards have three columns that represent condition of demands: To do, Ongoing, Done. Both methodologies do not limit teams concerning in which condition can demands be put in, so they can choose conditions that are more suitable for their process.

The difference between these two charts is that Kanban limits the number of orders per column. For example, in the column „Ongoing", there can be only 3 requests at the same time. Scrum does not have the rule that as prevention limits the team to put many requests at the same time in one column. On the other hand, Scrum limits the number of orders in the chart, because at the beginning of each iteration, the number of orders is being defined. Therefore both methodologies are limiting requests but in a different way.

Considering the fact that Scrum methodology functions with fixed number of requests within iteration, if a client wants to add a request in „To do" column, it would not be possible. If the team uses Kanban methodology, the request would be accepted only if the capacity of the column is not already full. Otherwise, the previous requests from that column would have to be finished first. Of course, none of these two approaches is exclusive. Scrum team can, as well, decide to allow product owner to change priorities in the middle of sprint, but it is considered an exception.

Another difference is that Scrum board is reset after each iteration, in other words, it is deleted after every sprint. New iteration starts after planning where the team will work, on a completely new Scrum board with new requests. In Kanban, the chart is mainly persistent, and there is no need for reset.

- Comparison by teams

Scrum team is functional team which consists of members who have necessary knowledge to solve any request in iteration (Figure 2). In Kanban, a team like that is only an option. It is important that requests can be fulfilled, but it is not important that every team member can solve every request (Figure 3).

Agile methodologies generally contribute to faster and more efficient information systems development. However, there are many tools and methodologies that are considered agile. That is why the choice of methodology that will be used is very important, and it should be taken into consideration if the methodology can be applied to all projects within organization.

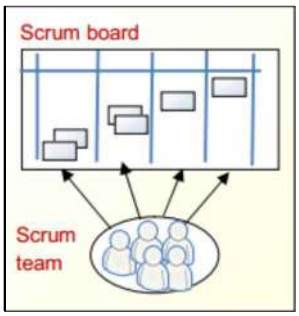

Figure 2: Necessary knowledge of Scrum development team (Kniberg & Skarin, 2010)

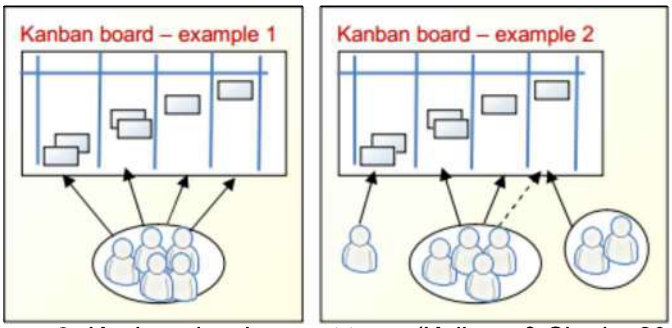

Figure 3: Kanban development team (Kniberg & Skarin, 2010)

Based on the comparison, it can be concluded that there is high number of advantages while using any of these two methodologies. Both methodologies are highly used and popular in the world and in IT companies in Serbia. Summarized overview of the most important differences in Scrum and Kanban approach is shown in Table 1.

Table 1: Differences in Scrum and Kanban methodology

Scrum	**Kanban**
Iterations are time limited	Time limited iterations are only an option
Uses speed and velocity measuring as metric	Uses lead time as metric
Team members have to be functional between themselves	Team members can be experts for only one necessary field of work
Time estimations are necessary	Time estimations are not determined
Forbids adding new requests if iteration is in progress	Enables adding new requests as long as capacity allows
Defines three types of roles	There are no predefined roles for team members
Scrum board is being reset after every iteration	Kanban board is persistent

Organizations have as well the possibility of combining these two methodologies. Teams can use those recommendations which are more suitable and helpful, making combination of Scrum and Kanban. Many Scrum teams decide to limit waiting lines, which is recommended by Kanban methodology. On the other hand, many Kanban users have daily meetings, like every Scrum team does.

4. CONCLUSION

Agile methodologies emphasize the importance of flexibility in more efficient information systems development. Product is being adjusted to the changes in user's requests, during development process itself. Changes in requests are normal and they happen after changes in business environment or user needs. Therefore the user is being more involved in product development process, after each iteration when smaller part of complete implemented requests is being validated.

This paper presented Scrum and Kanban methodologies for managing information system development, which are widely accepted and being used today. Lean Kanban strategy is more focused to have the job

finished in time, while there are no time limited iterations. By using special way of visualization, Kanban board, the project is being observed and focus is put on the problems on the board. Therefore this methodology does not imply characteristics of teams and daily meetings, unlike Scrum method. Scrum method is more rigorous and requests daily reports from every team member. It functions with fixed number of requests during iteration, which disables client to add any new request during the iteration. This situation can be overcome by Kanban method, so new request could potentially be accepted if there is enough capacity.

Based on the comparative analysis of Scrum and Kanban methodologies, as well as their tools, it can be concluded that these two methodologies can be used together successfully, by using only the best recommendations from both. Teams can use those recommendations that are suitable and helpful, by making a mixture of Scrum and Kanban methodology. Many Scrum teams decide for work in progress (WIP limit), which is Kanban recommendation. On the other hand, many Kanban users organize daily meetings like every Scrum team. It should be mentioned that a new software tool that gives the opportunity to combine Scrum and Kanban methodology by the name „ScrumbanTool", has been developed.

APPLICATION OF MULTIMODAL BIOMETRICS IN ACCESS CONTROL SYSTEMS

Ivan Milenković, Ksenija Ţivković, Dejan Simić
Faculty of organizational sciences

***Abstract**: Access control systems are part of our everyday reality. The choice of an authentication method has a significant impact on an access control system. Topic of this paper is possible application of multimodal biometrics in access control systems. Relevant papers and solutions are analyzed, and a review of different aspects of multimodal systems is given. Analysis results show that multimodal biometric systems have some significant advantages over unimodal biometric systems and other authentication methods. However, use of multimodal biometrics as authentication method may result in increased cost and lesser system usability.*

***Keywords**: multimodal biometrics, access control, performance evaluation*

1. INTRODUCTION

Increased risk of attacks such as identity theft has raised the importance of properly implemented systems for identity and access management. Identity and access management refers to an integrated system of business processes, policies and technologies which enables organizations to simplify and control user access to online applications and resources, while protecting confidential information from different types of attack (Bogićević, Milenković and Simić, 2014).

An identity and access management process has three interdependent main activities (Milenković, Šošević and Simić, 2012) - user identification, authentication and authorization. Process of claiming user identity is called identification, while the act of verifying claimed identity is defined as authentication. Authorization is the process of asserting user rights to access some resources, such as data, computer devices or offices.

Main goal of access control is controlling the activity of the system users. According to Sandhu and Samarati (1994), access control assumes that user has been successfully verified before enforcement of access control policies. Therefore, the effectiveness of the access control systems depends on reliable authentication of its users.

There are three main types of authentication methods today. First and the most common is the use of passwords. Password is something that system user knows. However, this knowledge can be easily shared with other people, or as easily forgotten. Also, people may choose passwords of insufficient security. Some of those security problems can be solved by the use of tokens. Token is something that system user possesses. Potential danger is that tokens can be stolen and system security compromised. Third type of authentication, biometrics, tries to overcome shortcoming of other authentication methods. Biometrics uses physiological or behavioral traits of a person for authentication, something that user is.

Biometrics relies on statistical or machine learning algorithms, and algorithm output is not a definite yes/no, but a score or probability (Šošević, Milenković, Milovanović and Minović, 2013). Therefore, biometric systems can make errors. One approach to making biometric systems more precise and robust is the use of multimodal biometrics. Multimodal biometrics relies on combination of several different biometric modalities. Different combinations are possible, such as face and voice, fingerprint and iris, face, ear and palmprint.

In order to secure an access control system, it is necessary to have a secure authentication procedure. In chapter 1, introduction to biometrics and access control was given. Topic of chapter 2 is performance evaluation of biometric systems. In chapter 3 different information fusion algorithms are described, and estimates of their precision are given. Chapter 4 is concerned with security of biometric systems. In chapter

5, different applications of multimodal biometric in access control are reviewed. Conclusions and guidelines for multimodal biometrics use in access control are given in chapter 6.

2. PERFORMANCE EVALUATION

According to Phillips, Martin, Wilson and Przybocki (2000), there are three different approaches for biometric system evaluation: technology evaluation, scenario evaluation and operational evaluation. The most general type of evaluation is technology evaluation.

Technology evaluation is used to determine performance of biometric algorithms. It involves the use of the standardized database for testing purposes. Performances of different algorithms can be compared on a common set of data. All the algorithms use the data gathered by the same type of acquisition devices. Only part of a database is given to algorithm developers, and the rest of the data is used for final evaluation. An example of technological evaluation is the FERET(face recognition technology) evaluation conducted by NIST.

Open-access multimodal biometric databases suitable for technology evaluation are few. Also, they tend to have biometric data collected from a small number of individuals. Therefore, researchers who want to test multimodal algorithm have to use chimeric datasets (Poh and Bengio, 2006). For fusion algorithms that work on the match score level, there is a possible alternative in using a NIST database with face and fingerprint match scores.

Numerous published papers confirm that multimodal biometrics improve system performance. Researchers have tested their algorithms on different sets of data, because of a lack of suitable multimodal database. Sim, Asmuni, Hassan and Othman (2014) have developed a multimodal system which uses biometric modalities of iris and face. For testing, they have created their own UTMIFM dataset (Universiti Teknologi Malaysia Iris 188 and Face Multimodal Datasets). For comparison, they have also used ORL database (Samaria and Harter, 1994) for face images, and UBIRIS v.2 iris dataset (Proenca and Alexandre, 2005).

Scenario evaluations are used to determine system performance in a specific domain of application. In a scenario evaluation, we would determine if a face recognition system can be used for access control at an airport. Biometric system is being tested as whole, and both algorithms and acquisition sensors are being tested. Testers should be chosen from population of real-world biometric system users. For example, in security applications, subject may be unwilling to cooperate with the system, which is a very important distinction. System environment, such as noise or lightning should match real world scenario as close as possible. Also, data enrolment must be done under same general conditions. Results of the scenario evaluation are partly repeatable, in according to the extent of the scenario that can be controlled.

Operational evaluations are used to determine system performance for a specific application. Example for operational evaluation would be testing a face recognition system for access control on Belgrade “Nikola Tesla” airport. There is little control over testing procedure, as subject should use the system in standard way. Evaluation results are not repeatable, because each specific application environment has specific characteristics which are hard to document.

3. MULTIMODAL BIOMETRICS - ALGORITHMS AND SYSTEM PRECISION

Multimodal biometric systems integrate information gathered from different biometric modalities. Different combinations are possible, such as fingerprint and face, voice, face and ear, iris and fingerprint. To integrate information gathered from different modalities, the use of information fusion algorithm is necessary. Choice of the fusion algorithm can have a significant impact on the system precision and performance. A classification of information fusion methods is shown on picture 1.

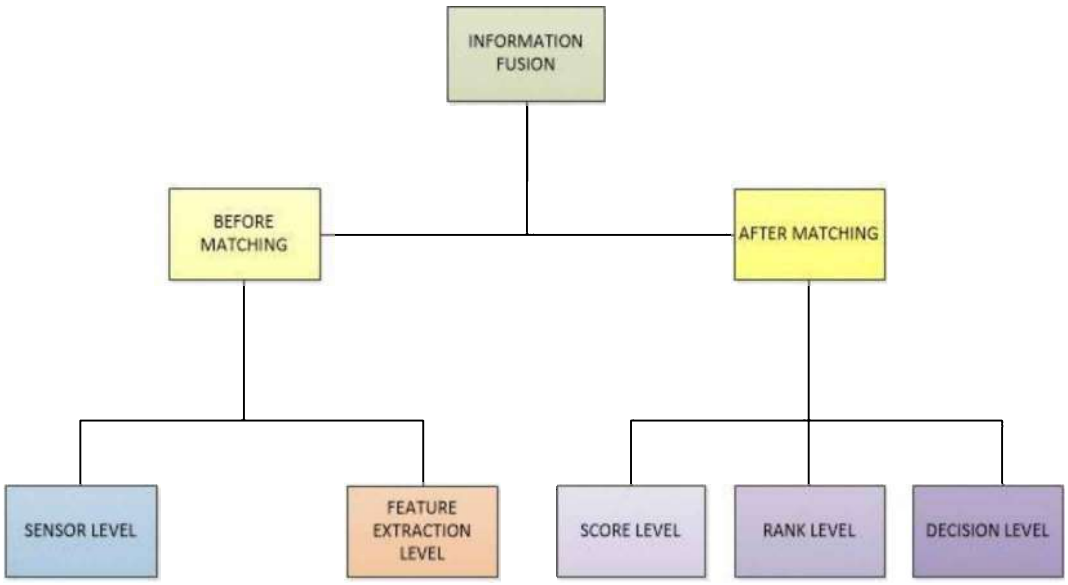

Figure 1: Different levels of information fusion in multimodal biometrics

3.1 Sensor level fusion

Data gathered from several types of sensors is integrated into single entity. At this level it is possible to fuse data from just a single biometric modality, so these methods are more likely to be considered multibiometrics than multimodal biometrics. It is important for consideration because this kind of fusion can improve system inputs.

3.2 Fusion at feature extraction level

Combining biometric characteristics extracted from several biometric modalities into a single biometric characteristic is considered as fusion at feature extraction level. Fusion methods defer from simple vector concatenation to more complex fusion methods.

Saini and Sinha (2014) describe a multimodal biometric system based on Gabor-Wigner transform. GWT is used for extraction of feature vectors. Biometric modalities used are face and palmprint, and test database had 150 subjects. Authors compare system performance with information fusion on different levels. When information fusion was employed at feature extraction level, best system EER was 3,36%. Information fusion at match score level yielded 1,89% EER.

3.3 Match score level fusion

In case of score level fusion, separate biometric characteristics are generated for each biometric modality. Each of the characteristics is matched with according template in the biometric database. The result of the matching is matching score. The greater the similarity between matched templates, the match score has the higher value. Generated match scores are used to generate new, derived match score, or are directly used to make a decision. Most of the published papers use this fusion method.

One of the first large scale evaluation of multimodal biometric system was performed by Snelick et. all (Snelik, Kisku, Bicego and Tistarelli, 2007). Prior evaluations where based on non commercial software, and smaller databases. Tests were conducted on a database of 972 system users. Fingerprint and face were used as biometric modalities. Fusion was performed on matching score level. Different combinations of score normalization and fusion techniques were applied. User weighted fusion and adaptive normalization where the most precise combination with EER of 0.63%.

Sim, Asmuni, Hassan and Othman (2014) have developed a multimodal system which uses biometric modalities of iris and face. Paper focus was toward non-ideal images, such as off-angles, reflections,

expression changes or blurred images. Information fusion is performed on score level, and matching scores weights are customized for each system user. For testing, authors have created their own UTMIFM dataset (Universiti Teknologi Malaysia Iris 188 and Face Multimodal Datasets). For comparison, they have also used ORL database for face images, and UBIRIS v.2 iris dataset. Results for multimodal approach show GAR of 95% when FAR is 0.01%, while at same FAR iris and face perform at 94% and 83% percent, respectively.

Table 1: Comparison of different fusion methods

Paper	Published	Biometric modalities	Level of fusion	Number of identities in test dataset	Unimodal systems EER	Multimodal system EER
Snelick, Uludag, Mink, Indovina and Jain, 2005	2005	fingerprint and face	Match score level	972	2.16% 3.96%	0.63%
Vatsa, Singh and Noore, 2007	2007	iris and face	Match score level	300	2%, 2.3%	0.8%
Sim, Asmuni, Hassan and Othman, 2014	2014	iris and face	Match score level	300	~7%, ~3%	~2%
Saini and Sinha, 2014	2014	face and palmprint	Feature extraction level	150	5.77%, 11.67%	3.36%
Monwar and Gavrilova, 2009	2009	face, ear, signature	Rank level	30	~5.6%, ~7.5% ~5%	1.12%

3.4 Decision and rank level fusion

If a biometrical system functions in the identification mode, it is possible to use rank method fusion. Such system could produce an ordered list of identities as an output. The first candidate on the list is the one system determined a most likely match, followed by the other candidates ranked by their match probabilities.

Some commercial unimodal biometric system function as black box systems and their only output is final decision. Integrating such unimodal systems into a multimodal recognition system requires the use of decision level fusion. Decision level fusion applies different voting algorithms to calculate the final decision. Monwar and Gavrilova (2008) describe a biometric system with decision level information fusion. Applied algorithms are AND/OR, majority voting, weighted majority voting and behavioural knowledge space.

4. SYSTEM SECURITY AND PRIVACY CONCERNS

Although using biometrics as authentication technique may result in improving system security, it does not necessarily imply that the system is secure. To achieve this desired security, various system aspects, both technological and organizational should be taken into account. Applying traditional cryptographic algorithms to secure communication channels, using biometric cryptosystems to secure biometric templates are just some of the security measures needed to be taken.

Prabhakar, Pankanti and Jain (2003) noted that biometric usage also rises some privacy concerns. Finding the balance between privacy and the public interest is a serious challenge, which has technological and legal complexity. There are debates whether biometric data should or should not be considered a "private" or "sensitive" data, and there are strong arguments for and against. For example, a company may collect fingerprint or facial data of its employees for its access control system. Company employees may use these same biometric modalities in some other system that uses biometric authentication, such as a health care

system. However, if biometric data is not properly secured, company could theoretically use this biometric data to gather information about health issues of its employees.

Adversary attacks generally exploit the system vulnerabilities at one or more modules or interfaces. Figure 2 shows eight points of attack in a biometric system.

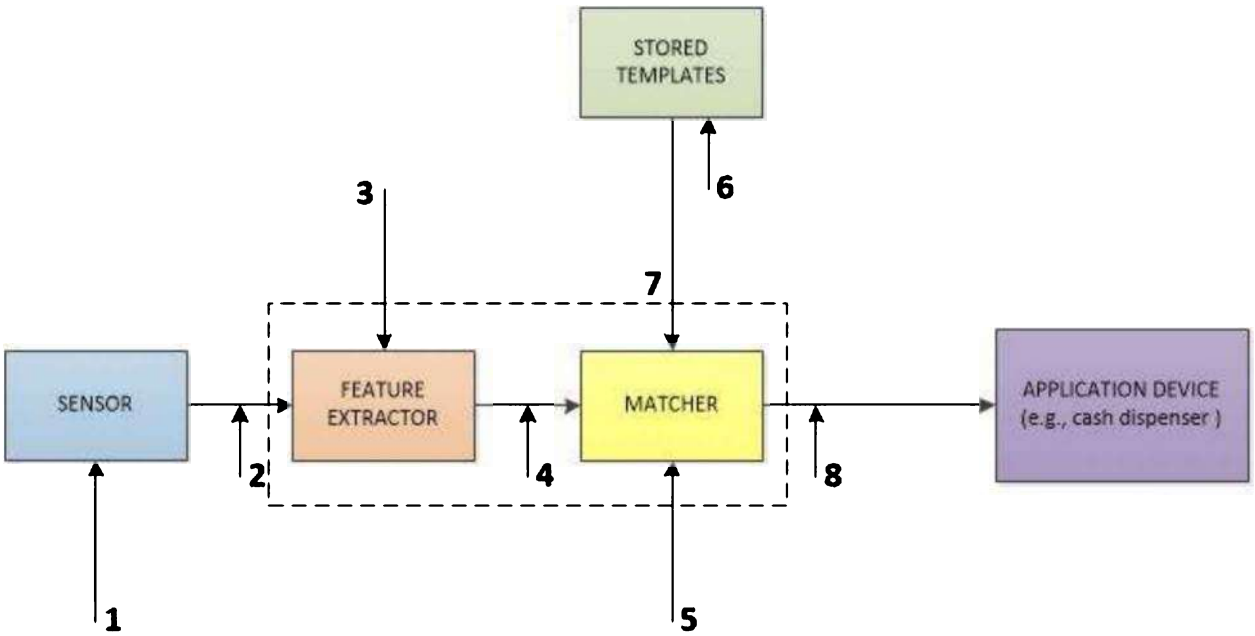

Figure 2: Points of attack in a biometric system (Ratha, Connel and Bolle, 2001)

1. Fake biometric submission at the sensor (fake finger, a copy of a signature, a face mask)
2. Resubmission of old digitally stored biometrics signal
3. Override feature extract (the feature extractor could be attacked with a Trojan horse)
4. Tampering with the feature representation (During the transmission of data between modules of extraction and corresponding modules, changing the desired set of functions)
5. Overriding matcher decision (Matcher also may be exposed to the Trojan horse)
6. Tampering with stored templates (The database of enrolled templates is available locally or remotely. The stored template attacker tries to modify one or more templates in the database)
7. Channel attack between stored templates and the matcher (attacks may change the contents of the templates before they reach the matcher)
8. Decision override (The final decision may be approved or not – YES/NO)

During the transmission of biometric data between acquisition sensor and feature extraction module there is a risk of eavesdropping. To prevent this attack, it is necessary to secure the communication channel. One approach is the use of smart cards, where the whole biometric system is integrated in such device. However, such solution is applicable only for certain scenarios of biometric verification. Some of the systems require external acquisition devices, or centralized biometric database.

A possible solution for this attack, and also other attacks which affect communication channels, is the use of cryptographic techniques. In smaller systems, where it is possible to exchange keys, symmetric cryptographic algorithms may be used. To prevent replay attacks, timestamps can be employed. In other, more complicated instances, it is necessary to protect the channel with some more complex solutions, like SSL/TLS protocol. Also, because biometric data is highly sensitive, multiple layers of protection (as used in financial transactions) should be applied.

5. APPLICATION OF MULTIMODAL BIOMETRICS IN ACCESS CONTROL

Many researchers studied multimodal biometrics in access control. Different applications of multimodal biometrics have been considered by the research community. Covered topics differ from more general, like securing access to a building or authentication for online systems, to more specific. Some of the more specific topics covered are car access control, application of multimodal biometric access control e-commerce systems access, and use of mobile devices.

Lupu (2011) proposed car access control using multimodal biometrics. System uses three biometric modalities - fingerprint, iris and voice recognition. Genuine system users are granted unlimited access to car controls. If an imposter would try to assume the car driver identity, he would be unable to drive the car. Also, the car would alarm security service or police using a GPRS system.

Maheswari et al. (2010) also used three biometric features, but instead fingerprint they used voice. Actually, they demonstrated an intelligent multimodal biometric verification system for physical access control using iris, face and fingerprint recognition. This system was created to show high security access control using multimodal biometrics. Another paper with building access control as the topic was published by Beattie et al. (2004). Paper describes a variation of sequential information fusion, based on so called path fusion algorithm. This new approach is designed for building with several authentication checkpoints. User motion through building is monitored and each system decision is influenced by previous authentications.

Common feature of the following papers is the use of hand geometry for access control. Ribaric et al. described an economical approach of multimodal biometrics in access control. They designed a prototype biometric identification system using hand-geometry, finger and palm-print. The system is based on a low-cost desktop scanner, which is used as the biometric acquisition device. Experimental analysis revealed that information fusion at the matching-score level enhances the results of the identification. Chike Obed-Emeribe (2013) stated that the palm geometry and the fingerprint are most suitable for verification. He presented implementation of multimodal biometrics as an access control tool for an e-commerce framework. Framework architecture consists of an e-commerce database server, a monitor server for transaction processing and a multimodal biometric database server.

Dehnavi and Fard (2011) proposed a multimodal biometric model for tracking students in virtual classes. Proposed model combines two behavioral biometric characteristics (mouse movements and keystroke dynamics) and a physical one (face features). This new approach allows continuous verification of student attendance. This is achieved by applying specially designed algorithm called ACT (Attendance Control Tracker). Student biometric data is continually sent to biometric server. Paper gives an architecture proposal of the described system. Testing was performed on Claroline open source LMS, and authors state that model is applicable for use with other LMS.

Trewin et al. (2012) tested usability of voice, face and gesture recognition as access control methods for mobile devices. For comparison 8-digit written and spoken PIN codes were used. Study did not take biometric system performance into account. However, because authentication causes interruption in the user's primary task flow, the impact of authentication methods on working memory was taken into account. Research results have shown that each modality has its own strengths and weaknesses. Voice was considered less usable than other modalities, because of the acquisition problems. Study participants also reported interference with the memory tasks. Combination of face and voice result in higher FTA (Failure to acquire) rate because acquisition process required more coordination.

Several commercial multimodal biometric access control systems are available on the market. One of the latest solutions in access control is Facebanx. It combines face recognition, voice recognition and document verification. For Facebanx users, first step of the registration process is adding personal data, followed by biometric data acquisition. Final enrollment step requires submitting some kind of personal ID. To prevent fraud data entered is compared to data on the identification document. Another available multimodal biometrics solution for access control is Vision-Box, the new application of biometrics for airline passengers. It is designed for automated border control at airports. It supports iris, fingerprint and facial recognition biometrics and can integrate with the advanced identity management infrastructure.

Another important area where multimodal biometrics is applied for access control are government systems, like voting or border control systems. For example, Kenya and Ghana have improved their voting systems by introducing automatic biometric recognition. Biometric modalities of fingerprint, iris and face are used for voter verification. Iris, palmprint, facial and vascular recognition are employed for voter verification. Governments of USA and Canada collect face and fingerprint data from visitors, students or temporary workers from certain countries.

6. CONCLUSION

Research papers available on the topic multimodal biometrics confirm that multimodal biometrics significantly improves system precision. However, it is difficult to compare different multimodal algorithms and approaches. Even in the case of the same combination of biometric modalities, unimodal systems and testing data often differ. Lack of multimodal databases with large number of subjects in the public domain leads to use of chimeric datasets gathered from various different sources. A framework for evaluating precision of multimodal biometric systems is still an open challenge.

Application of multimodal biometrics can remove some of the negative effects of biometric menagerie. This is achieved by applying user specific fusion, where poorly performing modalities are given lower priorities, or are not used for authentication. Therefore, the use of multimodal biometric leads to more precise and robust system.

Interoperability is still an open issue. Although there are several standards and projects, none are widely accepted for now. Some of the standards, like BioApi, depend on a specific programming language. Other, like WS-BD, target just one segment of biometric systems (acquisition). Integrating different unimodal components into a multimodal system could pose a serious challenge. However, this area is still in development.

Multimodal biometric systems share security threats of their unimodal counterparts. Some of the treats can be countered by applying standard security measures used in computer systems. However, securing biometric templates remains an open question, as all algorithms proposed so far negatively affect system precision. Multimodal biometrics can be useful here, because using several modalities improves system precision and counters some of the negative effects.

As a tool for access control, multimodal biometric systems are not yet widely accepted. There are some papers which speculate over potential use of multimodal biometrics for this purpose, however, they are not still very numerous. Although commercial multimodal biometric solutions are available on the market, they are not widely spread yet. Some governments, like USA and Canada gather several biometric modalities for border control, but resort to unimodal fingerprint recognition for most purposes.

After reviewing different aspects of multimodal biometrics, we can conclude that they have some important advantages over their unimodal counterparts, and against other authentication methods. However, when deciding whenever to apply multimodal, there are always other factors to be considered, such as implementation cost and usability. Generally, the technology is mature enough to applied, and we can expect its more widespread use in the near future.

OVERVIEW OF EAR BASED PERSON RECOGNITION ALGORITHMS

Sofija Krneta*[1], Uroš Šošević[1], Dušan Starčević[1]
[1] Faculty of organizational sciences, University of Belgrade,Belgrade
*Corresponding author, e-mail: sofija.krneta@mmklab.org

Abstract: *Biometric modalities in person recognition process were subject of interest for many scientists over the years. In order to make image evidences more reliable, law enforcement was the first one to see the potential in parts of the body for person recognition. One of biometric modalities that has a lot of potential but is still in developing phase is human ear. This paper explores current available algorithms, analyzes most significant ones and suggests place for improvement or focus of further research for the authors.*

Keywords*: human ear, ear based recognition, person recognition, biometric systems, multimodal biometrics*

1. INTRODUCTION

Although the beginnings of using biometric technologies are dating back to 1858 (Komarinski, 2005), their benefits are still not completely utilized. Of course some of biometric modalities already found their application in practice and are used for identification and verification of individuals in various circumstances. However, some biometric traits have not yet been researched enough to be used in real conditions. These facts represent one of the reasons why biometrics as a technology was present in only 20.5 percent of organizations that participated in the Computer crime and security survey conducted by FBI and Computer Security Institute (Richardson, 2011) on an annual basis. Most of used biometric systems rely on biometric modalities with high level of reliability such as fingerprint and iris. Unfortunately, those modalities are also highly intrusive. Immediately following these modalities are some less reliable modalities - face, ear, voice and gait. Those modalities are also subjects to occlusion and imitation which can drastically lower the reliability of the biometric system. On the other hand, they do not require that the person cooperates in recognition process. It is clear that low reliability of mentioned biometric modalities prevents wide application of biometrics. However, their unintrusiveness makes them popular for usage in applied biometric systems.

There is one popular approach that may increase the reliability of biometric systems - multimodal biometrics. Multimodal biometrics refer to usage of several biometric modalities in one biometric system. More precisely, multimodal biometrics combine information acquired with different biometric sensors in order to increase the rate of accurate recognition. Project “Multimodal biometrics in identity management”, funded by Ministry of Education and Science of Serbia (Starčević et al., 2014) is focused on application of multimodal biometrics in identity management. During the research in field of biometrics, researchers engaged in this project were exploring each of the modalities and their utilization in multimodal biometric recognition. One of the promising biometric modalities for person recognition is human ear. It is known that the structure of human ear is not only unique, but also constant as the ear does not change over the course of human life. Additionally, this biometric modality does not require person"s consent to recognition and thus it is considered as non intrusive (Pflug and Busch, 2012). In order to utilize human ear in biometric recognition process, system usually uses ear images. Ear images can be acquired on itself or it can i.e. be isolated from image of a person"s face. This fact also makes human ear an interesting biometric modality which is constantly researched in the last several years.

This paper focuses on algorithms used in person recognition based on human ear. In the next chapter, human ear as a biometric modality is presented and also ear biometric systems are described. Additionally, some applications of human ear as a modality in multimodal biometric systems are given. List of currently available ear recognition algorithms is given in third chapter. The algorithms are chronologically listed and also categorized in this chapter. Fourth chapter focuses on most popular ear recognition algorithms, their way of functioning, advantages and disadvantages. Conclusions and future work regarding the person recognition based on human ear are defined in the last chapter.

2.PERSON RECOGNITION BASED ON EAR BIOMETRIC SYSTEM

Ear biometric system can be defined as a typical pattern recognition system where the input image is reduced to a set of features that is subsequently used to compare against the feature sets of other images

in order to determine its identity (Abaza, 2013). It is a system that receives image as an input, uses details key features of human ear and gives person recognition as an output result. Person recognition can be used in two ways: Verification and Identification. Verification process uses ear features of an exact person to compare and verify person"s identity. Identification uses existing database to recognize which of existing features match features received as an input. Since identification process is iterative process through existing database, it"s duration is longer. However, the main recognition process stays the same, thus the output of person recognition process is identical - a match to a person in the existing database.

Physiological (anatomical) biometrics methods are based on the physiological features of humans. They measure and compare features of specific parts of human body in the process of recognition. So far the most interesting biometric modalities for researching are face, iris and fingerprint features since they are the most important discriminants of human identity (Perales and Draper, 2004). The advantages of anatomical biometrics can be summed into following statements:

- Acquisition of the data for input is a passive process and does not require participation of the person that is about to be included
- Acquired data is typically invariant over time, easy to acquire, and unique to each individual.

There haven"t been many efforts in application of human ear for personal authentication, even though it has proved its significant role in forensics. The main characteristics of the human ear that make it a good candidate for person recognition are (Kumar and Wu, 2011):

- rich and stable structure that is preserved since birth and is quite unique in individuals
- being invariable to the changes in pose and facial expression
- relatively immune to anxiety, privacy and hygiene problems

Human ear is highly curved 3D surface and therefore provides rich 3D features which can be used for exact feature selection and more precise person recognition. Using image processing when working with 3D images has proven to extract unique features which can"t be extracted from 3D images of other anatomical biometrics such as iris or fingerprint.

Whether the input is 2D or 3D image, it is processed to extract all the features as part of image processing and preparing input for any biometric system used for person recognition. These images are prepared for an ear biometric system.

The evolution of using person recognition based on person"s ears dates centuries back. In 1096, Richard Imhofer defined four different characteristics to distinguish 500 different persons by their ears (Imfoher, 1906). In 1949, Alfred Iannarelli determined 12 features needed for person recognition on 10000 different people (Imhofer, 1906). Iannarelli also discovered that ears are unique among twins, triplets and similar for relatives. Those discoveries made it clear that there are biometrical disadvantages of using ear for person recognition. However, studies in (Meijerman et al., 2004) and (Singh and Purkait, 2009) show by example that a person evolution, development and growth through years lead to possession of new individual characteristics. Those characteristics become unique features of the outer ear even for siblings.

There have been some questions and uncertainties about the accuracy of this modality in person recognition as standalone recognition mean. The Forensic Ear identification Project (FearID) was initiated by nine institutes from Italy, the UK and the Netherlands in 2006 (Alberink and Ruifrok, 2007). The study measured an Equal Error Rate (EER) of 4%. This error rate is satisfying even in forensics, which means that ear prints can be used as evidence in a semi-automated system. After this study, many systems implemented ear recognition as part of person recognition, but a minority of systems used it as a standalone solution, such as German police in their surveillance video analysis.

3. EAR RECOGNITION ALGORITHMS - STATE OF THE ART

During the evolution of the person recognition using ear as a biometric modality, many methods have been developed with different success on various test datasets. Main categorization could be done based on the input required for the algorithm. We can differentiate algorithms which use 2D or 3D images for recognition process.

3.1. 2D image recognition

In the list below, most of available works on 2D ear image based recognition are presented in chronological order (Pflug and Busch, 2012):

1. Burge and Burger (1998) Vornoi Distance Graphs
2. Hurley (2002) Force Field Transform
3. Moreno (2002) Geometric features with Compression Network
4. Yuizono (2002) Genetic Local Search
5. Victor (2002) PCA
6. Chang (2003) PCA
7. Abdel-Mottaleb and Zhou (2005) Modified Force Field Transform
8. Mu (2005) Geometrical measures on edge images
9. Abate (2006) General Fourier Descriptor
10. Lu (2006) Active Shape Model and PCA
11. Yuan (2006) Non-Negative Matrix Factorization
12. Yuan and Mu (2007) Full Space LDA with Outer Helix Feature Points
13. Arbab-Zavar (2007) SIFT points from ear model
14. Jedges and Mate (2007) Distorted Ear Model with feature points
15. Liu (2007) Edge-based features from different views
16. Nanni and Lumini (2007) Gabor Filters and SFFS
17. Rahman et al. (2007) Geometric Features
18. Sana (2007) Haar Wavelets and Hamming Distance
19. Arbab-Zavar and Nixon (2008) Log-Gabor Filters
20. Choras (2008) Geometry of ear outline
21. Dong and Mu (2008) Force Field Transform and NKFDA
22. Guo and Xu (2008) Local Binary Pattern and CNN
23. Nasseem (2008) Sparse representation
24. Wang et al. (2008) Haar Wavelets and Local Binary Patterns
25. Xie and Mu (2008) Locally Linear Embedding
26. Yaqubi (2008)HMAX and SVM
27. Zhang and Mu (2008) Geometrical Features, ICA and PCA with SVM
28. Badrinath and Gupta (2009) SIFT landmarks from ear model
29. Kisku (2009) SIFT from different Color Segments
30. Wang and Yuan (2009) Low-Order Moment Invariants
31. Alaraj (2010) PCA with MLFFNNs
32. Bustard (2010) SIFT Point Matches
33. De Marisco (2010) Partitioned Iterated Function System (PIFS)
34. Gutierrez (2010) MNN with Sugeno Measures and SCG
35. Wang (2010) Moment Invariants and BP Neural Network
36. Wang and Yuan (2010) Gabor Wavelets and GDA
37. Fooprateepsiri and Kurutach (2011) Trace and Fourier Transform
38. Prakash and Gupta (2011) SURF and NN classifier EER
39. Kumar (2011) SIFT GAR, FAR
40. Wang and Yan (2011) Local Binary Pattern and Wavelet Transform
41. Kumar and Wu (2011) Phase encoding with Log Gabor filters

The Force Field Transform by Hurley (2002) is one of the most frequently used methods for ear based recognition. This approach assumes mutual attraction of pixels that is proportional to their intensities and inverse to the square of the distance between them.

Structure of the outer ear proved to give extra information used for person recognition. Extraction of specific texture features can be extracted using Gabor filters. Wang and Yuan (2010) did it and then discriminately selected the most distinctive ones as they considered them to be the key information in the recognition. Kumar and Wu (2011) used Log-Gabor filters for extracting features of the local structure of the ear. Extracted features were stored in normalized grey level images. In their experiment, Log-Gabor based features had better performance than Hurley"s approach and landmark-based feature extraction approach.

Abate (2006) presented in his work generic Fourier descriptor for rotation and scale invariant feature representation. He used a polar coordinate system to transform the image into coordinates and then converted the coordinates into frequencies. The ear images had to be aligned in order to centralize the coordinate beginning before transformation into the polar coordinate system.

Wang (2010) composed six feature vectors with the help of seven moment invariants. The study showed that each of the moment invariants is invariant to changes in scale and rotation. The feature vectors were then set as input for a neural network for classification of the feature sets. Wang and Yuan (2010) then compared different feature extraction methods. They concluded that the complete accuracy of 100% is made by using moment invariants and Gabor transformation.

3.2. 3D image recognition

Recent papers focused more on 3D images in order to improve accuracy of the process. The strengths of 3D images are their immunity to rotation, scaling and translation. Shadows and special features discovered in a 3D image of an ear gave crucial addition to overall features used for person recognition. Usually, in the system where they bring more information than they take computational resources, 3D images can recognise a person based on their ear as a biometrical module only. Following algorithms gave significant results in this process:

1. Yan and Bowyer (2005) ICP using voxels
2. Chen and Bhanu (2005) ICP Contour Matching
3. Chen and Bannu (2007) Local Surface Patch
4. Liu (2007) Mesh PCA with neural network
5. Passalis (2007) Reference ear model with morphing
6. Yan and Bowyer (2007) ICP using Model Points
7. Cadavid (2008) ICP and Shape from shading
8. Islam et (2008) ICP with reduced meshes
9. Islam et (2008) Local Surface Features with ICP-Matching
10. Zheng (2010) Local Binary Patterns
11. Liu and Zhang (2011) Slice Curve Matching
12. Zhou (2011) Surface Patch Histogram and voxelization

Widely used method is ICP contour matching described in (Chen and Bannu, 2007). ICP requires double alignment of the models. They suggested extraction of point clouds from the ear contour and the registration of points with ICP (Chen, 2005).

Yan and Bowyer split the image of the ear and extracted features that give information about identity. In order to save computational resources in the recognition process, parts of the ear are indexed for faster ICP matching (Yan and Bowyer, 2005). That idea developed in direction of using Model Points in (Yan and Bowyer, 2007).

In (Cadavid, 2008) Cadavid presented a system suitable for video streaming and live image capturing, which can extract 3D models with the help of shading technique (Cadavid, Mahoor and Abdel-Mottaleb, 2009). 3D model is then set as an input in the system in order to be compared with the existing 3D images in the database.

All 3D algorithms mentioned in this paper present approaches that work satisfactorily with clear images and without occlusion. When introducing complexities such as earrings, hair etc. it has to be examined which algorithm might show best results.

4. ALGORITHMS COMPARISON

In this section of the paper we present the most important algorithms. Specifically, algorithms are presented chronologically and the way of their functioning is described briefly. 3D and 2D algorithms for ear feature extraction are separated and their advantages and disadvantages have been defined. Also, we presented recognition rates where provided by authors.

There are various research papers discussing about person recognition techniques based on human ear. Some of the papers present specific overview of algorithms used (Pflug and Busch, 2012), but none of them refers to recommendations for algorithm improvement in different segments. We believe that presenting most important algorithms for ear based person recognition and defining segments in which they can be used or improved makes room for future research in this area. In example, standardizing feature set which could lead to segmentation of ear in the recognition process. If the ear were segmented

into parts for examination, it would be possible to give significance or distinction to certain parts of the ear. Similarly, pose variations and occlusion might be partially solved by omitting occluded parts of the ear.

In case of 2D algorithms there are 5 which take precedence: Force Field Transform (Hurley, 2002), Fourier descriptor for rotation and scale invariant feature representation (Abate, 2006), Moment invariants with back propagated neural networks (Wang et al., 2010), Gabor filters (Wang and Yuan, 2010) and Local orientation features using even Gabor filters (Kumar and Wu, 2012).

Force Field Transform algorithm extracts wells and channels of the ear. It extracts a description based on the well position. It has been proven that these kind of descriptions are unique for every ear. Unfortunately, this approach has been tested on 9 subjects only, which is a setback. Room for upgrade of the algorithm could be increasing number of measures used for recognition. Additionally, by including channels into description better performance of the algorithm could be achieved. Advantages of this approach are that it is scaling invariant, it has high noise tolerance and there is no explicit ear topology description needed. No recognition rate of this algorithm has been presented by the authors.

Abate suggests Generic Fourier Descriptor for feature extraction. This algorithm is illumination and rotation invariant. Unfortunately, no testing or recognition rate information about this algorithm have been presented in the paper.

Wang, Xia and Wang recommend using improved moment invariants algorithm for feature extraction and then applying high order moment invariants for extracting 6 feature vectors. Good side of this algorithm is that it is invariant to translation, rotation and size change. By using BP neural network on 60 subjects data set, recognition of 91.8% was reached.

Gabor filter is robust and durable in case of illumination change, but Gabor features vector has immense dimensional space. Wang and Yuan use Gabor feature extraction and General Discriminant Analysis which effectively decreases dimensions of features vector. They have reached recognition rate of 99.1% on USTB database and also reported satisfying execution time - enough for real time system functioning.

Kumar and Wu achieved high performance as previous top approaches - eigen ear, force field transform, shape features. They reported recognition rate of 96.27% and 95.23% on databases containing 125 and 121 subjects, respectively. Authors used a pair of log-Gabor filters on IIT Delhi Ear Database. Disadvantage of this algorithm is that its performance has not been tested in different angles and occlusion. Testing has been done on a dataset that has small variation in image orientation and size. Thus, there is a need to test this algorithm in outdoor conditions in order to prove its performance. Outdoor conditions could greatly affect ear segmentation because of light changes and shadowing.

3D ear feature extraction algorithms that stand out are 3 algorithms presented in 2007. And 2008.

Contour matching (Chen and Bhanu, 2007) algorithm is based on contour of outer helix and uses ICP but it was improved to LSP since it has less feature points which made the process computationally cheaper. After the points were extracted, measured distances were compared to the existing ones in the database. The result was increase of recognition rate from 93.3% to 96.63% during an experiment with 302 subjects.

3D imaging (Yan and Bowyer, 2007) approach is based on contour function for describing ear shape and uses ICP with k–d tree data structure to efficiently search for closest point. The algorithm was evaluated in a large experimental study on 415 subject with accuracy rate of 97.8% and EER 1.2%.

ICP and Shape form shading (Cadavid, 2008) algorithm was presented by Cadavid as an algorithm that works well with real-time image extraction, where 3D images are modeled from CCTV images and shading technique for forming shape. Dissimilarities with existing images in the database is done by ICP. Downsides of this algorithm is its weak response to pose variations. Experiment with this algorithm on a 402 subject study showed 95% accuracy rate.

4. CONCLUSION

In this paper, there have been presented most of the available algorithms for ear based person recognition. The most important ones were applied on different databases and showed major success in accuracy. There is still a lot of room for improvement of various leading algorithms. Also,

In 2D images, pose variation and camera position change present a strong setback for most of the algorithms. Occlusion still remains the weakest link in ear based recognition. In this cases, it is indispensable to gather information about occluded parts. Occlusion caused by pose variations is especially neglected since there are no publications that tried to solve "filling the gaps" problem. There are feature extraction methods which partially solve pose variation disadvantages but they still have space for improvement.

Noticed shortcomings will be used in future works for ear based person recognition system improvement in terms of applying various algorithms in most suitable situations. Additionally, authors plan to explore possibilities for using only a visible portion of human ear in recognition process. This could be particularly useful in conditions of occlusion .

This approach might be used in all of the existing algorithms, in order to show proof of concept in improving accuracy. Also, This opens a possibility for using different algorithms on several parts of the ear.

marija.bogicevic@fon.bg.ac.rs

***Abstract**: Nowadays, fraud is the leading problem in electronic payment systems. The subject of this paper is a review of existing techniques for prevention of fraud in electronic payment systems. Prevention and detection of fraud are of extreme importance in the field of risk management, as well as fraud management in payment cards industry. The end goal is to reduce the number of frauds through application of multidisciplinary approach. The system for prevention of payment card frauds is a complex system that collects knowledge from more than one source. This paper shows current condition throughout the world and gives a detailed comparison of modern techniques for prevention, detection and fraud management in electronic payment systems. The paper also gives an example of possible enhancements when it comes to prevention of frauds in electronic payment systems.*

***Key words**: fraud management systems, risk management, electronic payment systems, security*

1. Introduction

One of the main problems of electronic banking is to be found in the fact that fraud transactions are increasingly showing as genuine, that is, legitimate.

As for the historical development of fraud in electronic payment systems, it could be said that stealing and forgery of cards was present during the '70s, but the cards were then physically stolen. In '80s and '90s, ordering by telephone/mail became a common thing. Online fraud inhabited the world scene as the Internet went live worldwide and developed into something that allows for anonymity, availability and swiftness to commit fraud on world level.

One of the fastest ways of shopping is shopping with payment cards, where one gets the goods instantly, and pays for it later. Electronic payment systems have a series of advantages, such as ordering products from far away, which allows for consumers' conformity. However, there are disadvantages as well, such as security of data being transferred and exposure to risk of compromising data. Therefore, credit cards fraud is a serious problem encountered by all participants in this communication chain.

Today, most people use e-commerce partly due to economic reasons, and partly for conformity reasons, because there's no need to leave home. However, card fraud is quite a serious problem indeed. Every year, card issuing organizations and the consumers themselves are exposed to significant financial costs, and potential loss of incomes. It is very difficult to cope with some techniques used by fraudsters, since some of the methods being used for authorization are genuinely wrong and inadequate. In most number of cases, the buyer himself is not aware of the process taking place in the system after he/she buys a certain product. Earlier, at time when cards with magnetic strips were used, the salesman was able to compare the signature on the slip with the signature on the back of the card. However, in case the card was stolen, the fraudster was most likely to practice the signature so that the comparison was no longer of any use. In that case, one could introduce even higher level of prevention and ask for an additional document that would confirm the identity of a person, such as ID card or driver's license. Even higher level that was introduced later was the PIN entry, which makes the user signature unnecessary. In case of frauds, when the card is not physically present, various methods are used in an attempt to gain necessary data.The more the card is used for online shopping, the more it is exposed to attacks and compromising. In some regions, one of the methods used by fraudsters is learning the social security numbers by using social engineering techniques, and this number is used to additionally determine the person's identity.

Banks are highly interested in processor speed that helps in detecting a fraud. Any activity can jeopardize the cardholder, and the banking institution itself. This could be either the bank in which the owner has an account tied for a card, or a processing company that supports the bank. Institutions mainly combine basic forms of prevention with more complex ones, and thus they form what is known as Fraud Management. Fraud technologies encounter the possibilities of active survey of an account in order to discover or at least sense all irregularities in transactions.

From the financial point of view, if we are to observe frauds, it's like a recursive life cycle that illustrates a continual response to fraudsters' behavior. Ever changing trends in the fraud development eventually led to the point where the systems are being continually developed and complex algorithms are constantly applied,

such as data mining and data analysis. The goal is to design new security protocols, as well as authentication protocols. In their response to these innovations, fraudsters develop new techniques that are to help them overcome these protective measures. New fraud patterns are identified as a result of security enhancements, including the development of new software solutions, or to be more precise, through stronger authentication and safety procedures.

2. FINANCIAL LOSSES OVER CARD FRAUD WORLDWIDE

Card fraud is becoming widely spread phenomena, which is supported by following statistical data. Namely, in 2012 alone, the abuse of credit and debit cards has caused a $ 11.7 billion loss worldwide. In the same year, the greatest number of fraudulent financial transactions over cards hit 47.3pct out of overall global transactions. Compared to 2010, up to 67pct of those exposed to frauds were the US citizens (Lindsay, 2014).

Table 1. shows regional losses caused by card frauds, where the P – predicted indicates predicted losses. Table helps us drawing a conclusion that the losses are immense, and that the prevention of fraud in electronic payment system is a problem that needs to be handled in a systematic manner.

Table 1: Regional forecast of spending and losses (Riley, 2012)

Regional spending in millions USD	2011	2012	2013	2014	2015	2016P	Annual growth
North America	$794	$794	$799	$800	$806	$816	0,5%
Europe	$444	$453	$460	$463	$465	$466	1%
Asia Pacific	$379	$416	$455	$491	$528	$564	8,3%
Latin America and the Caribbean	$98	$106	$114	$122	$130	$137	7%
Middle East and Africa	$31	$33	$34	$35	$36	$36	3,2%

2.1 Types of Fraud

According to the report of Aite Group from 2010, the frauds could be classified as follows:

1. *first-party fraud*
2. CNP (Card-not-Present)
3. counterfeit card – creating fake cards
4. lost and stolen cards
5. mail non-receipt fraud
6. card number theft / Identity theft

Figure 1. shows down the fraud losses by category according to Aite Group (Aite Group, 2012). This research has shown that the United States suffered greatest gross financial losses in 2008. CNP fraud represents the weakest spot for merchants. CNP fraud is growing faster than counterfeit fraud. Figure 1. shows that the First-party fraud is taking the greatest portion in this classification.

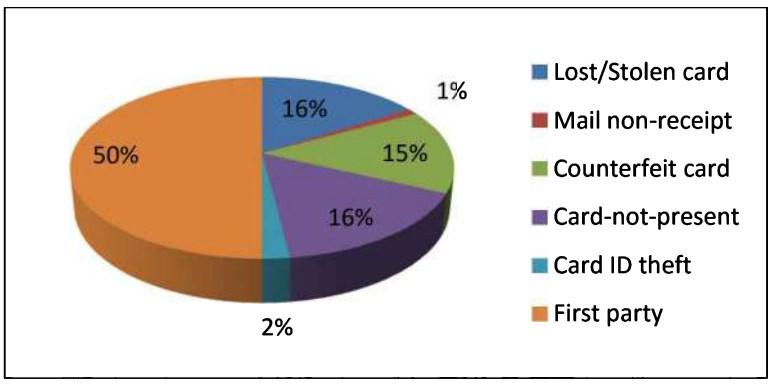

Figure 1: Portion of certain fraud types in 2012
(Aite Group, 2012)

2.2 The greatest attacks in the history of fraud management

Great attacks that happened over the last ten years, when this problem became real serious, speak of the importance of preventing credit card frauds. From July, 2005 to August, 2007, the attacks on the systems in TJX Company have exposed more than 46.5 million card details (Jones, 2013). Albert Gonzalez has been

accused of being a chief hacker who organized a group that carried out the attack. It is believed that Gonzalez, together with ten more associates, carried out this attack by using wireless scanners to find stores with vulnerable networks and them captured account information.

In August 2009, Gonzalez was again a main suspect for card fraud, or in this case, over 130 million cards that were stolen in Heartland Payment Systems, retailers 7-Eleven and Hannaford Brothers, and two unidentified companies (Godin, 2009).

In most number of cases, once the perpetrators obtained credit card data or the card itself, they pulled the money from victim's account in as short period of time as possible. This was one of the biggest ID theft case in the United States of America. The attack was carried out by using SQL injection to install sniffer software on the Heartland Payments System server to collect and intercept credit card data. This attack was a big disgrace and it hurt company's reputation badly, since the company processed more than 100 million transactions a month for more than 250.000 merchants.

In 2012, over 40 million cards have been compromised by hacking the Adobe Systems. The fact is that the total global payment-card fraud losses were $ 11.3 billion in 2012, up nearly 15% from the prior year (Economist, 2014). The United States is one of rare countries in which counterfeit-card fraud is consistently growing. Based on this, card issuers lost $ 3.4 billion in 2012 and merchants another $ 1.9 billion.

At the end of 2013 there were 1.2 billion debit, credit and pre-paid cards in circulation in America, which is more than in any other region in the world. That is nearly five cards per adult. As of 2012, 45pct of the world's payment cards and 76pct of terminals were equipped to use chip-and-PIN.

Already in July 2013, a new attack happened, and it was recorded as the 'largest hacking and data breach scheme ever prosecuted in the United States' (Benson, 2013). Russians and Ukrainians were involved in this case that took place in New Jersey, and which exposed more than 160 million credit card numbers. Those card numbers were later used for printing new plastic cards that were used for shopping. This attack resulted in hundreds of millions of dollars of losses.

Between November 27, 2013 and December 15, 2013 around 40 million cards were affected, including the cardowner name, account number, expiration date, and CVV (card verification value). The hackers hit Target Corporation, and estimates say that almost 70 million Target customers suffered losses due to this attack.

A newer attack occurred between July 16, 2013 and October 30, 2013 with Neiman-Marcus hit with a breach, when around a million of card numbers were found in their system (Wagenseil, 2014).

Recently, some banks in Indiana were also under attack. The hackers obtained card information from ATMs or through debit card payment, where more than 100 users were exposed. Transactions ranging from several hundreds to several thousands of dollars took place in Nigeria, Russia, Ukraine and Spain. A lot of cases were reported on behalf of Citibank the same year, where only two men executed hundreds of transactions and pulled around $ 750.000 from ATMs in New York. The target was a data server in Citibank. From 2007, FTC has recorded over 800,000 exposed users with total fraud loss of over $ 1.2 milliard.

In 2012, a new attack hit the payment processor company Global Payments, which resulted in exposure of 1 million cards. Visa and MasterCard payment systems were the target, and it was suspected that magnetic stripes, stripe 1 and stripe 2 were compromised. In May 2012, it became obvious that the hackers moved from Great Britain to France and Germany due to introduction of EMV in GB.

In the course of 2013, there was a great number of data breaches, when hackers used all of their abilities to take advantage of system malfunctions, as was the case with Target and Neiman-Marcus.

3. TECHNIQUES FOR PREVENTION OF PAYMENT CARD FRAUD

The development of new techniques for revealing payment card frauds is complex, mainly because of the limitations in exchange of ideas and information in this field. Once the details on fraud techniques are made public, persons in charge of the breach can use this information to avoid exposure, but at the same time these details are used for enhancing future breach techniques, by using current system faults. Set of data necessary for any of the fraud techniques is not available in public.

Techniques for fraud prevention could be classified in different ways, and one of them is as follows:

1. application of basic set of rules

2. implementation of EMV standards
3. use of complex security protocols
4. use of smart tools for prevention and detection.

3.1 Comparative analysis of fraud prevention techniques

Table 2. shows evaluation of fraud prevention techniques taking into account general and conceptual features of some techniques such as AVS, CVV2, Manual review, Negative & Positive list, Trusted e-mail, and biometrics (Bogicevic, 2014). These techniques have been compared for following characteristics: are they user friendly, are they easy for implementation, how fast are they, what's their price, is the service being charged, does it require a change in system if implemented, does it secure fraud reduction, and how realistic is to expect this technique to be applied. They came to a conclusion that the most user friendly techniques are AVS, CVV2, Negative&Positive list, authentication, and trusted e-mail. Biometrics, on the other hand, is not easy for implementation, which makes it expensive for realization. Unlike biometrics, AVS and CVV2 are fast and inexpensive techniques that make only slight changes in the system once being implemented. Buyer authentication, trusted e-mail and biometrics are most efficient when it comes to fraud reduction.

Table 2: Evaluation of fraud prevention techniques (Al-Furiah, 2009)

		Evaluation of techniques						
FEATURES		**AVS**	**CVV2**	**Manual Review**	**Negative& Positive list**	**Buyer authentication**	**Trusted e-mail**	**Biometrics**
General	**User friendly**	H	H	M	H	H	H	M
	Simple for implementation	H	H	M	H	H	H	L
	Speed	H	H	L	M	H	H	M
	Price	L	L	M	M	M	L	H
Conceptual	**Service payment**	M	M	NI	NE	H	H	H
	Requires change in the system	L	L	L	M	M	L	H
	Fraud prevention	M	M	L	L	H	H	H
	Real process time	H	H	NE	Hor NE	H	H	H

High -H, Medium -M, Low - L, Not indicated -NI, Not existing –NE

Table 3. displays advantages and disadvantages of following fraud prevention techniques: AVS, CVV2, *Manual review,* Negative&Positive list, Buyer authentication, *trusted e-mail,* Biometrics.

Table 3: Advantages and disadvantages of fraud prevention techniques (Al-Furiah, 2009)

Techniques	Advantages	Disadvantages
AVS	- simple, fast and easy for implementation - reduces fraud risk - AVS helps merchants to charge the service - there's no additional cost because AVS could be requested as a part of authorization	- In some cases, buyer's valid address differs from the one reported on the occasion of card issuing - It is not a perfect indicator of a fraud - AVS is not effective for *soft* products
CVV2	- Reduces *CNP fraud* - Prevents card counterfeit - No additional costs - Reduces costs induced by fraud	- Not applicable with stolen and lost cards - The hacker can obtain CVV2 values through system breach
Manual Review	- It's most useful when used with other techniques	- Not an effective technique for fraud prevention - Work quality depends on employees' experience and feedback - It's a very expensive and time-consuming method
Negative& Positive list	- It's a basic technique that serves as a starting point for further considerations - User friendly - Negative list is good for fraud reduction	- It cannot prevent the fraud – card number theft - Frequent updating is a must

	- Positive list decreases time needed for checking the valid order	
Buyer authentication	- It's a starting tool that secures protection of merchants from additional fraud-induced costs - Associations provide this technique in order to make buyers use online shopping - Total cost is low - Responsibility for costs is against the buyer	- Only Visa and Master cardholders can use this service - Buyers don't like this technique since it's time-consuming
Trusted e-mail	- It's an effective technique that helps in merchants' protection and cutting costs - Simple for implementation and use - Better than any other method that uses the delivery address or a verification code - Low price - Requires minimum amendments for all participants in e-payment - Doesn't stand in a way of other solutions	- No fault discovered yet
Biometrics	-Very efficient technique for authentication of buyer identity	- Hard for implementation - Expensive - Requires plenty of changes

4. ALGORHITMS FOR DETECTION OF PAYMENT CARDS FRAUD

Hackers use all possible ways to take advantage of some part of the communication chain between the entities, and thus gain data through payment cards use. The only logical solution is prevention and implementation of all the techniques in order to prevent fraud. There are numerous techniques for fraud prevention, and at the same time, those techniques are being enhanced as we speak (Kou, 2004).

Fraud detection is a very complex IT problem, and there's definitely no system that could predict with certainty which type of fraud is going to take place. There are basic rules that could be implemented and applied by Fraud Management Systems (FMS), but sometimes even they are not enough. For that reason, complex algorithms for reviewing and predicting transactions are being used, and they are supposed to tell us whether the transactions are genuine or fraudulent. Those complex algorithms are working on a principle of predicting the possibility of an event, and in this case the event is whether it's a fraud transaction or not. Techniques for prevention and detection are supposed to reduce the number of frauds, and they are a key part of risk management in banking sector, especially when it comes to electronic payment systems. Prevention techniques comprise a series of basic rules, and when that rules fail in preventing a fraud, detection techniques are being applied.

Given that there's a difference between online and offline frauds, we can also distinguish online and offline monitoring in FMS. Different techniques could be used for different kinds of frauds. FMS are to provide next conditions:

1. to detect fraud in early stage and with sharp precision.
2. to provide relevant information to fraud analysts in timely manner.
3. a good system shouldn't detect genuine transaction as a fraudulent transaction.
4. to make this process automatized wherever applicable.
5. to self-adapt to changes in fraud patterns.
6. to self-adapt to changes in consumers' behavior.

Techniques for prevention and detection could be implemented on behalf of the issuer, and also on behalf of the acquirer, but the main difference is that the suspicious transaction is mostly rejected by issuer.

These are the most often used algorithms for detection of card fraud (Zareapoor, 2012):

1. A Hybrid Approach using Dempspter-Shafer Theory and Bayesian Theory
2. Blast-Ssaha Hybridization
3. Hidden Markov Model
4. Neural network

5. Bayesian Network
6. Genetic Algorithm
7. Artificial Immune System
8. K-nearest neighbor algorithm
9. Support Vector Machine
10. Decision Tree
11. Fuzzy Logic Based System
12. Meta Learning Strategy

5. RISK MANAGEMENT

Risk and uncertainty are two key terms when it comes to decision making in any institution whatsoever, and especially in banking institutions that are of special importance for this paper. The probability is the measure of randomly selected uncertainty and statistical models, used to calculate statistical risk. Financial risk could be defined as a measure of uncertainty that the buyer is ready to accept while performing financial transaction. This kind of risk is associated with payment systems and credit options offered to consumers. In the very beginning of e-commerce development, the financial risk mostly referred to those articles that hold lower degree of risk, such as books, music, clothes, and journeys. In general, prices of products are more often viewed in offline shopping mode than in case of online transactions, which carries greater risk for this kind of shopping. Newer researches show that the financial risk depends on the user age, gender, education, and marital status.

For calculating any kind of risk, a math formula, the so-called ratio is being used for creating complex models that calculate more than one ratio and their mutual dependence. Operative risk is dealing with financial transactions and all consequential events. As for the operative risk and frauds in financial transactions, banks in Serbia lack models for that kind of risk, because it is believed that the fraud level is quite low. Therefore, the risk is being regulated by introducing standards, as well as all the methods for prevention and detection of algorithms, which are described in previous chapters of this paper. The most important thing is that all events that cause some kind of fraud are reviewed under operational risk and they are given a certain ponder – it is only important to recognize and define all the events that could happen.

Banks face different types of risks, such as credit risk, market and operational risk (Li, 2013). These risks were originally managed and measured separately. However, this limit moved in time so that in 2007, when the crisis started, it was realized that these risks interact with each other and are inseparable. Banks develop quantitative risk measures that are applicable to all types of risk.

By using different methods, financial analysts create financial data available for operational risk as one of the types of financial risk, and in this way, statistical models could be applicable on operational risk. Many large banks have already started with collecting data on losses and loss measurement through operational risk. Most of them have limited time series, but in spiteof fewer number of data regarding great losses, they represent a mandatory model.

If we are to observe operations of a banking institution, we can see that the credit risk accounts with 60pct, operational risk with 30pct, and the rest goes for market risk – 10pct.

The model of operational risk is a set of functions that represents uncertain future events. The uncertainty could be the occurrence of an event, the time of occurrence, as well as the amount of loss caused by an event (Kim, 2008). The uncertainty could be represented through probability, and therefore, the model of operational risk measurement is actually the probability model.

One of the models of measuring operational risk is the Advanced Measurement Approach-AMA (BIS, 2011).

6. SOLUTION PROPOSAL

Figure 2. shows solution architecture in case when the bank as a card issuer entrusts the service of transaction processing to Processor Company, while checking if the transaction is fraud or not is entrusted to a solution proposed in this paper. The solution proposal is also given for cases when the ATM, POS and Internet transaction (through payment gateway to the bank) are initiated on bank's devices.The cards of bank the issuer could be used on these devices, as well as cards of other bank issuers.

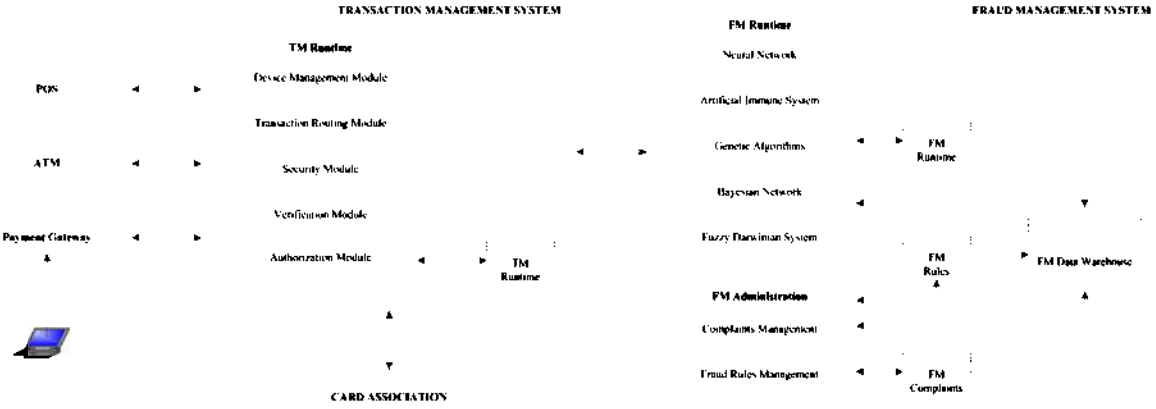

Figure 2: Architecture and software modules of proposed Fraud Management System

System components:

I Transaction Management System – TMS

1. Transaction management Runtime
   - This is a part of TMS that contains several modules that process transaction in real-time mode.
2. Device management module
   - It determines the type of the device on which the transaction is being carried out (ATM / POS/ Internet, i.e. payment gateway) and transcripts it to adequate format required for TMS.
3. Transaction Routing Module
   - Through BIN (Bank Identification Number) it determines to which bank the transaction belongs to,
   - Carries out validation of certain fields, transaction parsing.
4. Security module
   - Runs a check on PIN and decrypts encrypted elements of transaction message
5. Verification module
   - Validation of card validity, among other things, checking card expiration date
6. Authorization module
   - Checking if there's enough money on the account and authorizes the transaction
7. TM Runtime Database
   - All transaction that take place, either fraud or genuine ones, are stored in this base
   - Transactions that have been rejected in some of the modules TM Runtime are also stored.

II Fraud Management System

1. FM Runtime module
   - This module defines algorithms for detection of frauds, including Bayesian Network, Neural Network, Artificial Immune Systems, Genetic Algorithm, and Fuzzy-Darvin algorithm. These algorithms detect whether the transaction is fraud or not, because they implement defined rules within DB rules.
2. Fraud management runtime database
   - This is operating data base used by FM RT module, and which contains all data concerning the transactions that took place.
3. Fraud management data warehouse database
   - This is a DW database that helps in making decisions and serves for displaying statistical data and more detailed consideration of card owner behavior, which eventually leads to making a decision on whether the transaction is fraud or not.
4. Fraud management administration
   - This GUI can change parameters and introduce new rules in FM rules, or make new decisions on transactions based on information obtained by FM Complaints.
5. FM Rules database

- This base holds all the rules defined for fraud prevention, and in case of non-compliance with those rules the transaction is considered to be illegitimate, and this raises the alarm level. The values of parameters for those rules are defined in here.
- Visa's rules are adjusted to bank's needs
- General rules:
    - Tied to transaction location
    - If it's an Internet transaction, attention is paid to IP address
    - What's the time scope between two transactions
    - Type of account being used

- Control rules:
    - What's the BIN
    - What's the amount of transaction
    - Values for AVS, CVV – for cards with magnetic stripe, CVV2, PAN
    - User's limits
- Rules for operational risk measurement where we can monitor:
    - Risk given the territory of transaction initiation
    - Risk for merchants' activities
    - Risk given the financial effect.

6. FM Complaints database
    - In case some transaction left the system as being valid, and it turns out that there was a system error, i.e. it's a fraudulent transaction not recognized by the system, it is necessary to enter corrections into FM DW.

III Card Association

1. These are card organizations, which, in a solution presented in this paper, receive transactions from TMS, initiated by a payment card which is not issued by a bank that is in ownership of one of those devices (ATM, POS), and process them.
2. Card organizations are as follows:
    - VISA
    - MasterCard
    - Diners.

Steps with transaction processing:

1. Transaction is initiated by a device (ATM, POS, Internet transaction)
2. DMM determines the origin of the device and transcripts it to adequate TMS format.
3. After that, TRM determines the bank in question based on BIN, and if it's on-us (transaction from the card issued by a bank – issuer for which the processing activities are being done), it sends the transaction in FMS to check if it's genuine or fraudulent. In opposite, if the transaction is done with a card that belongs to a bank whose processing activities are not carried out by our processor, the transaction is sent out to Card organization for further check.
4. Once the transaction reached FMS, based on rules defined in FM Rules, FM Runtime processes a transaction by using an algorithm for fraud detection, and places executed transactions into FM Runtime operational base.
5. Upon the executed transaction, FM Data Warehouse is being loaded in real time, and updated with information from FM Complaints.
6. Based on all input streams, including reading rules from FM Rules, data Warehouse provides different types of reports which helps FM administration to change users' and system rules, and at the same time solves the problem of suspicious transactions in FM Complaints.
7. After the transaction is processed, FMS provides either positive or negative reply.
8. In case the replay was positive, the transaction is being sent for further processing to SM, together with all the necessary fields.
9. After that it is being forwarded to VM.
10. AM authorizes the transaction, or to be more precise, it checks whether there's enough money on user's account and then sends the response back to user in the form of successfully or unsuccessfully processed transaction. At the same time, it is updating TM Runtime database.

7. CONCLUSION

Over the years, we were the witnesses of greater use of electronic payment systems, but also of the attached risks. Just the same, payment cards are more and more used for shopping, while cash is used less, and the reason for this is to be found in a fact that people grow trust in the safety of these systems. Fraud systems and thefts are developing, but security measures for protection against fraud are getting better and up-to-date.

One of the directions of future research is the selection of complex algorithms that are best to be applied for modeling Fraud Management System that will be grounded on several algorithms. This FMS will apply positive features of every respective algorithm, and at the same time, it will try to eliminate their faults. On the other hand, back in the past biometrics was almost in the field of science fiction when it comes to e-commerce, while today this is something that is real and widely spread. Today, finger scanning is the most commonly used technique for determining the user identity. However, iris scanning is the future of electronic payment systems, with an aim to reduce frauds and financial losses, thus increasing the level of security.

CASH, HASH OR TRASH - HASH FUNCTION IMPACT ON SYSTEM SECURITY

Milos Zivadinovic[1], Ivan Milenkovic[1], Dejan Simic[1]
[1]Faculty of Organizational Sciences, Belgrade, Serbia
mzdv@outlook.com, ivan.milenkovic@fon.bg.ac.rs, dsimic@fon.bg.ac.rs

Abstract: *Authentication methods present an important part of every secure system. Traditional, but still dominant authentication method is the authentication by password. In order to be evaluated, passwords have to be stored on the system. Usually, stored passphrases are protected by the use of the hash functions. The goal of this paper was to test vulnerability of commonly used hashing algorithms to password recovery attacks. Hashcat and oclHashcat utilities were used to generate password hashes. The experiment results are given, and reveal potential weaknesses in some of the algorithms.*

Keywords*: hash functions, authentication, password security*

1. INTRODUCTION

A chain is as strong as its weakest link, says the proverb. Data security presents one of the cornerstones of modern business. As the amount of data generated and consumed by a business exceeds all expectations, our processes applied to securing it must become more resilient. Identity management within an organization must be organized utmost care. An important part of the identity management process is the activity of authentication (Milenkovic, Sosevic and Simic, 2012). As passwords are still a common authentication method used today, there is a need for their secure storage. Application of hashing functions to the domain of data security becomes more of a reality due to the increase of computation power, but it comes with a cost: users have to be more aware of the authentication tokens they are using.

With that in mind, users are quickly becoming the weakest link due to the fact that they are predictable and follow specific patterns in their lives, both conscious and subconscious. This allows us to easily “break the chain” and become one step closer to accessing unauthorized data by generating a large number of hashed words and then comparing them with the actual hashed data containing user authentication tokens (e.g. passwords).

This paper tests two popular password recovery tools on a real world scenario. A standard laptop with an Intel I5 processor and a dedicated graphic card is used for the experiment. Tested algorithms were MD5, SHA 512 and BCrypt. Section 2 of paper describes the problem statement in more details. In section 3 hash functions analyzed are described in more details. Password recovery solutions used are described in Section 4. Experiment results are given in Section 5, and they are followed by conclusions in Section 6.

2. PROBLEM STATEMENT

A hash function is a function that maps an arbitrary length input to a fixed sized length message (Andreeva, Mennink and Preneel, 2015). Ideally, the mapping of data from the original set to the data from the hashed set should be bijective - one element from the original set should correspond to one element in the hashed set. According to that definition, authentication of users becomes simpler since we do not need to handle the original access token, just its hashed representation which is then compared to the stored value.

With the improvement of technology and processing power, most prominently in the GPGPU and ASIC components, previous hash functions that were deemed secure in terms of collision, become compromised. Furthermore, the usage of processing power allows us to generate large amounts of hashes in a relatively short time, thus creating our comparison set upon which we can deduce the original authentication token. This process allows us to easily discover unsafe authentication passwords, such as short passwords or passwords without a large number of possible characters (e.g. plain numeric passwords such as dates of birth) even with continuous auditing with tools such as Seraphim (Zivadinovic, Milenkovic and Simic (2014)).

What is the best way to secure our data, our identities and our means of authentication in this highly competitive environment? There are two paths that provide answers to this question. One of them is to

rapidly improve and implement new kinds of hashing functions or to improve the ones that currently exist. This can become troublesome and problematic due to the nature of hash functions and mathematical foundations which is out of this paper's scope. The other path presents the possibility of improving hash function performance in securing our identities and data by increasing the entropy of available characters used for the creation of our authentication tokens which are then hashed for comparison. Furthermore, this process allows us to drastically improve our system's security with zero infrastructure changes and minimal interventions from the users of the system, thus reducing costs both in training and infrastructure and in technical debt.

3. HASH FUNCTIONS

In general, the output of a hash function can be considered as a data "fingerprint". An important definition concerning hash functions is the definition of an "ideal" hash function. An ideal hash function maps inputs of arbitrary length to outputs of finite length, where the distribution of the outputs is uniform over a given range space (Maurer, Renner, Holenstein, 2004). The mapping should follow the principle of a random oracle, as the mapping function is perceived as a black box. The definition of an ideal hash function is mainly important because real world examples are evaluated on their differences from the ideal case.

In practice, each hash function is characterized by following attributes: collision, preimage security and second preimage (Merkle, 1979). Collisions describe situation where two different inputs produce a same output value. Preimage security is connected to the following scenario, how hard is for a potential attacker to guess which input was used to generate a known output. In second preimage attack, we have a known input. The attacker goal is to find another input which gives the identical hash value as the known input.

MD5 is a cryptographic hash function which creates a 128 bit hash value. It was introduced in 1992 by Ron Rivest as a replacement for MD4 algorithm (Rivest, 1991). Today, MD5 is not considered a very secure algorithm, as it has several deficiencies. As first, MD5 is prone to collision attacks. In (Dobbertin, 1996), H. Dobbertin provided an example of pseudo collision for MD5. (Stevens, et al) presented construction of two public certificates. Although certificates had different public keys, the MD5 hash value was the same. In (Xie and Feng, 2010) first single block MD5 collision was published.

All of the attacks described above exploit either the collision or second preimage. As a consequence, a password hashes created with MD5 should be secure against a first preimage attack. Unfortunately, MD5 algorithm is very fast, and does not require a great amount of memory space for execution. Therefore, brute force and dictionary attacks can be a threat for MD5 password hashes. These treats are relevant, as it is still possible to find MD5 used in different applications (Silent Signal Techblog, 2015).

SHA-512 and SHA-256 (*Secure Hash Algorithm*) belong to family of SHA-2 algorithms, designed by National Security Agency (NSA). Difference between SHA-256 and SHA-512 is in the size of blocks used. SHA-512 uses 64 bit words, while SHA - 256 uses 32-bit words.SHA-512 is in literature considered cryptographically secure, as best attempts at breaking preimage resistance have succeeded at 57 out of 80 rounds of SHA-2 algorithm (Khovratovich, Rechberger, Savelieva, 2012).

BCrypt is hash function based on Blowfish cipher (Provos, Mazieres, 1999). It can be adapted in order to increase computational complexity, so it has an increased resistance against brute force attacks. BCrypt is used for hashing user passwords in BSD and SUSE Linux.

4. PASSWORD RECOVERY SOLUTIONS - HASHCAT, OCLHASHCAT, JOHN THE RIPPER

Hashcat is a popular CPU based password recovery utility. It is available on *Linux/Unix*, *Windows* and *OS X* operating systems. *Hashcat* works with more than 150 algorithms and focuses on high performance. Command line is used as a control interface. Support for multiple cores is included, and *Hashcat* also allows distributed cracking. *Hashcat* allows creating different types of rules to combine dictionary and brute force attacks, needed to defeat highly iterated modern hashes. Although it was closed source for most of its history, the author of *Hashcat* has recently moved the source code to open domain.

oclHashcat uses GPU for password recovery computations. Currently, it is fastest publicly available password cracker. It supports the use of up to 128 GPUs simultaneously. As for the hardware support, all CUDA and Stream enabled cards should be compatible with oclHashcat. Simple dictionary attacks are supported (such as combinator attack), together with brute force and mask attacks. A major feature of oclHashcat is the GPU based rule engine (oclHashcat, 2016). Sometimes, copying the wordlist for dictionary

attacks can have a significant impact on performance. Using GPU rule engine, it is possible to copy a relatively small wordlist to the GPU memory and then increase it size.

Hashcat, together with *oclHashcat* was used by team *Hashcat* for several victories in row on CMIYC (*Crack Me If You Can*) contests (Korelogic Security, 2016). For example, some of the competition themes were the ability to create wordlists based on certain categories, passphrases, creating custom rules based on cracks and cracking passphrase which use non standard character encodings.

John the ripper is an another popular password cracker. It is available on several different platforms, such as *Linux, BSD, Solaris, Windows*, etc. Basic version is somewhat limited in number of supported algorithms, but community enhanced version gives access to a wider array of available algorithms, such as raw MD5 and salted SHA-512. *John the Ripper* offers some GPU support, but when compared to *oclHashcat* it is more of an experimental feature. It has some advantages over CPU based *Hashcat*, such as preprocessor, which generates multiple rules for a single source line. However, superior speed and functionalities of *oclHashcat* make this tool somewhat lacking.

5. EXPERIMENT

Experiment consisted of performing twelve iterations of brute-force attacks on above hashing algorithms, with the final goal of determining if the GPU provides advantages in figuring out very strong passwords and how the algorithms above perform when they are applied in the creation of a very large number of hashes. The passwords chosen as an example during the experiment, where every password was regenerated for the next iteration, consisted of eight alphanumeric characters, including upper and lower case letters. This was determined to be the best-practice password pattern advised by security experts due to the amount of entropy generated by the number of possible characters and the password length.

The experiment was performed under the *Ubuntu 14.04* GNU/Linux operating system, running on a *Lenovo Y500* laptop, equipped with *Intel i5 3230* CPU and *Nvidia GT750m* graphics card. Software used for performing the experiment was *hashcat* and *oclHashcat*.

Following results present mean values of all twelve iterations both on *hashcat* and *oclHashcat*. These results may and will vary according to different CPU and GPU configurations, due to the fact that the experiment was performed on previous generation hardware laptop that was considered to be average in terms of consumer usage. The metric "*Number of hashes per second*" represents the generation and comparison of hashes to the hash we are trying to collide with.

Table 1: Comparison of algorithms and their performance on different hardware

Algorithm	CPU/GPU	Number of hashes per second (lower is better)	Estimated time
MD5	CPU	37 million	250-300 days
Bcrypt	CPU	75	Over 10 years
SHA-512	CPU	690	Over 10 years
MD5	GPU	847 million	90 days
Bcrypt	GPU	68	Could not estimate
SHA-512	GPU	23.315 million	9 years 1 month

We can see from the above table that, in general, MD5 performed the worst in both CPU and GPU tests, where the GPU brute force attack provided more than twenty times better performance. This confirms that MD5, as a legacy algorithm, should be avoided at all costs.

One more interesting thing is the performance of the BCrypt algorithm experiment which was ten percent worse in number of hashes when performed on the GPU. Main reason for this anomaly is hidden in the fact that BCrypt requires a lot of memory accesses, which must be pipelined through the CPU when the brute force attack is being performed on the GPU, thus increasing the number of intermediate steps in generating the hash that is being used for comparison.

SHA-512 gives us drastic improvements when it is being attacked using the GPU, which, in turn, opens questions of its ability to provide a secure mechanism of hashing in modern business.

6. CONCLUSION

Even though the experiment performed is highly reliant on underlying hardware, we can safely conclude several things. One of them is that BCrypt presents significant advantages over SHA-512 and MD5 hashing algorithms. According to that, BCrypt should be used in place of SHA-512 and MD5 algorithms, where it is possible. SHA-512 can potentially provide better performance than BCrypt, but this statement requires more data to be either proved or disproved.

Next, we can safely conclude that eight character passwords which contain alphanumeric characters are a safe bet against brute force attacks, and in some way, adequate protection against dictionary attacks (due to the ability that dictionaries do not contain numbers paired with words, while implementing checks for numbers transforms the dictionary attack into a brute force attack). Additional improvements to the safety of algorithms can be added by implementing password salts, adding an additional layer of security to the hash by transforming it according to random data which is used later, in a reverse process, to reconstruct the hash.

It would be interested to note the performance of these algorithms on machines with much more performant hardware, including CPU and GPU clusters augmented by high frequency RAM. Also, extending the experiment to cover the winner of PHC (Password Hashing Competition) - Argon2 ("Password Hashing Competition", 2016) and to include other PHC finalists, due to their novel design and possible improvements over BCrypt.

Abstract: *Nowadays, fast and effective decisions are the main request for the management staff in order to achieve company's sustainable development. Geographic information systems (GIS) are suitable ICT tool for management. GIS offers possibility to visualize spatial data and to make decisions faster. The authors are dealing with the problem how to improve internal communication within company. They are proposing application of GIS within company's communication what will bring benefit to the management teams in sense of more effective governing of their companies within the turbulent, changeable time. Their research, elaborated within a production company, proved that GIS contributes to better understanding between teams within company and to more effective decision making process when used for internal communication.*

Keywords*: GIS, business management, meter spatial information system, spatial data, visualization*

1. INTRODUCTION

Geographic information systems are a group of software useful to solve problems within many sectors of human activities. They are used in all areas which are dealing with spatial, georeferenced data. First implementation of GIS was by geographers and surveyors. They were designing different sorts of maps.
The scientists are conducting researches of various topics with GIS (Goodchild, 2010). They are presenting data into the maps, placed to their locations according to their coordinates, and separated into the more layers for doing investigations. Business subjects are implementing GIS with the goal to increase their profit. With GIS they do the following (Cheng, Li & Yu, 2007):

- Market research by:
- ✓ looking for the optimum locations of the headquarters, offices, distribution centers, selling points,
- ✓ analyzing trading possibilities, finding right empty niches for their products and services, (Moon, Lee, Ryu & Oh, 2014) and

- Marketing of products and services by:
- ✓ Presenting spatial distribution of consumers, distribution of customer's groups by their age, frequency of cooperation with the company, type of purchased products/services, results of surveys on customers' satisfaction etc. (Li, Kong, Pang, Shi, &. Yu, 2003), (Heywood, Cornelius & Carver, 2006).

Public utilities visualize utility infrastructure, maintenance centers, and malefactions locations, do project designs, prepare maps for the maintaining staff and doing new investments (Esri report, 2008).

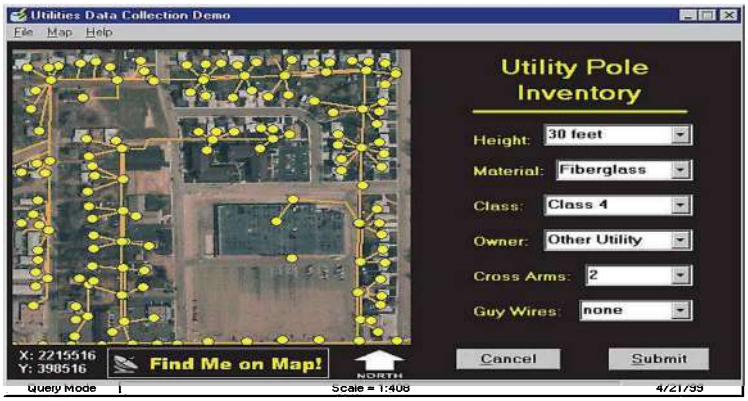

Figure 1: GIS in utility company. Source: http://www.esri.com/what-is-gis/who-uses-gis#utilities_panel

Prerequisite to utilize GIS software is to have data with geographic coordinates what enables their location on the maps. GIS maps consist of layers (Perry, Hakimpour, Sheth, 2006) which can be seen at the same time such enabling cross cutting of various data and watching them at the same time. Much less companies use GIS for solving management problems of companies and for decision making process. In some USA companies there are departments specialized in using GIS:

- for the problems solving (Esri in industry, 2015).

Utilization of GIS in such activities demands logical analyzing of problems and their decomposition into the spatial segments which are layers in GIS application. This process requests good experts knowing problems and their logical flows, as well as good experts of GIS presentation and if needed, experts for WEB surroundings. GIS enables viewing of decomposed layers and their overlapping which gives good platform to follow data influences, observe some significant inter-effects and to decide about problems' solutions (Kumar, 2013). Even, when problems are solved, new data are put into the layers and new effects can be again visualized and analyzed. This enables timely reactions and following the data changes through the time (Fu & Sun, 2010), (Kranjac, Sikimić, Dupljanin & Tomić, 2015).

The sector which is not covered by the use of GIS is business process management (BPM). Namely, BPM is a management discipline which integrates strategy and goals of a company with expectations and needs of customers in the way that "end to end" process is in focus. BPM includes policies, goals, culture, structure, IT to analyze, design, implement, permanently improves and compose good governing within "end to end" process in a company (Benedickt, Bilodeau, Vitkus & Powell, 2013). GIS is underestimated as ICT tool for visualization of existing business processes with their bottlenecks and milestones. GIS could enhance decision making process to company's management. GIS could be effectively involved as an ICT tool in:

- Meetings which should bring quick decisions
- Clear presentation of different business scenarios to the management
- Convincing the management into proposed solution
- Presentation to employees the situation
- Inform employees to know different scenarios of future development
- Proving what were good or bad solutions from the past (Burger, 2006).

These all should be done by GIS visualization much quicker than with other tools, because "an image is much more worth than thousand words".

The authors of the paper tackle the problem how to improve communication within actors of production process: management team and workers, by using geographic information systems. They are analyzing problem of workers' productivity by introducing spatial factors. Namely, spatial factors explain reasons of different productivity at the same type of machines within production plant. Reasons for differences can be discovered only when internal communication between management and workers runs smoothly. Spatial visualization created with GIS facilitates this good understanding (Kranjac, Sikimić, Vučinić &Trubint, 2015).

The authors want to prove that involvement of GIS applications into the dialogue between management and workers will bring better short-term outputs and long-term results of the companies and to prove the hypothesis that GIS can improve effects of the dialogues inside the company what brings total improvement of decision making process and better integral indicators of company's success.

2. LITERATURE OVERVIEW

Gaining competitive advantage is the main goal of the companies' management which will make company sustainable at the regional, national or international market or all of them. Growing number of corporations are looking for the ICT solutions which will enhance their functioning. The very important segment within companies is the way of communication between various groups: board members, management staff, employees in different departments, workers and the external world. External world are as the most important: costumers of products and services, distribution centers, dealers, financial institutions, logistic support points, marketing companies etc. Fast and clear communication without artifacts', confusions and conflicts makes company faster growth, easy functioning and spreading. Visualized data bring much more information into the communication process than any other type of data. This is even more important when one takes into account that companies' owners are not always experts from the area of organization activities and they need simple and exact explanations enough well presented to bring easy and right decisions.

GIS and data visualization as analytical and decision support packages are recognized as powerful tool in

corporations. When dealing with big data, what is usually the case, GIS contributes to the intuitive comprehension of big data. This enables bringing fast solutions. The experts who are preparing GIS presentations must identify crucial variables. Than GIS will help them in analyzing relationships between the significant factors. In some cases, when applications are user friendly and/or in put in web platform they enable end users investigations which they do by themselves (http://fargeo.com/blog/gis-and-big-data-visualization/). Sometimes, maps or layers made with GIS are too complicated, in too many colors what could make them incomprehensible for users who they are prepared for. This is a risk which new technology brings, that with desire to use it with more power, it could be turned into its opposite. Risks of GIS could appear during customization and integration. Sometimes layers could be visually overwhelmed what brings unclear vision to the users and even can confuse them. Deep analyzing process, careful approach and serious studding are inevitable when using GIS (Gioules, Hannmann Jodi-Lee& Evan Sullivan, 2010).
Some authors present a comprehensive approach for computing of navigation for an indoor space. They focus on a single floor, but the work is easily extensible to multi-level spaces. This is a small example of using GIS to solve some organizational problems. They use a formal model and combine map with geometric and semantic information. The program takes as input the building plans with geometric structure of the floors and semantics of the building and connects with GIS mapping (Yang and Worboys, 2015).
In some cases GIS is a mean for the interchange of information between departments what is shown in some papers. Such use is fostering horizontal connections between departments and it enables better understanding of "the whole picture of the comapany". Use of GIS when analayzing efficiency of a company, a postal enterprise, is described in paper of Kranjac, Sikimić & Vujaković, 2015. The authors explain some maps which reflects efficiency and productivity data within the postal department in JP PTT „Srbija".

3. CASE STUDY: GIS WITHIN COMMUNICATION PROCESS IN ENTREPRISES

Authors of the paper wanted to find GIS solutions which would enhance dialogue between:

- management staff and workers.

The goal was to improve companies' results. For this reason they explored a production company with 10 employees, 7 working on machines, in the production plant. They researched two problems:

1. problem of machines' productivity and
2. problem of employees' productivity.

They did following calculations:

Machine productivity = number of produced parts per machine per hour
Employee productivity = number of produced parts per employee per hour

These calculations are usual measures of production effectiveness. To better analyze and understand the situation, authors included the geographic position, actually locations of machines, as an important factor to analyze input elements of production's productivity. Data are presented in GIS layers what enables better understanding of problems.
The maps made in GIS can show different aspects of the quality and work's results and assist management to present this to workers on a visualized way, more understandable to workers.
The following example explains GIS maps which were used for the discussion between management team and workers about productivity of production process and reasons of the differences between workers/machines' results.
First example shows visualized data about productivity. The second example implements new factors which explain differences of production productivity elements, which workers pointed out and which are coming from their experience and explanations. These new spatial factors are described as bottlenecks in the process of taking input material for the machines. By simple actions they could be reduced or completely canceled and thus total productivity could be increased.

Example 1.

Figure 2. presents placement of machines in one manufacturing plant of the company. There are 7 machines in it and they are marked with labels: A, B, C, D, E, F and G.

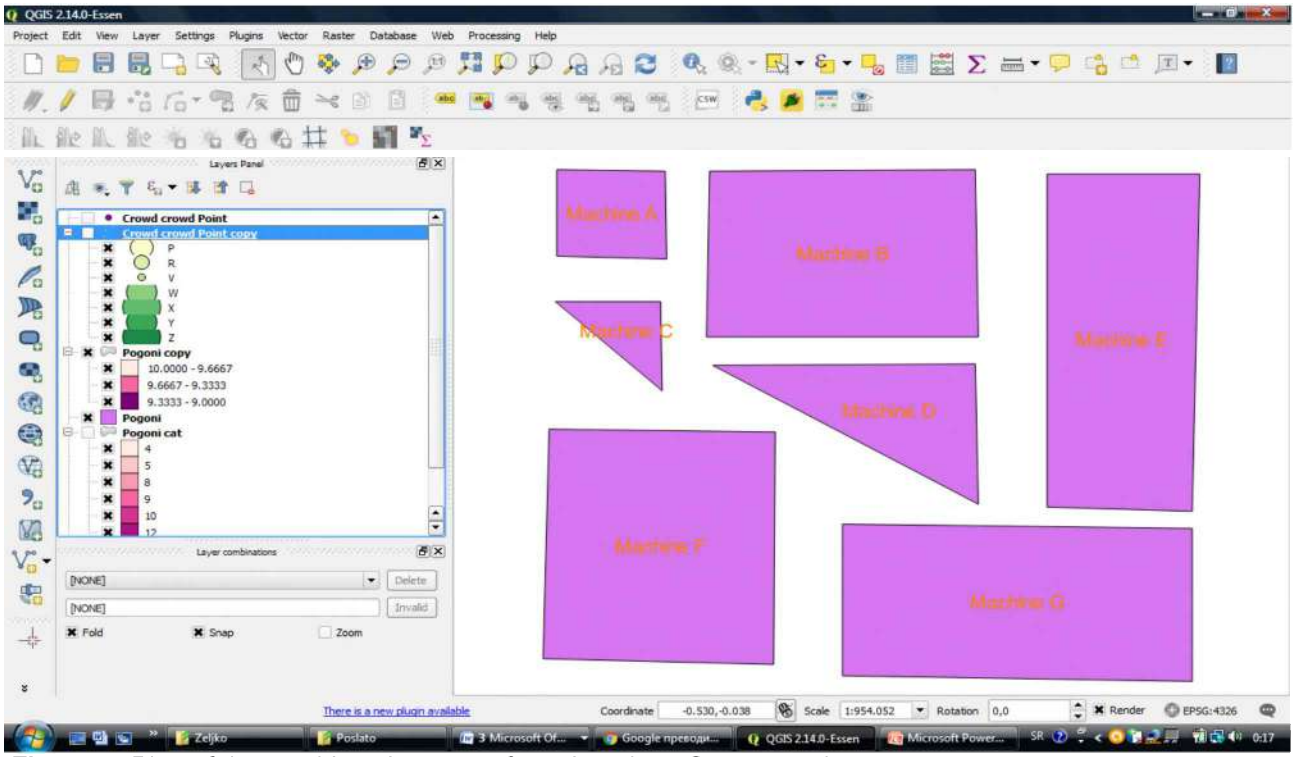

Figure 2: Plan of the machines in a manufacturing plant. Source: authors

In next Figure 3. are shown machines in different colors in such way that colors are sorted to the value of machine's productivity per one hour. The darker color, the more productive of the machine. The most productive is machine marked with A, with 12 produced pieces per hour and the least productive machine is labeled G, with 4 produced pieces per hour.

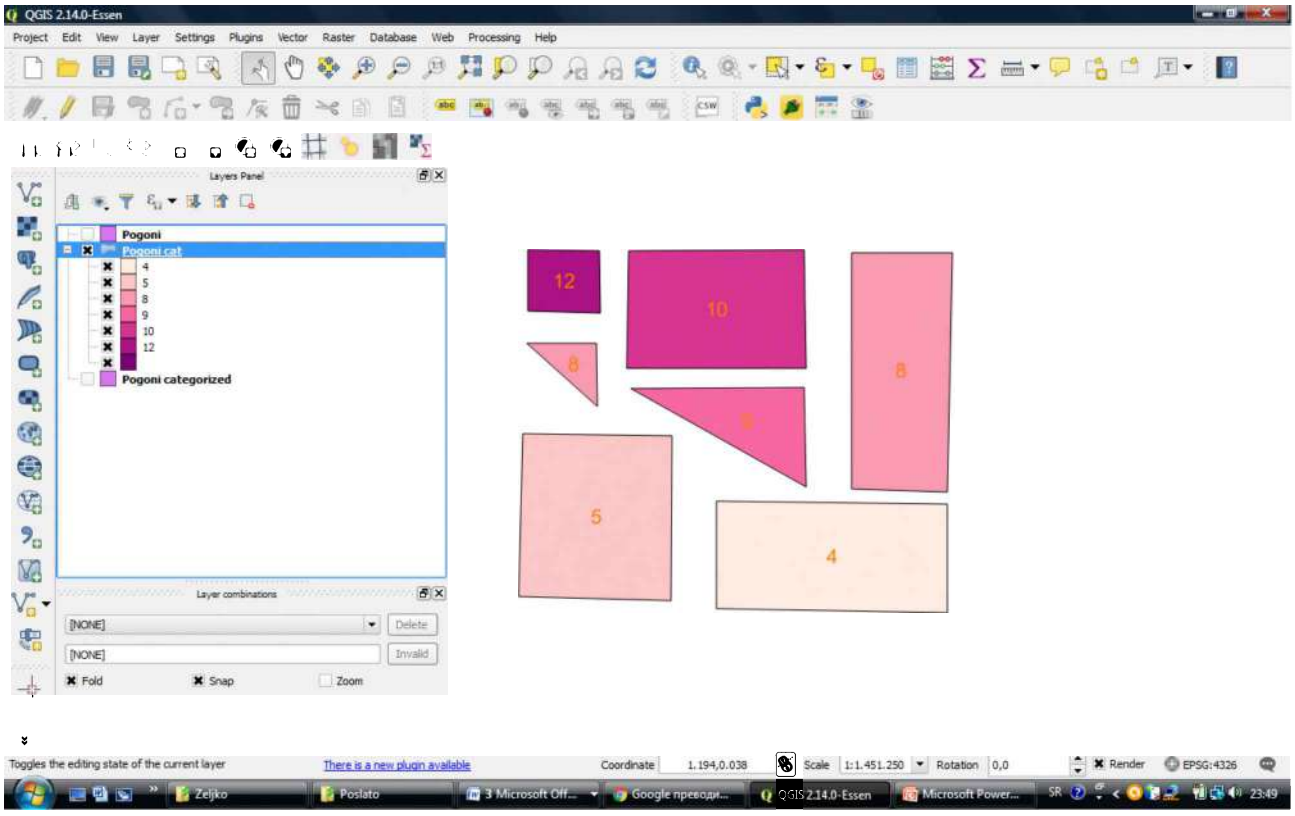

Figure 3: Colors ranged according to the machine productivity. Source: authors

Example 2.
This example shows the new factor which influences workers during their work on machines. Use of GIS map, in this case, is a tool for workers to explain their problem to the management. The circle's size presents

the bottlenecks for the movement of workers when they are taking input material for production. The spatial plan of machines or location of input materials, should be changed. GIS map is the best way to make the problem understandable to the management, by visualizing it. Namely, at Figure 4, the size of the circles and their color present the intensity of the problem which the workers have when they are moving through the production plant. If the color is darker and the circle's size is bigger, the problem is more expressive.

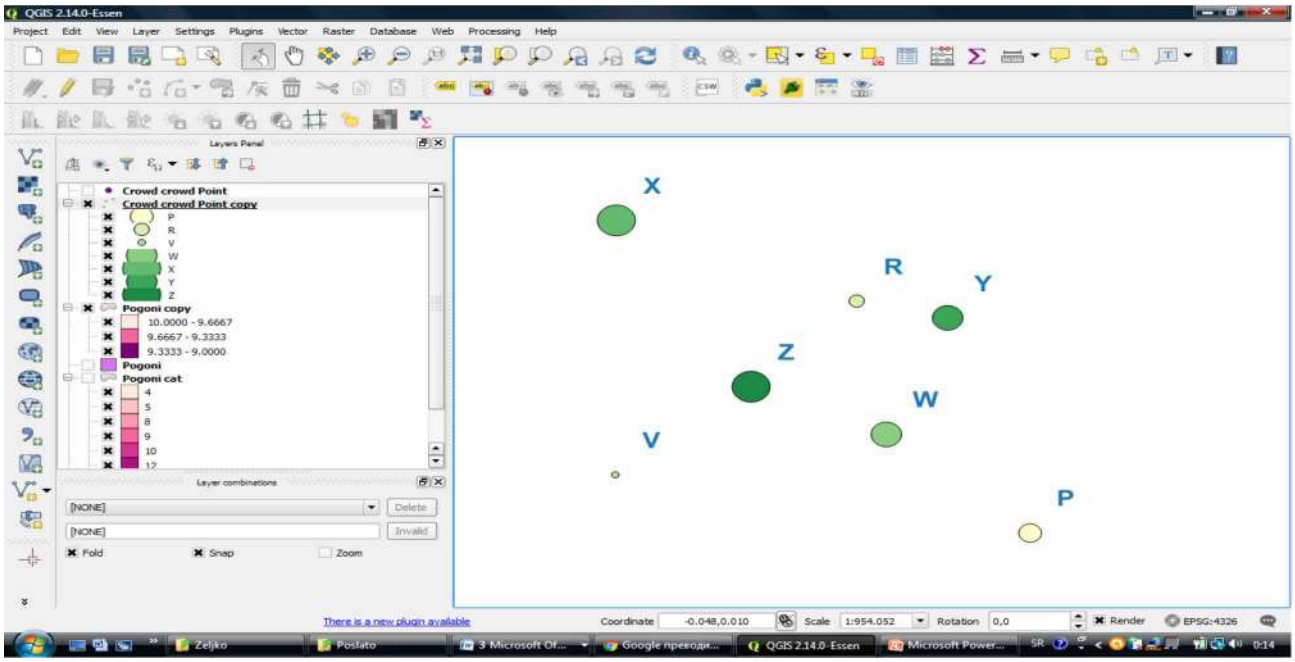

Figure 4: Bottlenecks in the manufacturing plant of the researched company, visualized by size and color. Source: authors

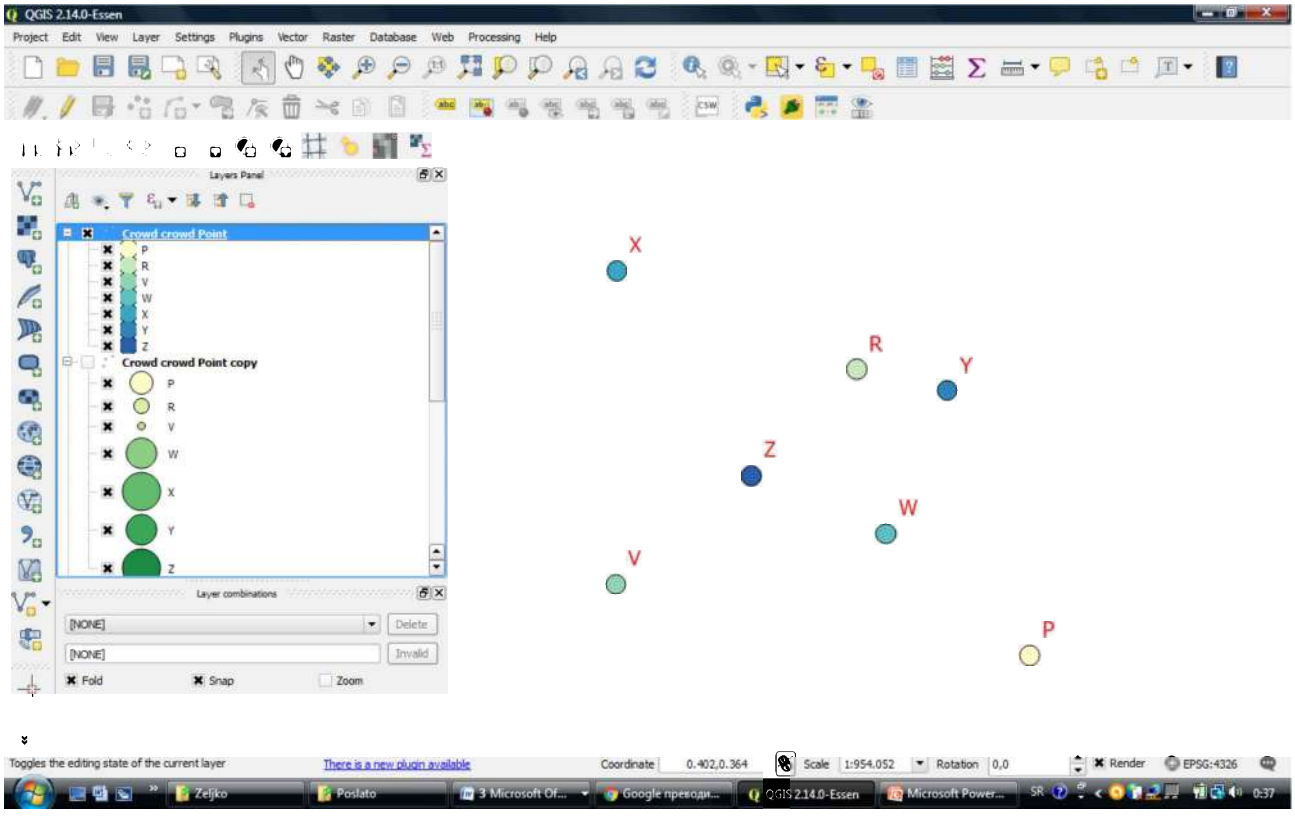

Figure 5: Bottlenecks in the drive of the researched company visualized by color. Source: authors

Figure 5 is less expressive; it presents the information only by color, and not by size of the circle.
Both examples show contribution of GIS in the process of communication within groups which are participants in the processes within companies.

4. TESTING RESULTS OF THE CASE STUDY

The maps described in examples 1 and 2 are results of authors' research. Maps are results of discussion between authors' team and two groups from the explored company: workers and staff members. Problems presented in examples were problems which these two groups from the company wanted to clarified and solve.

GIS maps were elaborated according to their demands. After the GIS maps were done, authors wanted to measure the effects of their use to the groups and made a survey. The results of survey made for workers are presented in Figure 6. The question was: "How do you assess the contribution of GIS maps to better communication between workers and management?"

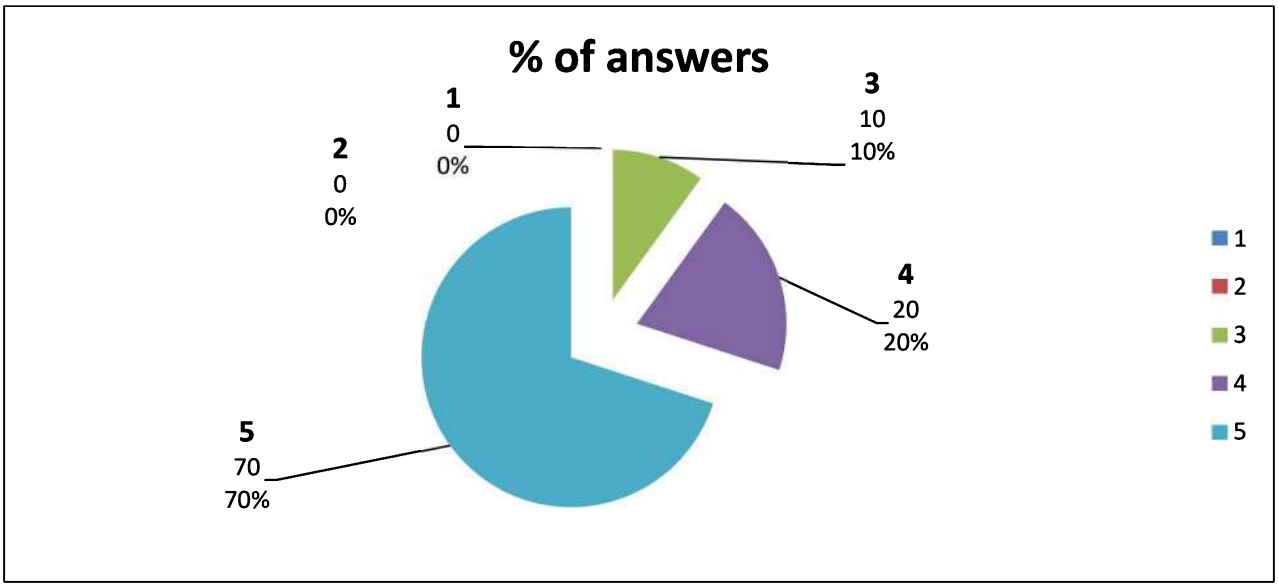

Figure 6: Assesment of workers (1 is the worse, 5 is the best). Source: authors

The results of survey made for management staff are shown in Figure 7.

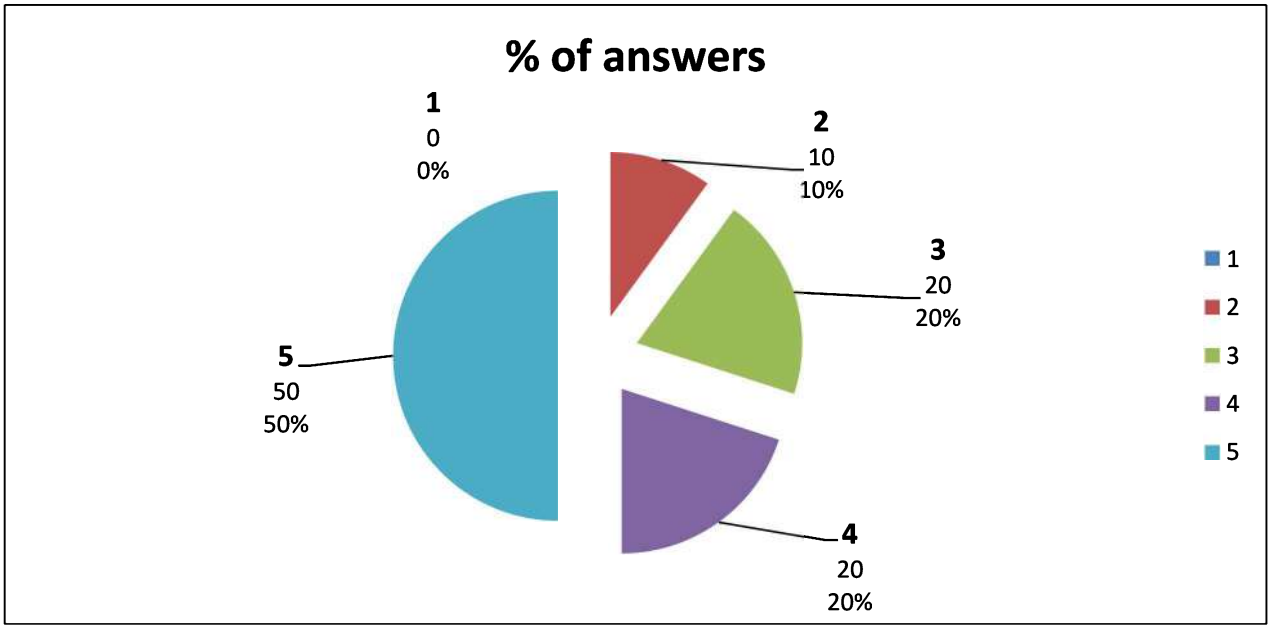

Figure 7: Assesment of management staff (1 is the worse, 5 is the best). Source: authors

The results show that management staff was less satisfied by the use of GIS maps, than workers. They had more doubt and have to be more trained about GIS and convinced of its usefulness.

5. CONCLUSION

The paper presents preparation for the meetings between management and workers enhanced by the use of GIS. GIS shortens their duration and improves the dialogue atmosphere. Authors' case study and survey prove the proposed hypothesis that GIS can improve effects of the dialogue inside the company and improve communication effects and business results.

The authors' scientific contribution is implementation of spatial information into the productivity problems that were subject of the internal communication. Spatial information is the digital connection between location, people and activities.

They presented use of an ICT tool, GIS software, in business management. Besides geographic information system which use is for larger spaces, authors introduce a sub GIS dimensions (defined by the accuracy of GPS), which are used in smaller spaces, like: production plants, logistic centers, laboratories,... This leads to the nano spatial management system which is dealing with nano dimensions.

Research should be continued and diversified to other factors of business management process with spatial components which were not analyzed before and which can bring improvement of business results.

PROSPECTS AND TRENDS IN THE DEVELOPMENT OF TELEMEDICINE

Marina Jovanovic Milenkovic[1]*, Dejan Milenkovic[2], Slobodan Ristic[1]
[1]Faculty of Organizational Sciences, University of Belgrade
[2] Serbian Armed Forces General Staff
*Corresponding author, e-mail: marinaj@fon.bg.ac.rs

Abstract: *The telemedicine has emerged middle of the last century but its implementation has just begun with introduction of the information - communication technologies. Information-communication technologies led to the fact that telemedicine is applied effectively, efficiently and with better quality. In European countries, telemedicine has developed with a different tempo. The paper describes the development of telemedicine trends during 2016, such as: Expanding Reimbursement, International connectivity and Arrangements, Continued Momentum at the State Level, The increase in telemedicine services in hospitals, Using Technology to improve care and reduce costs. The paper provides an overview of the application of telemedicine services in Europe and in Serbia, also the prospects of further development.*

Keywords: *health system, information - communication technologies, telemedicine, trends in development, telecardiology*

1. INTRODUCTION

The health system is one of the most complex systems of any country. The goal of health care system is a healthy population. In order to achieve the objective, the health system has experienced many changes. These changes relate to the introduction of the informational and communication technologies (ICT). ICT have led to the development of telemedicine services (Jovanović Milenković, Jeremić, Martić, 2014). Telemedicine aims to provide advice and support, and to reduce the chances of illness or injury. This paper gives an overview of trends in the application of telemedicine during 2016.

2. TELEMEDICINE

The primary goal of any health care services for the population is security, health and longer living. Prevention often reduces the need for treatment. Telemedicine therefore seeks to provide advice and support, and to reduce the chances of illness or injury. Historically, technology has evolved over the centuries to give the population a better future. That is why greater interest is to improve medical and health technology and to provide more efficient and accessible services to as many people as possible.

Medical and health technology is being used by everyone: patients, doctors, health care workers, end-users, engineers, clinicians and hospitals, etc. Health services are no longer restricted to be provided in certain locations such as clinics and hospitals, but communication technologies are transferred to users who are on the move or at home. Caring for the community is to assist people with disabilities, taking care of children and the elderly, treating sick or injured, as well as support to vulnerable individuals.

Telemedicine is a combination of information and communication technology, multimedia and computer networks for the transfer of medical data. The word telemedicine is composed of the Greek words *tele* which means distance and the word *medicine*, which means the medicine at a distance.

Today in the world there are following definition of telemedicine:

- In the journal The Telemedicine Information Exchange (Brown, 1996) defines telemedicine as the use of electronic services for the transfer of medical data from one side to the other through the Internet, phones, computers, satellites or video conferences in order to provide health care services.
- Author Reid (1996) defines telemedicine as a use of complex technology for the exchange of information of health and health service delivery, where there are geographical, temporal, social or cultural constraints. Telemedicine involves the use of informational and communication technologies, and two-way interactive audio/video connection and a computer. This allows the provision of health services to distant patients. This facilitates the exchange of information between primary care physicians and specialists who are far from each other.

- Telemedicine is extending health services to remote and exchange medical information using the information-communication technologies. Its meaning is broad and includes activities such as prevention and disease diagnosis, treatment, medical education of users, research and evaluation in medicine. The application of telemedicine beyond the physical, temporal, social, and cultural barriers. It reduces the potential time and cost of transportation of the patient to the doctor, or the doctor to the patient. The emphasis in telemedicine is the transmission of information between doctors and health care users.

Among these variations of the definition, there are several things that are common. First, the definition of the term was created in the 1990s. Secondly, it has been providing different kinds of medical services from a distance using information and communication technologies. The most important aspect of telemedicine is quality, because the diagnostic and therapeutic quality improves. It also allows early detection of adverse effects of the applied therapy.

In recent years, with the introduction of internet technologies, telemedicine is more developed. In the health system, telemedicine has experienced growth in all branches of medicine. On the global market, every country has done a lot on infrastructure development (Kamsu-Foguem, Tiako, Fotso, Foguem, 2015).

3. TRENDS IN THE DEVELOPMENT OF TELEMEDICINE

3.1. Development factors of telemedicine

Services of telemedicine are experiencing big growth in health systems both in developed countries than in developing countries (Ekeland, Bowes, Flottorp, 2012). But it has not being developed in all countries equally. Diversity emerged depending on the level of development of the country (Boubacar Traore, Kamsu-Foguem, Tangara, 2016). In developed countries, the country is faced with the following problems:
- An increase in the elderly population;
- Increased costs of technologies that provide medical services
- Patient expectations are higher
- Economic and social changes.

Their problems have led to disparities in the provision of health services. State governments have tried to solve this problem in two ways: through tax increases and increased costs of providing health services. Given the complexity and sensitivity of the problem, the only solution that arises is through a variety of telemedicine services, reduction of costs.

The key factors that have helped the development of telemedicine (Norris, 2001):
- Expanded access to health services;
- Health care for the population who is constantly traveling;
- Military applications;
- Tele-home care;
- Reduction of costs;
- Market Development;
- Health Policy and Strategy

Expanded access to health services
Expanded access to health services includes access to health services of individuals who live at a great distance from large urban centers. They are motivated to use telemedicine services. Some parts of Australia and America are examples where residents do not have proper medical specialists in the environment of life and apply these services. Also, these services are intended for the handicapped, the elderly and people who have mental difficulties.

Health care for the population who is constantly traveling
Telemedicine is an important factor in the health insurance department. Some examples can be sailors, who spend their life time at sea. In these circumstances, radio connections play a big role to provide medical advice for many years. Transfer of ECG, X-ray images and video conferencing can greatly help a patient who at that time seeks medical assistance. Similar problems may happen to astronauts or passengers while being on flights.

Military applications
Military insured person who is in the inaccessible terrain may seek medical care supported by applications. Video conferencing is the best way to communicate with the military insured.

The US military applied system *Primetime I11*, which provides an opportunity for health care, regardless of geographic location. This approach has been used by the troops who took part in the NATO operation in Bosnia and Herzegovina.

Tele-Home Care
Tele-Home Care is designed to provide medical care for the elderly. In 1998, there were 380 million people who have had more than 65 years. That number is growing all over. Two thirds of the population older than 65 years are living in developed countries.

Increasing the number of older population also leads to changes in diseases. The application of tele home care, leads to every patient and care of his health, but at the same time reducing the costs of hospitalization, which is very expensive and the arrival of a doctor on a home visit. Home visits are replaced with tele-visit.

Costs reduction
The application of telemedicine put an influence on reducing some of the costs in the health system. The costs include costs of arrival and departure physician home visits, reduce medical and economic costs that can occur when a specialist works in the rural areas.

Market development
A few years ago the world has been using only analog signals during data transfer. Today, digital signals are applied in telemedicine.

Health policy and strategy
Each country should adopt a health policy and future strategy of applying telemedicine in its country. Adequate strategy makes it possible to do the infrastructure required for the provision of such services.

3.2. Trends in telemedicine during 2016

The global telemedicine market will become larger at a compound annual growth rate of 14.3 percent through 2020. It is anticipated to reach $ 36.2 billion. During 2014 there was a $ 14.3 billion (Lacktman, 2015). According to some authors, these five trends will drive telemedicine's continued growth and transformation of health care delivery in 2016:

- Expanding Reimbursement
- International connectivity and Arrangements
- Continued Momentum at the State Level
- The increase in telemedical services in hospitals
- Using Technology to improve care and cut costs

1. Expanding Reimbursement
Private and state institutions continue to develop telemedicine services. This will lead to better service delivery and will lower the cost. The main obstacle in providing health services were cost. But changes in the law will lead to a reduction of these costs.

2. International connectivity and Arrangements
In 2016, hospitals and health services will have to establish ties overseas medical institutions. In this way, knowledge of health care expands abroad. This cross-border partnership will allow access to a larger number of patients, to generate additional income. According to the American Telemedicine Association, more than 200 academic medical centers in the US already offer video-based consulting in other parts of the world. While many of these are pilot programs, 2016 will come to the commercialization of the majority of those treaties. The increase of a purchase power happened in the middle class population in countries such as China, and also the opportunities for growth is in Western medical centers.

3. Continued Momentum at the State Level
State authorities are working on the implementation of telemedicine services. Many states have passed laws that provide health care services via telemedicine, during 2015.

4. The increase in telemedical services in hospitals
A recent study found that more than 35 percent of employers with onsite health facilities offer telemedicine services, and another 12 percent plans to add these services in the next two years. Other studies suggest that nearly 70 percent of employers will offer telemedicine services as an employee benefit by 2017 (Lacktman, 2015).
Additionally, consumers are increasingly willing to visit retail medical clinics and pay out-of-pocket for the convenience and multiple benefits of telemedicine services when telemedicine is not covered by their insurance plans.

5. Using Technology to improve care and cut costs
Using technology and Internet, 2016 will be the year of telemedicine. In that way, the costs will be so the patients would take the best health services.

4. PROSPECTS OF TELEMEDICINE SERVICES

4.1. Prospects of telemedicine services in Europe

Telemedicine applications are constantly growing. The following figure 1, according to research, is done for Europe (Somsainathan, 2011). It was noted that telemedicine in Europe is mostly applied in the UK. The second place is Germany, and then Scandinavian countries. Teleradiology is used 66% in the UK and Scandinavian countries, while services in Telecardiology are highest in the UK with 6%.

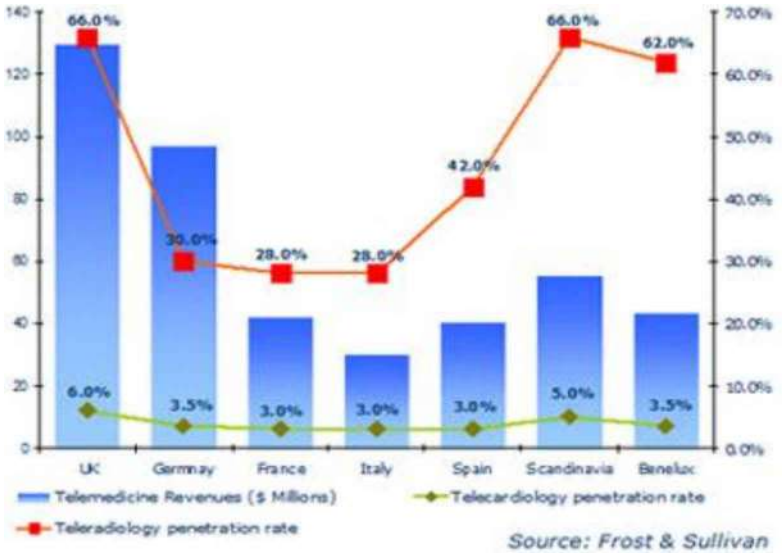

Figure 1. Application of telemedicine in European countries (Somsainathan, 2011)

According to a survey done in 2013, it is considered that the use of telemedicine and its services is increasing every year (UCLA, 2013). The study referred to the consideration of the parameters that affect the application of telemedicine. The period of time is perceived from 2005 to 2013. On that basis, forecasting is done of the application in telemedicine is to be in year 2030. This is seen in the graph Figure 2, which shows that the use of telemedicine increases, ie. that an increasing number of doctors applying telemedicine and its services and providing health care services over the years.

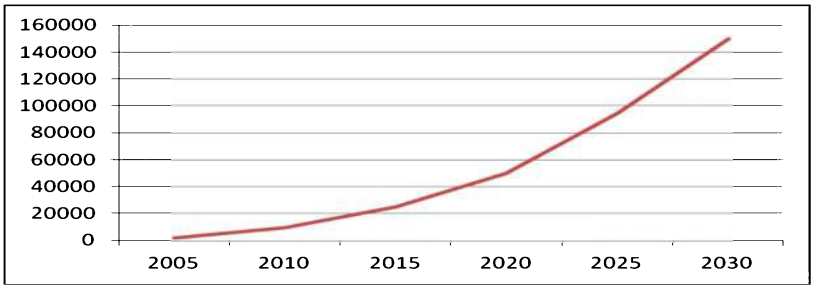

Figure 2. The application of telemedicine in the future (adapted from UCLA, 2013)

4.2. Prospects of telemedicine services in Serbia

In Serbia, telemedicine was developed in the 1990s. The first project was launched in the context of the Telemedicine Center in Belgrade, the Military Medical Academy (MMA), the Institute of Pathology and Forensic Medicine. When this project began, digitized libraries of classic glass started to slide. Telepathological established a permanent link between the Military Hospital and the Institute of Pathology, Faculty of Medicine and the Military Medical Academy in Belgrade, 1997. (Milosavljević, Spasic, et al 1997). The project was launched in the application of telemedicine services that related to sampling during surgery in Nis, and sent to Belgrade to determine the diagnosis. Although there was a modest technology, the telemedicine connection is proved safe. Since then it has functioned permanent connection to Nis, where the MMA has made several experimental relationship with other medical centers in Podgorica, Sremska Kamenica, KBC Bežanijska Kosa, where it carried out the transfer of radiological images, in addition to digitized microscopic images.

In recent years, Serbia was working on the introduction of electronic health records and electronic cards (Jovanović Milenković, Milenkovic, Jeremić, 2014). The hospitals are mainly used teleconsultation with doctors who are on other geographical localities. In most cases applied in cardiology.

In Emergency service vehicles are installed equipment that allows data transfer to the hospital. In Belgrade, Emergency service vehicles are equipped with modern apparatus for the transmission of ECG signals. These devices make it possible to record the ECG transmitted directly to the central Emergency Department regardless of whether the record was made in the apartment of a patient, in a public place or in the ambulance. The record is transmitted through GSM (Global System for Mobile Communications) on the server, where it is available for review and analysis by more doctors. In this way, by teleconsultation, doctors may indicate the doctor who is next to the patient so which is the best way to administer first aid to the patient. This ensures a higher quality of services and more accurate diagnosis. In addition, a team of doctors who are in the hospital can quickly and adequately provide further medical assistance (Reljin, Gavrovska, 2013).

In April 2016, MMA organized online course entitled "ENT surgery live - online". Speakers talked about education via the Internet as the most modern method of distant learning. Thanks to ICT technology, consumers had the opportunity to watch a live webcast of four operations in the field of otolaryngology, supported by the *Big Blue Button* software for distance learning, with a *Medapp Moodle* educational platform. The physicians performed in the operating room at the MMA. In addition to involvement in the educational platform of audio or video link, users had the possibility of direct communication with the operator. They were able to ask questions via the audio link or messages in real time, and the possibility of mutual communication and communication with the moderators of the course. The moderator has joined the course in Basel. Doctors for otolaryngology responded to the message. Clinic of ENT has organized such a course in which for the first time in the region otolaryngology surgery transmitted live via the Internet, certainly made a pioneering endeavor and set a new standard in the field of education (The Military Medical Academy, 2016).

Figure 3. ENT surgery live – online (The Military Medical Academy, 2016).

At the global level, it is necessary to support the development of adequate infrastructure for the development of telemedicine services.

4. CONCLUSION

The health sector has undergone various changes in recent years. These changes were related to the introduction of information and communication technologies. This was reflected in telemedicine. But telemedicine is characterized by various factors that makes it more efficient. These include: Expanded access to health services; Health care for the population who is constantly traveling; Military applications; Tele-home care; Reduction of costs; Market Development; Health Policy and Strategy.

Pursuant to these factors, the paper describes the trends that are crucial for the further development of telemedicine in the course of 2016. These are: Expanding Reimbursement, International connectivity and Arrangements, Continued Momentum at the State Level, The increase in telemedical services in hospitals, Using Technology to improve care and cut costs.

Analyzing trends can be observed on directions of development of telemedicine in Europe. The paper is an overview and future projections described providing telemedicine services in Europe. Telemedicine in Europe mostly applied in the UK. The second place is Germany, and then Scandinavian countries. Teleradiology is used 66% in the UK and Scandinavian countries, while telecardiology services are highest in the UK 6%. In Serbia, it is shown to be the intensive use of new technology in telemedicine. Devices are introduced into the ambulance, which will help in monitoring the health status of the patient remotely. In April 2016, the MMA did the first online operation in the field of otolaryngology. More specifically, doctors were able to follow four operations online in the field of otolaryngology, supported by the Big Blue Button software for distance learning, with a Medapp Moodle educational platform.

At the end, we can conclude that telemedicine is a sector that every day is more and more developed with the aim of better medical care of patients. Telemedicine influence to provide quality health services. The paper shows that hospitals in Serbia following the development and to provide of telemedicine services. This concept should be expanded to all hospitals in Serbia to the entire population had adequate health care. Constant development and growth in use of telemedicine in the future is inevitable.

Abstract: *Interoperability becomes one of the most important demands for IT function in company. 4GL-based information systems are present a few decades in IT industry and because of their inflexibility they make big problems in the design, implementation and maintenance of software for modern business. Large number of these systems are faced with the inability to meet the demands of design in a way that they does not support business processes or the inability to use the latest technologies and solutions. Because of that they are actually legacy system. Solution that exposes 4GL procedures of legacy system as Web services is not effective in a situation where we have a large number of changes in the legacy system and high dependencies between procedures. So, if we design executable specification of the existing 4GL procedures and execute it as runtime model we can achieve interoperability. In first phase we specified transformation of Web service model to 4GL procedures model and as result we have annotated model. In second phase we designed algorithm that performs interpretation of annotated model and runs existing 4GL procedures in legacy system. To achieve this we used MDA approach and UML profiles. Proposed solution is explained in the example of execution of the distributed workflow between public utility companies in Belgrade.*

Keywords: *interoperability, MDA, 4GL, legacy system*

1. INTRODUCTION

Fourth generation of programming languages, briefly 4GL, was created in the period from 1970 to 1990 with initial idea to reduce time, efforts and resources which are invested in programming and learning conventional programming languages of third generation, briefly 3GL, as Pascal, Cobol and C. The need in the industry at that time was to reduce the dependence of professional programmers and to shift the focus on the user, which led to the idea that the development environment will be opened to the general population and programming will be more simplified. 4GLs are designed for specific problem domain, e.g. development of business software. In comparison to the generation of programming language before them, they are one level of abstraction away from the machine, which means that they are closer to the problem domain. Depending on the application, they can be classified into several categories: table-driven programming languages, report-generator programming languages, forms generators and data management 4GLs. 4GLs can be procedural languages or not or they can combine both concepts. Examples some of these programming languages are: Clipper, FoxPro, PowerBuilder, SQL, Informix 4GL, Ingres 4GL, Progress 4GL, Oracle Reports, ABAP, Clarion etc.

Legacy systems are old information systems which are still in use in the organization because they support fundamental business processes and the organization cannot or does not want to replace them or to redesign them. Legacy systems developed in the past, usually used older or obsolete technology. These systems are consist not only of hardware and software but also they include legacy procedures and processes – old way of doing things that are difficult to change because they rely on legacy software (Somerville, 2010). On one hand, enterprises see legacy systems as barriers to implementing new business processes because they are hard to adapt to new business requirements. On the other hand, they contain priceless knowledge about business and business operations. Because of these facts, enterprises are in dilemma what to do with them. Van den Heuvel (2009) explains that this business knowledge is constructed not only by explicit knowledge about business processes, policies and data, but also by tacit knowledge, which is very important in daily business operations.

Interoperability viewed as the ability of two or more systems to exchange information and services and to use the information that has been exchanged, with no access restrictions, or implementing, becoming one of the most important demands for enterprise. If we look at the EU's initiative for the integration of European public administration, proposed as part of the European Interoperability Framework - EIF 2.0, interoperability between public companies is one of the common goals that information systems of those companies should provide (ISA, 2010).

This paper presents the preliminary design and the procedure for enabling interoperability of a legacy 4GL system. The basic idea is to enable interoperability between public utility companies in Belgrade by exchanging models between them, transformation and execution of models. Complete procedure is illustrated in the case of complaint. In example both enterprises are involved. Basic research questions are:

- mapping between models of Web service and model of legacy 4GL system

- transformation of this mapping in execution model and calling existing Progress 4GL procedures from legacy system

The procedure is performed using a UML profile, as well as annotating Web services model in the 4GL model and then use this annotated models in the execution. For description of the Web service we used SoaML, OMG standard.The paper is organized as follows. The next section briefly presents related works from the research field. Section 3 describes the problem scenario to be analyzed. Section 4 describes the proposed solution. Following this conclusion is presented together with reference material.

2. RELATED WORK

Martin and McClure (1983) display a large list of characteristics of 4GL languages, whereby it should be noted that some of the works challenged the future, were outlined Grub and Takang (2003). Some of the benefits of these languages in the context of software maintenance are: reduction of development cost, easy understanding, automatic documentation and reduction in workload. On the other hand Grub and Takang (2003) presented a list of weaknesses of 4GL languages. *Application-Specific* - 4GLs are hard to use in a different domain compared to the one for which they were originally designed. Proprietary - 4GL environments are proprietary and incompatible with other environments and the organization cannot simply get rid of them and move on to other or similar systems. It directly affects the long-term evolution of the system. *Hyped Ease of Use* - It's adopted that the 4GL languages are very simple and that the 4GL languages designed for non-professional developers. What had once been pointed out as the main advantage, may prove to be a major weakness. This attitude leads to a big risk that the program code is unsustainable, and the system poorly designed and implemented, due to the fact that the systems will be developed by people without expertise. In this way, existing investments in 4GL systems will fail. Linthicum (1994) emphasizes that 4GL tools bind companies to software vendor, which is not standard and 4GL languages do not have sufficient flexibility, which OO languages offer and therefore they may represent the best alternative.

Interoperability has been an important area for research for years. Numerous researches and organizations propose different definitions, concepts, approaches, levels, frameworks and maturity models (ISA 2010; Berre et al 2007; Chen and Daclin 2007, Winters et al 2006, Vernadat 2010). Panetto (2007) analyzed different approaches to interoperability and classified them in relation to applications, models and standards.

Davidson et al (2001) design 4GL applications through UML models via tool VG UML Modeler. The aforementioned tool enables connection between procedural 4GL language and OO software development, with the appropriate mapping UML class in 4GL parts. The model supports the three-tier Model-View-Controller architecture.

In the context of model-driven engineering (MDE), and their motto "models are all" models can be used for transformation between models. The transformation is usually carried out in two phases. First phase defines the mapping between the elements of one model in the other. Second phase is automating the generation of the actual transformation rules. System receives two model definitions, uses rule and produces transformation (Brambilla et al., 2012). Janković et al (2012) propose approach of formal modelling cross-organizational business processes (CBP) using UML profiles.

For modelling purpose we use OMG standard for modelling Web services, SoaML. Gebhart and Bouras (2013) describe mapping rules and transformation from specification to implementation artifacts, which we use in our solution in a way that we generate additional files which describe model implementation.

Mottupalli et al (2009) design approach to SOA for Informix 4GL system, with deploying of 4GL function as Web services. W4GL tool automatically generates required skeletons, headers and wrapper files that are required. Specification of Web service is provided through configuration file. In relation to the above approach, our proposed solution is distinguished by the fact that we can combine several 4GL procedures in common communication and exchange data between them.

3. PROBLEM DEFINITION

In Belgrade, there are two public utility companies, briefly PUC. PUC "Belgrade Waterworks and Sewerage", briefly PUC BWS, specializes in production, distribution, selling and payment of consumed water and sewage services. PUC "Infostan" performs payment service for many PUC in town. We analyze the non-automated operation between companies – raise a complaint. When customer raises a complaint about the invoice and submits it to execution manually in PUC "Infostan", PUC "Infostan" archives document and forwards complaint to the PUC BWS. PUC BWS solves the complaint and informs the customer. This situation is presented in Figure 1.

Operation between two companies, raising a complaint, should be executed automatically through the Web portal of "Infostan". When customer submits a complaint on Web portal, complaint should be transferred to PUC BWS and inserted into information system of PUC BWS. This practically means that it is

necessary to enable interoperability between information systems of two PUC. We have to consider that PUC BWS use legacy 4GL IS, designed and implemented in Progress 4GL. Also, there is no possibility to switch to a new environment, it is necessary to enable executions of Progress 4GL procedures.

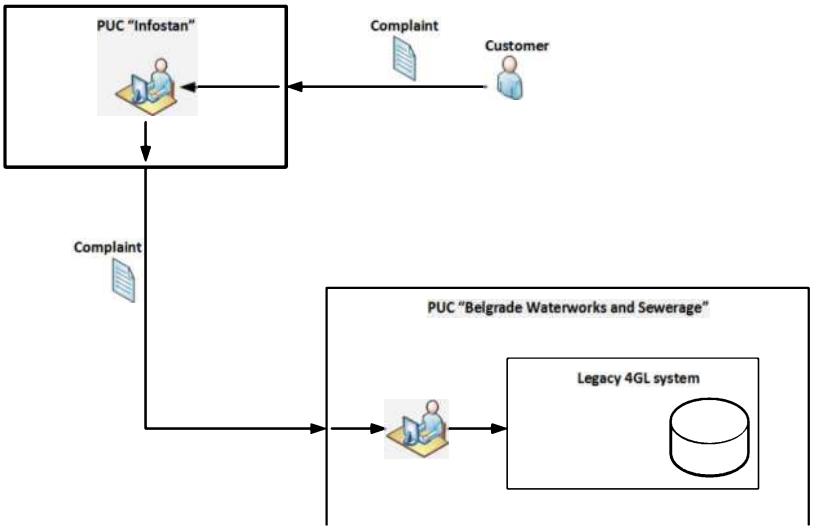

Figure 1: Current method of dealing with a complaint between companies

4GL procedure of legacy system can be exposed as set of Web services. To provide that, it is necessary to use a special tool to package and expose existing 4GL procedures, also with server which has to run existing procedures. Also, there is a need to achieve a higher degree of interoperability and exchange information between companies, and the above mentioned method can be proven as inefficient in situations which consider constant changes of existing 4GL procedures and changes in communication between Web services of two companies. It is also risky, changing existing procedures manually or programming the new ones, can prevent the legacy system from working. Such a procedure, in which we have frequently-changing ways of doing business, would require changing 4GL procedures, packaging 4GL procedures into Web services manually and the possible change in the sequence of communication between the Web services of companies.

4. SOLUTION

The proposed solution consists of several components, which are described in Figure 2.

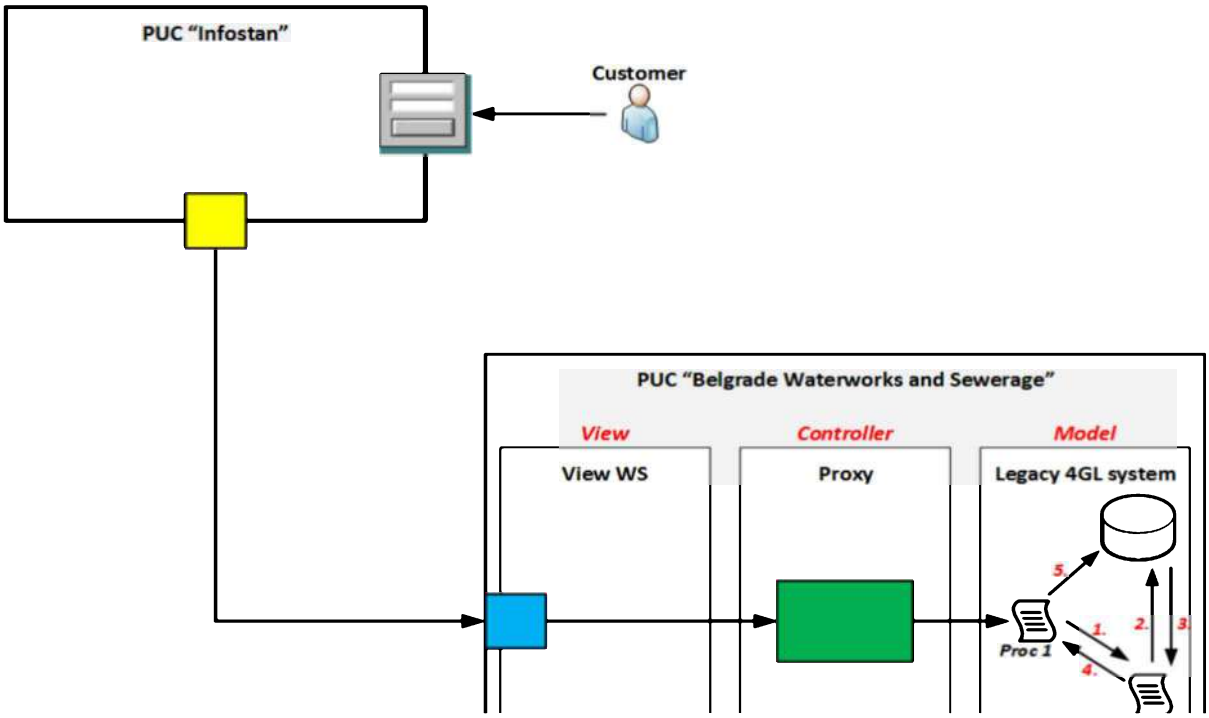

Figure 2: Proposed solution

Web service interfaces for legacy 4GL system consists of several components: ViewWS, Proxy and Legacy 4GL, which are organized according to the Model, View and Controller layers in architectural pattern Model-View-Controller, MVC. ViewWS is encapsulated functionality of legacy 4GL system, exposed to other systems as a Web service. When "Infostan" Web service forwards information about the complaint it calls ViewWS within the PUC BWS through SOAP message. In the context of MVC this component has the role of View, or the interface. Proxy is a component that accepts SOAP message from ViewWS, then make the annotation of model of Web service into 4GL and after that execute that specification from Web services into 4GL. Proxy component is the essence of the proposed project solution and the central theme of this work. Below we describe the component in a detail. In the context of MVC, this component has the role of controller.
Legacy 4GL system is existing legacy 4GL system that executes 4GL procedure. In contexts of MVC, this component has a role of Model.

Proxy Component has a role to implement the specification of annotated model Web services in 4GL model and then to execute 4GL procedures and that will way to execute business function of legacy systems. Running T2M transformation of existing 4GL procedures we can get M1 model of 4GL. M1 models of 4GL's are stored in the section Proxy component called the 4GL model Registry and it contains M1 model every 4GL procedures required for the execution of certain business functions of information system. M1 model of Web service is described by SoaML. Transformation Editor is part of Proxy component which specifies how annotation model of Web service conforms to 4GL model. After specification whole specification is memorized in WS model register component. Transformation Executor is part of Proxy component which executes specification and as result of execution procedures of Legacy 4GL systems are executed. Architecture of proposed solution is presented in Figure 3.

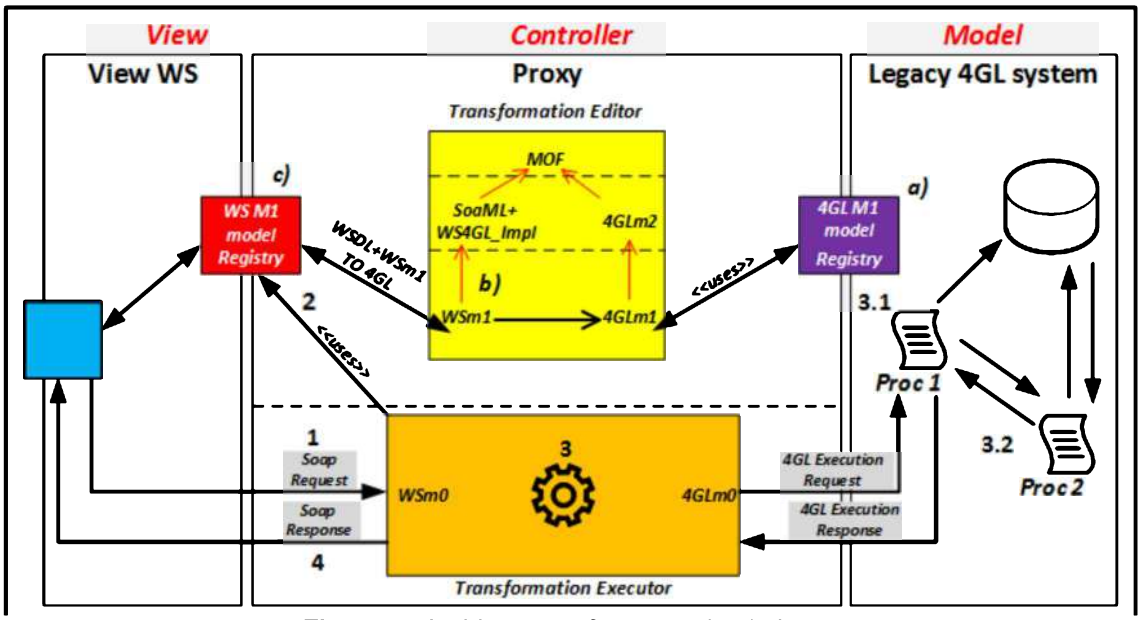

Figure 3: Architecture of proposed solution

Steps that are being carried out to build Web service interfaces for legacy 4GL system are:

1. *Service specification* – it consists of 3 steps, presented in Figure 3. and indicated as a), b) and c)

   a) *Description of 4GL procedures of legacy system and their registering into 4GL model Registry*

UML profiles used to extend the basic concepts of UML. UML profiles for 4GL are presented in Table 1.
Figure 4 displays models of two procedures from legacy 4GL system with the names CheckRegister and CreateComplaint and their attributes. Logic of 4GL procedures CheckRegister is to check whether the appropriate condition is satisfied, and if so, to call a procedure that raises a complaint - CreateComplaint and passes its parameters. CreateComplaint procedure stores Complaint into the table in Progress 4GL database of legacy 4GL system.

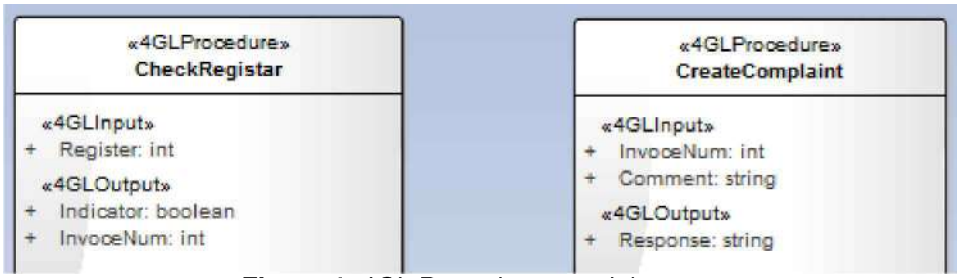

Figure 4: 4GL Procedures model

Procedures are stored in the 4GL model Registry in an automated way through T2M transformation.

Table 1: UML 4GL Profile

Stereotype	Description
	**a) stereotype: 4GLModule** Describes package which contained a set of 4GL procedures for some domains.
	**b) stereotype: 4GLProcedure** Allows to present 4GL procedure as a class. Performs a single business operation such as raising a complaint. Thus, the existing procedures are viewed as legacy systems functionality to be performed in the correct order
	**c) stereotype: 4GLParametar** Each 4GL procedure contains input and output parameters. Input parameters of one procedure can be output parameters to other procedures. Using this method, procedures are linked together.

b) the design of the implementation of Web services operations through 4GL procedure

In this part we will describe specification of Web services new part of system that needs to accept SOAP message and after that to execute functionality of legacy system, and after that to return the response to the consumer. OMG specifies UML profile for SOA to define SOA concepts inside existing UML concepts. Specification of Web services through SoaML is presented in Figure 5.

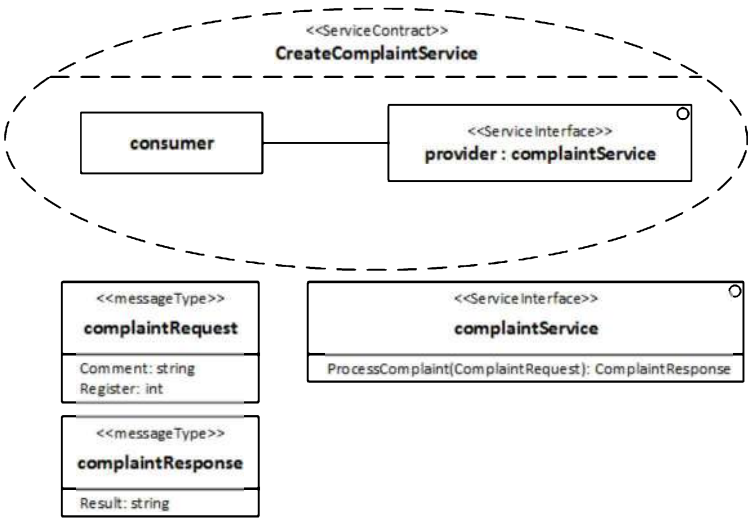

Figure 5: Specification of Web services

ServiceContract defines the conditions under which the participants in interaction must agree. Figure 5 shows that this interaction is simple and defines ServiceContract for CreateComplaintServis. In contract a consumer of Web service commits that will interact with provider, in this case complaintService. In general interaction can be more complex and include choreography, as defined in SoaML standard. MessageType describes the exchange of information between the consumer and the service. Provider calls CompliantService and send complaintRequest, which contains Comment and Register as data and as response it gets complaintResponse which contains Result. For each Web service operation it defines separate 4GL module i.e. component which presents control flow of execution registrated 4GL procedures. This description of service implementation is provided through WS4GLImp profile. WS4GLImpl profile is presented in Table 2.

Table 2: WS4GLImpl profile

Stereotype	Description
	**a) stereotype: WS4GLImpl** Indicates the component that performs 4GL procedures from the legacy system.
	**b) stereotype: Variable** Specifies the variables that will be filled with results of execution each 4GL procedures. Variables will be used for the exchange of values between procedures.
	**c) stereotype: call port** Specifies input port WS4GLImpl component. ComplaintService send message on these port. **d) stereotype: result port** Specify the output port component WS4GLImpl, which will display the result of execution flow of 4GL procedures.
	**e) stereotype: flow** Connects classes and defines execution flow of set of procedures.

Defined rules and constraints throught UML profile WS4GLImpl, which are not included in the table, allows valid specification of implementation of service with application general algorithm explained in step 2. of part *Service Execution*. Described model implementation of component which uses WS4GLImpl profile is shown in Figure 6. Diagram is created in Enterprise Architect tool. Specification implementation from Figure 6. describes how Web service ComplaintService, through operation ProcessComplaint initiates call of ProcessComplaint_Impl component and throught call port forwards complaintRequest message.

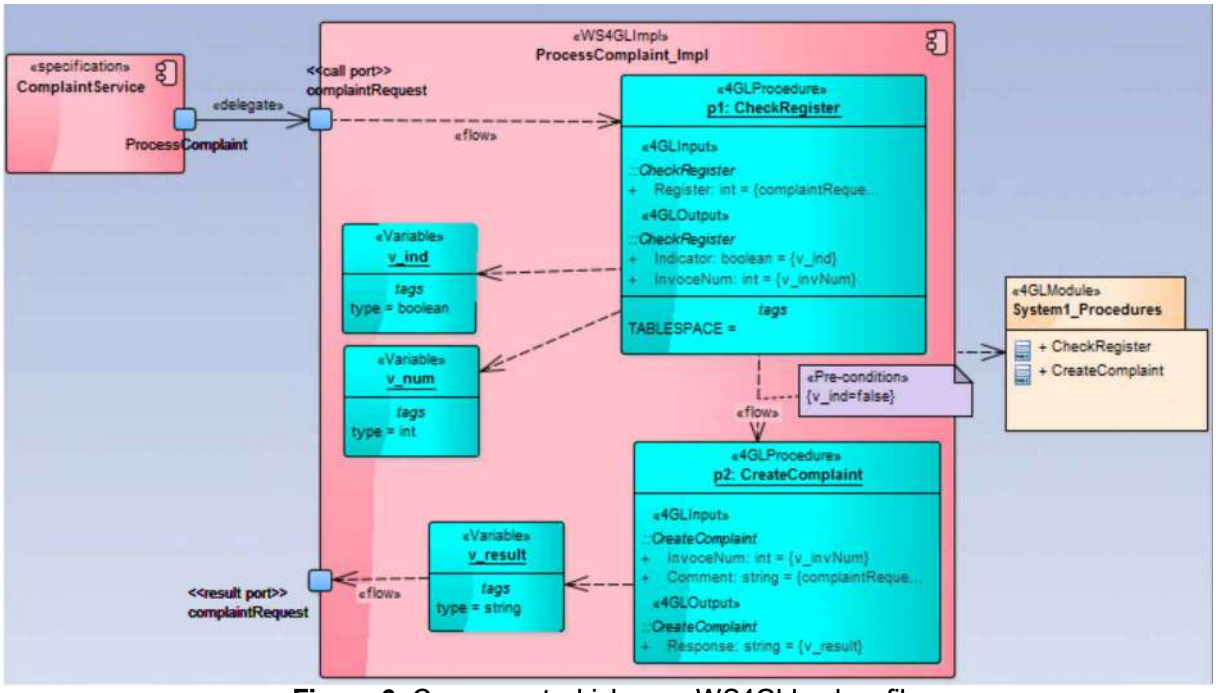

Figure 6: Component which uses WS4GLImpl profile

ProcessComplaint_Impl component takes the message, annotates the value from the message into the parameters of 4GL procedures and calls the object p1 of class CheckRegistar. The result of execution is stored in variables v_ind and v_num, in a way that object p2 of class CreateComplaint can use them. The result is memorized in the variable v_result. Web Service ComplaintServis through resultPort returns result of execution ProcessComplaint operations.

c) *check of designed model of Web services and their publishing into WS model Register*

In this step, constraints are checked with the values of input/output parameters in profiles and model is saved into WS model Register. This step is performed because model is exposed through WSDL and it is input for component which interprets that model in a runtime.

2. *Service execution* - it consists of few steps

    1. *When SOAP message arrives, there is recognition of annotated model which will be used*

    2. *Intepretation of annotated model, which is described in step b in first part Service specification, and executing actions which are described through algorithm in activity diagram presented on Figure 7.*

Interpretation of annotated models starts by finding corresponding component that executes 4GL Module, in this case WS4GLImpl. After that, the component WS4GLImpl finds the first procedure, which should call and evaluate parameters obtained from the annotated models. After that, algorithm prepares parameters, calls the procedure, accepts the result of execution and writes values into variables. Then algorithm checks is there further control flow of execution and if it exists, checks constrints, which can be defined before calling the procedure and relates to the value of the variable, which was set by previously performed procedure. If the constraint is satisified, algorithm calls next procedure. The process takes as long as procedures exists in control flow of execution. After that, algorithm is continued and prepares the response and sends it.

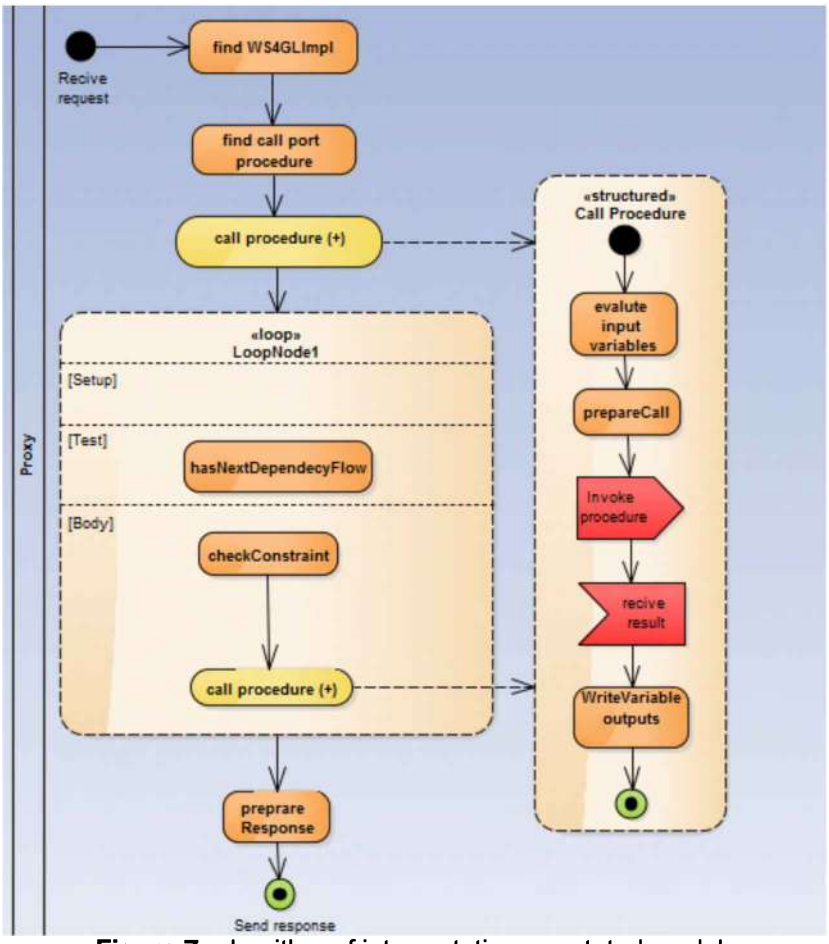

Figure 7: algorithm of interpretation annotated model

3. *component that preforms interpretation forwards response to the component which inovkes it*

Algorithm described in step 2 of Service execution is presented on an abstract level without technical implementation details of platform on which it is implemented. The task of the last activity in the algorithm is to prepare and validates the response message in accordance to specifications.

5. CONCLUSION

This paper addresses two major topics. First, it presents an approach to design Web service interface for legacy 4GL system which operates as runtime model and as such eliminates need for large number of changes in that system and also prevents potential malfunctions because of high dependencies between existing 4GL procedures. Second, it describes steps for the implementation of such an interface.

The key contributions of this paper are:

- the definition UML profile for 4GL, as specification mechanism of existing 4GL procedures
- the definition of specification Web services which calls 4GL module of legacy system, based on annotated model
- the definition of algorithm for executing that specification and calling 4GL procedures without additional changes of existing legacy system

We believe that our proposed approach is good in a situation where we want to expose modules of legacy 4GL system through proper operation of Web services, in a way that module can achieve interoperability with other system, without changing the way that existing legacy 4GL system operates. We are currently working on developing a framework to support this approach and we are experimenting with .NET development environment.

Abstract: *This paper analyzes the role of smart products and services with the view of their impact on competitiveness of company in international business environment. The paper reviews the importance of systematic organizational learning and dynamic capabilities development for smart business activities and overall performance. Strategic planning is observed within regional business units and how the flow of feedback information creates advance level of expertise. The emphasis is on the cross-department interaction and knowledge transfer for extensive capabilities of products and services formation. The efficiency is obtained through future oriented flexible adjustments, alongside with component knowledge for total product quality and intense responsiveness. Relevant examples show how successful smart systems expand their complex business networks and how they reshape management structure in accordance with international market demand. Smart products and services progress is examined in terms of increasing long term competitive advantage in international business. Accumulation and deployment of crucial resources are viewed as a result of effective knowledge articulation and superior operating routines. The paper also evaluates current strategies and possibilities of new business models for smart organizational learning as a perspective source of sustainable development.*

Keywords*: international management, smart products and services, competitiveness, multinational corporations, profit, dynamic capabilities, strategic planning*

1. INTRODUCTION

Creating competitive advantage by placing smart products and by providing smart services is a modern approach to business of enterprises oriented to future business success in an international environment. Business strategies, organizational skills and an entrepreneurial approach to solving business problems are relevant to the new system of managing companies' development. Consideration of the learning process based on experience and finding alternative options is viewed through the concept of organization that continuously generates new knowledge. Smart products and services require advanced structure, decentralization of the parent company and decomposition of the value chain based on business functions. The role of strategic business units is also significant, as they are in terms of the knowledge-based economy viewed as centres of responsibility and feedback information. In this context, the flow of information and improving all product components individually create competitive advantage based on efficient adaptation to market conditions. Long-term relationships with subcontractors, together with the perspective of investment in foreign markets, develop new sources of sustainable development of enterprises.

Business units autonomy based on the principle of loose structure of the company encourages creative solutions and helps protecting innovative ideas for upgrading the existing production facilities. The theoretical framework suggests the importance of delegating authority to lower levels of management and informal communication with superiors from the parent company. Incremental improvements in the vertical value chain and diversification of production form the basis for successful development of smart products and services. Equal distribution of dynamic manufacturing capabilities and absorption of relevant management skills strengthen the competitiveness of the entire organization, with an emphasis on operation efficiency. Meeting the needs of consumers stands out as a very important area, as evidenced by the fact that users of smart products and services are given special attention by reconfiguration of the products during the design phase. Strategic decisions at the enterprise level are adopted in accordance with the needs of local markets, which implies the emergence of a dynamic framework of organizational evolution of resources, capabilities and knowledge. Support to production sequence by complex coordination of activities and inclusion of non-routine management decisions creates a strong competitive advantage of the company to the resource-based approach (Helfat & Raubitschek, 2000).

2. COMPETITIVE ADVANTAGE AND SMART PRODUCTS DEVELOPMENT IN CONTEMPORARY INTERNATIONAL MANAGEMENT

Business enterprises in contemporary conditions of intensive competition require a flexible approach to the organization of business processes and decentralization of business units on the principle of lateral communication. The growth of value for international consumers by disruptive access to integrated business operations imposes the necessity of realization of strategic business objectives at the level of technologically rounded units of the company. Products at higher processing level are becoming the source of competitive advantage, with a focus on more efficient use of operating capital, increasing inventory turnover ratio, reducing product obsolescence, strengthening the responsiveness of consumers and other relevant factors. The integration of domestic and global business operations is achieved by standardizing business processes, improving operational performance and efficiency by using "pull" strategy, with the aim of taking advantage of economies of scale and aligning the physical capital of the company with the needs of the local market.

By providing specific and advanced services, a company is focusing on the value that its products can achieve in a competitive market and a long-term relationship of trust with consumers. Modern business model is transformed from the business philosophy of "value is in the product" to the modern concept of "value in the service that the product provides", thus obtaining a "return value" from satisfied customers. For active participation of consumers in creating a generic value chain the term *prosumer* is used in international management.

In the context of strategic planning, orientation to stabilizing the business and better positioning in the market has resulted in the "outward-in" management approach in the movement from the analysis of external environment to the analysis and adjustment of the company's internal environment (Davenport, Leibold & Voelpel, 2006). Bearing in mind that in terms of global business discontinuity accurate predictions of future market trends are hard to attain, incremental improvements in operations and expansion of business opportunities are considered to be insufficient to create a competitive advantage in foreign markets. Consequently, new strategies are needed to encourage dynamic capabilities of enterprises on the basis of continuous learning about the needs of the open business system. The acceptance of complex and interdependent network of intra- and inter- relationships of the companies is necessary in order to adapt the product to specific and individual needs of consumers and to incite changes in the organizational sense.

The development of smart products and services requires a significant change in the strategic approach to business and reshaping of the phases in terms of evolving enterprise management. Data exchange between business eco-systems and external sources of competence serves as a platform to support new technological infrastructure of the company. Combination of data controlling and the possibility of remote supervision of business processes creates new opportunities for business optimization in a broader sense (Porter & Heppelmann, 2015). The variety of smart products and services is also cost-effective, bearing in mind that the software engineering tools are changing the physical components of the product. Special attention is given to the interconnected system of production, in which the placement of related products is based on the relationship of trust with subcontractors, with special emphasis on system interoperability.

Analytical approach to creating business databases strengthens the expertise and facilitates communication between business units. Shorter development cycles of new smart products and services affect the responsiveness of the local markets to the approach of production integration and differentiation, with an emphasis on continuous improvement of the modification process of new product. In addition, smart products are designed according to the concept of voluntary exchange of information, which fosters consumer loyalty, facilitating further analysis of user preferences (Cronin, 2010). A new attitude towards certain other external stakeholders also becomes prominent (Milicevic, 2014).

Holistic approach to business eco-system consists of an efficient joining of resources, cooperation with business partners, suppliers and consumers in order to educate the established business networks based on organizational values, dynamic capabilities and company profitability. The principle of entropy, which originates from the field of thermodynamics, can describe the loss during the process of knowledge and information transfer within the company, according to which the ability of a business model to provide competitive advantage will decline due to pressure from uncontrolled market forces (Davenport, Leibold & Voelpel, 2006). Consequently, business eco-system must be able to continuously adapt to new market conditions in knowledge-based economy, related to "increasing returns". Thus, in modern international business an enterprise is considered to be an integrated business entity if it is made up of separate business units, which often include operations in different industries.

Smart product can be viewed as a series of post-added features in the process of the development of production line, which increases its usability and functionality. In other words, the competitive advantage of smart products and services is viewed from the aspect of dynamic approach of value creation, as opposed to the conventional model of achieving competitive advantage on the basis of the final production program (Annacchino, 2007). This offers new opportunities for growth of companies with a high degree of adaptive capacity. Managers should aim at accelerated growth in profit per product unit based on the uniqueness of the product, while the scale of business should gradually grow with the tendency of decreasing fixed costs per unit. When creating competitive advantages of smart products and services worldwide, managers should take into account the complexity of internal and external influences on the international competitive advantage of firms and the essence of sustained competitive advantage (figure 1).

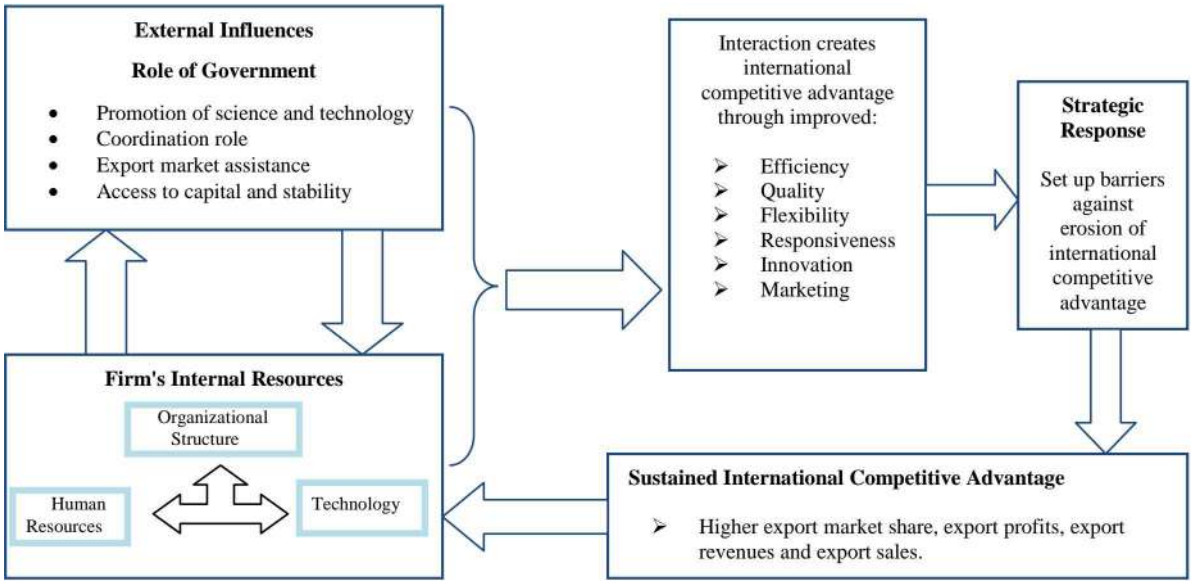

Figure 1: Internal and external influences on the international competitive advantage of firms
Adapted from: Chadee & Kumar (2001), p. 464

3. ORGANIZATIONAL LEARNING AS A SOURCE OF COMPETITIVENESS

Multinational corporations play a dominant role in present global market, considering the fact that the top 200 corporations combined sales were “bigger than the combined economies of all countries, minus the biggest 10” (Anderson & Cavanagh, 2000). This data implies the impact that globalisation has on all aspects of today's business landscape, and by that it emphasizes the importance of future intra-firm correlations. Here we must point out that the globalisation influences substitution of traditional assets in exchange for factors of paramount importance to the multionational corporations, where most crucial are technology, knowledge and capital (Demirbag & Glaister, 2010). These three factors are certainly the main causes for existence of competitive advantage. Nevertheless, they cannot be integrated into corporations operation processes if there is a lack of managing capability. According to that, the firm has to maintain and enhance its internal capabilities by learning from its own operations and by absorbing knowledge outside the firm (Andersson, 2003).

Capability can be defined as “the firm's capacity to deploy resources for a desired end result” (Capron & Mitchell, 2009). Therefore, it is essential to achieve quantity and quality overlap of these know-how and know-what sources. Several scholars have researched and empiricaly tested significance of capability transfer, as a genuine raison d'être of multinational corporations (Holm & Pedersen, 2000). Although there are various relevant studies that are built around premise of top-down capability flow (Porter, 1990), there are still only few studies concerning reverse-based relationship between headquarters and subsidiaries, especially in-between developed countries and countries in economic transition (McGuiness, Demirbag & Bandara, 2013). Giving the interest rate for this topic and its importance to firm's future organizational framework, it is vital to accentuate main reasons that could impact transfer of capabilities in a reverse based form. This contemporary management concept is particularly important for further smart products component development, as the dissemination of knowledge is used for establishing vital firm competencies.

Important aspect of capabilities development is subsidiary's absorptive capacity, which stands in correlativity with multiple factors. Furthermore, we can "assume that resources are limited, which means that the more engaged a subsidiary is in absorbing external knowledge, the less resources it is likely to allocate to interaction with its own sister unit" (Andersson, 2003). As a result, absence of developed transfer network generates knowledge-based diseqaulity, that eventually slows down integration process in foreign markets. Because of that, corporate management must be able to transfer available competence within subsidiaries, especially in market discontinuity conditions.

Even though empirical studies suggest that a transfer of capabilities is less difficult and more efficient within intra-organizational units (Zander & Kogut, 1995), some scholars specify several obstacles, recognizing that a transfer is not just an act, but a long-term process (Szulanski, 2000). On the basis of this empirical data, we can assume that "capability-development problems primarily arise from implementation difficulties, rather than from selection mistakes" (Capron & Mitchell, 2009). This acknowledgement refer us to several complex questions regarding intensity of intra-firm correlation and its effects on firm's productivity. Answers to these questions depend on the set of subsidiary characteristics.

High-order dynamic capability relevant for smart products and services strategies enables companies to develop lower-order partnering skills to manage different phases in alliances more efficiently (Kale & Singh, 2007). By accumulating and applying knowledge, organization deliberately articulate company's know-how in order to undertake complex tasks more systematically. Considering managerial aspects of providing smart products to new business environment, it is especially significant to emphasize the role of knowledge sharing and personal interactions between individuals. Absorption of learning process is associated with extraction of valuable task-related skills that involve proactive usage of available resources. This process provides then more ability for internationalization mechanism to be applied. The focal point of coordination is to share best practices within the company, that result in competitive advantage obtained through dynamic model of strategic product sequencing.

Adapting business processes to changing market conditions requires explicit dynamic framework, that tracks stages of organizational evolution through time (Helfat & Raubitschek, 2000). Knowledge that integrates in several stages of vertical chain demands advance management of codified information about smart products and services and research on how they affect other activities in company. This mechanism allows company to gain knowledge about their customers' needs and to give an upper hand for associated business activities. By doing so, company may introduce diversified portfolio of products and services in a separate market and therefore enhance horizontal expansion (Huang, Chang & Henderson, 2008). The possibility for replacement products utilization of manufacturing techniques and previous integrative knowledge could also lead to economies of scope, explaining how two systems of learning function within production sequencing. If separated, these two system would consist out of incremental learning and step function learning (Helfat & Raubitschek, 2000).

Incremental learning is referred to as a dynamic capability process in which company gains competitive advantage from accumulation and deployment of resources (Zollo & Winter, 2002). The systematic enhancement of intangible resources increases company's flexibility to set up smart services for new customers. In the value creation chain intuiting and interpreting acquired knowledge are essential elements at a micro level. Furthermore, it should be pointed out that incremental learning does not depart from current knowledge, but it emphasizes contemporary alterations of products and services with a view to generate growth of cumulative volume. Hence, customer can easily provide information about products characteristics and performances, which could be directly linked to business process modification and flexible adjustments strategy based upon clients' feedback. Thereby, incremental learning is becoming more path dependant and user oriented as specific products and services evolve (Kvalshaugen, Lowendahl, Skojlsvik & Fosstenlokken, 2006). With regard to product sequencing over the period of time, existed, assimilated and applied knowledge is underlying the smart product while there are closely linked to one another. The expected outcome is effective interdepartmental communication that results in progress of core capabilities for smart organizational evolution. Some companies, as for example *Suzlon Energy Limited* (Indian wind energy company), even reorganize entire business divisions by creating "operation and maintenance service" that allow them independent growth in different market of the world, which further promoted flexible approach (Backović, Ilić & Milićević, 2016).

In accordance with difficult challenges of new international business environment, some markets demand learning based upon on-going feedback mechanism that signal potential need for rethinking major areas of supply chain. Thus, step function learning involves recognizing the permanent dedication to merge core and integrative knowledge in order to reshape smart products and services in initial development phase. It is obvious that "one-size-fits-all" solution is not available, considering that adjustments are made during production process and that they are creating substantial differential company's success. By obtaining

information about shift in customer desires, alongside with benchmarking of competitors, organization effectively adapts to product sequencing within markets and across the value chain. A richer set of real options and product platforms form superior system of learning that is highly differentiated due to path dependence of new product and service learning process (Helfat & Raubitschek, 2000). Following these patterns, short term competitive advantage is converted into long term company's success. Co-evolution of reshaped knowledge and smart products in technology-intensive industries is a foundation for fundamental resource and capability expansion into different product markets. The logic behind this assumption relates to note that product is divided into multiple components that are analyzed individually under the architectural knowledge of various production stages (Zott & Amit, 2008).

Integrated circuit technology, as a basis for semiconductor chips, was a beginning of component knowledge which is emphasized across the vertical chain. This enables management to recognize potential threats and opportunities in the new business environment and to use tacit knowledge to conjoin organizational mechanism. Smart structures are developed from current system to understand the causal ambiguities surrounding a new technology, and are brought up to the forefront of strategic planning thinking. The new insights suggest that it is vital that major part of those capabilities stay within the company, as empirical studies indicate that greater outsourcing for business process enhancing technologies lowers a firm's integrative capabilities and performance in the market (Weigelt, 2009). Effective operating routines that involve experience accumulation, knowledge articulation and knowledge codification, alongside with superior operating routines of acts of creativity are sources of competitive advantage for extended period of time (Zollo & Winter, 2002). The degree of causal relationships clarity is also relevant for performance implications of specific subtasks actions.

A coherent organizational structure interact with the numerous learning patterns, which is why it is significant to avoid distorted versions of knowledge exchange, especially during managerial decisions for new product markets. Stable and reliable infrastructure is highly beneficial for companies with a high proportion of export sales from digital and remote-controlled services, that allow downstream activities to be offered independent of location (Lerch & Gotsch, 2015). The intangible assets have far-reaching consequences for customer oriented solutions, so it is expected they will create an external digital environment with the view of competitiveness increase. Gaining advantage will emerge from more customized products and services and intensive responsiveness on local markets. Managing value based activities in collaborative business networks through application of ecosystem models configurates company to continually sustain and reinvent itself to satisfy the multiple objectives of its various stakeholders (including shareholders) (Davenport, T., Leibold, M. & Voelpel, S., 2006). In order to compete in a well-defined industry, smart learning company has to construct disruptive business approach that magnify differences for discovering new ideas in dynamic nonlinear systems. Therefore, "an enterprise should simultaneously manage a family of incubating (being formed), experimental (being tested in the market place), and significantly reinvented (e.g., incrementally innovated) business models" (Davenport, Leibold & Voelpel, 2006).

4. THE RELEVANCE OF SMART PRODUCTS AND SERVICES FOR SUCCESSFUL INTERNATIONAL BUSINESS

Smart products and services built on dynamic capabilities and continuous learning process are difficult to imitate and create signature components for outstanding level of profit and, consequently, long term effectiveness. Well developed, idiosyncratic systems exclude a threat of innovation diffusion to other companies by constant modification of guiding strategies and policy. Entrepreneurial activities within dynamic capabilities are conducted by "identifying undersatisfied demands and mobilizing resources in such a way as to profit from satisfying them" (Teece, 2014, p. 335). It is important to highlight that these capabilities are not influenced by purpose of the product or service itself, but can be reused for similar purposes. The exceptional value for well-delineated tasks is what distinguishes smart strategies from ordinary one. Several advanced examples point out the relevance of smart products and services for competitive advantage and successful internationalization of core business activities.

Netflix, as one of the most successful online movie rental services in the world, revolutionized the movie rental business model, capturing approximately 33.3 million subscribers and offering nearly 100.000 movies and other entertainment videos to their customers (Hitt, Ireland & Hoskisson, 2009). Facing emerging competitors called "video on demand" business networks where the movie is viewed in real time, Netflix creates its competitive advantage by providing high quality smart services to clients for below average costs (18 US$ per subscriber), establishing partnerships with video recorder companies, investing vast amount of financial means for online advertisements and by running ads on the mainstream media networks (Hitt, Ireland & Hoskisson, 2009). Because Netflix is an online entity, it must have capability and foresight to manage extensive growth to maintain its stronghold position. Considering rapid expansion of its distribution

network, Netflix has an ability to compete effectively and to provide quick deliveries to dramatically growing subscriber base.

Sony Corporation is an impressive example of well-coordinated subsidiary initiatives and lucrative managerial actions, as parts of wider strategic context of devoting special attention to most successful regional business units and promoting functional and operational autonomy. Sony's management converted product-centred networks into solution-oriented companies by regrouping them into seven companies and allocating resources under the new management platform (Frynas & Mellahi, 2015). With the strategy of integrative learning called "four-network gateway", Sony managed to combine hardware and service businesses so that subsidiaries as centres of excellence could, with innovative products and fast paced information feedback, effectively control this over-diversified conglomerate company. Radical restructuring of divisions enforced cross-department collaboration and break down of the barriers between independent units. Sony removed overlapping business processes and focused on high growth businesses, such as UHD, 4K and 3-D technology, while forming two major groups inside the company: the "Consumer, Professional and Devices" group and "Network Products and Services" group (Frynas & Mellahi, 2015). Sony's step function learning has established strong link among smart products and services found on feedback from consumers, feedback from partner companies and integrative knowledge that facilitate these advantages. With products such as Smart Tennis Sensor, smart B-Trainer and SmartWear Sony has integrated several vital functions for inspiring ways of exploring new connection and communication devices (Sony Corporation, 2016). Sony's smartphone "Xperia" strategy rethinks flagship devices introduction to meet market requirements and to reach outstanding performance in midrange price section.

Integrating various features into smart products and services as a management tool for promoting overall production quality and reducing maintenance costs has been key to success of Huawei Technologies. Set up from a three-level technical support system, Huawei is a Chinese telecommunication company that offers total network products and end-to-end solutions based on its experience in technology and applications (De Toni, 2011). The most important component for Huawei regarding customers' needs is its application specific integrated chip. Highly skilled managers are committed at the two ends on research and development and market needs, representing typical knowledge-based firm. Huawei also gives special effort to promote component based system of interactive learning and to simplify the organizational structure and thereby to put an end to technology "leakage". Regional headquarters are established as a business philosophy of developing national industry instead of focusing on joint ventures with foreign investors (De Toni, 2011). Sustaining superior performance in fast moving global environment and transformational leadership are of great importance for Huawei's business identity. It is important to emphasize that Huawei is an example of outstanding diversification, having in mind that it is seeking to reduce their reliance on mobile phone industry and to increase strength in adjacent markets. "FusionSolar Smart PV Solution" incorporates accumulated knowledge and expertise in digital information technology, Internet technology and PV (Photovoltaics) technology. Huawei supports investors to maximize return on investment and other financial ratios within the solar power plant life cycle by enabling high-speed components applicable to various environments (Huawei Technologies Co. Ltd, 2016).

5. CONCLUSION

The analysis presented in this paper shows the significance of the development of smart products and services to a modern company, with special reference to the conditions of international business environment discontinuity. Investing in the business processes of technologically advanced systems is a challenge for the international management and imposes the need for adapting the basic functions of business to the new, holistic concept of creation. Free and efficient flow of knowledge between highly differentiated strategic business units generates competencies based on adaptive and proactive organization's ability to continuously evolve. Disruptive business models effectively allocate and employ resources to upgrade components of smart products and connectivity of services portfolio. Strategies of incremental and step-function learning have special significance for the stable growth of production, adapting services to the needs of users and gaining competitive advantages. Dynamic development opportunities depend on the change management and the ability to timely market products and services.

Research in the context of modern international management of smart products and services indicate the emergence of an integrated approach to understanding the capabilities of the company. Further development and technological completeness of strategic and regional business units is expected, where interactive relationship based on knowledge economy will have a major role in increasing the efficiency of the business entity as a whole. The decentralization strategy with clear restructuring will establish the necessary degree of autonomy in local business markets, with control by the parent company. Flexible customization of smart products and services to the needs of international consumers will create long-term stability of

companies' growth, focusing on the competitiveness derived from the improved management actions and commitment to preserve the existing benefits of the products and services, but also to create new advantages in international terms for future success.

INTERNATIONAL SOURCES OF FUNDING ECONOMIC DEVELOPMENT

Sandra Jednak*[1], Miloš Parežanin[1], Dragana Kragulj[1]
[1] Faculty of Organizational Sciences, University of Belgrade
*Corresponding author, e-mail: sjednak@fon.bg.ac.rs

Abstract: *In order to obtain economic growth and development, developing countries have implemented certain models, policies and funding. The aim of this paper is to analyse international sources of funding economic development of Serbia for the period 2005-2014. The structure and influence of international sources of funding (FDI, loans, aids, remittances) on the economic development of Serbia have been analysed. The results show that there is no statistically relevant influence of FDI on economic growth and development, that remittances have no influence on economic growth, but have certain positive effects on some components of economic development. Financial aids and loans have positive influence on economic growth and development in the short run. Apart of international sources of founding, there is a need for domestic sources for obtaining economic growth and development in the long-run period.*

Keywords*: economic development, international sources of funding, remittances, foreign direct investments, Serbia*

1. INTRODUCTION

Process of development in developed economies has been long-lasting and very complicated. These economies have obtained a high level of development in all fields: economic, political and social. On the other hand, most developing countries have not obtained such level of development. These countries are trying to find a way to obtain economic development more quickly and to decrease the gap in development between them and developed countries. Due to different levels of development of countries and complexity of economic development process, each economy should choose and implement suitable concept of development depending on their resources and possibilities.

There are different theories, models and policies of economic growth and development. Economic growth is considered to be a prerequisite for obtaining economic development. The two categories are mutually interrelated. In order to achieve a higher level of development, certain policies have to be implemented in order to obtain economic growth. The increase in national production, or economic growth, can be achieved by using resources more efficiently, or by increasing the resources, i.e. implementing new resources and technologies. Economic growth implies the growth in Gross Domestic Product, and thereby the growth of GDP per capita, which causes better standard of living. There are also some changes in allocation of the obtained income. Increased production, along with structural, institutional and other economic transformations brings to the economic development. That is why obtaining economic growth results in the increased level of economic development, which then results in the increased economic growth. Obtaining higher level of economic growth, the economic growth rate becomes more stable and lower. Developed countries have stable and low economic growth rates. Developing countries have the same aim. At the beginning of implementing economic reforms, developing countries achieve high rates of economic growth. Efficient use of resources and the foreign capital inflows lead to the increase in production which generates a higher level of income. Higher income enables higher saving, which is the basis for future investments that will influence economic growth and development. Obtaining economic growth and development in developing countries is related to choosing the appropriate model, policies and sources of funding. The aim of this paper is to analyse the influence of international sources on funding the development of Serbia for the period 2005-2014.

The paper includes following sections: Introduction is followed by Section 2 which provides an overview of economic growth and development theories. Section 3 provides an overview of sources of funding economic development. Section 4 is dedicated to the overview of economic development of Serbia, while Section 5 provides the analysis of structure and influence of international funding sources on economic development of Serbia. An overview of the achieved results is provided in the Conclusion.

2. THEORIES AND MODELS OF ECONOMIC GROWTH AND DEVELOPMENT

Economic development represents a progress in economy. Economic development is a slow, multidimensional and coherent process (Kragulj, 2014) directed towards the "improvement of living standard, greater availability and distribution of basic goods and services like food, shelter, health and protection, and expand range of social and economic choices available both individuals and nations (Todaro and Smith, 2009)".

After goals have been defined, there is a need for defining strategies and theories of economic growth and development. There are various strategies and theories of economic growth and development. Depending on the availability of certain resources, economic growth and development strategies can be based on: natural resources, labour or capital. Economic growth implies certain structural changes where the share of agriculture decreases in favour of industry and services sectors. Therefore, strategies can be based on the strategy of industrialisation or the strategy of agriculture. Furthermore, there are other criteria for defining strategies, according to which there can be strategies of balanced or imbalanced development, the strategy where state and market play dominant roles, the strategy of intensive and extensive development, opened or closed strategies, saving or consumer oriented strategies, etc.

If we consider the theories of growth and development, they can be divided into classical and contemporary theories. If we analyse only the growth theories, there are three basic groups of theories – classical, neoclassical and endogenous (Cypher and Dietz, 2009). Some growth theories, depending on the period of their application can be classified as a subgroup of certain theories of development. Each of the growth theories recognises certain economic factors that influence obtaining economic growth. Classical growth theory is related to natural resources and population. According to this theory the use of capital and labour increases income per capita, but population growth decreases it. Neoclassical growth theory explains that growth in gross domestic product per capita depends on technological changes that influence saving and investment, which further increase income per labour. If a country has a fast technology development, it will also have a high rate of economic growth, unlike the countries with the slower technology growth. Endogenous growth theory is based on innovation and knowledge. The theory is focused on human capital, which represents the entirety of knowledge, skills and competences of the employees in an economy, and which is the basis for increasing production.

According to Todaro and Smith (2009), classical models of growth and development are: 1) linear-stages theories, 2) structural-change models, 3) international-dependence revolution, and 4) neoclassical counter revolution: market fundamentalism. 1) Classical theories of growth and development recognize growth as the process of successive stages of economic growth. Each economy should undergo the successive stages in order to obtain economic growth through the mixture of saving, investments and foreign aid. Most frequently explained linear-stage theories are *Rostow's stage of growth* and *Harrod-Domar growth model*. The major limitations of these theories are that saving and investment are not a sufficient condition for obtaining economic growth. 2) One of the most popular *structural-change models* is Lewis Theory of development, i.e. the Lewis two-sector model. This theory focuses on structural transformation in underdeveloped economy. Economy consists of two sectors – traditional and modern sector. In the traditional agricultural sector there is surplus labour force that is transferred into the modern industry sector. Labour transfer and the increase in production and employment in the modern industry sector is the basis of this model and is determined by industrial investment rate and capital accumulation in the modern industry sector. *3) International-dependence revolution models* show that developing countries have dependence and dominance relationships because of institutional, political, and economic rigidities. These models see "developing countries as beset by institutional, political, and economic rigidities in both domestic and international setup" (Todaro and Smith, 2009). These models stress out the need for the policies that will decrease poverty, create new opportunities for employment and decrease income inequality. In developing countries, 4) *Neoclassical counter revolution: market fundamentalism* emphasises freer markets, dismantling of public ownership i.e. privatization of public enterprises and government regulation of economic activities. In addition to these activities, the model also recognizes other possibilities for obtaining economic growth like promoting free trade and export, drawing foreign investment and greater accumulation of capital as a consequence of decreasing influence of the state on the prices of goods and services and on financial markets.

Some of contemporary models of development are: 1) The Big Push and 2) Kremer`s O-Ring Theory of Economic Development. 1) *The Big Push theory* shows that market failures can be overcome by public policy. Furthermore, for development there is need for huge investment particularly in industry and infrastructure. 2) The basic idea behind *Kremer`s O-Ring theory* is that production requires a series of activities that should be done well in order to output obtains high value. Kremer`s O-Ring theory of economic development shows that development consists of a series of tasks, i.e. different economic processes that have to be interconnected. There have to be strong complementarities among economic processes. Beside

the mentioned classifications of theories, there is the classification of economic growth and development into – linear stages theories, balanced growth theory, theory of secular stagnation, the Gerschenkron effect and innovation growth theory.

3. SOURCES OF FUNDING ECONOMIC DEVELOPMENT

The role of the government in a developing country is to coordinate and make economic decisions in order to transform the economy and obtain higher level of development. Achieving economic growth and development depends on the source of funding. There are domestic and international (external) sources of funding. The basic sources of funding are – borrowing from IMF, the World Bank or other international organisations, various aids, domestic or foreign capital, especially foreign direct investments, and taxes.

Furthermore, sources of financing development could be divided into these categories: 1) accumulation and allocation of capital, 2) domestic saving and 3) external source of financing. 1) *Capital* could have different forms like: financial capital, capital goods, human capital, and natural resources. Regardless of the form of capital, the increase of capital and its efficient use remain the prerequisites for obtaining economic growth and development. Capital increase is through investments that are necessary for increasing production, productivity and growth. It is necessary for economy to properly allocate capital in order to achieve good economic performance and progress in the long run. 2) *Domestic savings* are the main source of financing investments at the level of individual economies. Savings represent a voluntary refraining from consumption in the present in order to achieve greater consumption in the future. If there would be no savings, but all the income would be placed into current consumption there would be no growth, but stagnation. Domestic savings depends on the amount of GDP per capita and the rate of national savings. Saving is a future investment that will lead towards economic growth and development. Within domestic saving, there is private and public saving. Private saving belongs to households and companies, while public saving can be positive or negative, depending on what is bigger – government revenues or expenditures. i.e. whether there is a budgetary surplus or deficit. Therefore, it can be concluded that savings finance investments, while budgetary revenues finance government expenditures.

External, i.e. international sources of financing are 1) foreign direct investments (FDI), 2) portfolio investment, 3) banks loans/ lending, 4) public international capital (Cvetanović, 2000; Dragutivnović et al., 2005), 5) foreign aids and 5) remittances. The inflow of foreign capital is determined by the return rate and/or risk. Capital inflows cause the increase in domestic savings, thus creating more funds available for investments and due to that, the rise in economic growth. High capital inflows increase total saving which brings to interest rate decrease and investment increase. It is necessary for developing countries to direct domestic investments that are financed by foreign funds in an adequate way. Otherwise, a debt crisis may appear if interest rates and dividends are not duly repaid to foreign investors. 1) Attracting *foreign direct investments* is one of the key issues for developing countries. The experience of some developing countries, especially transition countries, shows that FDI is an important driver of economic development. Campos and Kinoshita (2010) point out a strong connection between economic reforms (privatisation, financial and trade liberalisation) and FDI. FDI may have both positive and negative effects on economic performances. Positive effects of FDI are - generation of employment, raise of productivity, technology transfer, increased export and influence to obtain higher level of economic development (Parezanin et al., 2014). Due to that fact, developing countries try to improve many factors and policies that have influence on attracting foreign capital. Beside attraction of FDI, foreign portfolio investment has an important role in economic developing strategy. Portfolio investment is different from FDI. 2) *Portfolio investment* is composition of investment in shares, government and corporate bonds, treasury bills, different kinds of funds, deposits, etc. Composition depends on various factors, and one of the most important ones is risk. Portfolio investment diversification efficiently decreases risk, enables efficient allocation of resources and represents an important source of cash. Attracting foreign portfolio investment is connected to development of capital market in a way that if the market is well-developed, they can influence obtaining economic growth and development (Errunza, 2001). Most developing countries try to develop capital market to do market opening, regulation and liberalization. For example, Balkan stock market started trading in 1980 and continued until mid 1990s. The volume of circulation was quite small. Economic reforms (2000-2006) first affected financial sector. On average, stock prices on stock markets in Balkan countries increased over 70% in dollar terms (Kenourgios and Samitas, 2011). Market development causes foreign portfolio investments become more important source than debt, which is one of the major ways of funding in developing countries. Durham (2004) analysed the effects of FDI and foreign portfolio equity investment on growth and found that there is no direct effect on obtaining economic growth, but "the effects of FDI and foreign portfolio equity investment are contingent on the 'absorptive capacity' of host countries, with particular respect to financial or institutional development".
3) *Bank loans* are a form of lending where loans are provided by certain interest rates to a foreign country, institution or company. Such loans are usually granted by bank associations or a group of banks in order to

reduce risk. Bank loans provide more independence to the country or company that was granted the loan as for how the funds will be used. It is easier for a developed country to be granted a loan, because of a high level of political stability, lower risk, developed market and stable currency. 4) *Public international capital* is the most favourable source of capital inflows in developing countries. This form of financing refers to lending and borrowing between governments. Such capital flows are under direct government control. They are used to maintain credit stability, export and import financing or financing projects. 5) *Foreign aid* is international transfer of money, goods or technology in the form of aid that does not have to be given back, or as a transfer in the form of loan, where debt repayment terms (interest rates and repayment period) are much better than commercial terms. There are two basic types of foreign aid: a) public official bilateral and multilateral development assistance and b) private unofficial assistance provided by nongovernmental organizations. Donors, i.e. developed countries provide aid primarily due to political, economic or strategic interests, while donees, i.e. developing countries, receive aid for economic reasons. There are different views on effects of such aid. Some studies indicate that there are positive effects of foreign aid on structural changes and economic growth, while others show that there is no positive influence on obtaining economic growth through foreign aid. Edwards (2014) analysed the effectiveness of foreign aid. He claims that foreign aid tends to create dependency, fosters corruption and encourages currency overvaluation, but on the other hand foreign assistance should be increased in order to reduce poverty. OECD provided a term Official development assistance (ODA) that measures aid. Official development assistance (ODA) "is defined as government aid designed to promote the economic development and welfare of developing countries". ODA includes concessional loans and grants. ODA loans and grants are providing low-interest, long–term and concessional funds to finance the development in developing countries. ODA loans require repayment, and supervision of the projects financed by ODA, thus promoting the efficient use of the granted loans. 6) *Remittances* are increasingly important for poverty reduction, obtaining economic growth and development due to migrations. Remittances are associated with monetary gains and human development in the areas such as health, education and gender equality. Remittances that are transferred in developing countries are almost three times greater than official development assistance. It is estimated that in 2014 developing countries' remittances amounted to $ 427 billion. Remittances are greater in smaller and low-income countries (The World Bank, 2014). Remittance increase gains more and more importance in the international capital flows, especially in the countries with lots of migrations.

4. SERBIAN GROWTH AND DEVELOPMENT MODELS

Economic growth and development in Serbia rests on domestic demand, import and need for foreign funds. In the period 2001-2008 the economic growth average was 4.9% annually (Izvestaj o razvoju Srbije, 2010). When "Europe 2020" strategy was adopted, Serbia established a new economic growth model for Serbia 2020. The new model of economic growth changed from consumer-oriented to pro-investment and export-oriented. The growth of this new strategy is based on the reform of the public sector, economic restructuring (reindustrialization, development of agriculture, telecommunications and information society development) and infrastructure development. The main aims are – increase in employment, human capital improvement, investing in knowledge and technology, export-based growth, efficiency in energy use and poverty reduction. However, accomplishing such objectives depends on – fixed investment increase, reducing the share of public consumption in GDP, increasing the share of export in GDP and decreasing deficit of the current account (Jednak et al.,2014).

Since the end of the global crisis, Serbia has run tight fiscal policy in order to obtain economic recovery. Economic growth is mostly driven by investments. The greatest investments were in automobile and oil industry. Those two industries had a big impact on export and growth. It was projected that economic growth for 2015 would be about 0.5 % (the World Bank), and in 2016 the plan was to reach 1.8 %. According to National Bank of Serbia (2015), economic growth could be obtained by "monetary policy relaxation, business climate improvement, structural reforms and external demand recovery". Economic growth was also the result of new investment loans that pushed up private investments. Investment loans were 2.5 times higher in 2015 than in 2014. Besides, investment loans increased FDI inflows. In 2015 FDI inflows were 45.6 % higher than in 2014. Attraction of FDI was the consequence of implementation of structural reforms and better business and investment climate. External imbalance was reduced due to export increase. Internal imbalance was improved because of reduction of pensions and wages on one hand, and better collection of revenues, on the other hand. Lower interest rate should lead to recovery in lending activities i.e. rise in demand for loans. During the time, similarly to all the other countries, economic growth and development In Serbia was financed by the government, banking sector, financial markets and investors. External sources of financing, especially economic FDI and loans are considered to be crucial sources of Serbian economic growth and development. However, remittances are more and more important.

5. STRUCTURE AND INFLUENCE OF INTERNATIONAL FUNDING SOURCES ON DEVELOPMENT IN SERBIA

International sources of funding, such as FDI, remittances and official development assistance (ODA) have been significantly increased during the past few years, and more attention has been paid on their influence on economic development (Driffield and Jones, 2013). International financial institutions are of particular importance for financing economic development in developing countries (Dreher and Gassebner, 2012; Kanbur and Sumner, 2012; Greenhill et al, 2013).

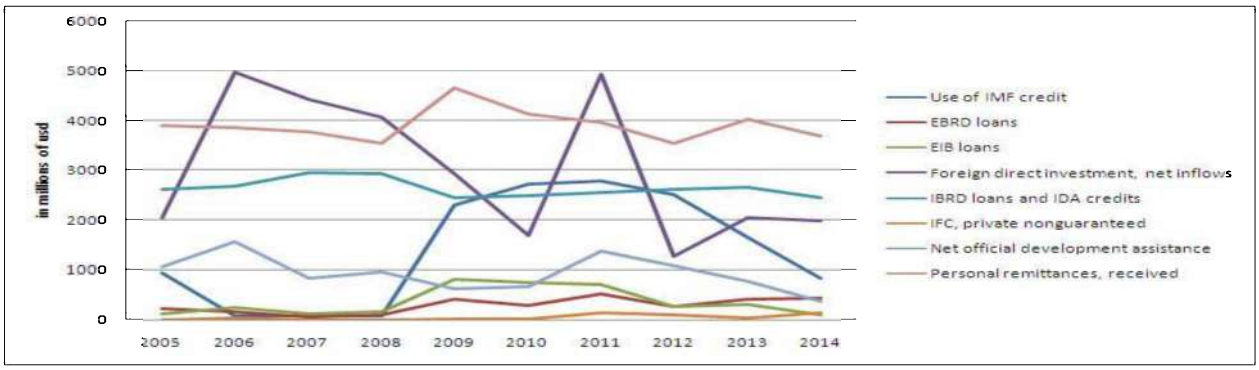

Figure 1: International sources of funding in Serbia (2005-2014)

Figure 1 represents the structure of international sources of funding in Serbia for the period 2005-2014 (European Investment Bank, 2016; European Investment Bank, 2016; the World Bank, 2016). The inflows of the IBRD and IDA loans are relatively constant. IMF borrowing started to increase at the beginning of the 2008 crisis, but since 2012 loan amounts have been decreasing. The loans inflows granted by other international financial institutions and from Official development assistance (ODA) is significantly lower. Such form of financing demands additional costs such as loans and losses due to changes in foreign exchange rates (Seiber, 2013).

It can be noted that FDI and remittances dominate throughout the observed period. However, the inflow is not constant. Remittance inflows peaked in 2009, but afterwards they decreased each year to reach their lowest level in 2012. Remittance inflows slightly increased in 2013. FDI showed significant fluctuations throughout the entire observed period. The greatest inflows were recorded in 2006 and 2011, and the lowest income was recorded in 2010 and 2012. In the periods 2008-2010 and 2012-2014 the remittance inflows surpassed the FDI inflows.

Remittances cause two kinds of effects. If they are capital-oriented, then along with FDI and foreign aid they can be significant for the long-term economic development. However, if remittance inflows are primarily used by households to alleviate short-term financial problems to finance consumption, then remittances do not influence economic development, but significantly increase living standard of the citizens in that country. There are certain cases though, when due to the increase in consumption, remittance inflows can influence long-term economic growth, even if they are used by households (Morton et al., 2010).

5.1. The Influence of Foreign Direct Investments and Remittances on Economic Development

Since FDI and remittances dominate in the structure of international funding of economic development in Serbia, it is necessary to determine whether there is a correlation between the mentioned sources of funding and economic development of Serbia. The following variables are used as the indicators of economic development: GDP per capita, unemployment rate, population (the World Bank, 2016) and HDI (United Nations Development Programme, 2016).

In the observed period (2005-2014) there was no statistically relevant correlation between FDI and economic development. Similarly, there was no statistically significant correlation between remittances and economic growth indicators (Table 1).

Table 1: Correlation between FDI net inflow / Personal remittances and GDP per capita, unemployment rate, population and HDI (2005-2014)

		GDP per capita	Unemployment rate	Population, total	HDI
Foreign direct investment, net inflows	Pearson Correlation	0.039	-0.306	0.447	0.222
	Sig. (2-tailed)	0.916	0.39	0.195	0.538
	N	10	10	10	10
Personal remittances, received	Pearson Correlation	-0.061	-0.172	0.097	-0.209
	Sig. (2-tailed)	0.868	0.634	0.789	0.561
	N	10	10	10	10

In order to discern whether these are the consequences of the global economic crisis or a long-term trend which indicates that there is no statistically significant correlation between FDI and remittances, and economic development in Serbia, the observed period was separated into two sub-periods - period 2005-2008 and the period after the economic crisis 2009-2014. The influence of the global economic crisis on the correlation between FDI and economic development is evident in almost all countries of Southeast Europe (Kragulj and Pareţanin, 2015).

Table 2: Correlation between FDI net inflow / Personal remittances and GDP per capita, unemployment rate, population and HDI (2005-2008)

		GDP per capita	Unemployment rate	Population, total	HDI
Foreign direct investment net inflows	Pearson Correlation	0.424	-0.215	-0.544	-0.004
	Sig. (2-tailed)	0.576	0.785	0.456	0.996
	N	4	4	4	4
Personal remittances, received	Pearson Correlation	-0.972*	0.993**	0.950*	0.885*
	Sig. (2-tailed)	0.028	0.007	0.05	0.115
	N	4	4	4	4

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

In the first observed period there is no statistically significant correlation between FDI and the chosen indicators of economic growth. However, there is a significant and strong correlation between remittances and economic growth indicators (Table 2). A significant positive correlation exists between remittances on one hand, and unemployment rate, population and HDI on the other. Strong negative correlation exists between remittances and GDP per capita, which means that remittances and economic growth are almost perfectly negatively correlated. Such observations are in accordance to the research (Barajas et al., 2009; Aggarwal, et al, 2011; Bettin and Zazzaro, 2012) that discuss negative correlation between remittances and GDP per capita in certain developing countries.

Table 3: Correlations between FDI net inflow/Personal remittances and GDP per capita, unemployment rate, population and HDI (2009-2014)

		GDP per capita	Unemployment rate	Population, total	HDI
Foreign direct investment, net inflows	Pearson Correlation	0.604	-0.011	0.238	-0.213
	Sig. (2-tailed)	0.204	0.984	0.649	0.686
	N	6	6	6	6
Personal remittances, received	Pearson Correlation	-0.111	-0.914*	0.771	-0.816*
	Sig. (2-tailed)	0.834	0.011	0.073	0.048
	N	6	6	6	6

*. Correlation is significant at the 0.05 level (2-tailed).

Throughout the observed period 2009-2014 no significant correlation between FDI and economic development was recorded. There was, however, a significant negative correlation between remittances and unemployment rate, and remittances and HDI. Throughout this period there was a decrease in remittance inflows into the Republic of Serbia, but there was also an increase in unemployment rate as compared to the previous period.

6. CONCULISION

Slow economic growth and drop in domestic demand caused stagnation in economic development and demand for additional capital. External sources of funding are significant for economic development of Serbia. At the beginning of economic reforms implementation, capital inflow contributed to economic growth and development. In the period 2005-2014, FDI showed downward tendency, except in 2006 and 2011 when the highest inflow was recorded. Low FDI inflows resulted in the fact that in the period 2005-2014 they had no influence on economic growth, and consequently on economic development. Constant remittance inflows are used for final consumption, therefore increasing purchasing power of the population. There was a significant influence of remittances on certain components of economic development, but there was also a negative correlation to economic development in the period 2005-2008. Therefore, we cannot talk about positive influence of remittances on economic development.

Financial lending (loans, grants and credits) and, aids and assistances provided by international financial institutions can influence financial development of Serbia, but only in the short run. However, if this way of funding continues to exist in the long run, it can cause a significant outflow in the form of debt repayment and losses caused by variation in exchange rate. Another issue arises when such approved funds are used for financing current government expenditures. Many credits were granted by international financial institutions to build infrastructure objects. Nonetheless, few infrastructure objects have been realised so far, and Serbia is still among the countries with underdeveloped infrastructure.

Implementation of the new economic growth model in Serbia has yielded some results. It is clear that long-term growth of Serbia should rest on clear development policies. FDI should be a dominant source of international funding and it should be primarily export-oriented. Although some important incentives have been provided to encourage foreign investments, underdeveloped infrastructure and low purchasing power of population make Serbia a less attractive investment destination, which currently prevents it from achieving a more significant level of economic development through external sources. Economic development should be funded from foreign sources, but domestic sources should be used as well.

TRANSFER PRICES - AN INSTRUMENT FOR BOOSTING COMPETITIVENES OF MULTINATIONAL ENTERPRISES

Snežana Popovčić-Avrić*[1], Marina Šestović[1], Tamara Todić[2]

Abstract: *In the era of globalisation and growing interdependence of the world economy, multinational enterprises are achieving competitiveness in the global markets due to their widespread and efficient distribution network and intra-firm transactions. Transfer prices are a tool that enables multinational enterprises to influence their level of profit in certain markets. Furthermore, they are able to redistribute the profit at the desired destination, thereby affecting their competitiveness, tax savings, operating results and volume of trade. Their intra-firm transactions cause an outflow of taxable income from one country to another. The paper will analyse the impact transfer prices have on boosting the competitiveness of MNEs and on redefining their business strategies against the backdrop of harmonisation of tax regulations.*

Keywords*: multinational enterprises, transfer pricing, competitiveness*

1. INTRODUCTION

The growing impact of globalisation has helped strengthen the position of multinational enterprises (MNEs) in the global markets. MNE expansion on the global level can be analysed from several economic aspects. Their biggest influence is reflected in the transfer of technology to developing countries and transition economies. Together with their growing trade volumes, this has lead to an increase in Foreign Direct Investment (FDI) inflow and to rising gross domestic product (GDP). MNEs are driven to expand into the new markets mainly by their desire to increase their market share and profits, receive a preferential tax treatment, and to compensate for the saturation of their home and existing markets.

MNE expansion into new markets and opening of new branches worldwide requires significant initial investments, and research of the market and local regulations. Many MNEs face serious legal barriers to establishment and entry of foreign capital. One such barrier is taxation of MNE's profits gained abroad. It is a well known fact that MNEs build their competitiveness in the global markets on the economies of scale and efficient production processes which depend on relocation of their production into labour-intensive countries. MNE's business processes are engineered to create savings by having transactions with associated enterprises within the regional or global group. Intra-firm trade within MNEs between their affiliates is based on pre-arranged preferential prices, better known as transfer prices. It makes sense for MNEs to apply transfer prices for transactions within group members, because this strengthens the competitiveness of the entire MNE. All MNEs defend this business model by citing business policies included in their articles of incorporation.

Many MNEs have recognised transfer prices as a tool that guides trade flows and relocation of capital to more attractive tax destinations. As transfer prices can influence net operating profit of an MNE in a given country, tax authorities in those countries have identified this channel of capital outflow as problematic and suspicious. To harmonise tax regulations in this area, Organisation for Economic Cooperation and Development (OECD) has provided a set of rules for testing and recognising these transactions, which both MNEs and tax authorities are required to adopt. While MNEs are striving to avoid double taxation of their global operations, it is in the interest of the local tax authorities to keep as much of the profit tax as possible in their own country.

Transfer prices are becoming an ever-growing challenge for both tax authorities trying to harmonise new regulations and for multinational enterprises whose main competitiveness tool is being scrutinised by the lawmakers. Harmonisation of international and local regulations does exist to a certain level, but is incomplete. The effects of differences between local regulations and OECD guidelines can significantly affect the changes in MNEs' business strategies. Due to application of rules on transfer pricing, MNEs may decide to relocate their business to a country where they enjoy better privileges and higher tax reliefs. Furthermore, MNEs are prompted to potentially manipulate transactions in order to optimise their expense and revenue levels in any case.

2. IMPROVING THE COMPETITIVE POSITION OF MNEs

Understanding the structure and the operational particularities of an MNE established as a corporate network of affiliates points to the main factors of profitability of multinational enterprises, (Cole-Ingait, 2015):

- *Price efficiency* in the production process and creation of the value chain, which ensures a competitive selling price. By integrating kindred production or marketing activities in one location, a lot of cost savings is achieved through economies of scale, and all this is achieved via transfer pricing.
- *Operational efficiency*, which entails integrated production processes, use of information technologies and strategic platforms to maximally cut wastage, production time and costs by applying transfer pricing.
- *Pricing strategy* involves an individual and proactive approach to price formation on a specific local market. Since it is impossible to unify the global market, in order to optimise sales volumes, MNEs resort to creating market-specific strategies. Their goal is to acknowledge the specific market conditions and adapt the products to those conditions, in order to optimise sales and profits.
- *International marketing strategy* whose objective is to overcome the cultural and local barriers when placing products or sending public messages of the multinational enterprise, thus creating a positive image of its brand across the markets. This approach provides also for global positioning and international brand recognition.
- *Production and distribution flexibility* allows multinational enterprises to satisfy customer preferences and maintain brand loyalty.

Local market imperfections help strengthen the competitive position of MNEs by allowing them (Wittendorf, 2010):

- to achieve economies of scale,
- through the process internationalisation, to manipulate the prices and tax burden on the local markets,
- through horizontal and vertical integration, to create competitive advantage for themselves and their consolidated enterprises,
- through vertical value chain integration, to reduce transaction costs,
- to use their bargaining power and price differentiation to create market entry barriers for new competitors.

It can be concluded that MNEs' competitive advantage is based on the economies of scale in production, financial channels available to them, research and development (R&D), as well as on the process of gathering market intelligence. MNEs are also in a much better position compared to local enterprises with regards to controlling their operating conditions, i.e. the ability to choose their business environment. For instance, when deciding on the location where they will manufacture their components, MNEs first carefully select countries with low wages that also offer the best incentives in the form of tax reliefs, subsidies and foreign trade benefits. The very size of MNEs relative to the economies they go into demonstrates how favourable their position is to influence the local authorities and benefit from that, compared to any other local company. Furthermore, MNEs can acquire any prosperous local firm and thus prevent having any future competition, just as it can apply other methods to limit exchange and increase their profit. Through greater diversification, MNEs manage to reduce the risk and usually earn a higher profit relative to local firms.

3. TRANSFER PRICES – ROLE AND IMPORTANCE

3.1. Transfer price definition

Transfer price (TP) is a price, i.e. the amount a company charges for goods, services and intangibles sold to a subsidiary or another associated company or natural person (Ljutić, 2014). When the transfer price deviates from the market price range at which independent entities trade, the profit gained by the buyer and seller is redistributed within the MNE. For example, when the transfer price of the seller is overpriced, the buyer's profit is reduced, while the seller's profit increases. The buyer reports higher expenses and lower profit, unlike the seller, who reports higher revenue and a higher profit. Though the profit has been dislocated at the local level, the consolidated profit at the level of the entire MNE group remains unchanged.

The previous example suggests that the transfer pricing policy for consolidated entities (within an MNE) is very important for achieving their financial goals. If these entities are highly decentralised, transfer prices are very important because they directly influence revenues and expenses, i.e. the distribution of the overall consolidated profit, as well as the transfer of profit between the consolidated entities.

When a group of associated persons operates at a national level, all group members operate within one country and under the same tax and market conditions. Application of transfer prices regulations has no tax

implications in this case, because the taxable income at the state level is the same, and the profit is transferred between associated persons, without affecting their consolidated profit.

When a group of associated persons operates on the international level, all group members operate under different tax and market conditions, and the profit is transferred via transfer pricing most frequently with the objective of reducing the tax liability (toward a jurisdiction with the lowest tax burden). This does not affect the consolidated profit within an MNE, but it does affect the level of tax burden for the individual MNE branch and tax revenues of countries in which each group member operates.

To prevent this allocation of the profit, and of the capital, tax authorities in most countries legislate how transfer prices are to be tested in order to establish whether the transfer price is close to the market range. This test entails that a transfer price transaction is to be compared with a similar arm's length transaction, i.e. a transaction between non-related entities:

- Internally, where MNE uses its own transaction with another, independent entity,
- Externally, where MNE uses the transaction of two other independent entities.

3.2. Controlled transactions

Controlled or intra-firm transactions are a common feature of modern operation and are generally manifested through transactions between associated entities. The main characteristic of controlled transactions is the absence of conflict of interest and the fact that they are made at transfer prices, which are pre-arranged and unaffected by external market factors. These intra-firm transactions can be of commercial (trade) or financial nature and they most frequently include:

- Selling or buying goods or production materials,
- Selling or buying property,
- Property rental,
- Delivery of services (IT services, management fees, marketing services, financial and consulting services, etc.)
- Transfer of intangible property (for instance research and development, trademark, licensing agreements),
- Guarantee, receipt or provision of financial services (loans and deposits),
- Joint investments etc.

Given that MNEs operate in jurisdictions with various tax rates and tax rules, the different transaction structures and intra-firm pricing policies may significantly influence the global tax burden of the entire MNE. Even in cases where there are no variations in tax rates, the possibility of double taxation still exists and poses a threat to an MNE's financial position. As transfer prices on their own require that a certain level of profit be made by both parties to the transaction, they play an important role in the decision making process of the parent company's general management with regard to assessing the potential profit of the business unit for the purpose of capital allocation. Apart from the general management, transfer prices are also of key importance for (Bronson, et.al 2013):

- *The MNE's tax department*, which is the one most affected by transfer prices. The tax department must be familiar with tax systems in different jurisdictions and reconcile them into a single transfer pricing policy in line with legal norms. Also, in exceptional circumstances, these departments are expected to prepare additional reports for tax authorities regarding their intra-firm transactions.
- *Financial department*, because the effect of the transfer pricing policy is reflected on the stated profit and on the tax on profit reported in financial statements. Whether an MNE is located in a territorial tax system where foreign income is taxed locally or not, transfer prices affect the general taxation of an MNE.
- *Company operations*, where the transfer pricing policy must meet the legal requirements of the environment. For an MNE not to jeopardise its tax burden, the MNE's tax department stipulates transfer prices that are within the market range and are thereby defendable before the tax laws of that country.
- *MNE's accounting department* is very important, because it confirms that the established transfer pricing policies have been properly implemented and ensures that the reporting system provides real information on transactions with associated entities, and in the required form for the purpose of transfer pricing analysis.
- *MNE's legal department,* because intra-firm transactions take place in accordance with intra-firm policies and agreements, which are generally regulated by the legal department.
- *Tax authorities* are mostly interested in the transfer pricing policy, because these prices directly affect the level of public revenue.
- *Independent auditors*, whose duty is to establish whether a company concerned has properly determined its profit tax. A part of that analysis definitely involves transactions with associated entities and transfer prices, because these are of material significance for operating profit.

- *External and tax advisors*, as many global and local consulting companies worldwide specialise in transfer pricing.

4. APPLICATION OF TRANSFER PRICING POLICIES IN INTERNATIONAL OPERATIONS

4.1. OECD guidelines

Taking into consideration the growing importance of transfer prices in MNE operations and their potential impact on tax systems, in July 1995, OECD Council approved the publication of *OECD Transfer Pricing Guidelines for Multinational Enterprises and Tax Administrations* (the Guidelines), compiled by the Committee on Fiscal Affairs (the Committee). The Guidelines are the key global regulation regarding the application of transfer pricing rules and tend to be periodically adjusted and updated to reflect the experience of the member states and the wider business community in application of these principles and methods. The Committee in conjunction with the OECD Council monitors the application of these regulations in most countries and takes care of their implementation and consistency. In essence, the Committee's monitoring role is to test the laws and practice of the member states against the Guidelines, to identify the areas of the Guidelines that could be improved and amended, and to notify the OECD Council accordingly.

One of the main principles contained in the OECD Guidelines is the arm's length principle, which represents an international standard established by the OECD member states for applying rules on transfer pricing for tax purposes. The arm's length principle follows the approach where MNE group members are treated as two enterprises operating independently, their agreed conditions are set aside, and market conditions valid for similar transactions are applied. When the separate entities approach is applied to MNE, and associated persons are treated as independent, the focus is placed on the nature of the transaction and whether it is different from a comparable non-controlled transaction. This approach is called a comparability analysis, which is in the centre of the arm's length principle.

The basis for comparability analysis is the comparing of conditions under which controlled and uncontrolled transactions are conducted and determination of profit when arm's length principle is applied. The first important assumption when comparing a market transactions and an arm's length transaction is that when assessing the conditions of a potential transaction, independent entities will take into consideration also other real options available on the market and will accept a given transaction only if they fail to find a more favourable alternative. This principle should also be applied by tax authorities when testing transfer prices. When testing comparability factors, it is vital to take into consideration real-world transactions realised between two independent entities.

When assessing the market reality of transfer prices, OECD Guidelines accept the following methods for testing:

I Traditional transactional methods:

1) Comparable uncontrolled price;
2) Resale price method;
3) Cost plus method;

II Transactional net-profit methods:

4) Transactional net margin method;
5) Transactional profit split method;

The objective of choosing one or a combination of these methods is to make it appropriate for the specific situation. Accordingly, one should bear in mind the advantages and flaws of the offered methods, their adequacy established through functional analysis, availability of data for their application, level of comparability between a controlled and uncontrolled transaction. No method is reliable in every potential situation, hence their applicability in a given test transaction needs to be proven.

4.2. Application of rules on transfer pricing in countries with preferential tax systems and rapid-growth markets

Repositioning a part of MNEs operation into jurisdictions with preferential tax regimes (JPTR) and rapid-growth markets, besides strengthening the competitive position and global risk diversification, is frequently motivated by financial and tax savings. From the viewpoint of transfer pricing policy and intra-firm trade between MNEs and their branches in those regions, various issues in applying the arm's length principle may arise. The key problem with rapid-growth markets and developing countries regarding transfer pricing

regulations is the absence of or lack of harmonisation of tax laws. This may lead to difficulties in applying the regulations in practice and eventually result in administrative costs for both the MNEs and tax authorities. In many developing countries the notion of determining transfer prices is still novel, and in some developing countries there is still no legal requirement to set those prices. The challenges the developing countries face when striving to implement OECD Guidelines in their regulations involve: absence of comparable entities and/or transactions in the market, insufficiently developed knowledge and skills in the area of transfer pricing, complexity of application due to absence of adequate administrative basis, growing importance of information technologies and new business models. This can create further problems for consolidated entities within MNEs with head offices located in developed countries having transaction with associated entities in developing countries.

The difficulties in applying the arm's length principle in jptrs and rapid-growth markets may be assuaged by establishing rules on tax havens for the mnes to follow, which would make transfer prices acceptable for tax authorities as well. A tax haven relieves a specific category of companies from paying some duties in exchange for fulfilment of other, simpler obligations. From the aspect of transfer pricing, requirements of a tax haven may range from a complete tax relief for a given group of taxpayers to the obligation for these companies to comply with national transfer pricing laws and different procedural rules in order to be allowed into the tax haven.

5. CONCLUSION

MNEs competitive position in the global business environment is primarily reflected in the sprawling network of MNE branches on the global market and their intra-firm trade. On top of providing for economies of scale, production efficiencies, specialisation, technology development and transfer, MNE influence the overall dynamics of global trade and shape the international business environment via intra-firm trade. Intra-firm trade at transfer prices has become a hallmark of globalisation, because it creates a powerful position for MNEs in the global and local markets. This power is primarily reflected in their ability to choose locations where they will operate and to use their dominance to influence local authorities to create a more favourable business environment. Their power is also reflected in their ability to use transfer pricing to diversify losses and tax burden, and consequently to increase their profit.

Because of these global implications, transfer prices have been in the focus of interest of international organisations, local tax authorities, MNEs and other stakeholders. Implementation of international regulations and OECD Guidelines in laws of the countries in question should limit the impact MNEs exercise via transfer prices. On the other hand, application of the rules on transfer pricing will persuade the MNEs to thoroughly plan the transfer prices they apply in intra-firm transactions, review their intra-firm agreements, and also to seek other mechanisms to optimise their consolidated profit.

ROMANIA AND SERBIA – SIMILARITIES AND MAJOR DEVIATIONS FROM THE STATISTICAL PROFILE OF A GENERIC BALKAN ECONOMY

Gheorghe Săvoiu[1], Marian Taicu[1],Mladen Čudanov[2*]

Abstract. *This paper uses the statistical method of profiling in order to detach a few defining aspects of Balkan economies of Romania and Serbia in the context of the peninsula where they belong geographically, and by confronting economic and social performance. The article presents several profiles, in a methodical and structured manner, in an attempt to identify significant similarities and deviations from a generic profile of the Balkan country or economy of the two economic entities and neighbours, one of which has already been a EU member since 1 January 2007, and placed within an intense and converging process of integration, and the second one located at the end of a long process of accession to the same European Union. A special case between the profiles analyzed is that of the energy dependence of GDP and that of flows of exports and imports at a macroeconomic level depending on fuel prices in both Romania and Serbia, which is actually the very illustration of the complexity of the econometric profile as part of the method of the statistical profile in general.*

Keywords: *profile method, Balkan economies and countries, the Balkan Peninsula, economic gap, statistical confrontation*

1. INTRODUCTION

The Balkan area is not homogeneously defined in the literature, and the media themselves provide delimitations based rather on the geographical criterion, as well as demarcations primarily based on political, cultural and historical criteria. The etymology of the peninsula's name is linked to the Turkish word "balkan", which means "wooded mountain" (Griffiths, Krystufek and Reed, 2004). All these issues have induced the idea of a Balkan economy or profile, with special emphasis on studying Romania and Serbia, as targets declared in the very title of this paper. From a geographical standpoint, the Balkan Peninsula can be defined in two distinct ways: by convention, and considering the strict definition of a peninsula. By convention, it is generally considered that the peninsula is bounded, on the north, by the waterways Soca-Vipava-Krka-Sava-Danube. Given the geographical notion, as the easternmost of the three major peninsulas in southern Europe, the Balkans encompass the entire territory between the Black Sea and the Adriatic Sea (including parts of Hungary, the Republic of Moldova and the Ukraine).

From a political point of view, the term Balkans is sometimes used to refer to a limited group made up of several countries (http://www.state.gov/p/eur/rt/balkans/). Thus, the acceptation given by the US State Department, includes the Balkan states of former Yugoslavia (except Slovenia) and Albania. Also for political purposes, the European Union institutions use the term "Western Balkans" to refer to the Balkan states that are not members of the European Union (http://ec.europa.eu/trade/policy/ countries-and-regions/regions/western-balkans/). Starting from the geographical criterion, and also from political and historical criteria, it can be considered that the Balkan Peninsula (or the Balkans) includes Albania, Bosnia & Herzegovina, Bulgaria, Croatia, Greece, Macedonia, Montenegro, Romania, Serbia, Slovenia and Turkey's European region. The Balkan states have a common history: their territories were included, in turn, in the Roman Empire, the Byzantine Empire, and later the Ottoman Empire. The Balkan Peninsula is the European region which had the most volatile borders: in the last hundred years alone they changed several times. Given that Turkey is located mostly in Asia, and also the fact that in point of area and population, it exceeds all the other Balkan states, we chose not to include Turkey in the analysis or the specific profile of a Balkan country.

If one takes into account the population and the size of the Balkan countries, they are generally small in both geographical and demographic terms. As far as the area of the Balkan states, it appears that most of them have less than 100,000 km^2. Romania is the only state with an area exceeding 200,000 km^2, followed by Greece and Bulgaria with an area of over 100,000 km^2. The only Balkan states with a population exceeding 10 million inhabitants are Romania and Greece. In keeping with their GDP, the countries with the largest economies are Greece and Romania, followed at a distance by Croatia and Bulgaria. Except for Greece, all the other countries included in this study belong to the group of the former socialist economies. The transition from socialist economy to a market economy occurred at different speeds in each country; the

transition has been influenced by a complex internal and external factors. Political instability and military clashes have seriously affected the economy of the states in the former Yugoslavia. The attractiveness of the Balkan states for investors was determined by their ability to provide guarantees of peace and stability (Redzepagić and Vukotić-Cotič, 2009).

The Balkan states share the link with the European Union: some states are already members (Greece, Slovenia, Romania, Bulgaria, Croatia), others have the status of candidates (Albania, Macedonia, Montenegro and Serbia) or potential candidates (Bosnia and Herzegovina). The results can be found in the literature of researches on the synchronization of business cycles in the Balkan countries with the European Union and European Economic and Monetary. The results of such research show that between the countries in the region there are great discrepancies, given the varying levels of economic development, and also the degree of integration with the EU or Eurozone economy (Gouveia, 2014). Tourism development is an opportunity for the sustainable growth of the Balkan states. Therefore, the governments of the states in the region have developed strategies for tourism development (Metodijeski and Temelkov, 2014). The precarious economic situation of most Balkan states has led to underfunding of education. Krstic and Dzunic (2014) state that "when it comes to education as a basis for the development of the knowledge economy, the Western Balkan countries Observed lag significantly behind the EU in terms of investment in education".

The economic situation is also one of the causes of the demographic problems of Balkan states, alongside emigration and aging. Lukic et al., referring to the Western Balkans, shows that "depopulation is evident on the whole territory of West Balkans". Pilc (2015) tries to identify common determinants of the shape of labour market institutions in a group of 25 post-socialist countries during the transition period. The author concludes that "the levels of political liberty, protection of property rights, international trade freedom and government expenditures did not appear to have influenced the labour market institutions in these economies".

In economics literature the issue of the "reputation" of the region for investors is also tackled. Estrin and Uvalic (2013) examine whether one can talk about the Balkans exerting a negative effect on FDI given the image problems of the states in the region. The cited authors conclude that, in addition to the factors that are acting on FDI in other transition economies, in the Balkans there is also a negative regional effect.

2. METHODOLOGY, OR ABOUT THE METHOD OF STATISTIC PROFILE

In this paper we present and apply the profile method, which gives powers to permanently shape the real outer environment, of the educational, human, entrepreneurship, etc. milieu, as well as the country profiles. We consider that the statistical profile method is one of the simplest solutions that can be used successfully to analyse the situation and the perspectives of Balkan countries.

The new method of statistical profile is a statistical method of investigation and knowledge with a decision-making impact through which the function of information and decision is hypertrophied; the decision may be completely influenced by the profiles used to support the statistical confrontation or comparison. The typology of the profiles that can be used is very diverse, ranging from temporal or dynamic profiles to territorial or hierarchical profiles, from profiles of coordination defined by means of sharp differences, to profiles of intensity, from structural profiles, to average profiles, from profiles focused on extreme values (minimum and maximum), to demographic profiles, from econometric profiles to climate profiles or geographic profiles, etc. One can define various specific operations using profiles, from the intersection of some of them, to combining others, or the complementary of a profile, as operations similar to those in set theory. A standard profile comprises both a selection of the variables for building the profile, i.e. the subsequent operation to that of analysis of variance, and the final ordering of the variables of the profile in accordance with the values of the coefficient of determination, for the characteristics considered to be explanatory or assumed to be able to solve the emerging managerial problem that requires prompt decision-making. (Săvoiu et al., 2008). Along with the models and variables, even the methods can become multidisciplinary, in their use within several specific disciplines, or simultaneously within a multidisciplinary reality. As part of this picture, one can define methods that can be applied in a multidisciplinary manner, being able to implement the method or approach mostly in multidisciplinary areas" (Săvoiu G., Čudanov M., Vladu M., 2012, p. 36).

The relativity of the exhaustive type of knowledge, or that of comprehensive analysis, limitation or restriction as a result of the imperceptible presence of the unknown, they all permanently offer both analysts and practice-connected researchers, and also theorists, a chance to identify and seek new solutions, as the realm of the unknown never has precise limits or bounds. The limitation caused by the researcher's or theorist's abilities or skills is a millennial tribute serenely bought to those competent, and especially to their strict scrupulousness in assessing their own incompetence. In this respect the limits of their own competence and powers of the method of statistical profile are metaphorically highlighted by the traditional Confucian

recognizing reciprocity as an active management principle, being expressed synthetically by this formulation: "I remember the days when scribes left empty spots on the page…" (Confucius, in the *Analects*). If the essential means designed to conduct an act of research interpreted scientifically is the one provided by the method, then the limits conferred to analysis by the statistical profile method, used in this article, are all the more important: "We can study real things, palpable things, but if we do not study them in keeping with a rigorous scientific method, those studies are not science. It is not the object or the subject, but the method that determines science" (Odobleja, 1984). The argument of the conceptual simplification of the applied multidisciplinary method is given by the previous statements made by Ştefan Odobleja in 1984.

The approach based on the method of profiling could be considered also a synectic approach or solution. Gordon's *Synectics* is suitable and indicated for selecting a single instrument, idea, concept, method, etc., or for identifying an original solution, and generates stages that have already become classical in the innovative research processes: forming the synectic group of entities, presenting the hierarchy or modelling problem, setting the synectic itinerary, developing the problem solving model, and finally testing or validating and applying the model (Săvoiu et al., 2008; Săvoiu, Jaško and Čudanov, 2009).

From the analysis of the typology of the statistical profiles, given the inherent complexity of modeling, the macro-econometric profile emerges, mainly through identifying the level and the intensity of the energy dependence of GDP and import and export flows, on a macroeconomic level, depending on fuel prices in both Romania and Serbia. The econometric profile begins with correlation matrices and is completed by four successive models focused on fuel prices as an exogenous variable revealing the instrumental diversity existing within the statistical method in general. The databases used were mainly those available at World Bank http://data.worldbank.org/indicator/AG.LND.TOTL.K2, and also at ChartsBin, available on line at http://chartsbin.com/, and not least for the domain of energy and the dependence on oil and its derivatives (gasoline, diesel, etc.) available at https://www.giz.de/expertise/html/4282.html (offered to users by GIZ-International Fuel prices).

3. RESULTS AND DISCUSSION

First, the econometric profile of the energy dependence of the two national economies is presented. The profile of the dependence of Balkan economies on the cost of gasoline and diesel is relevant – the level of intensity of connections between GDP, export, import and fuel prices is high, i.e. above 0.75, with a trend of reaching near 1.00 value, especially in relation to the export flow (0.97-0.98).

The macro-econometric profile focusing on quantifying the intensity of energy dependence of Romania and Serbia (i.e. GDP and export and import flows, on a macroeconomic level), is based on the dynamics of fuel prices in the two economies. The interpolation was conducted by the method of average annual modifications, reconstructing, with some error (under 3%), a data series impossible to use in modelling and in drawing the profile confronted. The econometric profile method has recourse, as a first instance, to correlation matrices defined for the two economies (Table 1 and Table 2 for Romania to Serbia).

Table 1: Matrix of correlation (Romania)

	SER01	SER02	SER03	SER04	SER05

Software used: E-Views

The econometric profile of energy dependence reveals four successive unique factorial competitive models with R squared values exceeding 0.86, and placed close to 0.93 in some the models typical of Romania. The econometric models that outline the profile of fuel price dependence, as an exogenous variable, are detailed in Table 3 for Romania and Table 4 for Serbia, and shows the diversity of existing tools part of the statistical method profile generally, and also the validity of the dependence on a level of intensity that is very high in statistical terms (the models are relevant in forecasts as well as scenarios or simulations correlated with expected developments on the market of oil resources, and especially fuels).

Software used: E-Views

Compared to the econometric profile of the energy dependence of the Balkan economy in general, both Romanian economy and that of Serbia are placed on a high level of intensity of modeling, with a high forecasting and simulation valences, which must be capitalized in the medium and short term. The same thing has also been found through an approach based on statistical simplexity, however only with reference to the Romanian economy (Săvoiu, et al., 2015; Săvoiu, et al., 2016), and is reconfirmed for Serbia in a similar manner.

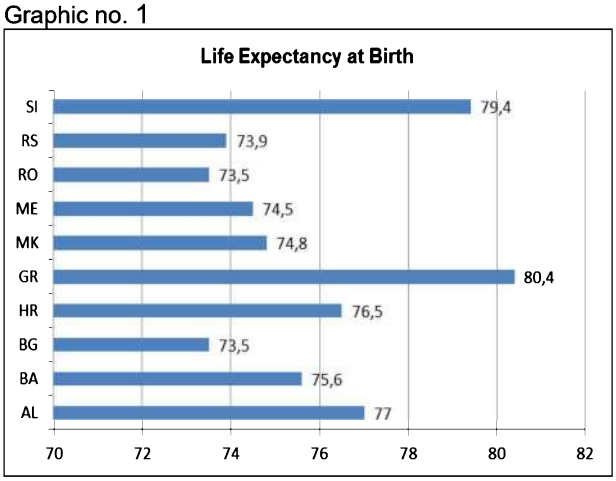
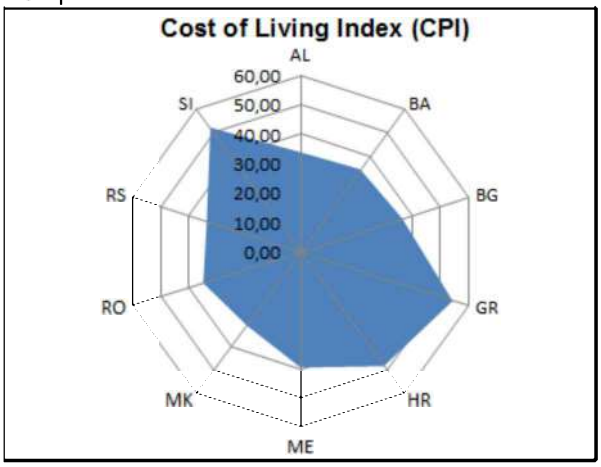
Detailed econometric profiles of Balkan entities (countries and economies placed within the area delimited in the introduction) are presented through representations in relevant graphical variants [Graphics no. 1 ÷ 10]. The statistical profile method applied to outline a Balkan pattern, and also some characteristic delimitations with reference to the economies of Romania and Serbia, succinctly reveals the following aspects through statistical confrontation of individual profiles in relation to the generic Balkan profile:

a) Synthetic evolution similarities in the Balkans (life expectancy at birth or LEB between 73.5 years and 80.4 years, and CPI within CLI between 31.10% and 54.50%):

Graphic no. 1



Graphic no. 2

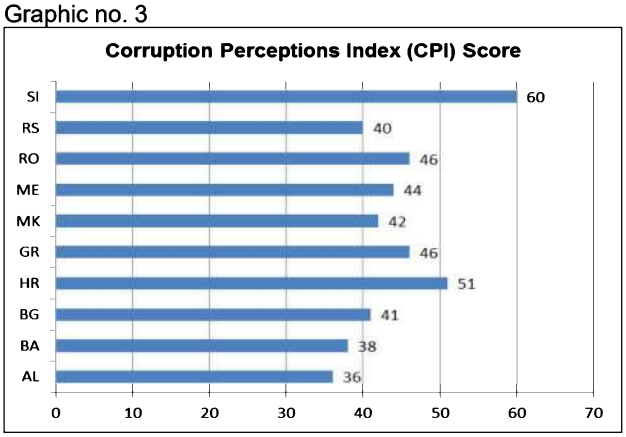


Sources: Life Expectancy at Birth in Years, ChartsBin.com, viewed 24th March, 2016, <http://chartsbin.com/view/33870> and Cost of Living Index 2016, ChartsBin.com, viewed 28th March, 2016, <http://chartsbin.com/view/39753>. Note*: RO and RS show very similar values in both statistical profiles (73.5 years and 73.9 years / 34.80% and 33.56%).

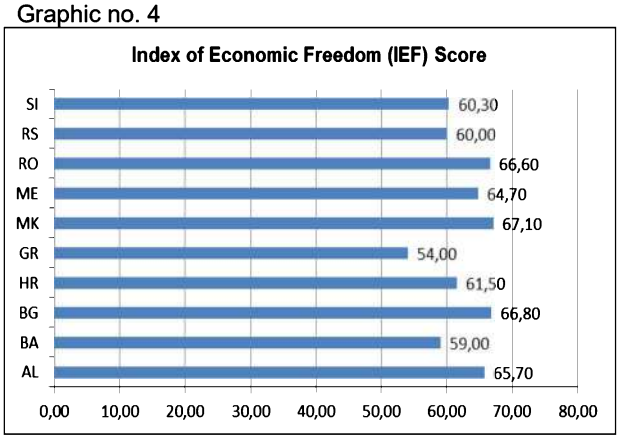
Cost of Living Index (CPI)

b) homogeneity in the Balkans in terms of Balkan profile of the population perception of corruption (8/11 of the populations of economies analyzed perceive a deep and aggravating internal corruption within a close interval between 36% and 46%, the CPI score being in inverse proportion to the minimum perception level, an index placed at 100%) and the profile of economic freedom (the range of variation is between 54% and 67.10%, with a low relative amplitude of about 20%):

Graphic no. 3



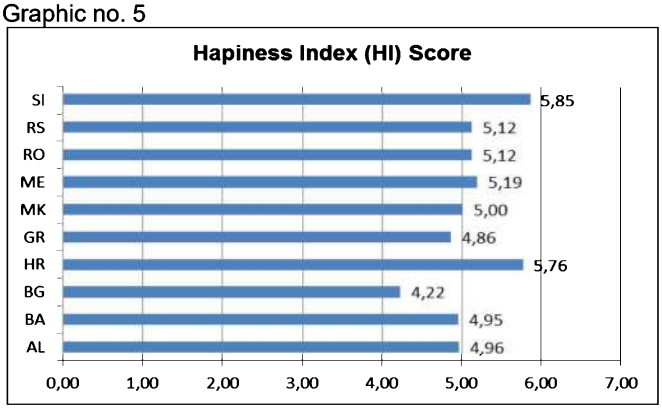
Graphic no. 4



Sources: Corruption Perceptions Index 2015, ChartsBin.com, viewed 25th March, 2016, <http://chartsbin.com/view/38836>. 2015 Index of Economic Freedom, ChartsBin.com, viewed 24th March, 2016, <http://chartsbin.com/view/38591>. Note *: RO and RS show relatively similar values in these statistical profiles (46% and 40% / 66.60% and 60.00%).

c) significant structural or temporal deviations in relation to the average EU-28 or EU-15 level are identified in the generic Balkan profile concerning happiness (except Bulgaria and Greece, all other Balkan countries have a happiness perception index, HI, much higher than that of corruption or life expectancy perception, standing at a level 10% lower than life expectancy in the EU-15); again structural deviations, this time related to income, are a major cause of a very low TTCI, as compared to the EU-15 average):

Graphic no. 5



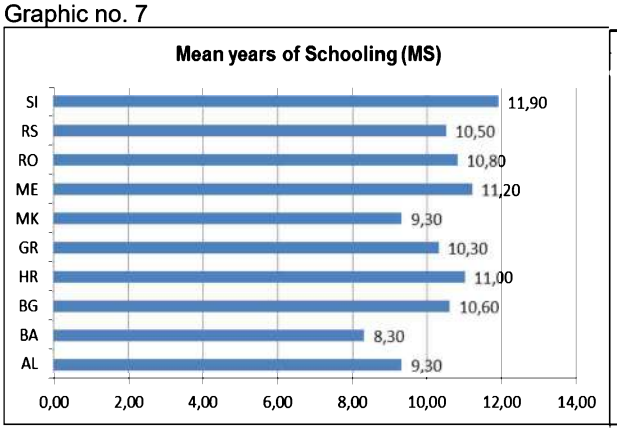
Graphic no. 6

Sources: World Happiness Index, ChartsBin.com, viewed 24th March, 2016, < http://chartsbin.com/view/38559> and Travel &

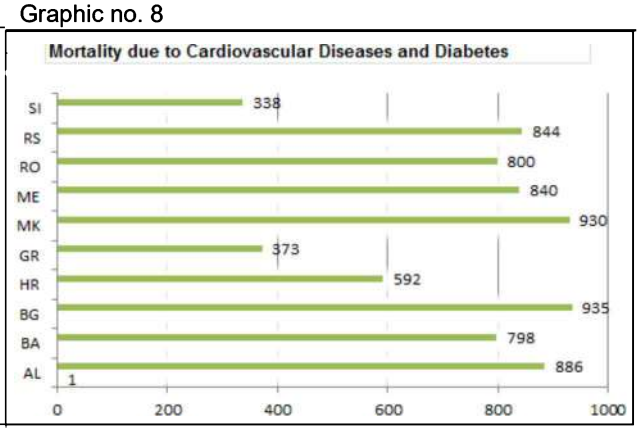
Tourism Competitiveness Index, ChartsBin.com, viewed 24th March, 2016, < http://chartsbin.com/view/38523>.
Note*: RO and RS show identical values in the statistical profile of the perception of happiness, HI, being deeply Balkan in spiritual terms (5.12), and relatively similar in the Travel & Tourism Competitiveness Index profile (TTCI) with 4 and 3.78.

d) relatively high statistical gaps between profiles that are individualized at the level of economy or country with values approaching 50% (the average length of schooling, or the average school years in the Balkan countries captures an obvious heterogeneity, but Romania and Serbia remain close in point of level, with the average of 10.8 years and 10.5 years, respectively) or even exceeding 100% in the profile of cardiovascular mortality and diabetes (the relative similarity is kept for Romania and Serbia):

Graphic no. 7



Graphic no. 8



Sources: ChartsBin statistics collector team 2011, Mortality due to Cardiovascular Diseases and Diabetes, ChartsBin.com, viewed 24th March, 2016, http://chartsbin.com/view/2621, Human Development Index, ChartsBin.com, viewed 24th March, 2016, <http://chartsbin.com/view/38512>.

e) major disparities or inequalities between Romania and Serbia appear only circumstantially in the profile of migration perception term, and derived from there, in the profile outlining crime and implicitly personal safety, with emphasis on the Balkan corridor of Mediterranean immigration.

A more detailed and pertinent analysis, having a real statistical comparability comprehensively insured, will be able to perform with Serbia's accession to the European Union, in the context of a sharp relative convergence and common objectives of both economies, here distinctly profiled through the new method proposed in the article.

4. CONCLUSION

There has been very much writing, sometimes too much, slightly tinged with irony or self-irony, and there is still as much writing about the existence of a Balkan spirit defining a Balkan model of a political, economic, social, educational, cultural, etc. specificity. Without exaggerating the importance of the method of the statistical profile in identifying and tentatively drawing this specific model, one in which economic freedom, the feeling of happiness on the one hand, and the average income or GDP per capita on the other hand, seem to be in a completely reverse relationship as compared to Central and Western Europe, one can finally make use of Basarab Nicolescu's concept of trans-disciplinary knowledge (lying at the intersection expressly formulated by Dan Barbilian the mathematician, alias Ion Barbu the poet) of a Balkan economy or country starting from Balkan nature generally.

In the process, and in the complex interstitial space of Isarlyk, the poet and mathematician Ion Barbu, a symbol of the Balkan Peninsula in Romanian poetry, and also of the Balkan spirit, an intoxicating and alluring component part is transposed, a part that is Peninsular and Mediterranean, mountainous through aspiration and also flat through survival, specific to thought, speech, human nature and action in the Balkans, which is identified by a special swinging, both normal and abnormal at the same time, between "abstraction and concreteness, the real and the imagined" (Nicolescu, 2013), and also between authenticity and borrowed thinking, between purity or ideal and compromise or contingent… The method of the statistical profile, emphasizing the importance of instrumental constructs as indexes the origin of which is purely sociological in this article, redraws a tumultuous and unpredictable, Balkan contours, difficult to understand from outside the economic entities of the peninsula, and yet representing the starting point of the history of science, modern education, but also some of the worst conflicts and disasters of a multi-millennial Europe.

Abstract: *This Paper explores technology transfer and spillovers when a company adopts the strategy of Merger and Acquisition (M&A) and gives us an insight into International Business arrangements that shape the business practice today. Companies are engaging in M&A with complex goals of entering new markets, improving and strengthening their technology and knowledge base, ultimately leading to competitiveness rise. The International Business literature has already acknowledged some positive outcomes for companies actively engaged in M&A, so we would pay special attention to technology spillovers, transfers, factors, and reasons of companies using these methods for improvement. The aim of this research is to deepen knowledge about M&A, to present technology transfer as one of the main reasons for companies doing M&A and to identify factors that are crucial for these companies' reactions.*

Key words: *International Business, Merger and Acquisition, technology transfer, spillovers*

1. INTRODUCTION

Nowadays, Multinational Companies (MNC) are aware of the importance of managing technology transfer as many of them review carefully all the factors before taking action. International technology transfer became a very popular theme for discussion among professors, students, business people, managers, and other stakeholders. Technology transfer is a process of transferring skills, knowledge, technologies, methods of manufacturing, employee's know-how, samples of manufacturing and facilities among Enterprises, Multinational companies, Universities, Countries... There are two kinds of technology transfer: horizontal and vertical technology transfer. Horizontal technology transfer is intentionally transmitted between countries and firms therefore we define "technology transfer" as a direct type of spillovers that occurs voluntarily from technology source to recipient. For example, Multinational firm transfer knowledge to local firm affiliating with supplied equipment (such as machines, equipment or manual) and with the form of software, know-how, patents, knowledge, and skills provided by education and training activities. Vertical technology transfer refers to the transfer of technology from Basic Research to Applied Research to development and then to production. It is the transfer of a pre-commercials technology from individual or institutional investor to an organization (L. Jakšić, et al., 2015). In this process, there are three factors that play an important role in technology transfer: the source, the recipient, and the technology itself. (Sonmez, et.al.2013)

There is long-term effect of spillovers and technology transfer when MNC acquire other company in order to use their technology potentials and to expand their business. The M&A are very interesting strategies and part of doing business today and it can be made for many reasons, but for us, the focus will be on technology and technology transfer reasons.

There are two main research objectives in this paper:

1) This paper is going to present technology transfer and spillovers of technology and knowledge as one of the main factors for MNC to execute M&A.

2) The second objective is to see potential progress, possibilities, and factors which influence on companies to apply M&A strategy and to make technology transfer and spillover effect.

1.1 Background of the study

Theoretical background of the technology transfer and spillover will give us better understanding of these subjects. Technology diffusion may rely on transfers or spillovers. (Keller, 2004) Technology transfer refers

to any process by which one party gains access to a second parity's information, and successfully learns and adsorbs it into his or her production function. Taschler and Chappelow defined technology transfer as the interpersonal, managed, and systematic process of passing control of a technology from one party to its adoption by another party. (Journal of Technology Transfer, 1999)

Research and development spillovers have been a major topic in the productivity, growth, and industrial organization literature for many decades. Technology transfer and spillover effect are happening in many situations but for us, the most interesting is when a company does M&A. What is a merger and what is an acquisition? The merger is when two companies join to create a new entity. In an acquisition, one company acquires sufficient shares to gain control of the other company. (Evans et. al. 2011) There are three types of M&A: horizontal, vertical, and conglomerate. Horizontal M&A are companies in the same line of business, often competitors. Vertical M&A means that companies are in the same line of production e.g., supplier or customer. Conglomerate merger refers to companies that are making M&A in unrelated lines and types of business, which are often motivated by acquired company's growth. (Clayman et al., 2008)

2. PROBLEM IDENTIFICATION

While many empirical studies appear to support the presence of technology spillovers, there remains a major problem at the heart of the literature. This arises from the fact that R&D generates, at least, two distinct types of "spillover" effects. The first is knowledge (or technology) spillovers that may increase the productivity of other company that operate in similar technology industry. The second type of spillover is the product market rivalry effect of research and development. Technology spillovers are beneficial to other companies, but R&D operations by product market rivals have a negative effect on a firm's value due to business stealing. Despite much theoretical research on product market rivalry effects of R&D, there has been little econometric work on such effects, in large part because it is difficult to distinguish the two types of spillovers using existing practical strategies. (Bloom, Schankerman, and Reenen, 2010)

The decentralization of R&D by multinational enterprises, for example the establishment of laboratories outside the parent company's home country, or the acquisition by foreign firms of R&D laboratories belonging to companies which were controlled by residents, are clearly not new phenomena. So far decentralized R&D has already been underpinned in some cases and accompanied by the tendency of shifting the relocate production. While the growth of this phenomenon is recognized, there is a need to assess the significance of that growth and its impact on different countries' technological and innovative capacity of MNC. The main question to prove that technology transfer is one of the main factors for company's decision to do M&A is: what is the growth of R&D in correlation with M&A arrangements and how far does it extend? (OECD, 2005)

With increasing competition at today's global markets, many firms and MNC choose to merge with one another to be able to compete internationally. M&A occur on all the markets and in all the types of industries, and that's why it's so interesting subject for discussion. In such competitive market there are a lot of questions, concerns, and problems and on some of them, we will give answers. Furthermore, we want to get insight into factors that contributed in increased cross-border M&A and technology transfer spillover. Managing mergers and identifying transformational value opportunities that stretch a company's capabilities in new ways require a dramatic change from the traditional approach to integration that has emerged as a best practice over the past 10-20 years. Companies were using templates, checklists, strong process management, and other methods to avoid risk but even now, this approach produces 66-75 percent of M&A failure rates. (McKinsey & Company, 2010)

3. CRITICAL ANALYSIS

Mergers and acquisitions are a popular mode of investment for firms wishing to consolidate, protect, and advance their global competitive positions, by acquiring strategic assets that enhance their competitiveness and selling off divisions that fall outside the scope of their core competence. For those firms, the "ownership" assets acquired from another firm, such as established brand names, technical competence, and existing distribution systems, and supplier networks can be put to immediate use towards better serving global customers, expanding market share, enhancing profits, and increasing corporate competitiveness by employing international production networks more efficiently. Most large-scale cross-border M&A have taken place in the energy distribution, pharmaceuticals telecommunications, and financial services industries. Small and medium-sized firms appear to have played a significant role in the growth of cross-border M&As

as well, particularly in the electronics, business services, personal services, distribution, healthcare, engineering industries and construction. (UNCTAD, 1996)

Growth of the main R&D sectors in the OECD area

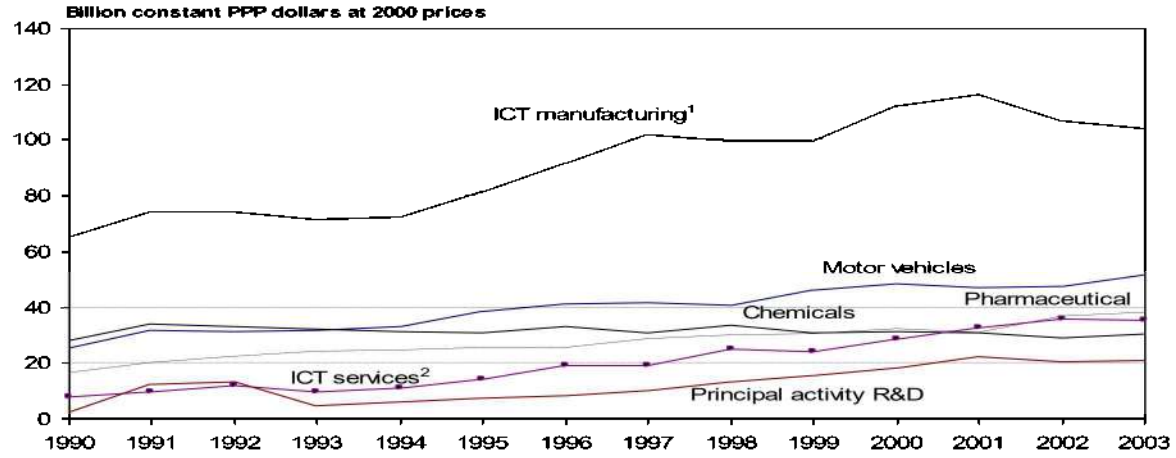

Figure 1: (OECD et al., 2005)

We can see from the table that there are big changes during the years in R&D, and we can notice that it matches with another literature in this paper and R&D rise is expected in the future too because of technology transfer and spillover that foreign companies bring in the host country. Furthermore, we will take a look into another table where is shown an inward cross-border M&A where we could get better insight into extending of technology transfer and spillover effect.

Inward cross-border mergers and acquisitions to G7 countries, (1995-2004)

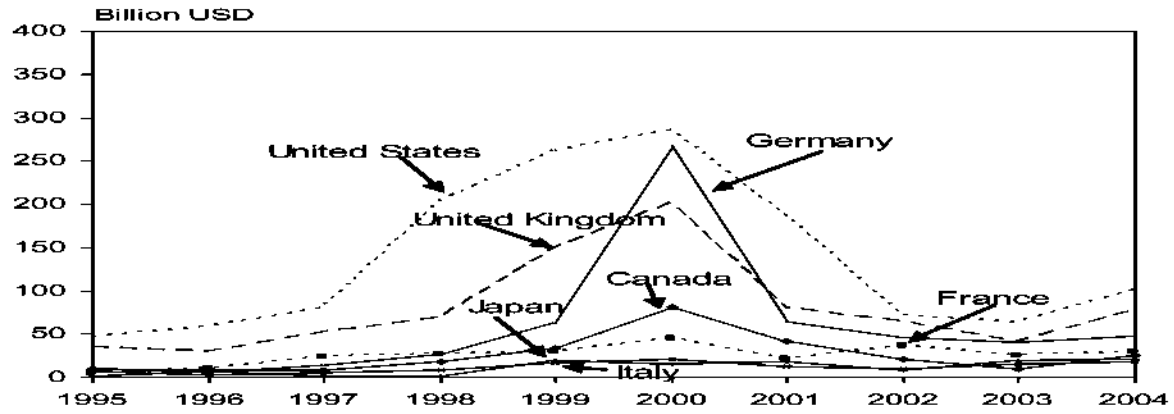

Figure 2: (OECD et al., 2005)

We can notice that these industry sectors were mentioned in the previous figure of R&D industries sectors which means that these trends were connected. From these facts, we can conclude that there is a big correlation between International M&A and technology transfer which confirms our first thesis.

3.1 Examples of successful and failed M&A

Disney-Pixar

The example of the successful merger is Disney-Pixar. The merger of legendary Walt Disney and Pixar was very good move from both sides. Disney acquired Pixar for 7.4 billion dollars in 2006 which made Disney largest shareholder. With the merger, the two companies could collaborate easily and freely. Pixar was American computer animation film studio based in California and after transaction they had produced many films that were very successful. Pixar has certainly gained the expert advice from Disney when it comes to

advertising and merchandising. When it comes to marketing to children, no one does it better than Disney. (Ruesink, 2009)

We can say that this project was quite conditioned by the technological superiority of both companies that manage to use this merger for filling gaps in their value chain because both parties were lacking some part of the business and that's why this merger was successful.

DaimlerChrysler

In 1998 Daimler bought Chrysler for $37 billion and idea was to form Trans-Atlantic Company which would dominate in the market, but in 2007, Daimler Benz sold Chrysler to the Cerberus Capital Management firm, which specializes in restructuring troubled companies, for $7 billion. Chrysler was nowhere near the league of high-end Daimler Benz. (Ruesink, 2009)

The plan was for Chrysler to use Daimler components, parts, and even car architecture to reduce sharply the cost to produce future automobiles. But problems surfaced when Daimler's Mercedes-Benz luxury division, whose components Chrysler would use, was unwilling to share with its mass market partner. In the end, Chrysler got only some steering and suspension components, a diesel engine, a transmission, and some purchasing deals. In return, Daimler had expected that Chrysler would dramatically increase its footprint in the promised land of auto sales in North America. But thanks in large part to stiff competition from Asian auto-makers, Chrysler fell short. Billed as a "merger of equals," the $36 billion deal turned out to be anything but, professionals said. Soon, control of the combined corporation fell to Daimler. (Mateja, 2007) This is perhaps one of the best examples of how problems can arise due to the motives of companies to improve their technological base by technology transfer.

4. CASE STUDY EXAMPLE OF TECHNOLOGY TRANSFER IN M&A

4.1 The rise of chip design in Asia: Case Study

Chip design is a good example to illustrate the complex interaction of factors currently favoring the expansion of innovative R&D in developing countries. Chip design not only creates the greatest value in the ICT industry while requiring highly complex knowledge, but it also involves a generic technology that affects a large number of user industries, including high-value services. Chip design has recently moved from centers of excellence in the Europe, United States, and Japan to sites in some developing countries, notably in South-East and East Asia. South-East and East Asia are now the fastest growing markets for electronic design automation tools, expanding by 36% in the first quarter of 2004 compared to 5% for North America, 4% for Europe, and -2 % for Japan. (EDA Consortium 2004)

This section explores the main drivers behind the technology transfer of chip design, drawing on interviews with 60 companies and 15 research institutions in the United States and Asia involved in designing integrated circuits, as well as systems. The Case Study includes global and regional carriers of chip design in Asia, including specialized research institutes and nine strategic groups of firms that participate in global design networks. The expansion of chip design and huge technology transfer and spillover in Asia has been the result of the synergistic effects of pull factors, policy factors, push factors and enabling factors.

Pull Factor- The cost of employing a chip design engineer in Asia is much lower than in the United States. MNCs need to locate design department near the rapidly growing Asian markets for computing, communications, and digital consumer equipment to interact with the lead users of new products. Furthermore, most of the equipment is produced in China, and the country has become the world's third biggest market for semiconductors, generating considerable demand for chip design.

Table 2: (UNCTAD 2005) Annual cost of employing a chip design engineer, including salary, benefits, equipment, office space and other infrastructure, 2002 (Dollars)

Location	Annual cost
United States (Silicon Valley)	300 000

Canada	150 000
Ireland	75 000
The Republic of Korea	65 000
Taiwan Province of Chine	60 000
India	30 000
Chine (Shanghai)	28 000
Chine (Suzhou)	24 000

Policy factor- Policies cover a wide range of factors, such as regulations, incentives, education and infrastructure they were all designed to attract R&D and other MNC innovative activities, including chip design, to particular locations. The progress in chip design has owed much too concerted efforts by both leading companies and governments to establish new sources of global standards and innovation.

Push factors- Some factors in developed countries are also greatly contributing to pushing firms to expand chip design in Asia. Three such push factors can be distinguished:

- Changes in the organization and methodology of chip design; since the mid-1990s growing pressures to improve design productivity, combined with increasingly demanding performance features of electronic systems, have produced turbulence in chip design methodology.

- Changing skills requirements; the expansion of chip design in Asia appears also to have been influenced by a perceived inflexibility on the part of design engineers in the United States and Europe to adapt to a better work organization (termed "innovation factory") and more structured ("automated"). MNCs have also searched for lower design costs by increasing the workloads and decreasing the design engineers' salaries, which rose rapidly.

- More outsourcing and multiple design interfaces because before companies system and integrated device makers did almost all their chip design in-house.

Enabling factors- Finally, new IT Companies facilitate the internationalization of chip design. Coordinating specialized design networks in Asia vertically can involve high communication costs (education systems, labor markets, corporate governance, regulatory and legal systems as well as Intellectual Property Rights protection). A second enabling factor is a spread of "transnational knowledge communities", such as professional and skilled staff. (UNCTAD, 2005)

Table 3: (UNCTAD, 2005)

In sum, in the case of chip design, a combination of pull, push, policy and enabling factors is creating a compelling case for MNCs to shift more of their design work to Asia. The trend is still at an early stage but is set to deepen. Over the past few years, all interviewed MNCs made substantial investments in chip design in Asia and were planning further expansion.

5. RESEARCH RESULTS AND ANALYSIS OF FINDINGS

5.1 Benefits from technology transfer

The internationalization of technology may help host countries move up the value chain and enhance competitiveness. Industrial competitiveness involves four interrelated types of upgrading: process upgrading, product upgrading, functional upgrading (new mix of activities or different activities in the value chain) and chain upgrading (moving to a new value chain in products of higher technology intensity) (UNCTAD, 2005). The home countries of MNCs face benefits and costs when their firms expand R&D abroad. The benefits are that R&D abroad may lead to reverse technology transfers, lower costs and, therefore, increased R&D, leading to improved competitiveness of the MNCs (which can also benefit other firms in the home country). However, such a reverse transfers are likely to be significant only if the host country is technologically advanced.

Improved overall R&D efficiency-R&D grows more complex, companies tend to use a more diverse set of information, skills, and knowledge. The availability of research workforce or a knowledge base abroad can accelerate new product development. Lower costs in developing countries can also make R&D more

economical. (UNCTAD, 2005) From the literature, we can conclude that the role of technology deals can expand company's competitive advantage, and there is also the advantage of co-funded programs with regarding strong incentives. This will also help to utilize the full potential advantage for public & private needs. Technology transfer creates a new market and also develops the needs of the consumer. Technology transfer can be effective for sustainable economic growth in the future development as well as the commercialization of new technologies.

5.2 Drawbacks of technology transfer

When MNC invest enough money and start operating in a foreign country after some time, it can make big problems that the company may not be able to control. For instance, the movement of labor from MNC to a domestic firm may enable the letter to benefit from the training and knowledge that the employee would have acquired from their time spent at the MNC and also a level of awareness about the knowledge that the MNC possesses is transferred. (Jones, Wren et al. 2007)

There is a big financial risk involved because licenses agreement can generate income, but patent applications that did not get licensed out will just cost money and in the case of MNC and International Business the extend of these loses could be huge. Especially if we take into account the ruthless competition that would try to use their weakness.

The controlling of the cost is the difficult and challenging task. MNC is exposing its know-how and technological abilities in M&A arrangements which mean that they are vulnerable to the pressures of competition that implies that they have easier access to market information. There is also the probability of high industry losses as well as inconsistent profits availability that could be major disadvantage. Technology transfer activities may put shareholders, companies, managers, and researchers in conflict of interest situations because each of them could strive for their benefits, especially when transfer involves M&A or creation of a spin-off company. Institutions should be aware of these possible dangers and anticipate them by elaborating a detailed conflict of interest policy. (Inzelt, Hilton, et al. 1998)

6. CONCLUSION

The purpose of this thesis was to explain international technology transfer and spillovers in M&A arrangements and to identify factors, problems, and reasons why companies use these strategies for improvement. Summing up various statements of different authors and considering best practice examples, it is needless to say that technology transfer represents modern trend that helped many companies to gain significant revenue and to expand their business worldwide. We gave recommendations based on problems and critical analysis which should help MNC to make better M&A in future.

We also found a huge correlation between international technology transfer and M&A strategies that are more numerous, regardless of their not-so-great percentage of success. The internationalization of R&D by MNCs opens up new opportunities for developing countries with strong skills and a technological base to enhance the development of their innovative capabilities. MNC will always search for a better place to deploy their technology, to use local technological know-how, and to decrease their expenditures and that could be the chance for developing countries. The work of this thesis has covered an interesting field of research, and there is a lot more we wish we were able to discuss. This topic will also be valid in the future in business life and the subject of many studies because it has great potential and opportunities for development.

OVERVIEW OF AIRLINE FLEET OWNERSHIP STRUCTURE

Slavica Dožić*, Radovan Krnić
University of Belgrade – Faculty of Transport and Traffic Engineering, 305 Vojvode Stepe Street, Belgrade, Serbia
*Corresponding author, e-mail: s.dozic@sf.bg.ac.rs

Abstract: *Airlines have recorded a significant increase in aircraft leases in recent years. In order to respond to market changes and offer corresponding capacity as promptly as possible airlines need flexible fleet. Flexibility which aircraft leases provide has motivated the authors to analyse fleet ownership structure. This paper gives an overview of airline fleet ownership structure, underlining differences that depend on business model, geographic distribution and alliance membership of large (more than 100 aircraft), medium (from 50 to 99 aircraft) and small (less than 50 aircraft) airlines. The analysis has shown that large airlines have a small percentage of leased aircraft, and vice versa, small airlines have a large percentage of leased aircraft. Moreover, it is noted that North American airlines have, in general, a smaller percentage of leased aircraft, and that membership in an alliance does not affect the fleet ownership structure.*

Keywords*: aircraft lease, low-cost airlines, full service airlines, geographic distribution, alliance membership*

1. INTRODUCTION

Constantly changing global airline market forces airlines to improve their levels of service in order to retain or even to strengthen the existing position. Nonetheless, airlines need to consider both passengers' and their own interests. They also need to satisfy different operational requirements and to make profit. Whereas the growth in air travel passenger demand (according to the International Air Transport Association – IATA) is expected to more than double in the next two decades with a 3.8% average annual growth (2014 baseline year), airlines need to adjust the capacity they offer. In order to accommodate rising demand, changes in fleet size/structure are needed. Therefore, airlines may need to acquire an aircraft.

According to Holloway (2008), there are two main reasons for aircraft acquisition: replacement of existing capacity and capacity growth. An aircraft should be replaced because of inappropriate characteristics, and more effective aircraft which will have the same mission should be placed in the fleet. Capacity growth could be growth within the existing network driven by the increase of demand. Moreover, growth could be induced by introducing a new service such as, for example, long haul or ultra-long haul routes. An airline can use different sources to finance an aircraft acquisition. Aircraft acquisition can be financed from the airline's own internal funds, or mixed internal funds and debt; furthermore, leasing options, which are the focus of this paper, could be used.

Air travel demand is directly affected by permanently varying conditions in the airline market. In order to respond to these changes and offer corresponding capacity as promptly as possible airlines need flexible fleet. With flexibility being an important issue, aircraft lease appears to be a suitable option for airlines. Whereas decisions related to aircraft lease are financial and connected to the airline policy, it is not surprising that appropriate data are, usually, unavailable. The airlines' reluctance to share their data limited our work to an overview, rather than modelling. Hence, the purpose of this paper is to review and analyse airline fleet ownership structure, namely to indicate the share of owned and leased aircraft in the airlines' fleet. Airlines included in the analysis are seated in different regions and have different business models. We distinguished between low-cost and full service airlines on the European and American market. Whereas most airlines tend to join an alliance, we found it reasonable to analyse fleets of member airlines.

After the introduction, literature review and the main definitions are given. The third section presents an overview of leased fleet depending on airline business model and geographic distribution. Finally, the last section points out concluding remarks and paper contributions.

2. LITERATURE REVIEW

Although available airline data related to financial information is rather limited, certain researches have been conducted and presented in the academic literature. Vargas and Saaty (1981) apply the Analytic Hierarchy

Process (AHP) to structure the problem and decide whether to lease or buy fleet in industry as a whole (not specifically for the airline industry). They suggest that, apart from economic factors that affect the final decision, non-economic factors such as company image, comfort and performance need to be considered because of their impact on the final decision. Oum et al. (2000) focus on operational effects of aircraft leasing rather than on financial implications. They indicate that for an airline which needs additional capacity leasing of aircraft represents a better option than buying, because a large leasing company can provide aircraft in short time periods and at lower prices than the manufacturers. Furthermore, they point out that an operating lease gives airlines the flexibility to accommodate their fleet as air travel demand changes, in order to adjust their capacity and demand. The authors develop a model which offers optimal share of owned-leased aircraft in the fleet, considering that air travel demand is uncertain and cyclical. Empirical results based on the data from 23 leading airlines indicate that optimal share of leased aircraft would be in the range between 40% and 60%. Gibson and Morrell (2004) indicate the advantages of operating lease over purchasing of an aircraft and, also, emphasize the issue of fleet flexibility provided by operating leases. They observe that airlines use operating leases for flexibility when adopting a new aircraft type.

Financial decisions should be made depending on airline's finances, its credit rating, as well as market conditions and global economy. In downturns of the economy, aircraft lease is a better option compared to buying the aircraft (Vasigh et al., 2012). However, financial decisions are not subject to long-term planning and should be made when acquisition procedure starts. It is noticeable that airlines operating the same market with the same business model have different shares of leased and owned aircraft (Mancilla, 2010), i.e. the ownership structure is not dependant on the fact whether the airline is full service or low-cost, as well as on geographic distribution.

Different researchers deal with optimization problems in order to help airlines make the right decision at the right time. They answer the question when an airline should be purchased, leased or retired. Hsu et al. (2011) propose a stochastic dynamic programming approach to aircraft replacement scheduling. The model is used to optimise airline's decisions related to purchasing, leasing or disposing of aircraft over time. The model was applied to an airline in Taiwan, and showed a growing interest for leasing over buying, especially in the time of severe demand fluctuations. Bazargan and Hartman (2012) propose a binary-integer programming model that minimizes total discounted costs over the planning horizon. The model is used for strategic fleet planning to help airline planners decide how many aircraft should be bought, leased and sold in the time period considered. After applying the model to two US airlines with different business models (full service and low cost) and after analysing the results obtained, the authors conclude that the solutions are similar for both business models. The recommendations they arrive at are the following: a new aircraft is favoured both for leasing and buying, short term leases are preferable, aircraft older than 12 years should be sold, fleet diversity is not encouraged, and leasing is a preferable option in comparison with buying. Analysis of airlines also shows that low-cost carriers have greater percentage of leased aircraft in comparison with the full service airlines, which is in contrast to previous research (Mancilla, 2010).

In view of the relevant literature cited above, one can conclude that aircraft lease has been playing a greater role in recent years in the airline market, which has motivated the authors to research it. Before the overview of airline fleet ownership structure is presented, it is necessary to give certain definitions related to aircraft lease and airline business models.

2.1. Main definitions

An aircraft lease will be defined as a contract whereby the owner of an aircraft (the lessor) grants to another party (the lessee) the exclusive right to the use of the aircraft for an agreed period, in return for the periodic payment of rent (the fee) (Morrell, 2013). Essentially, there are two basic forms of aircraft leasing, operating and financial. Wet, dry, cross-border and sales/lease back are forms of leasing which can be arranged through operating and finance agreements.

According to Morrell (2013), a finance or capital lease is an agreement signed for the period between 10 and 26 years, which means that it is a long term agreement. The lessee cannot cancel the financial lease or can do it only with a major penalty. In this arrangement the airline (lessee) enjoys some of the benefits and faces some of the risks of ownership. In contrast, the operating lease is a shorter term agreement (usually between one and seven years, or an average of five years), whereby the lessee can cancel the agreement and return the aircraft to the lessor without major penalty (Vasigh et al., 2012). Because of its flexibility, the operating lease is a common option for airlines. This statement is confirmed by the Boeing Capital Corporation, which indicates that the percentage of active global commercial aircraft fleet under operating leases has grown faster in recent years. Considering the period from 1980 to 2014, the increase from less than 2% in the 80s,

to approximately 40% by 2014, has been recorded. It is forecasted that operating leasing will account for 50% of the in service fleet by the end of this decade.

With regard to airline business models, in this paper we distinguish two of them: full service and low-cost. A full service airline is "an air carrier, typically a traditional national or major carrier that operates on a relatively extensive route network (thus also referred to as a network carrier) and provides a full range of services including different seating classes, in-flight entertainment, meals and beverages, on-board store, and ground facilities such as waiting lounges for premium class passengers or frequent flyer programme members" (ICAO, 2004). According to this document, a low-cost airline is defined as "an air carrier that has a relatively low-cost structure in comparison with other comparable carriers and offers low fares and rates".

The following section gives an analysis of airline fleet ownership structure. Due to unavailability of the corresponding data, the above defined leasing forms will not be separately presented. Hence, we will analyse the ownership structure regarding the number/percentage of leased aircraft in total.

3. ANALYSIS OF AIRLINE FLEET OWNERSHIP STRUCTURE

From the supply side, lessors (leasing company) offer their aircraft (capacity) in the market, where airlines appear on the demand side as players who need additional capacity. Whereas air travel demand is mainly influenced by economic factors such as gross domestic product (GDP), and air travel demand further influences aircraft demand, it is expected that the shape of GDP curve is very similar to the shape of lease rentals of the leading leasing companies (BBAM, AerCap, AWAS). According to the World Bank's (2016) definitions, GDP is the sum of gross value added by all resident producers in the economy plus any product taxes and minus any subsidies not included in the value of the products, while GDP per capita is gross domestic product divided by midyear population. Our findings (Figure 1) confirmed this statement, with significant values of coefficients of correlations between GDP and lease rentals by leasing companies BBAM, AerCap, AWAS given respectively: $r_{GDP,\ BBAM} = 0.83$, $r_{GDP,\ AerCap} = 0.72$, $r_{GDP,\ AWAS} = 0.82$.

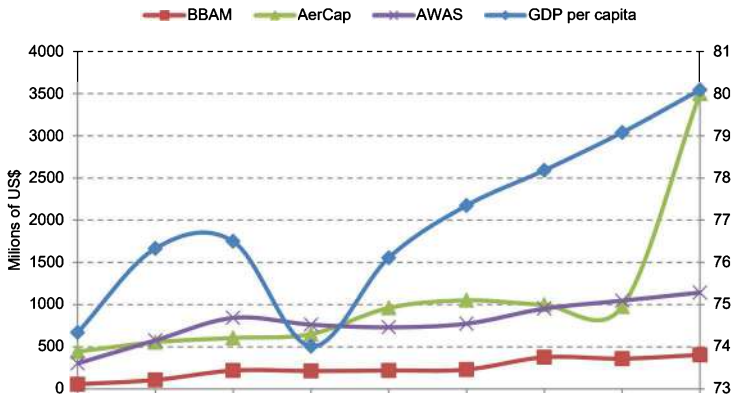

Figure 1: GDP per capita and lease rentals by leasing companies BBAM, AerCap and AWAS
(GDP data source: http://knoema.com/mhrzolg/gdp-statistics-from-the-world-bank?country=Europe%20%26%20Central%20Asia%20(all%20income%20levels); lease rental data source: Annual reports 2006-2014)

It should be noted that the global economic downturn characterized by the lowest value of GDP per capita in the year 2009 is not accordingly followed by lease rentals (Figure 1). This exception can be explained by the fact that aircraft lease is a preferable option for airlines in downturns of the economy (Vasigh et al., 2012) because it enables desirable flexibility. It is worth noting that lessors belong among the airline industry sector which achieved returns above the cost of capital, and they take the second place (after Computers Reservation Systems – CRS) when it comes to return of invested capital (Pearce, 2012). Also, more developed countries with higher value of GDP usually have better credit rating, which enables airlines from these countries to obtain favourable credits for buying aircraft.

3.1. Fleet ownership structure depending on airline business model

This sub-section analyses ownership structure of airline fleet depending on airline business model and geographic distribution. With regard to airline business models, as it is noted above, we analysed full service and low-cost airlines. With regards to geographic distribution, we examined European as well as North American airlines. The analysis is performed as follows.

Considering European full service airlines (35 airlines), it can be noted that airlines have different fleet sizes. In order to analyse airline fleet ownership structure, airlines were divided according to total fleet size into three categories: large (more than 100 aircraft), medium (from 50 to 99 aircraft) and small (less than 50 aircraft).

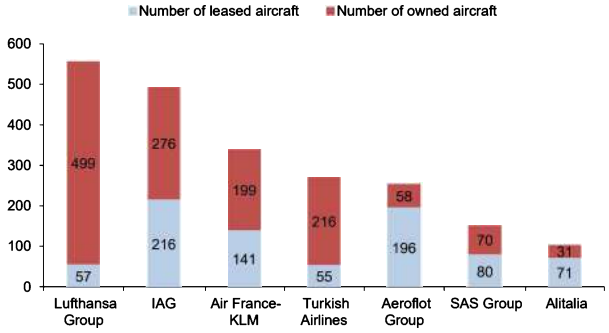

Figure 2: Fleet ownership structure: large European full service airlines
(Data source: https://www.planespotters.net/airlines)

It was determined that large airlines (seven airlines) had a smaller percentage of leased aircraft (Figure 2). The exception, i.e. large percentage of leased aircraft (77%) in the case of the Russian airline Aeroflot group, can be explained by the political situation in Russia. Namely, taxes for owning an aircraft of non-Russian production are very high. In order to avoid this payment, Aeroflot group founded a leasing company in Bermuda. This group bought and registered aircraft in Bermuda, and then, leased aircraft by itself. Alitalia is the airline with the smallest number of aircraft among these seven airlines (Figure 2) and the credit rating in Italy, according to Trading Economics, is recognized as lower medium grade, which could explain the large percentage of leased aircraft (70%). The smallest percentage of leased aircraft can be seen in the case of Lufthansa Group (10%), and it represents the policy of the Group. The total fleet of large European airlines consists of 2165 aircraft, and 38% of them are leased (on average, 45% of the fleet per airline is leased).

Among 35 European full service airlines, there are only four medium size airlines. The percentage of leased aircraft in their fleets varies from 39% to 78%. The total fleet of medium European airlines comprises of 235 aircraft, and 62% of them are leased (on average, 62% of the fleet per airline is leased).

Within small European airlines (24 airlines), as shown in Figure 3, the share of leased aircraft in total fleet is wide-ranging, from 0% to 100%. Three airlines have completely leased fleets, but there are also two airlines with completely owned fleets. Whereas Ural and Nordwind Airlines are Russian airlines, the fleets of which consist of aircraft produced by Airbus and Boeing, it is not unexpected that whole fleets are leased (the reason is the political situation, as in the case of Aeroflot). Air Malta is an airline registered in the country with lower medium grade credit rating (Trading Economics), which could be used as an explanation. The reason why TAROM has no leased aircraft in its fleet could be the majority ownership by the state. Luxair, on the other hand, is an airline from the country with a stable economy and prime credit rating (Trading Economics), hence it could afford to buy an aircraft. Total fleet of small European airlines includes 627 aircraft, and 59% of them are leased (on average, 61% of the fleet per airline is leased).

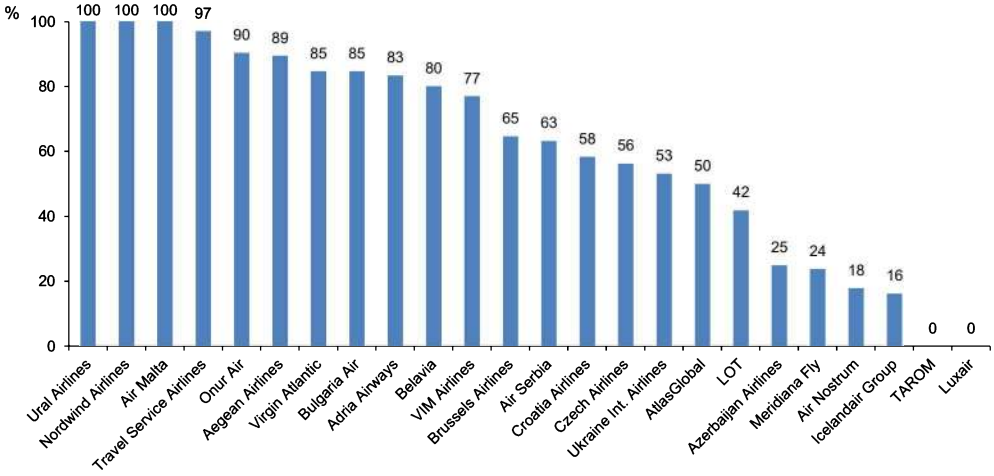

Figure 3: Percentage of leased aircraft in fleets: small European full service airlines
(Data source: https://www.planespotters.net/airlines)

Upon summarizing all leading European airlines (including small, medium and large airlines) considered in this analysis, it has been calculated that the percentage of leased aircraft ranges from 0% to 100%. Their fleets consist of 3027 aircraft in total, and 44% of them are leased (58% per airline on average).

In the case of the seven leading North American full service airlines, certain regularities can be observed. Actually, large airlines (five airlines), lease less than half of their fleet (Table 1). Total fleet comprises of 2814 aircraft, and 25% of them are leased (on average, 25% of the fleet per airline is leased). The remaining two airlines have different fleet sizes (one medium and one small fleet) and different percentages of leased aircraft in their fleets, as well.

Table 1: Fleet ownership structure – North American full service airlines

Airlines	Number of aircraft in the fleet	Number of leased aircraft	Percent of leased aircraft
American Airlines	944	397	42
Delta Air Lines	823	97	12
United Airlines	720	110	15
Air Canada	164	77	47
Alaska Airlines	163	13	8
Aeroméxico	63	45	71
Hawaiian Airlines	48	16	33

(Data source: https://www.planespotters.net/airlines)

The leading full service airlines in the world, as shown in Figure 4, own more than a half of their fleets. Hence, we can agree that these airlines do not favour leasing as an aircraft financing option. Each of these airlines (19 airlines, from different regions in the world) has a large fleet consisting of more than 100 aircraft. Their percentages of leased aircraft range from 3% (All Nippon Airlines - ANA) to 47% (Air Canada). Their fleets consist of 7137 aircraft in total, and 26% of them are leased (26% per airline on average).

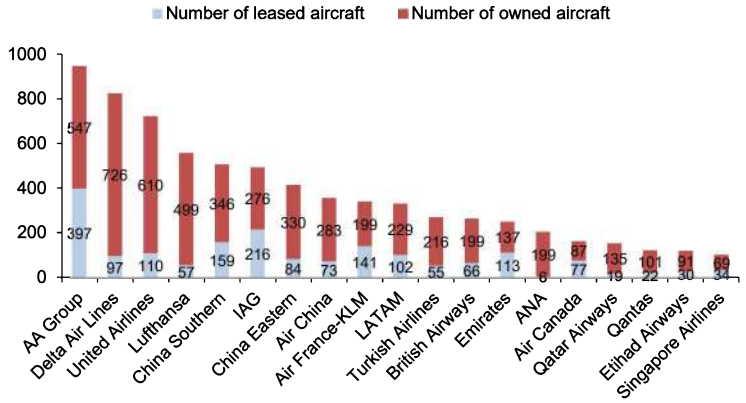

Figure 4: Fleet ownership structure: the world's leading full service airlines
(Data source: https://www.planespotters.net/airlines)

In the case of the 13 European low cost airlines (Figure 5), we can observe three large airlines. Two of them (Ryanair and EasyJet) have small percentages of leased aircraft (similar to any large airline), while this percentage in Vueling is high. This "irregularity" could be explained by the credit rating of the originating country. According to Trading Economics, the United Kingdom has the prime credit rating and Ireland has upper medium grade credit rating, which enables Ryanair and EasyJet to buy aircraft. Spain is ranked as a country with the lower medium grade credit rating, which therefore resulted in favouring lease options over buying (Vueling). Total fleet of the large low-cost airlines includes 661 aircraft, and 28% of them are leased (on average, 42% of the fleet per airline is leased). Percentages of leased aircraft in the six medium size European low-cost airlines vary from 18% to 98%. Their fleets consist of 395 aircraft in total, and 47% of them are leased (on average, 45% of the fleet per airline is leased). Small European low cost airlines lease large percentages of aircraft. Eurowings, an airline fully owned by Lufthansa, is an exception, which is expected because it is Lufthansa's policy is to buy aircraft. Their fleets include 7137 aircraft in total, and 67% of them are leased (on average, 68% of the fleet per airline is leased).

Percentage of leased aircraft in the European low-cost airlines, including small, medium and large low-cost airlines, ranges from 13% to 100%. Their fleets consist of 1156 aircraft in total, and 38% of them are leased (51% per airline on average).

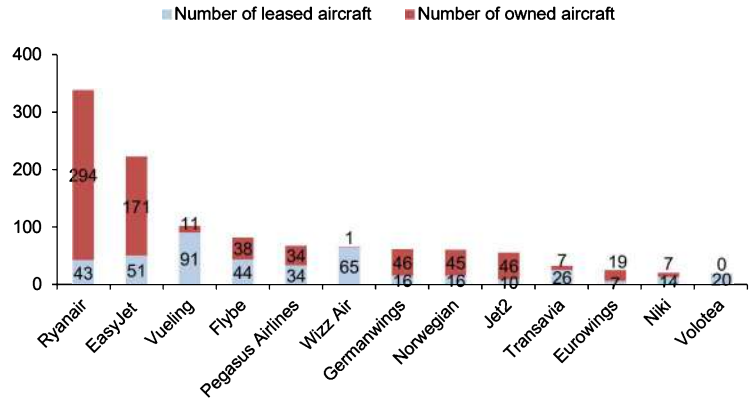

Figure 5: Fleet ownership structure: leading European low-cost airlines
(Data source: https://www.planespotters.net/airlines)

With regard to share of leased aircraft in the total fleet of low-cost carriers in North America, it is observed that large airlines have smaller percentages of leased aircraft and vice versa, small airlines have larger shares of leased aircraft (Table 2). The three large low-cost airlines have a total fleet of 1051 aircraft and 17% are leased (24% per airline on average). The six medium low-cost airlines have a fleet consisting of 403 aircraft in total and 61% are leased (on average, 64% per airline). The total fleet of the ten low-cost airlines consist of 1495 aircraft, 30% of which are leased (on average, 51% per airline).

Table 2: Fleet ownership structure – North American low cost airlines

Airlines	Number of aircraft in the fleet	Number of leased aircraft	Percent of leased aircraft
Southwest Airlines	716	86	12
JetBlue	217	54	25
WestJet	118	40	34
Allegiant Air	86	4	5
Spirit Airlines	80	57	71
Virgin America	60	50	83
Volaris	59	55	93
Frontier Airlines	59	54	92
Interjet	59	25	42
Air Canada rouge	41	22	54

(Data source: https://www.planespotters.net/airlines)

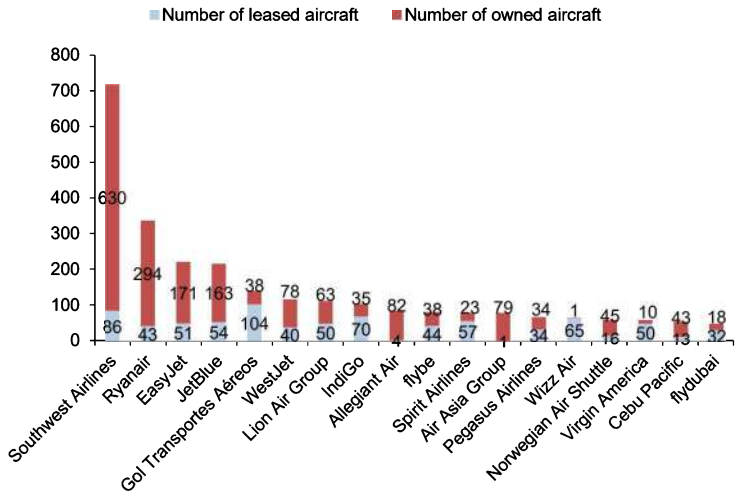

Figure 6: Fleet ownership structure: world's leading low-cost airlines
(*Data source:* https://www.planespotters.net/airlines)

We can distinguish between eight large and ten medium low-cost airlines among the leading low-cost airlines in the world, as shown in Figure 6. Percentage of leased aircraft in large airlines ranges from 12% to 73%. Their fleets consist of 1970 aircraft in total, and 25% of them are leased (on average 36% per airline). The percentage of leased aircraft in medium airlines ranges from 1% to 98%. Total fleet of medium airlines encompasses 689 aircraft and 46% of them are leased (in average per airline 48%). Bearing in mind the analysis performed, it can be noted that an airline's business model does not play a significant role in the fleet ownership structure. Both full service and low-cost airlines have similar percentages of leased fleet, which mostly depend on fleet size.

With regard to geographic distribution of airlines and all the above, slight differences between European and North American airlines can be observed. The European airlines prefer to lease aircraft more than the North American ones. In the European full service airlines' fleet, 44% of aircraft are leased compared to 26% in North American fleet, while in the European low-cost airlines' fleet 38% of aircraft are leased compared to 30% in the North American ones.

3.2. Fleet ownership structure depending on alliance membership

Whereas airlines tend to join some of the global alliances, it is interesting to analyse fleet ownership structure of airlines that are members of alliances. Star Alliance, SkyTeam and OneWorld are the largest alliances; therefore, we studied fleet ownership structure of their members.

Star alliance has 27 member airlines. The alliance's fleet comprises of 3589 aircraft in total, and 28% of the fleet is leased. Large member airlines (11 airlines) have a smaller percentage of leased aircraft (27% on average). The exception is Avianca, the Colombian national airline (60% of the fleet is leased). It could be explained by the credit rating of this country (lower medium grade). When it comes to airlines with medium size fleets (11 airlines), ownership structure is diverse. Small airlines' fleets (5 airlines) have larger percentages of leased aircraft in their fleets than the airlines with large fleets. Ownership structure of the Star Alliance member airlines fits very well with the pattern of fleet ownership structure observed in the case of European and North American airlines, as previously described. SkyTeam alliance has 18 member airlines. The alliance's fleet comprises of 2932 aircraft in total, and 36% of the fleet are leased. It is worth noting that ownership structure of these airlines does not fit well the previously described pattern of fleet ownership structure. There are three exceptions among nine airlines with a large fleet (Aeroflot, Garuda Indonesia and Alitalia). Oneworld alliance has 14 member airlines. The alliance's fleet comprises of 2575 aircraft in total, and 38% of the fleet are leased. Out of eight large member airlines, Airberlin is the one that does not fit the observed pattern.

It is worth noting that none of the airlines which are members of an alliance has a completely leased fleet. The maximum percentage of leased aircraft in their fleets is 90%. Also, it can be observed that the membership in an alliance does not affect the fleet ownership structure.

3.3. Fleet ownership structure

Apart from the analysis presented in the previous sub-sections, we extended the list of analysed airlines to airlines operating on the domestic market (Nikola Tesla Airport, Belgrade), as well as to additional leading airlines in the world (132 airlines in total). The set of 132 airlines encompasses all airlines, irrespective of their business models. In this set of airlines there are 43 large (Table 3), 37 medium, and 52 small airlines (Table 3). Summarizing all data, we established that 77% (33 airlines) of large airlines leased less than a half of the fleets; 51% (19 airlines) of medium and 69% (35 airlines) of small airlines leased more than a half of their fleets.

Table 3: Ownership structure – key indicators

Airlines' size	Number of airlines	Total number of aircraft	Total number of leased aircraft	Total percentage of leased aircraft	Average percentage of leased aircraft
Large	43	11603	3484	30	36
Medium-large	15	1244	454	36	37
Medium-small	22	1295	754	58	58
Small	52	1240	770	62	63

(Data source: https://www.planespotters.net/airlines)

Considering the set of medium size airlines, it was noticed that by dividing medium airlines into two sub-sets, medium-large (from 75 to 99 aircraft in the fleet, 15 airlines) and medium-small (from 50 to 74 aircraft in the fleet, 22 airlines), certain similarities with the small and large airlines could be observed (Table 3). Namely,

medium-large airlines have indicators similar to large airlines' indicators and they have smaller percentages of leased aircraft in their fleets, while medium-small have indicators similar to small airlines' indicators and they have larger percentages of leased aircraft in their fleets. Taking into consideration these similarities, we calculated the key indicators for large, medium-large, medium-small and small airlines (Table 3). Table 3 shows that the average percentage, as well as total percentage of leased aircraft, increases with the decrease in fleet size, thus supporting our findings from the previous sub-sections.

4. CONCLUSION

Having in mind that airline industry is highly dependent on economic cycles and that airline market is price- and time-sensitive, it is obvious that airlines need to react to market condition changes in a timely manner. The ability of an airline to respond in an appropriate way to these changes could be provided by fleet flexibility, which could be further provided by aircraft leases.

Based on the analysis of airlines from different countries and with different business models, the conclusions we arrived at are as follows:

- Airline's business model does not affect fleet ownership structure significantly;
- European airlines slightly prefer to lease aircraft compared to North American airlines;
- Small number of aircraft in an airline fleet (less than 50) implies higher percentage of leased aircraft (more than 50% of the fleet is leased);
- Larger number of aircraft in an airline fleet (more than 100) implies smaller percentage of leased aircraft (on average, approximately one third of the fleet is leased);
- Membership in an alliance does not affect fleet ownership structure; member airlines fit very well in the observed pattern of fleet ownership structure;
- Average and total percentages of leased aircraft increase with the decrease of fleet size.

The paper results in practical contributions, providing an ownership structure analysis and summarizing all data related to previous experiences of different airlines which could help an airline when considering whether to lease or buy an aircraft. Furthermore, the analysis could help not only airlines, but leasing companies as well, to define a target group of airlines to whom they could lease corresponding aircraft in appropriate time.

AKNOWLEDGEMNT

Abstract: *Transnational R&D cooperation is becoming an increasingly important factor in improving cohesion and for increasing the competitiveness of countries through cooperation. Globalization of research activities has contributed to the increase in endeavors in exploring international scientific and technological cooperation. The aim at this paper is to review the current situation of international cooperation in the Danube region with regard to co-publication analysis and to introduce barriers that influence transnational R&D cooperation with a special focus on Serbia. The main results conducted under the research project Danube-INCO. NET are presented.*

Keywords*: R&D, barriers, international RTDI cooperation, danube region*

1. INTRODUCTION

Some previous results, of analysis of the national innovation system (NIS) in Serbia, given by Kutlača and Semenčenko (2015), shown that cooperation, on the different levels of the NIS, is one of the crucial problems of system's functionality. Although, international cooperation was always seen as a more preferable than cooperation within the system, in particular, between its parts - science and research (S&R) sector and business sectors, as it was stated in Semenčenko (2009) and Semenčenko et al (2013).

International research and development (R&D) cooperation is quite demanding, objectively as well as subjectively. This is not only regarding inner capacities of the R&D but also concerning certain R&D programs ' rules, the geopolitical affiliation with the country e.g., which are changing into the time , however in the particular period constitute meaningful obstacles . Having in mind trends in regional clustering of European countries, Serbia is mostly connecting with West Balkan and South East European countries, but through the long period of time, and geographically and historically, more logical affiliation is within the Danube Region, which is also confirmed with the latest European Union's strategy for the Danube region (EUSDR) (2010, 2013).

The Danube region is characterized by much diversity: starting with the countries' level of economic development and political status regarding EU, up to the often different and contradictory observations of the region in the context of research and development systems' excellence and cohesion. The aim at research which we are calling upon in this paper was to clarify the relationship between scientists and researchers from the Danube region towards cooperation in one hand, and barriers and various concepts of scientific and innovation work in the other hand, regarding their R&D cooperation inside the region. Therefore, the territorial limitation could be one of the consequences although, as it was shown, chosen indicators were fairly enough for making a picture of the current situation of international cooperation in the region. Therefore, the territorial limitation could be one of the consequences but, as it was shown, chosen indicators was fairly enough for making a picture of the current situation of international cooperation in the region, as well as barriers which make obstacles in stronger cooperation achievements. Our analysis is grounded on researches done in the frame of the FP7 project Danube-Inco.net, where authors have been team members.

Specific attention will be devoted to these subjects' features of Serbian R&D system.

The project Danube-Inco.net is gathering researchers from 19 partner organizations, belonging to 14 DR countries. One of the preconditions for the region definition is classification of countries/regions of the Danube region, according to geopolitical affiliation: EU member states (MS) and regions upstream of the Danube: Austria, Croatia, Czech Republic, Hungary, Slovakia, Slovenia, Germany – in particular Baden-Württemberg and Bavaria; EU MS and regions downstream of the Danube: Bulgaria, Romania; Enlargement countries: Bosnia and Herzegovina, Montenegro, Serbia; Neighborhood countries: Moldova and Ukraine (in particular oblast Odessa, Uschhorod, Ivano-Frankowsk and Czernowitz).

In general, two types of analysis have been done, first one regarding cooperation barriers in the Danube Region and the second one within activities regarding monitoring of research and innovation cooperation. In the frame of the project, authors of this paper particularly were working on the analyses of barriers to cooperation in R&D cooperation in DR.

The first type of study supposed to increase awareness of the presence of barriers to cooperation and to offer recommendations for overcoming of such kind of obstacles. In this way, stakeholders will be able to better understand potential omissions in cooperation and communication, including social and cultural aspects of them. Somewise similar survey was conducted in 2008 in the frame of project WBC-Inco.Net, where have been identified differences in barriers perception of R&D projects cooperation among Western Balkan countries and EU member countries, results of which are presented in Švarc, J. et al (2009).

The second type of studies was focused on identification of synergies, initiatives for joint activities improvement. This study scrutinizes both the co-publications and the co-patents in Danube Region Countries (DRC) and the Western Balkan countries (WBC) for the years of 2003-2013, and cooperation in projects also. Each analysis has its distinct methodology and yields specific results which are shortly presented below.

2. SCIENCE AND RESEARCH COOPERATION IN THE DANUBE REGION

2.1 Co-publication analysis

As already indicated above, the Danube Region is a very diverse geographical area, especially in terms of national research and innovation systems, ranging from highly developed countries like Germany or Austria to less developed ones like Moldova. The following circumstances should be taken into account, when looking at the numbers of publications, since a less developed country usually also spends smaller money on its RTDI system, hence affecting herewith also the publication output of its scientific/academic institutions. In general, the share of internationally co-authored publications is between 40-50%. Further, the general estimation that smaller research communities are, due to limited national capacities, better internationally connected seems to be valid. One of the first research in international cooperation as co-authorship did by Frame and Carpenter (1979) resulted in three main rules: 1. international cooperation has a higher intensity in basic research, 2. the bigger national research system – less international cooperation in co-publication, 3. the external factors play the major role in international cooperation. As Glänzel and Schubert (2005) point out, this “international ambition” in producing publications has another positive consequence: International co-publications are more likely to appear in high-impact journals and have a better chance to be cited, than “domestically” produced papers. Austria, for example, has one of the highest shares of internationally co-authored publications. We registered fewer international co-publications for Croatia (26%), Romania (26%), Serbia (31%), Czech Republic (33%), and Ukraine (34%).

The analysis of the publication data was carried out along several dimensions (data is available in the study Lampert, D. et al (2015)): overall co-publication output numbers per country to provide an overview, the internationalization of publications, the strongest co-publication links among the countries under scrutiny, main scientific research fields, and some highlights regarding scientific impact.

The methodology of the co-publication analysis was based on the two main academic citation databases, namely Web of Science and Scopus. By unification of data onto these two databases was achieved high quantity of 25% higher publication coverage, and quality because each data source can be taken as a quality check for the other or as an additional source for missing information.

The study analyzes all publications of both databases that featured any affiliation with one of the countries of the Danube Region in order to be able to draw conclusions of the differences between “all publications” and the “co-publications”. Regarding document types, scientific articles are taken into account in the same way as conference proceedings, academic letters, and other document types that were tracked by the both data sources. The reason for this procedure is the idea that jointly published conference papers can indicate international cooperation activity, which is of prime interest in the Danube-INCO.NET project. The data are available only with partly different field names and different quality (depending on the data source).

Over 1 million records were analyzed and almost each has, on average, been authored by 7 researchers affiliated with 1.8 countries and been cited about 6.5 times. Of those overall publications, around 394,000 are Danube Region co-publications, each involving at least one DRC and one other country outside the DR in

the period between 2003 and 2013. Each of those co-publications has, on average, be authored by about 13 researchers affiliated to 3 countries and been cited 11.87 times. Output patterns suggest the following three country groupings: Austria, Czech Republic, Romania, Hungary, and Ukraine (between 8,000 and 25,000 publications per year); Serbia, Croatia, Slovenia, Slovakia, Bulgaria (between 1,000 and 8,000 publications per year); Bosnia and Herzegovina, FYROM, Albania, Moldova, Montenegro, and Kosovo* (between 40 and 1,000 publications per year).

In addition to the absolute number of DR publications, the growth rate of production of their publication of the reporting period of eleven years is obvious. Among all DRC, Romania and Serbia have expressed particularly high growth in their production of publications.

2.2 Scientific research fields in Serbia's (co-)publications

As it could be found in the analysis presented in Lampert, D. et al (2015), "Serbia's specialization in the area of Clinical Medicine is clearly visible but does not translate into the situation in Serbia's co-publications - whereas the share of Clinical Medicine co-publications in Serbia's overall international co-publications is 22.89%, the share of Clinical Medicine in Serbia's publications is 29.11%." Clinical Medicine is followed by Physics & Astronomy (10.43%) with even a higher share for Serbia's co-publications (17.50%) and Danube Region co-publications (18.74%). Science Metrix fields in Serbia's publication and co-publication are shown as a whole in the table 1.

Table 1: Science Metrix fields in Serbia's (co-)publications, 2003-2013 (Source: Danube-Inco.net project D.4.16, according to WoS+Scopus)

Science Metrix fields (most important)	RS overall publications	Share	RS co-publications	Share	RS-Danube Region co-publications	Share
Agriculture, Fisheries & Forestry	1,833	**3.59%**	502	**3.27%**	311	**4.14%**
Biology	2,688	**5.27%**	865	**5.63%**	503	**6.69%**
Biomedical Research	2,177	4.26%	709	4.62%	333	4.43%
Chemistry	4,239	**8.30%**	1,298	**8.46%**	671	**8.92%**
Clinical Medicine	14,858	**29.11%**	3,514	**22.89%**	1,792	**23.83%**
Earth & Environmental Sciences	943	**1.85%**	320	**2.08%**	185	**2.46%**
Economics & Business	708	1.39%	169	1.10%	82	1.09%
Enabling & Strategic Technologies	4,085	**8.00%**	1,344	**8.76%**	642	**8.54%**
Engineering	3,847	7.54%	958	6.24%	528	7.02%
Historical Studies	338	0.66%	121	0.79%	77	1.02%
Information & Communication Technologies	3,979	7.79%	941	6.13%	366	4.87%
Mathematics & Statistics	2,715	**5.32%**	1,166	**7.60%**	263	**3.50%**
Physics & Astronomy	5,324	**10.43%**	2,687	**17.50%**	1,409	**18.74%**
Social Sciences	1,334	2.61%	238	1.55%	141	1.88%

According to the above mentioned study Lampert, D. et al (2015), in Serbia's DR co-publications, strong growth (more than 800% growth rate) is visible from Agriculture, Fisheries & Forestry, Biology, Biomedical Research, Clinical Medicine, Enabling & Strategic Technologies, Engineering, and ICT. Contrary to Romania, there is a rather strong growth visible from Physics & Astronomy as well, from 34 Serbian DR co-publications in 2003 to 288 Danube Region co-publications in 2013. Compared to the growth rate of the above-mentioned fields with strong growth, this is not as much, but nevertheless, the yearly co-publication output is more than six times as high as in 2003. But, Physics & Astronomy, like for Romania, is at least not the main driver behind the output growth of Serbia. Compared to the average times cited counts in the Danube Region collaboration output, the strengths of Serbia are in physics & astronomy.

2.3 Overview of research and innovation projects in the region

The main objective of this activity was to identify and analyze the project results in the field of cluster development, technology transfer and other innovation support measures that have a transferability potential for the Danube Region. The activity is not focused on analysis of research cooperation in the region as such but rather on selection of most relevant success stories (results of the EU-funded projects implemented during 2007-2013) that have significant relevance and potential for transferring the know-how, methods, schemes and tools to the Danube Region in implementation of research and innovation strategies and targets set on the macro-regional level.

The results of analysis (for more details Filus, I., et al (2015)) are targeted to national or regional administration and policy makers, future programs participants, relevant stakeholders and members of the EUSDR Priority Areas or respective parties involved in planning and implementation of the funding programs (e.g. DRRIF) for sectorial replication, implementation of proven tools, making synergies and creating further added value based on already available resources. The presence of such tools in the EU and/or Danube Region creates a potential for transfer of the success stories in the region, mutual learning, building the synergies and possible development of common mechanisms for the region. The analysis might be also used as a knowledge base and inspiration for the other macro-regions, for authorities on regional and local level or for the development of the R&I support actions.

According to this analysis, 75 projects were gathering partners from DRC as it is shown in Table 2.

Table 2: Number of analyzed projects per area (Source Danube-Inco.net project D.4.15)

AREA / PROJECT	SEE	CE	FP7	CIP	TOTAL
Cluster development	4	9	20	1	**34**
Technology transfer	15	14	26	4	**59**
Financing tools	3	3	3	0	**9**
Non-financing tools	12	15	13	3	**42**
TOTAL PROJECTS	**18**	**21**	**32**	**4**	**75**
TOTAL RESULTS	**46**	**92**	**130**	**6**	**274**

Serbia was a partner with other DRC in 13 different projects out of 75: AUTOCLUSTERS (SEE), CAPINFOOD (SEE), ClusterPoliSEE (SEE), EVAL-INNO (SEE), FORSEE (SEE), I3E (SEE), INTERVALUE (SEE), IPRforSEE (SEE), ISEDE-NET (SEE), SEE-IFA Network (SEE), TECH.FOOD (SEE), BALCON (FP7), Enterprise Europe Network (CIP).

3. BARRIERS TO R&D COOPERATION FOR SERBIAN R&D COMMUNITY

3.1 Perception of barriers

Data collection method, which has been used by authors of this paper, in the study about R&D barriers, was a web-based questionnaire. The questionnaire was delivered to the respondents through the dissemination of information about the survey (with the link to the questionnaire). The questionnaire was mainly addressed to the wider science, research & innovation community from all Danube Region countries. At the end of the process, 1590 answers to the questionnaire were received. More details of methodology are available in Kutlača, Đ. at al (2015). A sample of respondents from Serbia included 425 respondents of different ages, research areas, and work experience. The highest percentage of respondents in the sample was between 41-50 years old, while over 75% was between 31-60 years old, 56% of them had a minimum 10 years of work experience.

The survey consisted of 5 main parts and 22 questions in total: general data, general data on international cooperation, priorities in selecting the country of cooperation, barriers to cooperation, and recommendations. Statistical analysis is conducted using Statistical Package for the Social Sciences (SPSS). The following statistical methods were applied: descriptive analysis, t-test for equality of means, chi-square test, one-way and two ways ANOVA, factor analysis. The first level of the analysis was descriptive statistics of general data which enabled an overview of the socio-demographic characteristics of respondents, general information about the cooperation, and priorities of respondents in selecting the country for cooperation.

The following figure 1 shows experience of respondents from Serbia in cooperation with the Danube region countries in all research programs measured on the Likert scale from 1 to 5, in the last seven years. Among four types of cooperation, partnership in RTDI projects inside the region exists on the highest percentage. Although the sample of respondents consists mainly of experienced researchers, it can be concluded that the experience in international RTDI projects is not high. If we limit RTDI projects only on the Danube Region and 14 countries in the Danube region, only 37% of Serbian respondents participated in the international cooperation with these countries. On the level of the whole DRC sample, the highest differences are perceived regarding participation in international collaborative RTDI projects inside the region, where EU MS and regions upstream of the Danube have the most respondents with positive answers – 72.22% while only 37.39% of participants from Enlargement countries have been involved in such projects. Respondents from Enlargement countries also have the smallest percent of visits to the Danube region countries for RTDI cooperation - just 38.03% (in Serbia only 36%) of respondents had that kind of visits in the last 7 years. EU MS and regions upstream of the Danube and Neighborhood countries have a higher score – more than 57 %.

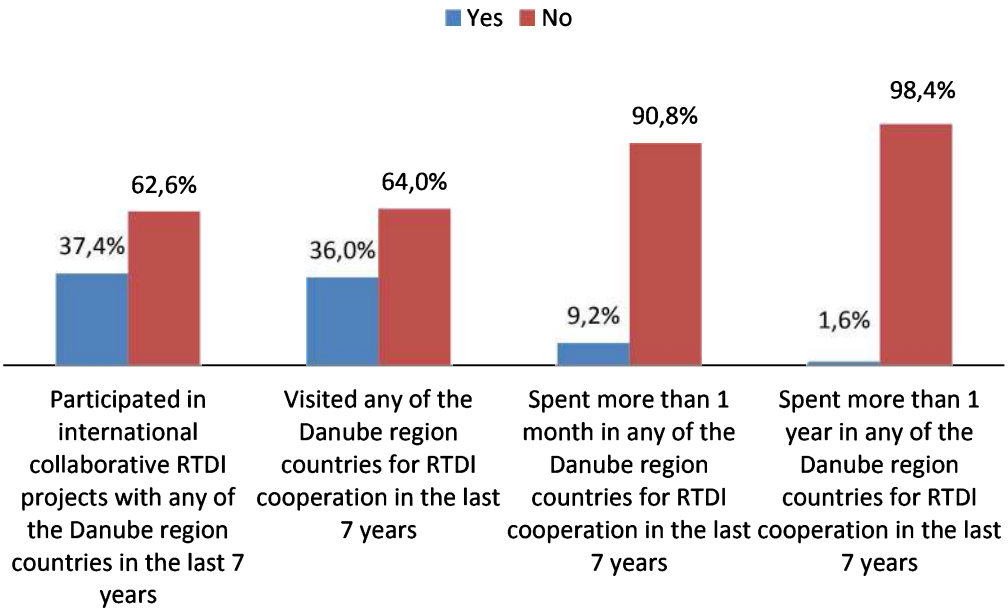

Figure 1: Experience of respondents in cooperation with the Danube region countries

Respondents from EU MS and regions upstream of the Danube have also significant results when it comes to the living in DR countries with the purpose of RTDI cooperation – 12.78% of them have spent more than 1 month in some of the DR countries, while 5% have spent more than 1 year in some of these countries. EU MS and regions downstream of the Danube have low share in visits to DR countries which last more than 1 month, but a very high share of visits that last more than 1 year (9.52%). In Enlargement and Neighborhood countries the situation is quite opposite – the share of shorter stays in DR countries is much higher than the share of longer stays in these countries.

In addition to descriptive statistics and basic data on the perception of barriers in the Danube region, particular attention was given to the perception of barriers according to demographic characteristics of respondents, in that way we have defined 5 working hypothesis.

Hypothesis 1: Older researchers (minimum 10 years of working experience) have a lower perception of barriers in international R&D cooperation in comparison with younger researchers (less than 10 years of working experience). Using T-test of independent samples, medium values of barriers in R&D cooperation between older and younger researchers were compared. According to results, it could be concluded that there are no significant differences in barriers perception of less experienced and more experienced researchers. Hypothesis 1 was not justified.

Hypothesis 2: The age of researchers influenced barriers in R&D cooperation perception. Results of one-way ANOVA analysis shown, that there is no differences in perception of barriers, according to the age of respondents. Although there was an assumption that researchers at the beginning of their careers will have more obstacles to cooperation, this difference was not statistically significant.

Regarding gender ratios to this sample were prevailed women, thus, 53% of respondents were women, and 47% men.

Hypothesis 3: In the perception of R&D barriers in international cooperation there are differences between female and male. A t-test of independent samples was used for the variable "gender" since in this variable is only two answer groups. There is a significant difference between male and female with regard to the perception of administrative and personal barriers.

Barrier perception mean values of the Likert scale of 1 to 5 indicate that women have statistically significant difficulties in international cooperation when it comes to problems with projects application, then the process of project implementation and reporting. Furthermore, personal factors, such as gender, family situation, the preferred career, are significant barriers more for women than for men.

The vast majority of respondents in the sample came from the high education sector (70%), followed by public sector (mostly public institutes) 25%, and only 4% was from the business sector. Relatively a small number of respondents from business sectors are a limitation of the analysis due to the inability of overview the whole R&D sector in Serbia. All in all, the sample corresponded most to the structure of human resources in the R&D system in Serbia (based on the statistical data of the Statistics Office of the Republic of Serbia), and the results can be considered adequate for making conclusions and recommendations.

Hypothesis 4: researchers from the different types of institutions have the different perception of barriers in international R&D cooperation. Using one-way ANOVA analyses of variances mean values of barriers in international R&D cooperation of respondents from all three sectors had been compared. According to the results, we can conclude that there is the significant difference in perception of institutional barriers among respondents. Researchers from faculties have statistically significant barriers in international R&D cooperation in comparison with researchers that are working with public institutes.

The vast majority of respondents are in engineering sciences (29%), following with natural sciences and social sciences with percentage respectively 21% and 17%. The category "other", covers 4% of the sample of respondents that are not directly from R&D sector, they are rather stakeholders from the business sector and public administration.

Hypothesis 5: There is a difference in perception of barriers in R&D cooperation among researchers from different scientific fields. Hypothesis testing showed that there are no significant differences in barrier perception of researchers from different science fields. Hypothesis 5 has not been justified.

3.2 Defining activities for overcoming barriers

With the aim to overcome barriers to international R&D cooperation, researchers assessed 15 suggested measures on the Likert scale of significance from 1 to 5. The mean value of activities' significance (with a range from 4.15 to 3.05), shown that researchers consider realization of those activities, as an important step in overcoming the barriers.

The most important activities to the majority of researchers are international conferences attendance and program of mobility - single visits to research organizations of the aim at the joint project proposals preparations. Besides mentioned, very important and necessary activities are those which promote more efficient information canals about potential projects funding, in order to promote international cooperation and increased the number of project applications.

Respondents were given the opportunity to propose measures to overcome barriers in international RTDI programs in reply to an open-ended question. Responses were classified according to the criteria to whom the activities are directly or indirectly related to. According to the level at which the improvement should be implemented, 4 main groups were identified:

- Support from the European Commission (EC) - activities related to project financing, administration and legal framework of projects, better reallocation of funds etc.,

- National support - activities to be undertaken at the state level in order to overcome barriers to international cooperation.
- Institutional supports - activities to be undertaken at the level of institutions
- Objective problems - problems that should be solved by the teams, include personal approach.

Based on defined key stakeholders for activities implementation, according to respondents' answers, it is necessary to undertake concrete measures.

European Commission has to contribute to following:
1. Improving control of project implementation (Allow individual faculties to be independent of the university; Nullify all university regulations specifying that international cooperation must be done at the university level; Preventing of abuse in spending project funds by university management office; Introduce penalties for head/director who abused their position of authority for personal financial gain).
2. Addressing legal and administrative problems (Better harmonization of different programs; Reducing lobbying for other countries in EU administration).
3. Increasing funding opportunities (More calls for small collaborative research projects; More money for infrastructure facilities; More study visits to other countries, and more opportunities for research fellowships).

National support refers to following:
1. Solving legal issues (Adjustment of legal provisions; Harmonization of laws and science programs with EU; Mismatch between international and national law and economy regulations; Improving high education and scientific youth).
2. Financial support (National financial support for strategic international project proposals; Increasing investment in RTDI; More investment in science; More investment in science and RTDI; More investment into institutional capacity building).

Objective problems would be solved in the following way.
1. Improving communication between partners and colleagues (Better communication with colleagues; Better communication and collaboration between scientific institutions in the Danube region; Better overall communication; More individual contacts between experts from the same or similar field of research).

2. Other (Implementing in all research institutions an advisor regarding project preparation and submission; Better distribution of tasks at the university; Proactive approach; Professional help in writing proposals).

4. CONCLUSION AND RECOMMENDATIONS

Since our research shown that the most significant obstacles to the cooperation of researchers from Serbia within the Danube region (and beyond) are those related to the 1. The overall capacity of the country; 2. The administrative and bureaucratic procedures in the application process, implementation, and reporting on the international projects and 3. Socio-political conditions in the country, we will conclude this paper with an attempt to define specific recommendations.

1. Barriers regarding overall capacity of the country are the most important barriers in international RTDI cooperation among the Danube region countries. Strong recommendation to the S&T policy makers in the countries of Danube region is to increase investments in science and technology and particularly increase financial support for international cooperation from public sources.
In addition, Serbian government should harmonize the laws and science programs with EU. Aligning national strategies is a crucial point in order to improve the cooperation in the Danube region.
2. Following the findings based on the analysis of administrative and bureaucratic barriers, recommendations for S&T policy makers not only in Serbia but also in EU countries are:
- to establish efficient processes for programs and projects evaluation.
- to reduce the quantity of projects' documentation.
- to speed-up evaluation procedures and to shorten the time needed for contracts.
- to standardize procedures for project submission and monitoring.
- to secure forehand / on time payment by funding organizations, reducing delays.

3. Socio-political barriers are not so important to the international cooperation at the whole sample of the Danube region countries. As the main obstacle, an inferior position of research and innovation compared to the economic development and political stability was emphasized. Accordingly, it can be concluded that in order to improve international cooperation, the greater concentration of resources on research and development in the Danube region is needed.

If we call upon above mentioned three main rules of international co-publication, in the case of Serbia we can agree with two of them: 1. international cooperation has a higher intensity in basic research 2. the

external factors play the major role in international cooperation. Although Serbia is a small country percentage of co-published papers are under average bellow of DRC, which could be the only result of barriers explained in our analysis. As production of publications is, in general, the outcome of joint projects an additional recommendation to the S&T policy makers in the region is to promote S&T cooperation within the Danube Region in order to increase motivation and interest of the participants for such cooperation.In order to avoid fragmentation of the innovation efforts in the future, we recommend implementing efficient coordination and communication mechanisms between the programs on EU level, e.g. between Framework programs (Horizon 2020, COSME) and trans-regional programs (Central Europe, Danube Region) as well as within these groups. Coordination and synergy building have to be developed also between programs on the EU level and national or regional programs and initiatives (including specific operational programs of the European Structural and Investment Funds).

Socio-political barriers in Serbian international cooperation are primarily caused by its geopolitical status (small, non-EU member country), this is not possible or, it is very challenging to change or overcome. However, expenditure of research and technological development are also limiting factor for Serbian researchers in international cooperation, and recommendations for improving the overall capacity of the state are also very important to be applied in this area.

ACKNOWLEDGEMENT

Research presented in this paper was supported by the Ministry of Education, Science and Technology Development of the Republic of Serbia, under the projects: reg. no. III 47005, and by the FP7 project Danube-Inco.Net.

COMPETENCY OF REGISTERED FARMERS FOR INDEPENDENT BUSINESS

Slobodan Miladinović*[1], Nikola Ljiljanić[2]
[1]University of Belgrade, Faculty of Organizational Sciences
[1]Institute for Science Application in Agriculture, 68b Blvd. despota Stefana - 11000, Belgrade
*Corresponding author, e-mail: miladinovic@fon.rs

Abstract: *Subject of this paper is a state of competence of the owners of the registered agricultural holdings to independently lead operations of their farms. The aim of this paper is to determine the extent to which holders of registered agricultural holdings are trained to independently perform tasks which require basic economic and technical knowledge in business like bookkeeping, calculation of production costs, business plan, whether they use incentives for the development of agriculture, banking services and the like. Findings are not encouraging. Therefore, it is necessary to conduct an organized social action aiming to educate farmers in the area of keeping business on their farms. Advisory services play an important role in this process. Their task is to mediate between farmers and other institutions that may contribute to the development of agriculture.*

Keywords*: farmer, holding, knowedge, business, advisory sevices*

1. INTRODUCTION

Based on the Regulation of 2004 The Ministry of Agriculture, Forestry and Water Management of the Republic of Serbia has started registration of agricultural holdings with the intention to have a clear record of who has the right to use the funds from the agricultural budget. The aim of these measures is to control the use of funds to encourage the development of agricultural production and the establishment of direct links with government services to agricultural producers, without intermediaries. Registration is based on a voluntary basis and is not related to the time period, but only the registered holdings have the right to use earmarked funds from the state budget for premium, subsidies and lending and other services of government extension services.

Into the Register of agricultural holdings may be entered: (1) natural persons - farmers, together with members of their family farm; (2) companies registered to perform agricultural production; (3) agricultural cooperatives; (4) entrepreneurs registered for carrying out the agricultural production, and (5) scientific research organization in the field of agriculture.

The subject of this paper is to analyze farms that are owned by private individuals. More specifically direct object of research is a state of competence of the household heads to independently lead operation of their farms. It is assumed that farmers are mostly lower educated and are generally not familiar with what is the bookkeeping, which it serves, how records of costs and revenues are kept and how to make a calculation of production costs, what is a business plan, whether they need assistance in its drafting, which it serves for, who gives incentives for the development of agriculture, how to apply for them, if they need assistance in applying for these funds, do they know which are the instruments of payments and the like. The aim of this paper is to determine the extent to which holders of registered agricultural holdings are trained to independently perform tasks which require basic economic and technical knowledge in business.

Here are analyzed the results of the survey research performed in 2014 in three regions of Serbia (Šumadija and Western Serbia, Southern and Eastern Serbia and the Belgrade region). It covers 344 villages in 83 municipalities. The survey was conducted by 73 interviewers - the adviser of total 167 currently engaged in the Agricultural Advisory and Support Service of the Republic of Serbia (AASS). They are arranged in 21 AASS covering the entire territory of the above mentioned regions (Institute for science application in agriculture, Report 2015). AASS advisors actively and continuously are monitoring agricultural production to 3,005 family farms selected according to the criteria for the selection of agricultural holdings (Official Gazette of the Republic of Serbia, 2014). Selecting the surveyed households is covered the entire territory of the observed region, made proper pattern dispersion, in proportion to the surface covered by AASS and the number of holdings for each AASS which came to approximate number of required number of surveys. In this way it is provided the homogeneous sample and comparable with the results of the Census of

Agriculture at the same time, as well as the mutual comparability of the indicators between the regions, thereby creating the conditions for the application of the comparative method where they are synthesized characteristics of the region and the entire sample. Data were collected in the field in written form, and then entered and processed in Microsoft excel and SPSS. The sample included 165 households with a dominant crop-livestock production. With only livestock production are 142 holdings, with a crop production is 43. These three types of households are represented with 68% in the total sample followed by fruit farms with 99 - wine with 15, vegetable farms with 38, beekeeping farms with 8 and 6 others.

2. FARMERS AND THEIR BUSINESS

According to the agricultural census in 2012 family farms dominate in the total structure of agricultural holdings in Serbia (99.6%), while the remaining 0.4% consists of legal persons holdings (companies, cooperatives) and entrepreneurs (Statistical Office of the Republic of Serbia: 2012: 190). According to the findings of the Census the total number of members and full-time employees on farms totaled 1,442,628 persons, of which 421,016 were holders of farms and 537,479 the members of households engaged in agriculture out of which 243,380 were employed full time throughout the year. These data refer only to households that are in the possession of more than 0.5 hectares of utilized agricultural land and/or above a certain number of cattle, poultry, etc. By this, 108,230 households and their members are excluded from the list (Bogdanov and Babovic, 2014: 20). Three years later, the structure remained practically unchanged (Trezor, 2016). At 31 December 2015 there were 346,135 registered farms in active status, of which 344,404 family farms, 1,448 agricultural enterprises, 114 agricultural cooperatives and 70 agricultural holdings with legal personality and 7 research organizations.

These data speak eloquently about the importance of agriculture in the overall economy of Serbia. Despite two and a half decades of transition, similar trends are happening which are registered in neighboring countries. In Serbia, outside the large urban centers and urban areas agriculture has a key importance for the development of the local economy but nevertheless it has a low economic efficiency. Similar trends were recorded in the neighboring countries and even those that joined the European Union, such as Romania and Bulgaria (Andrei Eftimie & Matei, 2014: 121).

Nowadays there is almost theoretical consensus that the family farm are socio-economic base around which is creating the peasantry as a social class and as long as it exists, it will reproduce interpersonal relations and the local cultural patterns typical for the rural environment. Additional problem is the fact that the land property of agricultural holdings is quite fragmented, consisting of a plurality of mutually separate plots, which only contributes that the overall agricultural production remains extensive. This greatly contributes to the fact that today's agriculture in Serbia lags behind on agriculture of the European Union, according to farmers' income and to the technical equipment, productivity and most of the other economic indicators (Mitrovic, 2015: 114).

In recent years, innovation has become one of the most important factors of economic development. They ensure the competitiveness of the market. Their importance is even greater in agricultural production since they enable the production of larger quantities of high-quality food for a steadily growing population and the need to release a wider and even the world market but also for the local and regional self- sustainable development.

In recent years, innovation has become one of the most important factors of economic development. They ensure the competitiveness of the market. Their importance is even greater in agricultural production since they enable the production of larger quantities of high-quality food for a steadily growing population and the need to release a wider and even the world market but also for the local and regional self- sustainable development. Therefore, modernization and implementation of innovations in agriculture should be seen as a very important factor in the competitiveness of agriculture, starting from the level of individual farms up to the level of the national economy (Rumanovská, 2013). In our conditions, one of the imperatives of economic development should be the development of sustainable agriculture based on innovativeness of production and business innovativeness. With regard to the overall structure of domestic agriculture particularly important place is occupied by registered farms, great attention must be just paid to vocational training of farmers to understand the importance of innovation not only in manufacturing but also in everyday business and farm management and to apply them in practice.

The problem is that our society may be understood as a society of belated modernization. This means that the majority of the population is dominated by traditional conscience and traditionalism as the dominant value orientation. Rural areas typically are not ready to accept modernization and innovations that it brings, and may be considered as centers of resistance to all major social changes (Pešić, 2015). Accordingly, it may be

expected that the rural population, including the holders of registered farms, is mainly traditionally oriented and that is not ready to change neither checked patterns of traditional ways of the agricultural production nor everyday social life. This fact constitutes an aggravating circumstance in any attempt to improve the agricultural production.

Given that one of the main objectives of each production is income generating (profit) then it is important for each producer to have permanent insight into the financial flows of its own business. Given that the Serbian agriculture is dominated by the production of a relatively small land ownership, and that farmers generally have low level of education, it is understandable that they did not have the habit of keeping accounting records of production costs and incomes. Another important question is whether if they may, with regard to their education, understand the importance and necessity of bookkeeping of its own holdings and whether they were sufficiently expert to independently perform their job.

Given that one of the main objectives of each production is income generating (profit) then it is important for each producer to have permanent insight into the financial flows of its own business. Given that the Serbian agriculture is dominated by the production of a relatively small land ownership, and that farmers generally have low level of education, it is understandable that they did not have the habit of keeping accounting records of production costs and incomes. Another important question is, with regard to their education, whether they understand the importance and necessity of bookkeeping on its own holdings and whether they are sufficiently expert to independently perform their job.

Table 1: Do you keep records of expenses and income of agricultural production on your holding?

Yes, I do	32.6%
Yes, I do it with the help of another person	41.7%
I do not keep records	25.0%
Yes, I pay an accountant	0.8%
Total	**100.0%**

Even nine-tenths of the holders of registered farms argue that they are familiar with the concept of bookkeeping records the cost of production (91.5%). Even though only three-quarters of them say that they keep records of the costs. This is a relatively high number of holders of registered farms. The assumption is that the record keeping is necessary, for various reasons, to obtain loans, grants, subsidies, aid from the various funds and similar but also for personal insight into the profitability of its own business. What is interesting is that only one in three keep personally this records, two-fifths of them do it with the assistance of a professional person while very few of them pay an accountant. So, for the contemporary registered farmers we may not say that they are enough versed or knowledgeable enough to take their own business on (registered) farms.

Of course, it's not just about the need to keep accounting records of production costs. Keeping family farm means not only responsibility for the successful business but also the ability to survive in the market conditions. This includes rationalization the business and achieving the cheapest possible production of a satisfactory quality and scope with the intention to achieve a satisfactory profit in the final realization of production in the market. Therefore, it is necessary to do the previous calculation of costs and benefits with the bookkeeping as well as the question of whether the farmer is able to do that alone. It is not necessary to speak about the importance this work. It is much more important question of whether the holders of registered farms practice it. Without it can not be assessed in advance the real profitability of the production cycle or the amount of expected profit.

Table 2: Are you doing calculations of production lines that you do?

Yes, with the advisers during their visit	69.0%
Yes, with an another expert	2.4%
Yes, I do it alone	9.5%
I do not do the calculations because I do not know how	19.0%
Total	**100.0%**

On the question of whether you make a calculation of your production lines seven-tenths of them answered that they makes it with the help of a professional person or adviser during their visit to the farm. Thus, the vast majority of them use the assistance of the advisor while a small number of them rely on the assistance of some other specialist and one in ten said that work on calculation himself. On the other hand, every fifth declare that they do not calculate their production lines. Ultimately, it means if they do not work the calculation they let go the elemental forces of the market and expose themselves to a series of accidents and adverse trends that can be counteracted by good planning.

Considering the above findings and observations, it may be assumed that the majority of farmers constantly need the help of an expert. On the other hand, it is required organized education just in the field of management of finances. This would expand their knowledge related to business problems which could help them in quality performance of their core business. It should be added the need for advisory services to have experts on this matter in their composition, but also that every advisor needs to know the basics of bookkeeping in order to help farmers who use their services.

Research findings show that two-fifths of the farmers (39.6%) had an opportunity to learn how to make evidence of expenses and income or making calculations on organized training while the rest (60.4%) claim that they learned to do it on the easiest way for them. The conclusion is that it is necessary to devise a systematic training to farmers to empower them for this activity. Of course, we can assume that the situation is much worse for those farmers who have not registered their farm. They rely solely on their own strength in business and they are left at the mercy of uncontrolled functioning of the market where perhaps the greatest benefit have middlemen and stockbrokers but direct manufacturer remains unprotected.

Lack of formal education has long been a major problem in the agricultural population. In recent years, it is significantly reducing their exclusion from education. Moreover, the research findings show that there is less of those whose education ends with 8 years of primary school (27.8%) compared to 34.43% in the general population according to the last Census (2011). There are significantly more of those who have some level of secondary education (62.2% compared to 48.94% according to the Census). We can conclude that those who have gone through a systematic formal education has primarily decided for registration and that on the other hand those who do not have formal education largely left to themselves. On the other hand, there are significantly less of those with higher education among them (11% compared to 16.24% of the total population). In contrast to this it is the fact that only 13.2% holders of registered farms have the agricultural education.

Here observed trends are typical for other transition countries. An example is Poland where, since 2000, has been observed trend of rapidly raising educational level of the rural population. There were registered 26.4% those with primary education, 61.4% with all levels of secondary education and 12% with high education (equivalent to higher and university education in Serbia) in 2011. In both countries, there is the same number of people who have agricultural education (13.2%) (Chmieliński & Karwat-Woźniak, 2015). Here should take into account the experience of Slovenia in which higher education of the farmer increases his chance to leave agriculture and go to any other occupation (Juvančič, 2005: 325). In the event that this tendency has been registered in Serbia, we would run the risk of reducing educational level of those who continue to engage in agriculture, which could have multiple negative consequences on the further development of agricultural production. It is therefore of particular importance to develop state aid for retaining educated in agriculture.

Table 3: Have you heard the term business plan and do you know what this is?

Yes, but I do not know what it is	19,2%
Yes, I know what it is	74,0%
c) No, I do not	6,8%
Total	**100,0%**

In the world of entrepreneurship business plan plays an important role. Today, many researchers believe that the business plan is of particular importance for the newly-established but also for small businesses (Brinckmann, Grichnik, and Kapsa, 2010: 24). If the registered farm look like a small company then owning a business plan plays a positive role in obtaining state aid, various subsidies, loans and the like. Business plan becomes more and more important in the organization of agricultural production. The data indicate that the majority of them, three-quarters (74.0%), declares that they heard about the concept of a business plan and to know what it is. One in five (19.2%) said that he heard but did not know what this is about until and approximately one in twenty (6.8%) declared that never heard of a business plan.

Table 4: Business plan

	Have anybody done a "business plan" for your holding?	**Do you know what is "a business plan" made for and if you can specify for what?**	**Do know/Do not know**
Yes	15.7%	74.8%	7,6%
No	84.3%	25.2%	92,4%
Total	**100.0%**	**100.0%**	**100.0%**

It is interesting that despite the fact that such a large number of registered farmers claimed that they are familiar with the concept of a business plan and to understand its essence and to know why it would be made (three quarters) still relatively few of them has even tried to made it (about one in seven), with the help of professionals. It must be admitted that this is quite unusual discrepancy between knowledge of the importance of something and trying its application, especially if it is about something that is of great importance in practice. Therefore, respondents were asked to indicate for what it is used. After examining the replies it was concluded that the vast majority of them however do not know what is the wright meaning and the purpose of business plan (92.4%). Only 10.7% of those who said that they know gave the right answer.

It follows from this that the average owner of a registered agricultural household does not have enough expertise for conducting their own business. Keeping the registered family farm is a specific type of entrepreneurial activity and it involves mastering of many skills and knowledge not only in relation to the technology of agricultural production but also to the management and entrepreneurship as well as too many other areas. From this arises the necessity of systematic professional training of farmers in different areas of knowledge.

Table 5: Using incentives and other funds

	Do you use incentives from the state for agricultural production?	Do you use incentives from the local government?	Have you heard of the possibility of obtaining financial resources for agriculture from EU pre-accession funds?	Do you know the way to receive these funds, and what do you need for it?	Have you had the opportunity to attend a lecture on which explained how to use the pre-accession funds?
Yes	98.4%	54.6%	86.2%	30.6%	27.8%
No	1.6%	45.4%	13.8%	69.4%	72.2%

One of the key issues in the operations of each business entity is issue of providing the necessary resources for normal functioning. Nowadays there are various funds which grants means to farmers for different purposes. The most important resources are mostly in state funds, funds of the local community and the pre-accession funds of the European Union in recent times. Of course, only registered farms could apply for obtaining these funds.

The data show that the registered farmers commonly use financial incentives from the state. Almost all of them do it. Taking into account the fact that the state's resources are given exclusively to registered farms, and then we can assume that this was a moment of great motivational significance in decision about the registration. The incentives that give local governments use a little more than half of the registered farm holdings, which only confirms previous finding.

It is interesting fact that the vast majority of registered farmers are informed about the possibility of obtaining financial resources for agricultural production from pre-accession funds of the European Union. These funds use a relatively small number of them, only three tenths. Despite the fact that many of them are informed of the possibility of obtaining aid from these funds, which are quite significant resources, most of them (more than two-thirds) is not informed in the way how to use these funds and what they need for and only one in four has attended the lecture which was discussed on how to use pre-accession funds. Thus, a significant majority of them do not have adequate knowledge about the possibilities and how to apply for obtaining those funds.

The global trend of the European Union, is that agriculture is supported and protected by Common Economic Policy with the intention to ensure the rational development of agricultural production and full utilization of factors of production and especially of the labor force as well as to increase revenues and provide adequate living standards of farmers. Some of the elements of the Common Agricultural Policy, by themselves, do not stimulate the growth of agricultural production, but given that they have the form of the transfer of knowledge related to agricultural holdings they have important significance for the final economic result in business of the holdings. The experience of the European Union in this regard is very inspiring. Various subsidies have given a special contribution to the development of agriculture but no less significance have the other means from the Rural Development Program that enable other aspects of adjustment to the conditions of market economy and overcoming severe competition (Kołoszko-Chomentowski, 2014: 65-66). This does not mean that it is exclusively about investing in production technology and equipment modernization. Great importance has investments in cultural and human capital of agricultural production and in the first place in

the training of farmers and members of their households on a variety of issues related to agricultural production and farm business.

It seems that the lack of information one of the key problems for faster and easier applying for various forms of support from the above mentioned state, local and international funds. Confirmation of this is found in the fact only 30.9% of them submitted the requests alone while 69.1% said they do it with the assistance of an expert or advisor.

Table 6: Using bank services

	Do you use loans to finance agricultural production?	Do you have the bank account?	Do you know what is a promissory note and what is it use for?	Do you know what is a check and what is it use for?
Yes	23,8%	97,7%	91,9%	97,1%
No	76,2%	2,3%	8,1%	2,9%

Based on the answers it can be considered that the majority of farmers are addressed to the possibility of their use when it comes to the use of banking services. Almost all (over 97%) have opened a bank account and know what the check is. Based on this we can assume that they are trained to perform basic operations related to receiving money and payments of liabilities to third parties. Many of them are probably forced to use banking services since the vast majority of legal persons with whom they cooperate carried out their financial operations exclusively through the account.

In addition to payments, it can be important for farmers some other banking services including perhaps especially important place has the option of taking the loan. Slightly less than a quarter of them say that they use bank loans to finance agricultural production. This is still a small part of them. Of course, we can ask why more of them does not do it with respect that the loan for many of them give chance to purchase the necessary equipment to build greenhouses or other facilities, irrigation, to buy some of the agricultural machine or something else that would have ensured expansion of production and acquisition of higher revenues in the future. The answers probably should be sought in high interest rates, confidence in the bank, long production cycles, unstable purchasing prices, uncertainty of operations due to dependence on natural disasters and etc.

3. CONCLUSION

General social modernization, which, among other things, is characterized by a rapid development and expansion of the educational system, is coming slowly to rural areas which are under the strong influence of traditionalism, relatively static and unprepared for significant changes in patterns of social behavior. This is reflected on the way of the business of agricultural holdings including registered farms which may be considered for more advanced part of the rural society.

This view is confirmed by the findings of the research. A very small number of farmers, owners of registered agricultural households are qualified to perform some of the basic activities related to independently doing business of their own holdings. Every third keep records of expenses and income and one in ten do calculation of its production lines, most of them do not know what a business plan is and why they should have it, many of them do not use the incentives provided by different funds. Moreover they do not know how they can apply for them. Many of them have attended various courses on the conduct of the business but obviously it is not enough to run their own farms. Certainly it requires a broader social action in order to introduce innovation in agriculture, modernize farms and the rural areas as well.

The question is how to accelerate the modernization of rural communities and agricultural holdings. In order to respond to it we firstly need to identify the key actors in the creation and transfer of knowledge relating to agriculture as a productive activity. The key actors in this process are (1) research and educational institutions that are responsible for the development of new ideas, (2) advisory services that mediate between researchers and innovators on the one hand and (3) the end-users of new knowledge on the other hand - the direct beneficiaries of knowledge (farmers) and indirect beneficiaries and i.e. various organizations that fulfill their goals through the application of new knowledge in agriculture and rural development (Tudor, Florian & Chitei, 2013: 91).

Intermediaries linking the farmers with the creators of knowledge and innovation have special importance in activating the direct beneficiaries of knowledge and innovation in agriculture. They ought to have direct cooperation with educational and research institutions and to suggest problems that notice on the ground in

direct contact with the farmers. Educational and research institutions should create specific training plans and programs which will aim to complete the skills that are necessary for the rational organization of agricultural production and management of farms. It is necessary regular interaction of all in the chain of transfer of knowledge for successful resolution of this problem.

Abstract: *Importance of online marketing research has been increasing over the years. According to ESOMAR report (2014) around half of overall research budget in market research agencies globally is spend on online research, and majority of quantitative online research is now conducted via online research panels. Three focus groups with University students were conducted with the purpose of exploring students' experiences with online research panels, motivations to participate in research and their general attitudes about participation in online survey research. Analysis of the qualitative data transcripts of the focus group discussions indicated that although participants took part in number of online surveys, most of them were not familiar with online research panels. Helping friends was identified to be a most frequent motive for survey participation. Aside from helping behavior, personal interest in a research topic, opportunity to share their opinions and opportunity to learn from the survey were also identified as motives for survey participation. Majority of participants considered current form of surveys obsolete and uninteresting and suggested a number of creative approaches to survey research and solutions for panel participant recruitment. Based on analyzed conversations recommendations are made for development of the recruitment strategies for panel research participants with more creative approach to online survey research, utilization of Internet multimedial potentials and social media integration in panel software.*

Keywords*: marketing research, Internet, panel research, focus groups, millenials*

1. INTRODUCTION

Technology development has enabled new ways of conducting research. Online surveys and qualitative research are becoming more common tools for conducting marketing research. New technologies along with a continuous increase in the number of Internet users worldwide, are bringing opportunities for further improvement of methods of online research. The share of online marketing research in overall marketing research activities has been continuosly increasing. According to the Internet Society Report (2015), a global Internet population in 2015 exceeded 3 billion users. It is estimated that by the end of 2016, 45% of the total population of the planet will use Internet. The highest rate of Internet usage is in North America, where Internet users make up to 87.9% of the total population. The incidence of Internet use clearly indicates that today's population is largely focused on Internet-based contents. This is especially true for younger generational cohorts, also called millennials, from educational and informative content, to entertainment, communications and online shopping activities, Internet use has become intertwined with most of their daily activities (Wang et al. 2015). A whole new generation of Internet-savvy customers emerged, and the need for finding out more about their habits and attitudes has became prominent in the past ten years.

Before the era of information technologies and Internet, survey data collection has been conducted in two ways: in person or by telephone. In the mid nineties with the introduction of web-based services as well as with the increase of number of Internet users globally, Internet was recognized as a suitable medium for carrying out quantitative research (Hoonakker & Carayon, 2009; Groves, 2011; Göritz, 2004). Hoonakker and Carayon (2009) suggested four possible methods to perform online quantitative research: (1) via e-mail attachment (Word document), (2) in the body of email messages, (3) .exe file within the email message, (4) a web-based questionnaire. In a web-based questionnaires survey is completed directly on the website, and data automatically stored on a web server. This concept was used for development of online research panels.

Online research panel is a pool of registered individuals who have agreed to participate in Web surveys on a regular basis (Göritz et al, 2000). An increasing number of market research agencies worldwide opted for

establishing their own online research panel. Evans and Mathur (2005) estimated that online research panels can be more cost-effective compared to traditional customer databases. Moreover, market research agency practices indicated that use of online research panel can considerably reduce the time required to conduct the survey. Over the time panel research became the most popular way for conducting an online marketing research, and quantitative online research today is increasingly conducted through online panels (Sikkel et al., 2009). The use of such research panels promises a high response rate, sample control, access to the general population, as well as detailed demographic information about the respondents and the possibility of preselection and segmentation desired group of respondents (Bruggen et al, 2011).

There are different sizes and structures of online panels. Panels may consist of consumers / customers, potential customers / users, partners, employees and other target groups - potential participants in research on specific topics. ESOMAR (2014) recommends having more than 10000 respondents in database in order for panel sample to represent online population in satisfactory manner. However, some online panels that are used by specific industries can have only several thousand members. At the same time, there is a number of large commercial international online panels with millions of registered participants from different countries. Typically, those panels (such as Cint, one of the largest online panels) consist of number of smaller specialized or local panels (Babin & Zikmund, 2015). This trend is also noticeable in Serbia: previous research conducted by Ljepava and Janicic (2015) indicated that approximately 80% of the interviewed market research agencies used online research panels with number of panel participants ranging from 2000 to 10,000 panelists.

However, McDaniel and Gates (2010) argued that establishment of online research panels led to the creation of specific category of professional survey participants. They indicated that professional survey participants often fill a number of different surveys on a daily basis, and that quality of collected information can be compromised. This is why it is very important to understand motivational factors that influence participants when joining online panels, and to carefully plan panel recruitment strategies as well as mechanisms for quality control. In order to achieve long-term successful implementation of online panel studies, researchers face several key issues: how to recruit a sufficient number of panel participans, how to maintain a critical mass of participants and continuously recruit new members, and how to motivate them to participate in studies and provide valid and credible information. Additionally, most of the information collected in quantitative research, is limited to participants' self-report. According to McDaniel and Gates (2010), such information can be subject to various flaws that may depend both on the methodological errors and ambiguities in designing research instruments, and on inadequate and inaccurate information provided by research participants.

The starting point in addressing all abovementioned challenges of online research panel is to understand the motivations of the respondents - the motives for both panel registration and research participation. The value of survey participation for the research participants is not always clear; completing the questionnaire requires cognitive effort, takes time and interrupts other activities respondent implements. Consequently, type of motivation for research participation can be an important factor affecting the quality of the collected data. (Bruggen et al, 2011). Žabkar and Kolar (2010) also discussed the importance of understanding of the Internet habits, behaviors and participants' motives for market research agency doing an online research.

The literature also indicates that there is a link between the level of Internet activity and participation in online research. For example, Göritz (2004) in her study showed that the response to participation in the panels was higher when the call for registration was distributed via email compared to more traditional recruitment methods.

In order to further explore motivational factors and habits of Internet users, specifficaly the group of Internet-savvy millennials, an exploratory focus group qualitative research was conducted in order to find out more about their knowledge and attitudes about online panels and survey participation, along with their willingness and motivation to participate in online panels.

2. METHODS

For the purpose of the present research, exploratory qualitative research has been conducted and three focus groups held with the students from University of Belgrade. The study included a total of 30 students divided into three groups of 10 participants per each focus group. Out of the 30 participants, there were 18

females and 12 males. Students responded to a series of questions related to their habits of Internet use, previous experience with participation in online research and survey participation, and attitudes and motivational factors influencing research participation. Focus groups were recorded and written transcripts created for each focus group, and then cumulatively analyzed in order to identify key themes. Qualitative analysis and content analysis were performed on collected data. Responses were categorized in accordance with the prevailing themes and presented cumulatively with the citation of the individual statements in order to illustrate a certain trend or prevailing attitudes about a particular subject.

3. RESULTS

Results of the analysis of the focus groups transcripts indicated that majority of the respondents use Internet continuously on a daily basis; consequently, they are mostly unable to determine the exact number of hours spent online. High level of Internet usage via mobile phone opens the possibility of continuous networking and interactions that are taking place throughout the day. Majority of time is spent on social networks, and besides social networks Internet is also extensively used for entertainment, informational purposes, and listening to a music.

Respondents generally do not like to participate in survey research, and the most common reason stated for participation is to help friends for a project or research. Additional motives for completing surveys are the possibility to express their opinion, to contribute to products or services improvement or to contribute to solving some social problems or increasing their visibility.

3.1 Internet and Social Media use

Facebook, Twitter and Instagram are found to be the most popular social networking websites, along with instant communication services such as Viber, WhatsApp and Skype. University students that participated in the research used social networks mainly to communicate and maintain contact with their friends and acquaintances, as well as to find information on latest news and events and friends activities.

When accessing Internet in addition to social networks (Facebook, Twitter and Instagram) participants spend most of their time on news websites (Blic, B92, Mondo) and extensively used YouTube. Websites with movies and TV series streams are also found to be very popular. Respondents also spend their time playing games, in many cases again in the context of social networks (specifically Facebook). A small number of respondents in this sample, mostly male, spends his time playing multiplayer MMPORG games.

"I cannot say how much time I spend online. When I see notification on my cell phone I check it."

"I use Internet continuously on a daily basis. I spend most of time on Facebook, YouTube and I read news on news portal such as Blic."

"We used to read printed newspapers. Now you can find anything you want online, that is cheaper and more convenient."

Participants are not frequent users of traditional media such as TV and/or newspapers and Internet is their main source of information. It has been observed that, for number of participants, social networks (specifically Facebook and Twitter) represented a starting point for information about latest news and events through content shared by their friends.

3.2. Web panels and survey participation

Majority of respondents considered online surveys to be boring, perceived participation in those surveys as a waste of time, and expressed low levels of motivation to participate in surveys. In most cases they stated that they will only participate in surveys in order to help a friend who is doing a research. Participants expressed particularly negative attitude towards Likert-scale type questions; a number of them stated that if there are too many Likert-scale type questions in the survey they would provide random response without carefully reading questions. Moreover, participants do not prefer to respond to open-ended questions in surveys where they need to write a more detailed response.

"I don't like to participate in surveys. I think it's a waste of time and their results often do not correspond to reality. "

"I filled out a number of online surveys. Frankly, I do not remember exactly what they were about. Mostly customer satisfaction surveys, some survey about juvenile delinquency ... I dont find then particularly interesting."

"My colleagues always ask me to fill out surveys for their research and I want to help them. "

"I do not like this scale type questions, they are boring and take too much time to respond"

"I do not like those surveys that are very long and have a number of some questions on a scale like agree disagree. I will only participate if a friend needs help."

It is interesting that a number of respondents considered participation in popular quizzes and personality tests on the web and social networks as participation in survey research. Although they are aware that majority of those tests have no scientific background, respondents stated that will participate in those tests regardless of their length and question type since they are finding them interesting and engaging, and they will receive test results immediately. Additional factor that influence popularity of those tests is the fact that results can easily be shared on social networks.

"What I love in such tests, is the fact that I can get results immediately after completing the test and I can share them on Facebook. I know they are not really scientific but they are fun."

" I participated in some surveys related to my colleagues' research to help them. And I like to participate in those fun surveys on Facebook that we can share on our profiles. "

"I don't t mind doing psychological tests and personality tests, but I find other type of surveys boring."

None of the respondents actively participated in a web panel. Some of them stated that they registered at some of the local online panels but they were never actively involved in a web panel. They were also not very familiar with the concept of earning by filling in surveys, although some of them were interested to find out more about this possibility.

Minority of respondents who declared that they participate in surveys on a regular basis stated that they more often participate in studies related to topic they feel close to, and that they would appreciate if they could see the results after filling in the survey. They are also willing to participate in a studies related to products and services of their interest.

"I want to fill out a survey in order to share my views, experiences, satisfaction and to give suggestions for further product development or improvement of services to which the survey refers."

"If a topic is interesting I will respond to a survey, but it is usually not."

Survey length and time needed to fill in the survey were also found to be an important factor. Most of the focus group participants were not willing to participate in a survey that takes more than 10 minutes to fill in. In a situation where they did fill in the longer surveys, they mainly did it to help a friend with a project, but they complained that that was too long, time consuming and in some cases they noted that they did not really pay attention to questions.

"I once helped my friend with his graduation project. The survey was too long; it took more than half an hour to fill it. I ended indicating any random response just to finish it. I do not understand this type of research I don't believe any of the respondents carefully reads those questions and whats the point in that? "

3.3. Motivational factors for survey participation

When asked what would motivate them to participate in surveys aside from helping their friends, respondents mostly identified intrinsic factors such as contribution to a social cause, opportunity to provide opinion, opportunity to suggest improvement of products and services. Generally, majority of the participants expressed willingness to participate in surveys that cover important social, cultural, humanitarian or economic issues; on the other hand, there were less willing to participate in commercial marketing survey unless they are specifically interested for services or products. The prevailing view is that surveys that aim to

draw attention to a social problem can motivate participants more, compared to strictly commercially-oriented surveys. In addition, opportunity to express opinion and to influence a change can also motivate participants to participate in a survey research.

"An interesting topic and the opportunity to affect some important social issues."

"Surveys should draw the people's attention to a problem and try to find way of solving the same. If I know that my response really means something, that something can be improved and changed based on my opinion I will gladly participate in such survey. "

"Survey should be interesting and informative. I would be motivated to fill in the survey that serve the common good and maybe the survey from which I can learn something new. I am also very much interested in psychological surveys and tests"

Participants were also more willing to complete a survey if survey topic was related to their personal interests. They also emphasized the importance of survey being short, concise, and specific in order for survey completition rate to be high. Respondents also consider survey research to be a valuable source of information, and for some of them possibility to access results is also important factor that can influence their decision to participate in certain survey.

"If a topic is interesting I will participate. For example, recently I participated in a survey related to improving conditions for the use of bicycles as a means of transportation in Belgrade."

"Survey should be short, specific, related to the topic of my interests in order to complete it. I believe people participate in surveys they want their voices heard. "

".. to create short, clear, simple survey, explain why it is conducted and to be able to access the results."

"Survey research can provide us with opportunity to find out more about the society and people, of course, if the results of these studies are available later."

3.4. Suggestions for conducting online survey research

In order to find out more about participants' opinions and suggestions related to online survey research, respondents were asked to discuss how they would perform online survey research if needed. In recruitment strategies respondents mostly relied on snowball sampling via social networking websites, starting from their own circle of friends. Among social networks suggested for recruitment Facebook was dominant, although some respondents perceived the possibility of using other social media channels in order to recruit participants for online research.

"I would probably use Facebook in order to collect data. I would post the link on my profile and ask my friends to share it"

"I would post a link on social networks and I would also directly contact my friends via direct messages and emails. If I had some money to invest I would pay a banner on some popular websites to recruit more people."

"I would open a dedicated Facebook page and promote it via Facebook ads in order to recruit people to fill in the survey."

Respondents believe that online surveys should be short, interesting and engaging for participants. It is indicative that most of the respondents stated that they would completely change the form of surveys, their visual design and level of interactivity. They believe that the existing forms of online surveys are outdated and that possibilities of multimedial presentation on Internet should be used and surveys presented in more creative forms, such as games, quizzes, videos and graphical presentations in order for surveys to become more interesting for potential participants. They also emphasized the importance of accessing the results and having a possibility to easily share the results on social networking websites.

"I'd like to try something creative because this form of surveys is now outdated and boring."

"I'd make a game (something similar to logo quiz for example) in order to make it interesting. Survey feedback and possibility ti view results is also very important. "

"I'd maybe make surveys the form of a comic book. Also results should be immidiatelly accessible and shareable on social networks – this is also a way to promote a survey and to gain more attention and recruit more participants."

4. CONCLUSION

Importance of using online tools for conducting marketing research has been increasing over the past ten years. Number of market research and public opinion research agencies using research panels for online survey research has been continuously increasing both globally and regionally. In order for panel survey results to represent opinions and attitudes of a specific consumer/target group, special attention needs to be given to recruitment strategies in order to minimize number of extrinsically-motivated professional panel participants.

The present research provided an insight into motivations and attitudes related to online research participation of an average University student. The research indicated that respondents are avid Internet users, who use Internet daily and continuously with majority of participants not being able to determine the exact number of hours spent online. Although they devote most of their online time to social networks, Internet is also used for entertainment, informative purposes, and leisure time. These findings are in line with online behavior habits of University students in other countries and regions indicating that there is a number of similarities in millenials' behavioural patterns worldwide when it comes to online behavior and daily Internet use. These patterns of Internet use place focus group participants into a group of potentially valuable online panel participants; however, majority of students that participated in focus groups were not familiar with the concept of online research panels.

Almost all participants have experience in participating in online surveys, although a number of them considered participation in the popular quizzes and tests equal to research survey participation. Opposed to standardized questionnaires and surveys, that they believe to be mostly uninteresting and boring, participants stated that they gladly participate in popular and psychological quizzes and tests and that they find them interesting and engaging. Participants also suggested a number of changes in survey visual presentation and levels of interactivity in order to make surveys more interesting and engaging for participants. The findings indicated that researchers should consider re-thinking a paradigm of survey research, moving from classical forms of survey research transferred from classical face to face to telephone research, to new, multimedial, more interactive form that would be more interesting and engaging to new generation of millennials. Research also showed that survey participation is primarily intrinsicaly motivated with following motivational factors prevailing: helping behaviour, possibility to express opinion and to contribute to improving products or services, possibility to contribute to some social issue that respondent consider to be important and possibility to learn something from survey results.

Overall, the research indicates that for the new millennials generation of prospect survey participants, the traditional approach to survey research might not be efficient in a long term, especially for Internet-based surveys. Multimedial online environment provide number of opportunities for creation of more engaging and dynamic content, and researchers should consider using these opportunities along with social media integration in order to make survey more appealing for prospective participants, increase the number of panel participants and quality of data collected.

Abstract: *Modern trends in the field of marketing communications require the implementation of new instruments that would enable easier adjustment of the characteristics of target groups, delivering the desired message and achievement of desired effects. Given the expansion of the video game industry and the increasing number of users, of all demographic and sociological profiles, computer and video games have become one of the most attractive medium for advertising. Indirect advertising in video games is specific in relation to other types, both direct as well as indirect advertising, and, therefore, the focus of this paper is to identify its key advantages and disadvantages from the side of advertisers. As yet there are not enough studies on this subject, so more complex research in this area are necessary in order to understand the real potential of this modern channel for advertising.*

Keywords*: indirect advertising, video games, characteristics, effects*

1. INTRODUCTION

In the recent time, besides television, the interest for Indirect advertising has expanded to other forms of media, particularly on video, computer and online games (Chaney et al., 2004; Schneider, Cornwell, 2005; Nicovic, 2005; Yang et al., 2006). The expansion of industrial video and computer games influenced the development of consciousness of advertisers about their potential as an effective channel for advertising. An increasing number of users make video games and computer games attractive for advertising (Yang et al., 2006; Russell, Stern, 2006), mainly due to a simple reaching to the target group of consumers through the integration of products in games' plot (McClellan, 2005).

Studies in the US show that 42% of the population play video games and players can be identified among all age groups, with 26% of players under 18 years, 30% aged between 18 and 35 years, 17% of those between 36 and 49 years and 27% of those older than 50 years. Men make up 56% of the players, and women 44%. When it comes to the average player, in case of men, it is 35 years and for women 44 years (ESA, 2015). Revenue from advertising in video games showed an annual growth rate of 11.2% for the period from 2010 to the present. In 2010, global revenue from advertising in video games was around 1.9 billion US dollars, in 2014 it counted 3.1 billion US dollars and, by the end of 2015, it amounted to 3.41 billion US dollars. Projections for 2016. Says it will even reach 3.72 billion US dollars in 2016 (Statista, 2015).

The increasing sophistication of mobile technology, as well as the degree of personalization and customization of mobile games, makes the sphere of the games industry attractive for advertisers, though, for now, it is dominated by forms of mobile phone games designed specifically as a promotional means for individual brands (Eng. Advergames). These games are less complex and demanding than classic games, in which brands are incorporated. Due to the simplicity of design, it can be easily distributed among players (Cauberghe, De Pelsmacker, 2010).

2. EFFECTS OF INDIRECT ADVERTISING

Indirect advertising in video games has a number of positive aspects. It may be noted that the main advantage is the experiential nature of video games, thanks to which the desired information about the products are marketed to active and engaged audience (Sierra, Taute, 2013). Certain studies on this subject have indicated that the interactive environments in video games encourage better memory of marketing information (Jeong et al., 2008; Jeong et al., 2011). This is due to the different treatment of messages placed by an indirect advertising and entertainment media than those obtained through traditional advertising. While in the case of traditional advertising, consumers usually recognize the commercial function of the message, it triggers their skepticism and resistance and limits the effects achieved (Obermiller et al., 2005), Indirect

advertising is less likely to activate these mechanisms of defense (Grigorovich, Constantin, 2004). Also, in the case of traditional advertising, the brand message has been the focus of attention of viewers, whereas in the case of indirect advertising, audience consciously participates in entertainment content, which occupies its primary attention, while simultaneously receiving advertising messages (Lowrey et al., 2005).

For the video game industry, indirect advertising can provide extra income, taking into account that advertisers are paying for the incorporation of the product in scenario of games. Another important advantage is enhancing reality gaming (Yang et al., 2006). Improving the technology of video games provide advertisers the opportunity to create extremely realistic simulations of their products, thus improving the unique experience of the players. Some games designed as simulated motor racing, imitate a very real scenarios that could be equated with "test drives" of various brands of cars in the real world (Mackay et al., 2009).

For this reason, the results of some studies suggest that the audience believes that indirect advertising actually improves the experience by increasing the realism of certain media formats (Avery, Ferraro, 2000). Similarly, Nelson et al. (2004) found that, in terms of players, realistic sports games depends significantly on the brands that appear in the game. An additional advantage of indirect highlighting in video games is the possibility of identifying players with famous sports figures that appear in the game (Nelson, 2002). In fact, 17.9% of regular players of video games take into account the celebrities involved in the game as one of the main reasons for their consumption (ESA, 2015).

Indirect advertising has a longer lifetime than conventional advertising (d'Astous, Chartier, 2000). The lifespan of brands that are embedded in video games can be an important (Nelson, 2002), especially in the case of regular players of this game. In addition, the practice of dynamic ads in the game that can be easily changed often, so, an opportunity to incorporate new brands and preventing obsolescence is higher (Shields, 2005).

Studies have shown that audience, generally speaking, has a positive attitude towards indirect rather than direct advertising. In addition, most players do not have a critical attitude to advertising in video games does not consider that it affects their attention and distort a unique experience, and does not consider this type of advertising to be a deception (Nelson, 2002).

For advertisers, an important concept is personalized indirect advertising because it increases the positive experience of players and increases the time and frequency of play (Kwak et al., 2010). A study of Hang, and Auty (2011) found that allowing players to choose integrated brand that will "use" in a video game increases the efficiency of advertising. The results of this study clearly indicated that a group of players who had the opportunity to choose a brand they prefer, have a more positive experience in comparison with the group to which personalization was not enabled.

However, like other instruments of advertising, indirect advertising in video games can have negative aspects. Given all the common practice of advertising in video games, not enough research has been done in relation to its actual effects. Little is known about the extent to which advertising in video games affects the attitude of players toward certain brands and buying behavior (Yang et al., 2006). Although some studies have indicated that indirect advertising really influences the development of awareness of brands that occur and that the interactive nature of video games is responsible for this (Nelson, 2002), some authors suggest that it may just be a barrier to achieve maximum effect in terms of advertisers (Vorderer, 2000). Unlike television shows and movies that require the presence of a passive audience, video games require manipulation of control functions and progress through the game (Yuping, Shrum, 2002 Yuping, Shrum, 2005). Therefore, interactive features of video games can reduce the perceptive possibilities of the members of the audience, because their attention is divided between what we visually perceive and control the game (Grodal, 2000 Chaney et al., 2004; Nicovich, 2005). For example, Shapiro and Krishnan (Shapiro, Krishnan, 2001) found that, when the attention of the audience is divided between visually displayed advertising messages and listening to the sounds unrelated to them, remembering advertising messages becomes reduced.

Still, it is still not entirely clear how the interactivity of video games and the active role of players can affect the indirect effects of advertising when the memory comes to advertising messages (Yang et al., 2006). By conducting two studies on sports games Nelson (2002) found that players remembered from 25% to 30% of the brands that they saw immediately after they finished the game, and 10% to 15% of brands after five months of playing. A telephone survey conducted in 2005, which included testing of men aged 18 to 34 years, found that more than 25% of the players could not remember the indirect advertising from the last session of play (Activision, 2004). It is interesting to note that about 33% of the players in the survey mentioned that indirect advertising in video game influences their behavior at a later purchase (Activision,

2004). The research carried out by Chaney, Chaney and Lin (2004) found that players who prefer games with a first-person shooting cannot remember stating that his character "passed" virtual billboards in the game, but there were little or no recall of brands or even product categories displayed on billboards. Similarly, Grigorovich and Constantin (2004) pointed out the complex relationship between the type of indirect advertising (virtual billboards in relation to the displayed objects) and later ability to recall their names. For example, players tend to more easily remember brands when they were placed as billboards, from those that are otherwise presented related to the plot of the game, except when it comes to brands of cars. Accordingly, there is a possibility that indirect advertising has not reached full effect in video games, because the interactivity and involvement in the game that could affect the ability to perceive advertising messages. However, one must keep in mind that advertising in interactive video games has an impact on both explicit and implicit memory. Previous studies have shown reduced indirect effect of advertising on explicit memory than is the case with implicit. This means that even though players often cannot explicitly recall brands that were seen in video games, indirect advertising can affect their implicit memory and, hence, the subsequent buying decisions (Yang et al., 2006)

There are differences in the perception of the message and the achieved effects depending on how and where brands are "embedded". Studies have shown that audio-visual and verbal forms are easier to remember than purely visual forms. Russel and Stern (2006) found that verbal forms are better remembered than visual and that the connection with the action has no effect on auditory form, while improving memory of visual form. Due to the above mentioned reasons, the involvement in the game harms memory of discreetly displayed brands (Grigorovich, Constantin, 2004), while more prominent brands will probably be better remembered (d'Astous, Chartier, 2000).

Another disadvantage makes the violent content of many video games, which have been shown to instill an aggressive mindset and violent behavior of users (Anderson, Bushman, 2001), which may adversely affect the image of the brands that are advertised that way. Also, in some video games, realistic models of real weapons of real producers appear, which otherwise could not be legitimately advertised, therefore, indirect advertising of such products entails certain ethical questions.

3. CONCLUSION

Indirect advertising in computer and video games is undoubtedly a perspective media for advertising, taking into account the speed of the development of the games industry and the need to use innovative types of advertising in order to achieve the best effects. Based on the analysis of literature, it is obvious that it has positive effects on audience memory and attitudes when advertising strategies with are aligned with characteristics and preferences of target groups. Also, brands should adequately fit into the context of the game and be displayed in a way that enhances the gaming experience. Usage of interactive elements and, whenever possible, allowing players to personalize their characters has also shown to be valuable. The brand should be displayed in a way that is not invasive, but which draws attention and raises awareness of the brand. Finally, it is highly recommendable to conduct evaluation of the effects achieved by indirect advertising for the purpose of modifying and improving this practice in the future, so it would fit best the preferences of advertisers and audience.

ATTITUDES TOWADS INDIRECT ADVERTISING IN TV SERIALS

Milica Kostić - Stanković[1], Jelena Cvijović [*2]

Abstract: *This paper investigates the impact of indirect advertising on American television series audience in Serbia. On the basis of current theory in this area, the study assesses following audiences' attitudes on various types of indirect advertising. Full-length episodes were used as experiment stimuli and accompanied questionnaires were filled in natural environment in order to obtain more accurate results. Three groups of factors: presentation likability, proactive behavior and attitudes towards audio placements appear to be influential to the overall advertising success, while the proactive behavior generated the best results and, therefore, should be considered as the most important.*

Keywords*: indirect advertising, attitudes, audience, TV serials, experiment*

1. INTRODUCTION

Since contemporary marketing environment is more and more characterized by focused communications and media fragmentation, it is obvious that effects of traditional advertising are gradually reducing (Perez-Latre, 2009). Also, various electronic devices allow audience members to easily skip advertising blocks (O'Neill, Barrett, 2004), so they are becoming more distant to traditionally advertised messages. As a result, advertisers are searching for more innovative and effective ways to reach their target audiences, which resulted in increasing use of indirect advertising (Smit et al., 2009; Babacan et al., 2012), which is simply defined as brands' and products' inclusion in different media content in order to influence viewers' attitudes and behavior. This communication instrument is used for targeting more complex and more marketing-aware audience members (Hackley, Tiwsakul, 2006) because they most often do not perceive embedded products as advertising forms (Guido et al., 2010). That is happening due to the effective integration of products and brands within different situations of plotlines, which enables audiences to receive brand messages in more natural situations that significantly reduce the possibility of their rejection. Indirect advertising has, therefore, become one of the important differentiation strategies of corporate brands and products (Wilson,Till, 2011) which affect their brand image and viewers' attitudes towards them (Arrazola, 2013). Also, the important fact about product placement is that it is effective for all three sides – advertiser, which implements innovative promotional strategy, the medium or the production, which gains financial benefits and auditorium which gets new kind of branded entertainment (Russell, Belch, 2005).

Nowadays, indirect advertising appear in movies, television shows, music videos, novels and video games. Although mediums of indirect advertising differ, the main purpose of its every form is to obtain the ad recall and positive affective reactions (Moser et al., 2004; Lehu, 2007). That happens most often due to audience's positive perception of a medium or plot protagonists, which reflects further on the brand image or attitude and, eventually, may stimulate purchase behavior (Wiles, Danielova, 2009). Therefore, one of the main types of advertising effectiveness are brand attitudes (affective outcomes) (Balasubramanian et al., 2006). However, indirect advertising should be used moderately, as exaggeration may produce a negative impact on the audience and its effectiveness may decrease, as they gradually start to recognize the advertising intention (Homer, 2009; van Reijmersdal et al., 2010). Therefore, it is highly important to detect reactions and preferences of target audience first, before implementing any of indirect advertising strategies. Although this kind of research is common in USA and some European countries, in Serbia it is still not the case. So, a gap is detected in both, theory and practice, which should be thoroughly investigated in order to improve advertising practice in developing countries and gain certain value for both, advertisers and audience and make a step in that direction.
.

2. ATTITUDES TOWARDS PRODUCT PLACEMENT

The study was performed in 2015. On the sample of one hundred and fifty seven participants. All respondents, aged 19-23, were undergraduate students at the Faculty of Organizational Sciences, University of Belgrade. Majority (70.5%) of respondents was female, while 29.5% were male. All respondents

voluntarily participated in the research. This research was based on watching of three episodes of American serials shown on television in Serbia by participants and answering questionnaires. These episodes were chosen as the experimental stimuli because they contained at least 23 examples of product placements and their plot can be considered relevant to the sample of participants. Two of the episodes lasted approximately 20 minutes, while the last one lasted little less than 42 minutes. The questionnaire consisted of various statements that could be evaluated on the Lickert scale (from 1-Absolutely disagree to 5 – Completely agree). Following statements appeared in the questionnaire:

In this part of the research, the goal was to investigate which groups of positive attitudes related to indirect advertising influence placement success best. Previous research have shown that the vast majority of viewers takes a positive attitude towards indirect advertising (Kramoliš, Drábková 2012), especially as it contributes to the viewing experience (Redondo, Holbrook 2008; Sung et al., 2009). However, opposite situation can happen – it can trigger counter arguing or irritation (Cowley, Barron 2008; van Reijmersdal 2009) and negative attitudes if indirect advertising intrudes viewing experience (Cowley, Barron 2008; Wei et al., 2008). Russell (2002) found that viewers' attitudes were more favourable in case of visual and low plot connected and auditory and high plot connection placements, than in case when they were incongruent – visual with high plot connection and auditory with low plot connection. Some researchers found that inclusion of the brand is crucial for the effectiveness of indirect advertising (Kamleitner & Jyote, 2013). Indirect advertising is accepted as an essential part that adds value if they are perceived to be connected to the plot (Yang, Roskos-Ewoldsen, 2007; Yoon et al., 2011; Dens et al. 2012). On the other hand, if indirect advertising is observed as intrusively integrated sales pitch, the effects could be negative (Homer, 2009). Dens et al. (2012) found that plot connection is not a sufficient factor to cause positive effects more than a marginally significant change towards positive attitudes. Some researchers found no difference in attitudes toward subtly and blatantly placed brands if program liking is moderate and exposures are limited to one viewing (Cowley, Barron 2008; Gillespie et al., 2012). The few studies indicated that prominence can have a negative effect on attitude toward placed brands (Bhatnagar et al., 2004; Dens et al. 2012). On the other hand, subtle placements are less likely to provoke negative shifts in attitudes. Law and Braun (2000) found that there is an increase in brand choice after viewers' exposure to (Cowley, Barron 2008; Gillespie et al., 2012). Indirect advertising may also improve brand attitudes without necessarily be highly recalled (Cowley, Barron, 2008). Also, positive attitude is transferred from a well-known actor or well-liked scene to a presented brand. However, there is also a potential negative shift in viewers brand attitudes after they feel forced to view some brand information (Lee et al., 2011).

In order to detect the most influential groups of attitudes, exploratory and confirmatory factor analysis of obtained results were performed and three crucial components were determined (see Table 1) that appeared to be correlated with indirect advertising success, measured in percentage of recalled brands. The first subgroup, titled "Presentation likability" (PL), represents the general attitudes towards brands shown in TV serials and it consists of following statements: "The way brand is used or shown in TV serials affects my attitude towards it" (marked as PL 1); "When character I like uses some brand in TV serials, my attitude towards that brand becomes more positive" (marked as PL 2); "When character I dislike uses some brand in TV serials, my attitude towards that brand becomes negative" (marked as PL 3). The second subgroup, determined as important, was the one called "Audio placements" (AP), which consisted of attitudes towards placements that are solely mentioned in TV serials and it consists of following statements: "I don't mind when characters in TV serials mention or talk about some brands" (marked as AP 1); "I like when characters in TV serials refer to some brands" (marked as AP 2); "I don't mind when names of famous brands are often mentioned in TV serials (marked as AP 3)". The third subgroup, titled as "Proactive behavior" (PB), consists of statements regarding making certain actions after seeing product placements in TV serials. They are: "I actually searched for brands I saw in TV serials on Internet and/or in stores" (marked as PB 1); "I wish to try certain brands after seeing it in my favorite TV serials" (marked as PB 2); "I started using some brands after seeing them in TV serials I regularly watch" (marked as PB 3). Obtained regression factor scores of three components were introduced into multiple regression analysis and results imply that the third component (Proactive behaviour) is statistically significant predictor of recall success (standardized $\beta = 0{,}170$; $p < 0.05$) (see Figure 1).

Table 1: Principal component analyses of attitudes towards product placement and their impact on overall placement recall

	Component		
	1	**2**	**3**
PD2	0.853		
PD3	0.829		
PD1	0.795		
AP1		0.886	
AP3		0.853	
AP2		0.792	
PB4			0.882
PB5			0.805
PB6			0.724

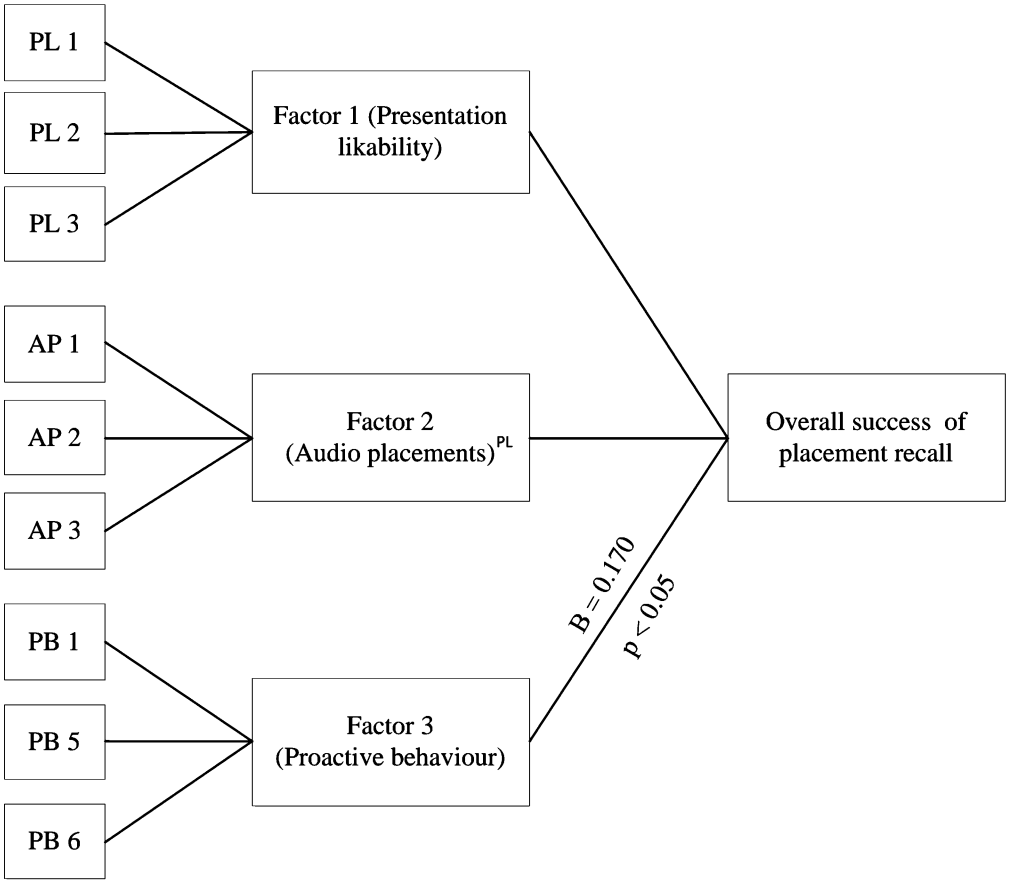

Figure 1: The impact of three groups of attitudes on overall placement recall success

The important finding is identification that proactive behavior of respondents (searching information on placed brands, desire to possess and consume certain brand and actual consumption of placed brands) influences the overall success of indirect advertising. In another words, placed brands indeed generate viewers' action, and, therefore, reach the advertisers' major goals. Since there are certain limitations of this study, it can be used as the theoretical basis for more complex analyses in the future.

3. CONCLUSION

This research supports the growing theorethical and empirical evidence that indirect advertising has become effective marketing communication instrument. It has shown that it impacts audience in Serbia, although it is sill not frequently used in domestic media space. Since viewers are often exposed to indirect advertising incorporated in popular foreign TV serials that are shown on national and cable television stations, it is obvious that its effects should be investigated thorougly. This research offers basis for future planning and implemetation of indirect advertising as communicaation instrument, in accordance with viewers perceptions and attitudes, in order to obtain desired effects. The results show that advertisers should place focus on more subtle placements, although it might appear that explicitly integrated ones achieve better results.

IMPROVEMENT OF SERVICE ENVIRONMENT AT POSTAL NETWORK UNITS

Bojan Jovanović*[1], Dragana Šarac[1], Momčilo Kujačić[1],
[1]Faculty of Technical Sciences, University of Novi Sad
*Corresponding author, e-mail: bojanjov@uns.ac.rs

Abstract: *National postal operators have an impressive network of postal units, which occupy prestigious locations in settlements. Customer's waiting is an inherent element of the services provision in postal network units. Improving service environment, or interior of the postal unit has the same importance for customers as does the service level of the requested services. This paper considers the improvement of waiting process during the realization of service delivery at postal network units. Waiting phenomenon is analyzed. Current situation at postal network units is observed. Possibilities of improving the current situation towards developing a marketing concept are considered, in order to create a proper service environment.*

Keywords: *postal unit, customers, service environment, waiting time, digital signage*

1. INTRODUCTION

The realization of activities in service industries is usually inseparably connected with forming of queues. Considering that complete elimination of queues is economically unjustified, the efforts are focused to establish optimal levels of service and to find a balance between customer requirements and requirements of the service provider. This is also the situation in postal office units.

National postal operators are faced with important changes in their business area during the last decades. The task that is set in front of them is to reform themselves into market sustainable entities, that can successfully deal with growing direct and indirect competition. Besides direct competition, that provides the same kind of services as national postal operators, indirect competition with technology development provides substitutes for traditional postal services, which leads to decreasing demands for services offered by national postal operators.

Meeting universal service obligation, national postal operators have developed significant infrastructure capacities over time, which is primarily reflected in extensive network of postal units. Besides the burden which that resource represents in relation to maintenance costs, it has a large potential for improving the market position of national postal operators, which is not fully utilized in most cases.

The quality of service delivery at postal network units, from a customer's point of view is most commonly viewed as time spent waiting before being served at an adequate counter. In that way, one of the basic questions is how to improve conditions in waiting space and to achieve that queueing process passes as painlessly as possible for customers. If value-added services are not provided in postal units, technological improvement will dramatically reduce the scope of realized services.

2. CUSTOMER WAITING EXPERIENCE

Waiting is usually inseparably connected with a sense of displeasure. Pleasure can be defined as a dimension of experience that refers to hedonic tone (Barrett and Russell, 1999). Taking into account that waiting comes in between customers and their wishes, waiting often creates frustration and lower level of the sense of pleasure. Shorter queues lead customers to desired aims more quickly, thus contributing to a more positive overall evaluation of the service (Maister, 1985). People are also more likely to notice others who are in front of them in the line (perceiving them as an obstacle), rather than those standing behind them in the line. The question is why the number of people who are behind a particular customer is also important. Certainly, a large number of people behind a particular customer indicates a large queue length. Perceiving a large queue can lead the customer to two conclusions (Zhou and Soman, 2003):

- it may serve as a social validation that the service is worth waiting
- it may lead the customer to expect a longer queue if he returns at another time

These conclusions make the customer less willing to leave the queue. Also, the number of people behind can lead to the process of social comparison. It becomes obvious especially when waiting is unpleasant. In that case a large number of customers behind is experienced like "there are customers in a worse position". On one hand, waiting process is focused on achieving a personal goal, and at same time it contains a social dimension, where other individuals want to achieve same goal. This act of social comparison with people in the queue who are behind, who are not so lucky as the customer making the comparison, can contribute to a feeling of comfort (Zhou and Soman, 2003). Some of the basic motives for social comparison include: self-evaluation, self-improvement and self-preservation (Taylor et al., 1996). The motive of self-evaluation originates in a human need to have a stable and precise mark for oneself. When objective standards for self-evaluation do not exist, people usually turn to social comparison, in other words they evaluate themselves through the prism of comparison with others. The motive of self-improvement refers to the desire to improve oneself. Self-preservation refers to the interest in maintaining positive feelings about themselves. Since waiting is an unpleasant experience that causes frustration and stress, customers in queues may search comfort and try to reduce anxiety and anger through comparisons with users behind them. Seeing a large number of people behind them, users can have a positive affective reaction, which leads to the decision to remain in the queue (Zhou and Soman, 2003).

Negative reactions in terms of waiting are usually associated with the outcome of a certain experience and a choice that results in the experience (Voorhees et al., 2009). The outcome of the experience is covered by the user's anger, which represents a negative emotion that arises from the experience of waiting. Customers' regret can be evaluated by their selection of a particular service provider. The evaluation of users' choices is not only influenced by their experience, but also by the perceived benefits from missed alternatives (Tsiros and Mittal, 2000). After negative experiences such as waiting, customers often experience regret about their choices. Regret in service realization can be experienced in a number of situations from a sense of false timing for make a decision to dissatisfaction with the service. As a result customers can regret their decision to visit a post office if there is a large crowd, or be dissatisfied with empathy of workers at the counter.

3. MARKETING COMMUNICATION

Marketing communication is expected to provide feedback from service customers, as well as from all entities that have a direct or indirect impact on business results. Postal services operators realize marketing communications through:

- advertising - a form of communication with the purpose of influencing the current and potential customers, and their selection of services provided by the postal operator;
- public relations - represents "management function that establishes and maintains mutually beneficial relationships between an organization and the public on whom its success or failure depends" (Cutlipet al., 2000);
- sales promotion - includes additional actions to increase the scope of provided services that are aimed at rewarding existing and attracting new users (various giveaways, promotional price for a certain period, "aggressive" campaigns in the areas of service implementation, etc.);
- personal selling - postal operators implement this set of activities through counter workers or sales representatives who are focused on the segment of large customers; it requires an appropriate structure of counter workers, which is the result of: selection of workers, constant training, information and stimulation; vendors of services for large customers are required to have: a highly-professional staff who is well familiar with technology, postal services, user characteristics, characteristics of competitors, good verbal skills (presentation skills), etc.

Taking into account that postal units are places where customers come to a direct contact with postal employees, they have a considerable potential for the implementation of the marketing concept. An appropriate mix elements of marketing concept can contribute to improving the customers experience with queues.

3.1 Service systems

Primary questions posed in organizing service systems are (Durrande-Moreau, 1999):

- How can we help customers during the waiting?
- How can we make this time more agreeable?
- How can we avoid impatience?
- How can we give managers relevant recommendations concerning this weakness in the quality of their service?

Since the customer's satisfaction with services is under the influence of perceptions of waiting time, an alternative approach to the problem of waiting can be made in finding ways to make the passage of time as fast and comfortable as possible (Pruyn and Smidts, 1998). Maybe one of the easiest conditions for the queue management is the control of the environment in which it takes hold. In terms of the realization of the service, ambience or atmosphere is often designed to provide customers satisfying experience with the service and to create a desired image with the aim of causing a positive evaluation of service quality.

Customer behavior is the result of his emotional state and his individual experience that is influenced by the environment (Mehrabian and Russell, 1974; Barrett and Russell, 1999). The elements of the environment can cause different customer emotions, which results in a certain customer's behavior (Chienand Lin, 2015). Environmental elements include ambience, design and social elements (Baker et al., 2002). Ambient elements can be seen as sensual (lighting, temperature, music). The design elements are tangible and visual (color effects, furniture, spatial layout). These elements belong to the group of physical elements and can be an important factor in managing the perception of time, as well as the emotional response on waiting (Hui et al., 1997).

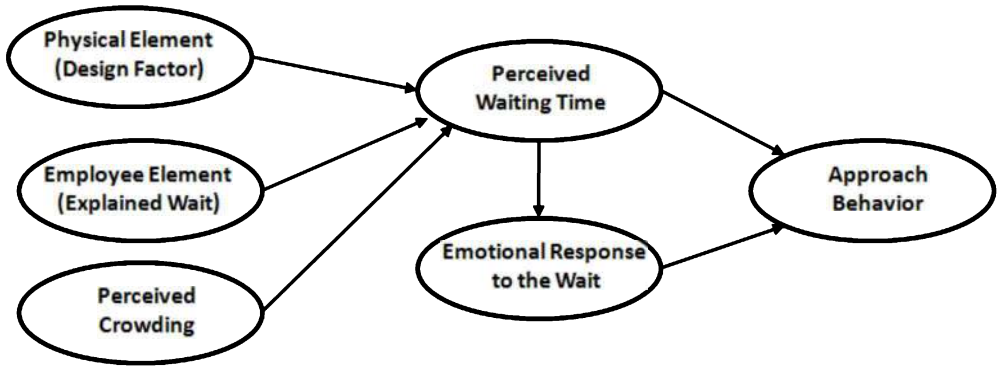

Figure 1. Estimates of the perceived waiting time route (Chien and Li, 2015)

In Figure 1 it can be seen that the observed waiting time is directly influenced by: physical elements, employees and observed level of congestion in the realization of services. Perceived waiting time causes an emotional response on waiting. Finally, the perceived waiting time together with emotional response on waiting, determine the behavior of the customer while waiting to be served.

The theory of justice can be used for grouping customers inside social interaction with employees, where interaction can be viewed from the perspective of interactional and procedural justice (Goodwin et al., 1991). Interactional justice during waiting includes visibility of employees, whereas procedural justice includes fairness and an explanation for waiting. In the case when the number of employees is less than the current state demands, customers becomes frustrated and angry. This situation is particularly evident in cases when even if it is obvious that the system is overloaded, and the activation of new available capacities (new service channels) is missed.

3.2 Digital signage

Advertising activity contains several vectors (Marion and Berengen, 2004): a still image, a moving image, a sound and a written word. With the aim of better understanding the conscious and unconscious messages transmitted by an advertising spot there are two possible approaches: semi-pragmatic and audio-visual.

Semi-pragmatic approach considers two areas of communications: information content and relationship that is established in the advertising message. The subject facing advertising spots faces the picture first, which has a greater power of integration than words. Regardless of the fact that images belong to the domain of the unreal, they provide the illusion of immediacy. The development of pictorial representation (from drawings and paintings, photography to the film) resembles a permanent quest towards a greater degree of realism. It can be said that there are tendencies to cover up the unreality of images in favor of transparency (attempts to make an image a direct connection with reality, not just a show of reality). Image tries to provide certain segments of reality, usually through already familiar forms. The processes of assimilation on the basis of proximity (i.e. on the basis of similarity) represent relatively unconscious cognitive processes. Such processes have influenced the formation of opinions and customers shows, in that way that customers are not aware (this is used a lot in advertising with the aim of reaching to the basic cognitive level of customers).

The audiovisual media are formed by integrating sound, image and movement, where the movement connects the other two elements, enabling the visual aspect of the current dimension in order to achieve the illusion of life in space and time. Movement dictates a tempo in audiovisual media where the arrangement of rhythmic, dynamic and kinesthetic sensations forms a whole that represents a coherent set. Such processes use audio and visual channels, so it can be observed like a transfer of meaning between two or more sensory systems (processes of synesthesia). Taking into account that processes of synesthesia belong to relatively unconscious processes, for advertisers they are an effective way to persuade potential customers. Audiovisual media can be based on the principle of empathy or on its absence (Marion and Berengen, 2004). Digital signage is a rapidly evolving market, whose products replace paper-based posters with public electronic displays. The success of this concept is based on reducing the costs associated with printing and updating of printed materials. More and more companies are starting to use this type of media and its capabilities, combining them with various forms of external activator (video processing, RFID, NFC, etc.). So the basic question is how to provide the appropriate content for a specific segment of customers at the appropriate time.

Digital Screenmedia Association defines digital signage as "the application of electronic displays or screens (LCD, LED, plasma, etc.) for delivering entertainment, information and/or advertising in public or private spaces outside the household". Basic components of digital signage include: display / screen, content on the display and some form of content management system.

Unlike traditional signs, digital content can be changed quickly. Another advantage is reflected in the fact that the content of digital signage can be delivered in different ways besides static image, (content can be interactive via the touch screen or via motion control). Digital signage can include technologies that enable a certain system to recognize the observer's age, sex and in some cases applies technology to recognize facial expressions. These technologies offer a possibility for digital signage to deliver targeted messages in a very efficient way. During the specified time interval, a larger number of messages adapted to specific audiences can be broadcast by using techniques such as daily broadcasts (period of time during the day is divided into segments so that a targeted message can reach target audience at the right time). Through digital signage the interaction between viewer and content is enabled (by touch or navigating through mobile devices). Another advantage of digital signage is reflected in the fact that it can achieve audience analysis by specific content. Apart from these obvious advantages of digital signage, the biggest obstacle to wider application is a relatively high initial investment (although, in the long run, the return on investment is much higher with a digital signage in comparison with traditional advertising) (Bauer et al., 2011).

There are three basic types of digital signage related to (Kelsen, 2010): point of sale, point of wait and transit hubs. The main objectives of digital signage at the point of wait are: communication through key messages that are oriented on brands and products related to service providers, increasing customer satisfaction so that it affects their perception of waiting time and providing interesting and relevant content in different ways. In situations where customers are waiting for the realization of certain services they represent "captive audience" (Schaeffler, 2008). Digital signage, that is positioned and presented in a good way (with appropriate and stimulating initial content) can contribute to not only the feeling of faster flow of time but also leads to the inclusion of other products or services that are provided to customers.
Factors such as the size of the display, installation height or angle of the display in regard to the direction of customer movement can have a significant impact on the user's perception. Nevertheless, the content of advertising has the decisive influence on customer's expectations, in other words whether the user expects interesting content (Müller et al., 2009). If advertising transmits relevant information, the customer will see that as a benefit, otherwise it can be seen as an unnecessary cost for the user. Digital signage systems include at least three key market participants, depending on whether the platform and space are provided from the same or different entities (Bauer et al., 2011):

- advertiser is a participant whose product or service is promoted,
- customer is the person to whom the content is directed
- and platform provider is an entity that provides digital signage network (infrastructure, software, customer rights management, content management).

There can also be a space provider, as the owner of the space where displays are installed. The space provider can often be the same entity that promotes a product or service or entity that provides a platform for advertising.

Considering the increasingly demanding customers, modern advertising should also fulfill the requirements in terms of aesthetic appeal, informativeness, emotional outreach to observers, and bring observers to the state of surprise through appropriate advertising rhetoric (Beyer et al., 2009). Computer techniques for

reading, analyzing and influencing the cognitive-emotional state of the customer represent a new field of research to discover the range of external conditions such as pleasure, boredom, anger or intensive mental activity. By merging the patterns of behavior with physical information about the customer, the system is enabled to become aware of the customer.

Adapting to the customer means adjusting the process of inclusion of the observer and the inclusion of balanced content according to the customer's cognitive-emotional state. An application that involves downloading "fingerprint" of observers to detect his content awareness and facial expressions in order to reach to the indicators that indicate whether the applied social technique is justified from his point of view, or an another type of content will be selected and put to the forefront. Thus, the system can transmit more information or more entertainment content if an observer shows indications of declining attention to details or emotions that may prevent the effective reception of information.

Basic advantages of digital signage over traditional static tags are reflected in the fact that the content can be changed instantly, at any time without major effort. The content can be adapted to the context or to present customers, and may even be interactive. It can have the following functions:

- informative - providing various pieces of information, which are important for the participants,
- advertising which refers to the location where it is,
- advertising for third parties,
- improve the customer experience - reducing perceived waiting time,
- influencing customer behavior - incorporating in the queue management,
- brand building – as a part of the decor, which creates an image of a certain brand.

4. POST OFFICES OPPORTUNITIES FOR ADVERTISING

In order to improve the customer's experience with the service process in post offices, and bearing in mind the opportunities to influence the subjective customer experience with past waiting time, we are considering the advertising potential of post offices. Apart from that, this tendency makes space for postal operators to improve their relations with customers, as well as to show them the full range of services that can be provided.

The continuous changing of market relationships creates the need for some kind of organized public relations. The basis of the relationship with the public is making an impact on the public, establishing and improving the image and so on. The purpose of communication with the public is to achieve marketing goals and defined policies of business operators.

Delayed pieces of information have extremely negative consequences on the postal systems. In order to ensure the survival of the postal systems on the market, it is necessary for them to own a competitive system for the exchange of information. In that way, the necessary preconditions are met for the assessment of their own capabilities, and also for defining business strategies. Segments that are essential for the survival on the market are: customers, competitors, the government and the public. Business communication with customers of postal services represents a continuous activity, which includes efforts to identify the needs of customers and familiarize them with the services.

Postal system can be emphasized as an important channel for advertising. It is estimated that around 300,000 users pass through postal network units of PE Post of Serbia per day. Advertising can be placed in three segments: for their own use, for the purposes of third parties and for the public needs (the state and state authorities). In the Post of Serbia there are certain activities within the first two options, which are grouped into the following options that are available (Post of Serbia, 2015):

- advertisement on poster places (the possibility of placing the poster content in over 500 post offices in the territory of the Republic of Serbia);
- advertisement by holders gives the availability of promotional materials (flyers) in places where holders are arranged;
- delivery of flyers at counters in postal network units (after the requested service is performed, employees at the counter directly deliver the advertising materials (flyers);
- display of branded items (branded items of third parties are placed on counters within a counter hall);
- promotion in the postal network units (placing of promotional equipment (stands), the presentation of products or services with the engagement of promoters, giving the possibility of direct contact with potential customers);
- advertising on plasma screens (88 of most frequented post offices are selected and they are supplied with plasma screens);

Plasma displays are supposed to have the greatest advertising potential. However, this concept has not been developed in the direction to fully exploit opportunities that Post of Serbia has. The original content of broadcast consisted of advertising sequences which referred to the segment of Post Express service. The question that has not been resolved in the development of the concept refers to the elements that influence customers and draw their attention to the broadcast content. The answer to this question may be found in the analysis of customer's interest points during the process of waiting. In that situation the customer is primarily interested in waiting time. Queue systems with tickets are certainly an optimal solution for these problems. They provide unquestionable comfort for the customers, when their presence is not required at a particular place to "defend" their position in the queue. In addition to that, their attention is attracted to the monitor displaying the data concerning the direction towards a defined service channel. That approach leads to the situation where the customer moves are forced, in other words his attention is directed to the control monitor. When all the prerequisites are fulfilled, a high level of efficiency of advertising content can be achieved. Unlike the previous approach, where content existed, but there was no certainty that it would reach each customer waiting in the line, the situation is changing in that each customer (who wants to be served) is actively or passively directed to advertising sequence.

The previous business of postal operators shows that the total population of customers is not homogeneous. Therefore, it is in their interest to divide users into characteristic groups. The most massive segment of customers (standard) requires special attention, as their relationship with the employees directly affects the service quality and the overall image of the company. Considering the range of realized services, they are subject to standardization, so that they can be predicted and organized (a customer comes to a pre-prepared and selected position, requiring a service for which the staff is adequately prepared). Models of behaviour with certain categories of customers are derived from a certain business policy and appropriate business strategies through a process of internal communication. Predictability of communication allows standardization of customer's requirements. Among the important factors that affect the process of communication with this group of customers are: environmental conditions, organizational behaviour and direct communication.

The counter is not only a place for work and provision of information, but it can also serve as a place for getting information (proposals, suggestions). Counter workers are expected: to professionally implement business activities, to be polite, kind, hardworking and tactful in contact with customers. The activities that take place in direct relation with the user are reduced to: customer access, demonstration services, overcoming any obstacles, contracting, monitoring of service and development of cooperation.

Besides the practical value for development of its own marketing concept, the space of postal service units can have significant commercial value since it can be made available to other advertisers, as well as to the government and government authorities (taking into account the number of customers that visit postal network units during the day and territorial coverage at the national level). Traditionally close relationship between the national postal operator and the government and its improvement provide timely access to certain information that can be of great importance for the further development. The decisions made by the national authorities often have crucial consequences on the economic development of certain subjects, so the communication with the state should be given special importance. Better positioning on the market is certainly more likely to be achieved if notifications concerning certain legal provisions or guidelines for future economic development can be achieved timely.

A postal operator as public service is expected to bring closer the organs of local administration or government authorities, and these expectations will be fulfilled within the public role. On one hand, important data will be provided for customers on their local level (announcements, advertisements, lines of public transport, traffic congestion, weather information, water level forecast, service information, cultural events, opening hours for upcoming holidays, etc.), and on the other hand data relating to the entire territory of the country (cultural events, road conditions, weather forecasts, congestion at border crossings, activities and campaigns of individual department, marking national holidays, etc.). The next stage could be related to the outsourcing of certain activities from local and government authorities. During the process of waiting for the service realization, customers could be able to use a mobile application for electronic download of certain forms. After filling in the form, it could be sent back to the appropriate authority. An opportunity for outsourcing is also an opportunity for the postal operator to use the resources more efficiently, and for administrations to reduce the costs of their operation by giving a chance to the postal operator, as an institution of trust, to realize some of their activities.

5. CONCLUSION

The national postal operators in many countries are going through a difficult period of transformation as a consequence of transition from a monopoly position to a state of complete liberalization of their environment. The experiences of postal administrations indicate that considerable resources are invested to develop postal network units at a high level. Besides investing in the exterior and interior elements of postal units (in order to provide customers with a more comfortable environment while waiting), investments are also made in technology in order to reduce work activities in contact with customers to the smallest possible period of time.

The situation in terms of queuing at postal network units is implemented either through the queue barrier or the absence of any mechanism of control (customers respect the FIFO rule or give way to vulnerable categories of customers). In order to improve the customers experience during the process of waiting for the service realization, the possibilities of postal units as advertising channels are observed.

The implementation of the queue management system with tickets, where LCD monitors are used, although it requires a significant initial investment, can achieve all the goals that are set in front of it. That approach in postal network units creates an environment that contributes to a better position of postal operators on the advertising market. Pillars on which such orientation is based are: the promotion of its own range of services, the public role of the postal operators, the commercial role for third parties and the impact on the subjective perception of time.

OPTIMIZATION OF LOCAL MEDIA BUSINESS IN THE CONDITIONS OF TURBULENT ENVIRONMENT

Dalibor Bubnjević*[1]
[1] NIP „Zrenjanin“ a.d. Zrenjanin,
*Corresponding author, e-mail: daliborbzr@sbb.rs

Abstract: *The local media are facing strong competition, educated and self-aware audience in the choice of content. As a result of technical, economic, social, cultural and global convergence, it leads to the founding of new communications paradigm. New media which appear do not reverse the previous but rather unite their characteristics. The survival of journalism at the threshold of the information society is based on the creation of a broad portfolio of media products and multiplatform expertise of staff which need to win over a large number of audiences. The fact is that citizen journalism is gaining in importance thanks to the possibilities offered by the Internet. However, some theorists predict the survival of professional journalism at the local level, as new media technologies are not acceptable for all layers.*

Keywords*: marketing, local media, optimization, business environment, strategy*

1. INTRODUCTION

The means of mass communication have existed for about 150 years. All this time the **media's mission** has not changed: providing the public with *complete and accurate reports* on all public matters and *mediation in expressing opinions*. Today the media are *engine of globalization* and often *determinant of the organization's life of the individual*. The degree of their development in a country is conditioned by a number of factors: economic wealth, the achieved level of technological achievements, scope and schedule of the audience, political system, cultural environment, etc. The media industry is very similar to the function of research and development (R & D) in the other branches: a necessary technological sophisticated equipment and skills, retains the character of the labor-intensive activities, the marginal cost of acquiring a new customer is low, however, the need to develop economies of scale.

Today, **the media public** is *more educated and self-conscious in choosing content*, and journalism reserves the traditional role in society (Milivojević, 2012):
[1] The collection, selection and formation of conscience that are of importance to the public debate (gatekeeping role);
[2] Definition of issues of public interest (agenda setting role);
[3] Saving Democracy (watchdog role);
Above all, journalism is searching for its new identity in a coordinate system that is formed by the logic of speed, brevity, competition and superficiality.

The print media are in an *unenviable position* due to *the technology they apply*. "Newspapers have long been the fastest mass medium. Advances in technology and, above all, taking the primacy of audio-visual media have made the newspapers come by little into the background" (Bulatović and Bulatović, 2009, p. 29). *Readership is declining*, especially among young people, due to changes in lifestyle (for example, flexible working hours). Advertisers are increasingly opting for *advertising on the Internet* (particularly in the field of real estate). The number of specialized websites that allow presentation of content on more attractive and less expensive manner is increasing on the global network. Taking into account the facts enumerated, it is not surprising that some theorists predict an apocalyptic end of the press!

However, there are numerous **advantages of print media** (Bulatović and Bulatović, 2009): 1) *more thoroughly (more interpretative) coverage* of people and events, taking into account all aspects; 2) readers achieve *better control over the elements of news* by opting for articles that are more relevant to them / hold their attention; 3) daily disclosure of *important information for the life of the community* – people born, married or died, promotional campaigns, etc.

In the new millennium, so-called general readers, who are interested in a wide range of topics (from the world news, through the national to local), is increasingly declining. "One thing is quite certain, and that is that the press in its new guise, or online edition, can integrate all the traditional media, and therefore

becomes a participant in the most important competition in its centuries-long history" (Ugrinić, 2012, p. 88). This conclusion is the result of the realization that **the new media does not reverse the previous one**, but rather *consolidates its features*.

The influence of information and communication technology has led to **the transformation of journalism** into **the media business**. It is *a mature market* in which the information is no longer viewed as a commodity but as a service that has a limited time value. The goal is to find the optimal business concept to charge it. Changes occur in (Stamenković, 2015): 1) the method of distribution of content - the chain of production is being shortened, thanks to social networks, 2) media content - anyone can create information ("social activism"), 3) production. As a result of technical, economic, social, cultural and global convergence, it leads to the founding of *new communications paradigm*. Modern technology does not impose a specific editorial policy but, above all, influences decisively on journalistic practice and organization of the newsroom.

Technological determinants influence **the change of use of the media** and modification of **the structure of the media content**. Two groups coexist (Milojević and Ugrinić, 2011): 1) *technological enthusiasts* – who are ready to face the changes, show an interest in learning new technology, believe in the progressive potential of new media; 2) *technological skeptics* – who are traditionally oriented, express opposition to the adoption of new technologies and trends, seeking to preserve the existing professional methods.

The Internet as a meta-media has enabled a drastic increase in the number of participants in the public dialogue (debate). Consequently, the media *have lost their right of priority in the public sphere* and *are no longer the only privileged producer* of public information. The business model on which the industry they belong is founded, is coming to the collapse, and the profession is at a crossroads. "Many problems in the traditional media, from political pressures and ever growing influence of economic power centers to ever more difficult working conditions and financial situation in which journalists are, media professionals are forced to seek new business models in order to survive in the media sphere" (Stamenković, 2015, p. 845). In response to the new circumstances, **the concept of entrepreneurial journalism** has been developed in the United States. The increase of productivity, efficiency and profitability is required. The emphasis is on economy of scale, analysis of competition and the potential for further development.

The survival of journalism at the threshold of the information society is based on *the creation of a broad portfolio of media products* and *multiplatform expertise of staff* which needs to win over a large number of audiences. New professions in the media sphere are created, such as the organizer of content (*content curation*). Journalists and editors are no longer considered in isolation in relation to the media business. They are expected to think about the advertisers. Requirements for achieving the (positive) financial results and the need for editorial freedom create **systemic conflict**!

2. PARTICULARITIES OF LOCAL MEDIA BUSINESS

The famous saying "Life is global, living is local" most graphically explains **the cause of survival of the local media**! "The Future Foundation" has concluded that the daily activities of individuals occur (on average) at a distance of 22.54 kilometers: distance from work - 13,04 km, distance to the store - 6.11 km. Radius of movement of elderly people and women and men with low income is less than the average (Aldridge, 2007)! The connection with the place of residence is based on convenience life and feelings (sentiments). Owing to the above, the need local news has developed. It is particularly evident during the aging process of an individual.

Commercial local media are an important factor in informing the community. Many regard them as guardians of indigenous identity! Hence it is not surprising that *public attaches great attention to them*. For example, in 2005 the UK's readership of local / regional media was higher than the followers of national daily newspapers. France and Canada recorded a similar trend, ie. regional media dominate. In the new millennium, they are faced with the emergence of web journalism, the development of digital platforms and multimedia services, unwillingness of advertisers for pay for advertising via global network. Due to *financial difficulties,* they are often not in a position to transform and progress technologically. "The situation is such that they are trying to cope with unfair competition and survive in the market by using different strategies: some of them see the way out of the unfavorable economic situation in the help of the state and the others in the development of advertising via the Internet and e-business" (Krstić, 2012, p. 118). Regardless of the approach that they choose, the media managers are aware that if they do not adapt to changes in the environment, there is little chance for survival between Scylla and Haridb of the new millennium media market.

The advantages of the local media are:

- *They are part of the community* – they are formed as a testing ground for answering questions that are of importance to the daily life of an average citizen (local exclusivity and deep research of news background). "The main reason for the continuation of the popularity of local media is in their ability to capture and celebrate the life of the community "(Aldridge, 2007, p. 29);
- *They realize direct contact with readers* - reporters "live with them";
- *The audience is defined at the level of locality* - advertisers are aware of the above facts and therefore use them to publish job ads, advertisements for local products / services, etc .;
- *The level of freedom* (moral) *is higher*,
- *The ability to diversify content*- editorial is facing a complex challenge, because it needs to adapt content to different demographic groups.

They are considered to be **the need of democratic society**, because it is the place where local democracy takes place! Although located in the center of the culture of professional journalism, *they are often ignored* by the public and the academic community.

The process of digitization provides the technical basis for *further localization of news* and, at the same time, *intensifying competition* in the battle for the favor of the audience. In recent years there has been a **consolidation of the local media market** in most developed countries, which is characterized by: non-appearance *of new actors*, the absence of *divestment*, earning *profits*. In mid-2005 in the United Kingdom, the key publishers in the relevant segment realized the profit rate of 28% to 30%. To survive in stagnant and declining industries, *active and aggressive management* is necessary. Companies are opting for various business strategies:

- *Rationalization of assets* - centralization of administration (for example, departments of Human Resources and Marketing) changes in the role of editors, etc.;
- *Reducing the cost of employees*;
- *Economy of collection and use of content* - the use of *citizen journalism*;
- *Creation of multiple and targeted content*.

The development of inexpensive printing technologies at the end of the twentieth century largely contributed to the proliferation of **local press**! "They are intended for informing local community and are very popular in their environment. Small groups of people regulate and prepare them, they are cheap and usually financed by the local community" (Bulatović and Bulatović, 2009, p. 35). They act independently or as part of the media group. In the countries of the European Union regional and local newspapers are increasingly dominant in relation to the national! Readers are becoming saturated by global issues and increasingly give attention to the events and the people in their environment. Regional newspapers are *different from supplements* in national publications (they have a different concept, greater freedom in the choice of topics, familiarity with readers, fewer barriers, etc.).

Local press has to be *reactive, reflexive and non-profiled*. It has *a limited shelf life* (from one day to several weeks) and *the limited number of potential customers* (who live in a particular geographic area). Consequently, logistical issues are becoming important. Readers are heterogeneous, increasingly *seen as customers / consumers* rather than as citizens with rights and responsibilities in the public sphere. *Primary target groups* are individuals older than 50 and residents who are in the process of forming a family. It is insisted on *maintaining contact with the audience*(for example, the publication of positive and micro local news). Volunteer journalists are becoming more important (*volunteer community correspondents*).

The future of local newspapers will largely be determined by the attitude of the audience formed towards the mass communication media. The fact is that *citizen journalism* is gaining in importance thanks to the possibilities offered by the Internet. However, some theorists predict *the survival of professional journalism at the local level*, as new media technologies are not acceptable for all layers. Some social groups question the quality and credibility of the information given by the amateurs on the global network, since they do not possess the necessary knowledge and skills to perform a very responsible job. That target group actually pays attention to reporting on local issues in an analytical and in-depth way!

3. BUSINESS ENVIRONMENT

Variability is immanent for the business **environment**. At one stage in the company's development, the environment may be *more inclined to management*, while at certain moments dangers dominate in relation to opportunities and thus prevent the realization of the set goals. Some authors associate state in the business environment with the phase of the life cycle of the branches. As a rule, the environment is stable in the early stages, but later becomes restless (Pokrajčić, 2009). "Ansof also states that the environment can be classified according to the degree of restlessness and he proposed five levels: stable, reactive, forward-

looking, exploring and creative. Factors relating to this restlessness are measures of strategic activities, such as investment in research and development, predictability and frequency of changes, new changes and the company's ability to transfer previous experience, level of knowledge for successful responses and applicability of technology predictions" (Flečer, 2003).
In the newly created atmosphere (the recession, the expansion of digital media, hyper-competition, market fragmentation, etc.) there is a need to **change the method of doing business**. "The twenty-first century is said to be the century of changes. All economic entities and people must learn to adapt and change quickly and in a timely manner, or they will not be able to survive in the variable environment as it is today and what it will be in the foreseeable future" (Vujić, 2008, p. 17). Companies that are willing and able to *create value on the basis of socially responsible marketing* have higher chances of achieving market success, given that the interested public approves corporate action which is focused to increase social welfare.

Differentiation of *external and internal environment* is conducted in the literature. "Typically, the external environment is divided into **macro** and **micro marketing environment** and means the initial step in analyzing and formulating business opportunities of the company" (Milisavljević et. Al.,2004). *Macro marketing environment* affect the company's operations in an indirect and long-term way. Factors that determine the relational environment are beyond the control of management (demographic, economic, legal, political, cultural environment, etc.). Changes in the macro-marketing environment can be systematic (which are, as a rule, sustained and predictable) and irregular (random). *Micro marketing environment* directly affects business performance achieved by companies. It is about organizations and individuals with whom the business entity comes into contact (competitors, customers, suppliers and intermediaries). **ETOP**matrix (Environmental Threat and Opportunity Profile) is often used for the analysis of the macro environment, as well as **PEST (E)** analysis (Pokrajčić, 2009). In continuation, the attention will be paid to PEST (E) analysis of the general environment of the media industry in Serbia. We will focus on understanding the political / legal (P), economic (E), social / cultural (S), technological (T) and environmental factors (E).

Table 1*:* PEST analysis of the general environment of businesses in the media industry

Political/Legal factors	**Economic factors**
1. Law on Public Information and Media	1. High unemployment
2. Law on Business Companies	2. Low purchasing power
3. The restrictive fiscal policy	3. Recession
4. Amendments to the Labour Law	4. Unfavorable trends in GDP
5. Inconsistent judicial practice	5. High interest rates
6. Frequent elections	6. Reduced budgets for advertising
Social/cultural factors	**Technological factors**
1. Depopulation	1. Small investment in R & D
2. Uneven distribution of income	2. Insufficient focus of the state and the industry to new technologies
3. Changes in lifestyle	3. The lack of new discoveries
4. The attitude towards work and leisure time	4. Low speed of technology transfer
5. Consumerism	5. Application of outdated technologies
6. Low level of education	

According to IREX's Media Sustainability Index, which recorded a *minimal improvement* over the previous period (unsustainable mixed system),**Serbia is in the group of unsustainable systems.** The transition of the media market from the post-communist into liberal has been implementing in a slow pace. "The slow adoption of laws and their slow or lack of implementation, lack of support of the state apparatus and the like - no matter how paradoxical, make Serbia attractive for all kinds of risky investments" (Bulatović and Bulatović, 2009, p. 35). *The sales of printed media are declining* and the *pressure from advertisers is increasing*. Yearly income from advertising in media in Serbia is between 150 and 160 million euros. "Journalists at the local level are particularly exposed to the unpredictability of local politicians who can interfere with the activities of journalists" (EUROPE & EURASIA MEDIA SUSTAINABILITY INDEX, 2015). Collecting information from branches of republican bodies acting in the local community is more difficult.

The company must look at the immediate neighborhood by applying sophisticated techniques. **SWOT analysis** is the most common instrument used for the purpose of exploiting opportunities in the region and the benefits of the company, ie. avoiding risks and improving the shortcomings. A precise analysis of *the level of attractiveness and the probability of realizing opportunities ie.severity and probability of overcoming danger* is required. "Based on the analysis of opportunities and threats the company is able to identify four possible outcomes in business: ideal business (big chances – small risk), speculative business (big chances-high risks), mature business (small chances-small risk) and problematic business (small chances-high risks)" (Milisavljević et. al., 2004). SWOT analysis should allow *consideration and determination of the relevance of marketing trends* in the macro environment, as well as to contribute to *a precise projection* of these long term trends. As a result, the available opportunities will be used and the risk will be avoided by the implementation of the necessary redesign within the organization in order to determine the area of operation management.The process of strategic management becomes important in conditions of the crisis, as the basis of its three key elements for survival in turbulent conditions of the environment - *strategic analysis, strategic choice* and *strategy implementation*. More specifically, after defining the vision and mission of the company, a thorough analysis and forecasting environment and internal capabilities is needed. Based on available data the objectives, critical success factors and concrete strategic options will be defined. In the last step, the strategy will be implemented, and then controls and audits will be executed.

4. STRATEGIES IN THE MEDIA INDUSTRY

There have been great discussions on the topic - how can companies, in the most painless way, pass between Scylla and Haridb which are accompanied by the turbulent business conditions? The opinions are mainly positioned in two ways. On the one hand there is **a school of thought** that advocates rationalization, ie. savings in order to increase business efficiency (*reactive approach*). Another group of businessmen and theorists emphasize a *proactive* approach to the problem and highlights the planning of process management. We believe that that division is too radical for the newly formed business environment and actually represent the subject of theoretical discussion more than the alternative solution to a particular problem.

Even one company, that exclusively adapts to the status quo in the form of a sort of incremental march, trying to base their success solely on cost reduction, can not survive on the market. Similarly, the so-called unilateral application of proactive approach would have resulted in a low probability of business success for most businesses, because it is unrealistic to expect that a significant number of individuals due to personal ingenuity flourish, rather than competition, to seize the opportunity posed by the business environment. **The optimal model of management** these days is actually *a combination of the two approaches*. From businesses, particularly in the media industry, almost impossible business scenarios are expected. It should not be surprising, since, in troubled times, the most effective effects are achieved by implementing a seemingly controversial strategy.

The literature increasingly states so-called **entrepreneurial approach** of copying with changes in the environment, which is based on *the exploitation of chances and internal resources* of the company. In the first step, the company is trying to observe the extent to which the assets and capabilities at its disposal are unique, valuable and prone to imitation. This is a critical point, because only on the basis of that analysis, the company can objectively examine the challenges in the business environment that can be used. In the next iteration, using Porter's value chain, *ways of achieving added value* are identified. Source of market power can be either in the primary or in the so-called support activities.

In the new circumstances, it is possible to achieve a competitive advantage **by combining simultaneously a number of activities** in which the company achieves superiority in relation to market opponents. For the company in the recessionary period, *existing customers* are *the most important assets*. It is unrealistic to expect that, during the plunge in living standards and the fall of gross domestic product, classic marketing tools will succeed in gaining a new audience or advertisers. Existing customers of media content and advertising space must be met adequately by delivering superior value.

Strategic marketing is certainly a perfect weapon that is available to the media. "Key issues in strategic marketing are: whether a company should perform existing tasks, which are the products and markets of special importance for the survival, growth and development of companies, which new products and markets to look for and how to find those where it is possible to achieve a certain different or competitive advantage with respect to the potential of the company" (Milisavljević, 2006, p. 30). Consequently, all products, services, activities, resources and individuals are *subject to (pre)testing* in order to eliminate "idle" and the efficient and effective use of available resources. Regardless of the aggravating circumstances imposed by new constellation of forces in the region, any measures taken must be viewed in terms of consequences for

consumers, ie. users. The leaders of businesses should especially take into account the lump-saving actions, which may have far-reaching consequences - loss of customers. Strategic marketing therefore should provide a framework for the implementation of both internal and external analysis.

5. CONCLUSION

The twentieth century has created economic and technical-technological prerequisites for *a different way of life* of people in the community, but at the same time gave birth to the greatest *bloodletting* in human civilization. Hence it is not surprising that Eric Hobsbawm called it the "century of extremes". "This is the century in which the capital with liberal democracy has turned itself into ... neoliberalism of globalized economy for whom politics, morality and law, whether national or international, have no autonomy, but are functionally set as a mere service logos of globalized capital personified in profit "(Balj, 2009, p. 252). Some theorists (Pepper, Fukuyama, Giddens et al.) consider neo-liberalism, which is based on the free market and democracy, as the best political and social system, while on the other hand, critics point out that the new order annulled the man as a political being and instead produced a man as a consumer.

Almost no one expected the recession in the first decade of **the new millennium**! Today, many are trying to determine the real causes and consequences of the same. The fact is that the collapse of the global economic system was not only caused by economic but also numerous social failures (the crisis of the value system, greed, etc.). Therefore, managers will have to devote more and more attention in the future to the analysis of macro environment in order to be able to predict a new "social-economic tectonic disturbances" some extent, which will affect the competitive position of the company which they lead.

Companies that choose to fulfill their mission in the conditions of **complex environment** are faced with numerous *legal, economic, political and social challenges*. Each of these challenges will have certain implications on the business policy of the company. It is far more difficult to predict demand in the complex environment. Consideration of planned decisions must be implemented through the prism of analysis of *exchange rate fluctuations* and other macroeconomic aggregates (such as inflation). Companies must take into account the *infrastructure problems* that may be encountered (for example, the absence of press outlets in certain urban areas).

The economic and media crisis, which swept across Serbia as "tsunami", should not only represent a limitation in achieving the set goals of planning of the company, but also a challenge. In business, the above mentioned business strategies present a possible dike to protect the local / regional media from overflowing threats in the environment and their own weakness. In conditions of the crisis, *additional caution* is required, as there is a reasonable risk of bankruptcy of the business which the media cooperate with. Therefore, fair and open cooperation of all partners involved in delivering superior value to customers is more necessary today. In times of economic crisis, there is no right to make mistakes!

GASTRONOMIC FESTIVALS AS A FORM OF BRANDING SERBIA AS A TOURIST DESTINATION

Milena Vukic*[1], Marija Kuzmanovic[2], KsenijaVukic[2]

*Corresponding author, e-mail: milena.vukic12@gmail.com

Abstract: *Gastronomy represents a form of social interaction which is increasingly attributed significance by tourism destinations. The gastronomic offer of Serbia is a fusion cuisine which integrates not only cuisines of neighbouring countries but of the entire Balkans as well. Considering the rich cultural and historical heritage of Serbia, organizing a food festival would represent a creation of new sources of branding, as well as a source of economic development based on innovative means of creating a holistic experience.A better understanding of the attitudes of gastronomic tourists may help tourism marketers to increase the effectiveness of their branding strategies by creating an adequate offer to appropriate market segments. The findings of the study offer insights not only to food festival organizers but also to the national tourism organization for success in destination marketing. Also, the analysis of the obtained results may lead to the conclusion that food festivals can play an important role for destination branding.*

Keywords*:food tourism, destination branding,festivals,Serbiangastronomy*

1. INTRODUCTION

Challenges which arise from rapid global changes and issues arising from economy restructuring, more and more lead to the fact that destinations base their positioning strategy on their own resources such as culture, history, gastronomy and other anthropogenic values. Creation and promotion of festivals and events is nowadays a crucial branding strategy component of many tourist destinations.

With an increasing role of food in tourism, many researchers devoted themselves to researching the connection between food and certain tourist destinations, tourism and food, culinary tourism and gastronomic tourism. According to Santich(Santich, 2004), gastronomic tourismis every journey whose motivation, even if it is not the main motivation, is tasting food and beverages. This author also points out that gastronomic tourism refers to the involvement in another culture especially the part which involves food, beverages, people and places.

Food consumption was treated for a long time only as a supplement to the daily experience of tourists and its role as an invisible part of daily tourism activities for a long time has created a problem of acceptance of gastronomic tourism where its character and contribution to tourism is considered to have little importance. Very small number of works investigated events dedicated to food. Hjalager and Corigliano (2000) found that availability of specific types of food, including wine, fruit, vegetables, and fish was the reason to organize festivals and events that tourists and local population will like.

Events, festivals, fairs, exhibitions, events, complement tourism portfolio of a country by enabling ways for non-elastic tourist offer elements to be flexible and offer a unique experience that can increase value of current image of a country. Main characteristics of the events are the following: limited duration, occur rarely or only once, offering social experience, they are unusual, raising awareness of the region, creating a positive image and attract tourists and thus affect the development of tourism in general (Bodwin et al., 2007).

Within the tourist offer of Serbia, event tourism is a type of tourism that can contribute to increasing volume of tourist demand, especially to natural and anthropogenic values of tourist places or regions (Bjelac and Curcic, 2007). Event tourism first appeared in the strategy of tourism in Serbia in 2006, where this form of tourism was seen as a significant global market potential which contributes to the return of Serbia to the world market. Many tourist destinations use their food and cuisine to position themselves in the tourist market.

Extensive literature in the field of festivals and other events identify that festivals are being used as a means of destination branding (Chalip and Costa, 2005).

There are several factors which can influence the creation of a positive perception of these events both with existing and potential visitors. First, positive impressions from gastronomic festivals can be transferred to the entire tourist region which can influence future visits as well as purchase of gastronomic products. Gastronomic festivals can influence creation of consumers' awareness of brands they did not know of. Awareness can further influence visitors to prefer brands they know more about. These manifestations also provide an opportunity for gastronomic producers to educate visitors, because only educated and well-informed visitors are prepared to buy premium gastro products (Vukic et al., 2015)

In addition, food festivals are used to promote local commodities and differentiate themselves from metropolitan community festivals (Cela et al., 2007; Sharples, 2008).

The objective of this study is to investigate attitudes of tourists when it comes to gastronomic events in Serbia as well as to outline possibility of branding Serbia as a culinary destination. Although it is considered that food festivals are an opportunity to promote local gastronomic products, it is considered they would be a good opportunity to connect the entire region of South East Europe through creating regional food festivals.

2. THE GASTRONOMIC PRODUCT OF SERBIA AS A DESTINATION BRAND

In the past few decades, growing competition in tourist destinations has led to the development of more appealing attractions that will occupy the attention of potential tourists. Some countries opt for an integrated product branding of the country as a tourist destination, while others see their opportunity in branding partial tourism products. For a tourist destination, the brand is very important because it represents more than products and services, as it includes trust and emotions. A destination becomes a brand only if it is permeated with high values. According to Morrison and Anderson (2002), destination branding is the process used to develop a unique identity and personality that is different from all competitive destinations. As state or city brands reflect a part of a national brand, regional brands reflect specific regional branding under the overall umbrella of a state brand (Crockett and Wood, 1999).

Events are part of the attraction of a destination and as such should be included in the integrated marketing campaign for the destination and incorporated into a destination's branding strategy (Jago et al., 2003).A large number of authors has studied festivals as a way of branding destinations (Derrett, 2003; Jagoet al., 2003; Kim and Morrsion, 2005; Lee and Lee, 2009); however, only a small number of them has dealt with food festivals (Arcodia and Lee, 2008) as a means of branding.

Even though there is no natural or automatic harmony or synergy between events and other products offered in a destination (Fyall and Garrod, 2005), food is one of the few products in which a clear link between gastronomy and destination brand can be seen. Hjalager and Richards (2002) stated that tasting local food is an essential part of the tourism experience since it can serve as both a cultural activity and entertainment. Telfer and Wall (2000) suggested that spending on eating out during a holiday constitutes approximately one-third of all tourist expenditures.

In Serbia, there is a large number of traditional events, local manifestations, festivals, celebrations, et al. In addition to being popular in the domestic market, some of these events have the potential for the international market where they have so far reached a certain degree of popularity (Tourism Strategy of the Republic of Serbia, 2005). Even though event tourism was recognized in the Strategy of Tourism Development of Serbia in 2006 as a form of tourism that can increase the volume of tourist demand, in comparison with other destinations which significantly use food as a way of positioning, Serbia has not sufficiently used its potentials, especially if we bear in mind that its authentic cuisine is rich and unique.

To create a culinary brand is not easy, but there are huge benefits to it. First of all, customers save their time when choosing between different brands and instead of considering all possible options, the brand encourages customers to take into consideration only those products which possess the required characteristics. For brand strategy to be successful and useful in creating a brand value, consumers must be convinced that there are clear differences between brands in a category of products. The importance of creating a culinary festival is to indicate what might be the significance of the production of private brands of food on the performance of the company itself together with the economy of the whole country as well as neighboring countries.

Besides the authenticity of the cuisine of Serbia, culinary knowledge and skills were influenced by other nations and cuisines. Depending on the region, these impacts can be reduced to the Ottoman Empire, i.e. Turkish cuisine, the Austro-Hungarian cuisine as well as modern Italian cuisine, whose biggest impact was in the coastal regions of the former Yugoslavia. The cultural and culinary influences are intermingled, creating a new fusion cuisine of the Balkans where everyone participated so much that now everyone has the right and claim over the same product.

Even though the term Balkans, as a geographical region of Europe, is nowadays slowly being replaced by the term Southeast Europe, when appearing in the global market, the term "Balkan food region" could achieve greater recognition and authenticity. The reason for this is a rich cultural and historical heritage as well as the previously mentioned culinary influences, which is why it is possible to link the whole Balkan region as a unique gastronomic destination, and place it under the name of "Balkan food region", in order to achieve recognition in the international market. This approach to branding represents an alternative opportunity for tourism development in the whole region, particularly because food festivals, rather than other types of festivals, are one of the common types of regional festivals (Kalkstein-Silkes et al., 2008).

3. ATTITUDES OF VISITORS TO GASTRONOMIC TOURISM

In order to examine attitudes of visitors to gastronomic tourism (gastronomic manifestations) in Serbia, a research was conducted in the period between February and July 2014. The sample was composed of 431 respondents, with an average age of 24.94 (SD = 9.39), where the youngest respondent was 15, and the oldest was 63 years old. From the total number of respondents, more than a half were women (54.8%), while 45.2% were men. When it comes to monthly income, there were an equal number of respondents whose monthly incomes were between 20,000 RSD and 40,000 RSD and between 40,000 RSD and 80,000 RSD. There were 19% of respondents with incomes below 20,000 RSD, 10.9% with incomes between 80,000 and 160,000 dinars, whereas only 2.9% of respondents had monthly incomes higher than 160,000 dinars. As far as the employment status is concerned, the largest number of respondents were university students (36.4%), 29.5% were high school students, 28.5% were employed, 4.4% were unemployed, whereas the number of the retired was the smallest (1.2%).

Besides questions related to demographic data, the questionnaire also contained questions concerning the respondents' attitudes to gastronomic tourism, which referred to the frequency of visits, the state of being informed as well as reasons for not visiting gastronomic manifestations. From the total number of respondents, the survey showed that almost a half of respondents (207 respondents) were familiar with the term gastronomic and culinary tourism. 108 (27%) of them were not sure what this form of tourism represents, while 116 respondents (26.9%) had never heard of this form of tourist movement (Figure 1).

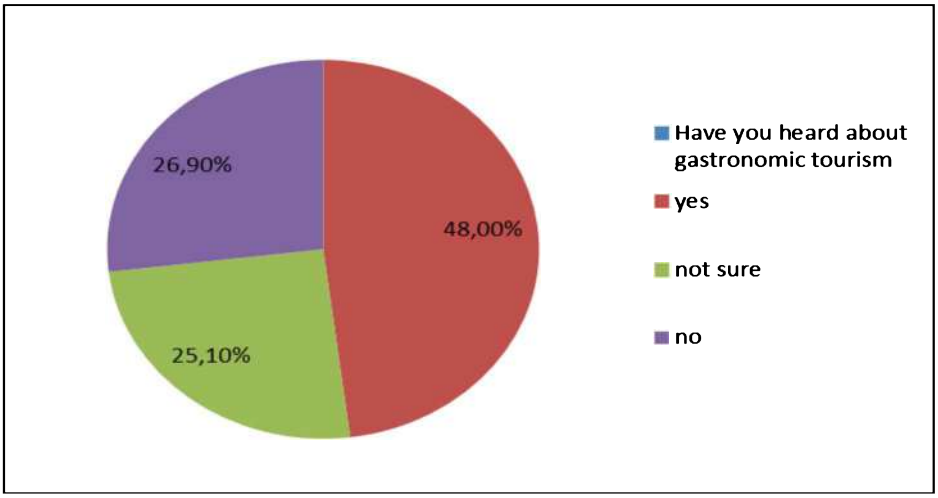

Figure 1: Awareness of gastronomic tourism

Regarding the frequency of visits, only 12 respondents (2.8%) visit these forms of manifestations several times of year, 187 respondents (43.4%) visits them occasionally, whereas the largest number of respondents, more precisely 232 (53.8%), never visit gastronomic manifestations (Figure 2).

The respondents gave reasons why they rarely or never visit gastronomic manifestations, where they were able to choose one or more reasons, but they could also choose not to name one. 392 respondents named

the total of 451 reasons, whereas 39 respondents, mostly those who occasionally visit gastronomic manifestations (32 of them), did not give a reason.

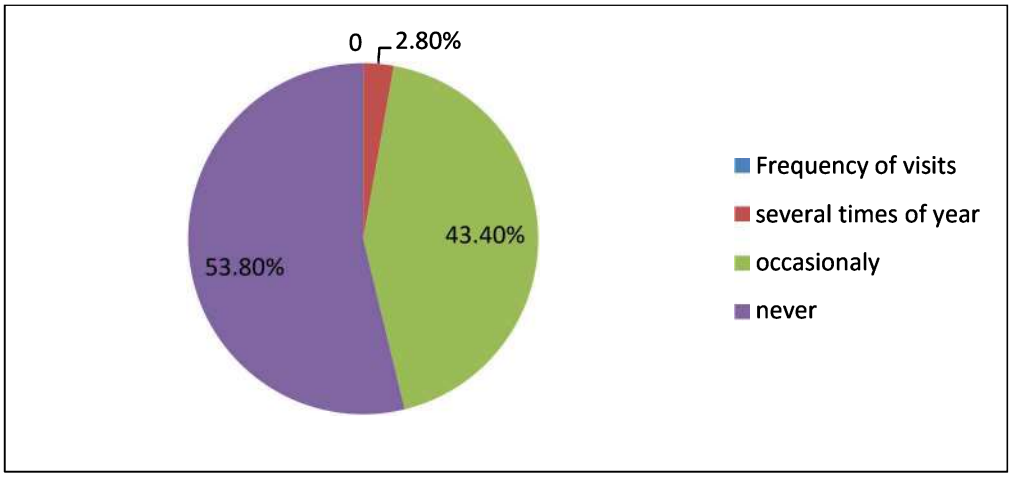

Figure 2: Frequency of visits

The analysis of answers given by the respondents (see Figure 3) have shown that the reason which is most often chosen is insufficient information, even 220 of them (51%) chose this as the only reason. Many respondents besides insufficient information stated other reasons as well such as financial reasons, the lack of free time and other reasons; therefore we may conclude that this group contains very few respondents who are not at all interested in gastronomic tourism. This also points to one of the biggest problems for marketing experts, and that is to ensure that potential consumers are informed and that they will remember their products and services.

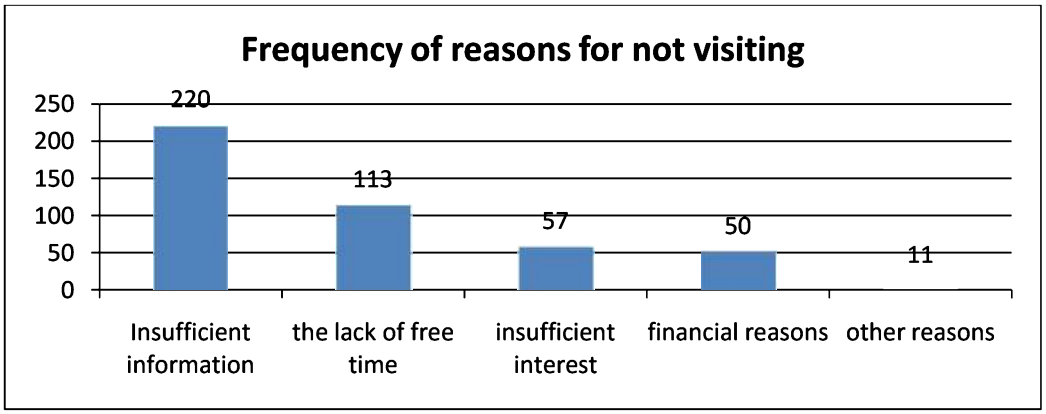

Figure 3: Reasons for not visiting gastronomic festivals

At first glance, one can say that a solution to this problem lies in the domain of planning and conducting the economic advertizing; however, the problem is more complex and we should start from a fact that it takes more than previous knowledge and understanding of a way consumers in tourism can be informed about tourism products in order to be well positioned in the tourism market. In the process of informing the consumers, both of its components, i.e. sensory and conceptual systems should be comprised (Maričić, 2008). The sensory system refers to the functioning of sensory receptors (senses) and marketing experts should strive to activate all five senses in order to influence a consumer's behaviour, although they might opt for selective approach as well. The conceptual system refers to mental processes and thoughts and considerations and it takes place when a consumer wishes to understand the meaning of a stimulus in their environment. This part of information process enables a creation of new knowledge, meanings and beliefs regarding the stimuli they are exposed to.

The second reason why the respondents rarely or never visit gastronomic manifestations is a lack of free time, where 113 respondents (26.2%) chose this as one of the reasons, and 60 respondents (13.9%) chose it as the only reason. It is very important to bear in mind that the very need for travel tourism is not sufficient for its realization, but what is also important is a possibility to manage free time as well as free funds as objective factors of forming a tourism demand. Even though working hours were even 12 to 14 hours a day in the early stages of capitalism, the situation has dramatically changed in the past 150 years, so tourism has obtained a dimension of "leisure time" industry. However, this research has shown that the turbulent times

Serbia went through nevertheless had an effect on tourism demand and that there is a considerable amount of those who are left with little free time available.

The lack of interest as a reason for not visiting gastronomic manifestations was chosen by 57 respondents (13.2%), whereas only 36 respondents (8.3%) were absolutely not interested, while others stated that they are either uninformed or lack financial means, so we may conclude that it is possible to create interest of these respondents if they are well informed.

Free funds, in addition to leisure and motive are still one of the drivers of tourist movements and can be an objective obstacle in meeting tourism needs. The research has shown that 50 respondents (11.6%) do not visit gastronomic festivals for financial reasons, of which 20 (4.6%) chose finances as the only reason. However, with the growth of income, the propensity to consumption increases as well and vice versa. In particular, it is known that an increase in income leads to a decrease in the share of expenditures for food and an increase in the share of expenditure for meeting the needs of a higher order (education, recreation, travel, etc.).

This interdependence was first studied by Engel in 1857 and formulated in the form of four laws on consumption (Maričić, 2008); therefore it can be said that Engel's laws also reflect consumer habits of today's customers, who spend much more on nights out, travel and other services and products of a higher order. Considering all these facts, there is a possibility that an increase of financial funds with these consumers pours into service activities and that they change from potential to real visitors of gastronomic manifestations. Other reasons were chosen by 11 respondents (2.6%), whereas 46 respondents (10.7%) did not know the reason for not visiting these forms of manifestations.

According to the answer to the question about how frequently they visit gastronomic manifestations, a statistically significant difference between male and female respondents was noticed (sig = 0.009). Namely, out of 12 respondents who frequently visit gastronomic manifestations, even 10 were men. The largest number of respondents who never visit this kind of events are women (59%), whereas the number of men and women who occasionally go to gastronomic manifestations is almost the same. Therefore, it can be concluded that the gender affects visits and that men more frequently visit this kind of manifestations (Table 1).

Table 1: The results of comparing the frequency of visits with the respondents' gender

Question:	**How often do you visit gastronomic festivals?**				
Gender		Often	Never	Occasionally	Total
	Female	2	137	97	236
	Male	10	95	90	195
Total		12	232	187	431

By cross-referencing data on the education of respondents and the frequency of visits, we can see that there are significant differences in visiting gastronomic manifestations depending on the level of education (sig = 0.000). It can be seen that out of 12 respondents who often visit gastronomic manifestations, three (25%) have a high school diploma. On the other hand, 8 respondents (67%) who often visit gastronomic manifestations have a college degree, and the smallest number of respondents who visit manifestations have a university degree (8%).

From the total number of respondents who never go to these manifestations, 51 of them (22%) have finished elementary school, 67 respondents (29%) have a high school diploma, 16 respondents (7%) have finished college, 84 respondents (36%) have a university degree, and 14 (6%) have a master's degree . The analysis of the respondents who occasionally visit gastronomic manifestations has shown that 43 respondents (23%) have finished only elementary school, 38 respondents (20%) have a high school diploma, 31 respondents (17%) have finished college, 56 respondents (30%) have a university degree, whereas there is only 1% of respondents with a PhD.; however, the 1% is comprised of the only 2 respondents in the entire sample who own a doctorate. Table 2 indicates that gastronomic manifestations are most often visited by respondents with a college degree, that respondents who occasionally visit them are university graduates or own a doctorate, and those who never visit these manifestations are mostly university graduates (Table 2).

The following analysis refers to respondents who never visit gastronomic manifestations and the reasons leading to this. From the total of 232 respondents who never visit gastronomic manifestations, only 11 respondents (4.74%) chose finances as a reason. The lack of free time was given as a reason by 39 (16.8%) respondents, whereas 20 respondents (8.6%) did not know the reason why they do not visit these manifestations. One of the reasons for 48 respondents (20.69%) was not being interested.

Table 2: The results of comparing the frequency of visiting manifestations with the level of respondents' education

Question:	**How often do you visit gastronomic festivals?**				
Education level		Often	Never	Occasionally	Total
	Elementary school	0	51	43	94
	High school	3	67	38	108
	College	8	16	31	55
	University	1	84	56	141
	Magister, Master	0	14	17	31
	Doctorate	0	0	2	2
Total		12	232	187	431

However, what could be interesting for potential planners of this kind of manifestations is that the largest number of respondents, 102 (44%), to be more precise, who never visit such manifestations said that insufficient information was one of the reasons for it.

4. CONCLUSION

Today, organizing festivals with different content represents a unique opportunity for tourists to experience leisure, social and cultural experiences but they are also a generator of economic development of a destination. Since food is important component of attractiveness and image of a destination, organizing food festivals can only add value to the overall tourism product. Tradition of food festivals is very long and this type of tourism is even recognized as one of future trends of tourism development in Serbia.

The results of this research showed that although more than half of the participants are familiar with the concept of culinary tourism, only a small number of them visit these events several times a year while more than half of them do not visit them. Such a small number may not be a significant indicator of the possibilities of branding Serbia as a gastronomic destination due to its great gastronomic heritage. This thesis can also be demonstrated through results from the answer to the question why they seldom or never attend this type of events. Most of them stated the reason of not visiting is insufficient level of information that indicates the need to create a clear and consistent marketing on strategies designed for this type of tourism.

When creating marketing strategy of gastronomic festivals, interests of larger and smaller segments or market niches should be taken into account. Serbia as a gastronomic destination can position itself as a competitor compared to countries in the region. However, it is possible that new events for competition with other countries, encounter a situation to cope with current events at home. Having in mind these circumstances, one of possible positioning strategies could be based on collaborative marketing across the region, launching "Balkan food region" as a destination brand. Better coordination of an event calendar would help to avoid rivalry among regional events and create cooperative marketing activities because gastronomic events in Serbia have a gastronomic tradition of its population in the territory of Serbia (Serbian, Montenegrin, Croatian, Bosnian Hungarian, Romanian, etc.).

The positioning of Serbia as a gastronomic destination implies the existence of a quality gastronomic product, a design of a communication strategy that would make a gastronomic product become recognized by tourists whoprefer it to other competing destinations. Branding this form of tourism means communicating values, mission and vision to tourists.

MARKETING AND SUSTAINABLE DEVELOPMENT

Marija Jovic*[1], Branka Novčić[1]
[1]Univerzity of Belgrade, Faculty of Organizational Sciences
*Corresponding author, e-mail: marijaj@fon.rs

Abstract: *The concept of sustainable development has become a widely used catchphrase in contemporary organizations .This concept is nowadays central to the programs of many government and non-government organizations, as well as in many businesses around the world. Still, scientific literature lacks a thorough and encompassing explanation of this concept through a variety of scientific disciplines and areas of business. This article aims to contribute to the literature in the field of marketing and sustainable development for understanding and effective implementation of this concept in real environment. Sustainable development refers to satisfying needs of people, without compromising the ability of future generations to satisfy their own needs. Here, marketing plays an important role, not only through the alignment of the company's strategy with the environment, but also through the promotion of the importance of the application of this concept.*

Keywords*: sustainable development, sustainable marketing, sustainable customers, sustainable products, sustainable market*

1. INTRODUCTION

Sustainable development, as a relatively new and evolving area of theory and business, can be considered an emerging concept. Accordingly, sustainable development concept is continuously changing in relation to local contexts, needs and interests. However, there still exists a lack of a thorough and encompassing explanation of this concept through a variety of scientific disciplines and areas of business. On the other hand, there are several things which academic community mostly agrees on. First, the question is no longer about contradiction of development and environmental concerns. The question is how sustainable development can be achieved, while phrase “sustainable development” has become pervasive (Lele, 1991). This phrase is becoming more common as a topic of conferences, as a slogan of environmental activists, or development planers (Lele, 1991). Second, describing the sustainable development concept, most researchers point to its three main pillars in society: economic, ecological and social (Dyllick & Hockerts, 2002; Holling, 2001). Third, the solution of the problems of sustainable development is one of the priorities for national governments, global companies, and all forward thinking people of the world.

So far, a lot of papers have been written on this topic, but authors still do not agree on the definition of this concept. Moreover, some authors believe that there is no need for a universal definition and that the value of this concept lies precisely in its ambiguity (Lele, 1991). According to some authors, the vagueness of the definition of sustainable development enables people who have had opposing views to jointly find a solution for the definition of this concept through a debate. The lack of a harmonized definition of the concept of sustainable development hinders the application of this concept in practice.

The basic elements of the complex problem of sustainable development are poverty and harmful impact of excessive consumption of the rich population on the environment. At the United Nations Conference on Environment and Development (UNCED) held in Rio de Janeiro in 1992, the governments of the member countries of the United Nations highlighted the need to focus international and national policies of countries in such a way that the impact on environment should be discussed when making any economic decisions. This message has contributed to the principle of eco-efficiency to become one of the guiding principles not only in companies, but also in government institutions. For example, different modes of production, especially the production of toxic substances, such as lead in gasoline, or poisonous waste, are under both the UN (United Nations) and governments scrutiny; they seek to replace fossil fuels, associated with global climate change, with alternative sources of energy; they seek to develop public transport systems in cities, in order to reduce the pollution resulting from the emissions from vehicles (UNCED, 1992).

With increasing modern society awareness of the importance of sustainable development, an area that can be called sustainable marketing is also developing. The importance of sustainable marketing for sustainable development can be seen in the fact that there is a significant part of marketing theory which is related to the promotion of new ideas and consumer behaviour. In particular, marketing should make a significant

contribution towards overcoming the gap between the already confirmed fact that consumers care about social and environmental issues and their influence, which is often contrary to the interests of the environment.

As a contribution to the development of marketing and sustainable development, this paper analyses the concepts of sustainable development and marketing theory and practice that can be linked with this concept. Specifically, after a review of the key elements of the concept of sustainable development, a variety of marketing strategies and tactics that could contribute to the development and popularization of the concept and contribute as much as possible to its application in practice have been considered.

2. SUSTAINABLE DEVELOPMENT

Sustainable development, as a relatively new concept, was created as a result of understanding of people's harmful effects on their environment. This concept has been seriously accepted after the United Nations Conference on the Human Environment in Stockholm in 1972. Apparent climate changes, which present response of nature to harmful effects of people, contributed a lot to understanding the importance of this concept.

Sustainable development has been defined in many ways so far. The definition that perhaps best describes the essence of the concept of sustainability is one that was given by Brundtland (1987) "Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs ". This definition is not precise enough (Lele, 1991), but it illustrates two fundamental problems related to environmental degradation that accompanies economic growth, as well as the need for such growth, in order to reduce the level of poverty (Adams, 2006). Also, Martin and Schouten (2012) described sustainability as the ability of the system to continuously maintain or renew itself, pointing to an important feature of this concept, where the system is inevitably changing, and it is not preserved or kept in a static form.

The essence of modern theories of sustainable development is the notion that there are three dimensions of the concept: environmental, social and economic (Adams, 2006; Dyllick&Hockerts, 2002) (Figure 1). From the environmental standpoint, sustainable development should enable integrity of the natural environment as well as unhindered development and change. In doing so, the point is not to preserve and keep the system in a static state in which it loses its biodiversity, but to enable it to smoothly reproduce and adjust to various changes.

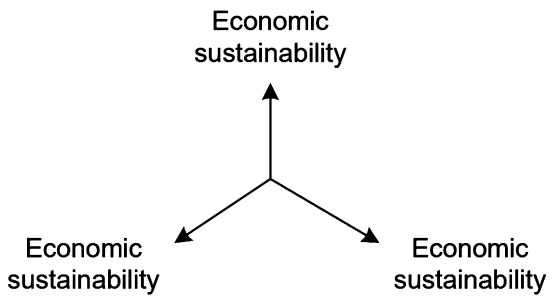

Figure 1: Dimensions of sustainable development (Dyllick & Hockerts, 2002)

The social dimension is focused on human development, maintaining the stability of the social system and preventing social conflicts. A human being should be an active participant in development, through the management of his/her life. An important prerequisite for this is a fairer distribution of resources between people i.e. reduction of the so-called GINI-index, as well as tolerance among people and preservation of cultural heritage.

The economic dimension refers to the optimal use of limited natural resources, as well as development of technologies that will achieve better energy savings. The essence of the economic dimension is to ensure the growth and to achieve the efficiency.

Each of these three dimensions should be optimized in relation to itself, and also in relation to the other two dimensions (Meier & Magas, 2014). Coordinating these three dimensions of sustainable development is a very complex task. In terms of socio-environmental relation, it is necessary to preserve the ability of future generations to use natural resources that are available to today's population. When it comes to socio-economic relation, it is necessary to achieve a better distribution of wealth among people. Economic-

environmental relation requires constant alignment of the cost with the impact of technology on the environment.

The solution of the problems of sustainable development is one of the priorities for national governments, global companies, and all forward thinking people of the world. Today, the majority of UN member states have ministers and departments in charge of the environment. In Serbia, this segment belongs to the competence of the Ministry of Agriculture and Environmental Protection. Also, as a body within the Ministry of Agriculture and Environmental Protection, Environmental Protection Agency performs expert tasks related to environmental protection, the development of an information system on the environment, as well as tasks related to cooperation with the European Environment Agency (EEA) and the European Environment information and Observation Network (EIONET) (EPA, 2016).

The Sustainable Society Foundation has developed Sustainable Society Index (SSI), which enables comparison of the level of sustainable development among different countries (SSF, 2014). This index integrates three dimensions of sustainable development, whose main goals are the welfare of mankind and environmental welfare. The economic welfare itself is not a goal, but it represents the means of achieving social and environmental benefits. The framework for the interpretation of this index is presented in Figure 2.

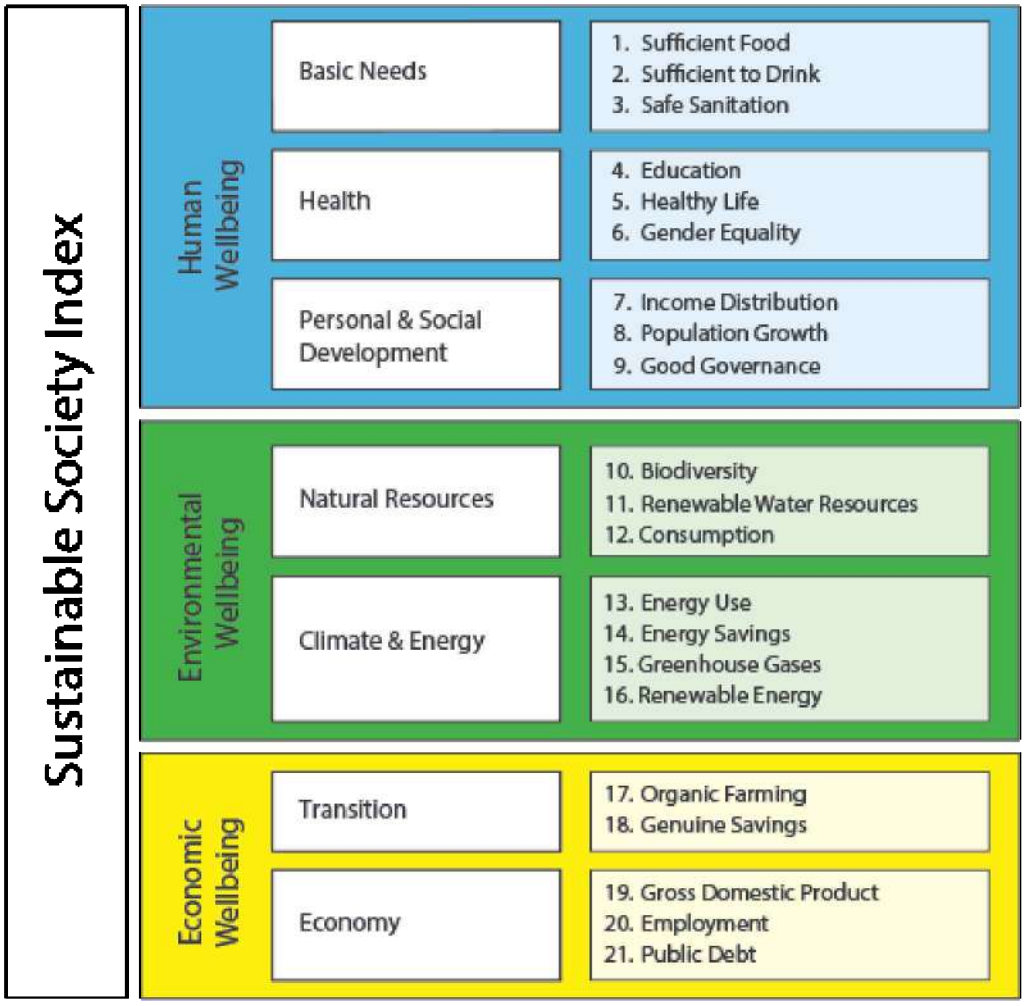

Figure 2: Framework for SSI (SSF, 2014)

According to this framework, out of the 151 countries in which SSI is being followed, Serbia is in 34th place in terms of the social welfare, in 60th place in terms of the environmental welfare and in 135th place in terms of the economic welfare (SSF, 2014). Viewed globally, social welfare occupied the highest level in 2014, which in the scale to 10 had a mark between 6 and 7, followed by ecological welfare with a mark between 4 and 5, whereas economic welfare had a slightly lower mark (SSF, 2014). On the other hand, in comparison to 2006, progress in the area of economic and social welfare can be noticed, while the environmental indicator is worse for a little more than 0.2 compared to 2006 (WSF, 2014). This indicates that despite the development of awareness of the importance of environmental conservation and protection, people are not ready to behave responsibly in this regard.

3. SUSTAINABLE MARKETING

The increasing demand and interest in the issue of sustainability have led to the expansion i.e. the development of the concept of marketing in the direction of sustainable marketing. Among the key drivers of sustainable marketing development there is customers' increasing awareness about the issue of sustainability, as well as the growing demand for "sustainable products, " possibility of gaining competitive advantage in the growing "sustainable market", as well as government regulations and various laws that encourage the adoption of the concept of sustainability.

Sustainable marketing is focused primarily on sustainable market that includes a growing number of companies, different products and services and of course customers, all of which are somewhat aware of, and take care of the problem of sustainability. The concept of sustainable marketing, in addition to the company's profits, also takes care of long-term environmental, social and economic effects of different activities. This approach represents a significant improvement in relation to traditional approach, which was focused mainly on the economic benefits of the company.

Bearing in mind the growing awareness of people about the issue of sustainability of 61% compared to 2012 (National Geographic, 2014), as well as a number of developed marketing tools used to change consumers' behaviour, a surprising fact is that consumers themselves continue to present a significant obstacle to the implementation of the concept of sustainability (The Guardian, 2016). Moreover, despite a growing awareness in key markets such as the US, Germany, Japan and China, sustainable purchasing behaviour has actually decreased compared to 2012 (National Geographic, 2014). Many authors have tried to find the reason for this "value-action" gap, where the majority came to the conclusion that although people attach importance to values such as sustainability, morality, ethics, etc. these values are not included in the consideration when purchasing.

Sustainable Lifestyles Frontier Group was founded with the intention to try to save the value-action gap that is present between attitudes about sustainability and behaviour when purchasing. One of the conclusions reached is that the problem is not in consumers' value system, but in the value that is offered to consumers (The Guardian, 2016). More specifically, customers are interested in the answer to the question what they get out of that. When creating a supply of sustainable products, in addition to general arguments which are related to the conservation of eco-systems and planets, it is necessary to include elements from a traditional marketing theory which are related to the offer of value to customers (Kotler& Armstrong, 2014). Three basic types of value that customers expect from products are functional, emotional and social value (Sweeney &Soutar, 2001). Thus, a sustainable product must keep relation value-money which customers are already accustomed to, must involve emotions of a buyer by offering him to feel better, smarter and more valuable, and also to understand that such behaviour will encounter a positive response from environment.

In practice, marketing campaigns related to sustainable products are mainly oriented to highlighting the social and planetary benefits, instead of the values which are of key importance to consumers (The Guardian, 2016). A good example in the food industry would be messages related to the health of customers with the absence of pesticides and other harmful substances that contribute to health and reduce the risk of various diseases or obesity in people, showing people what the benefits of sustainability are for them.

In addition, it should be noted that sustainable marketing at the same time contributes to building long-term customer relations. Given that relations are created when customers believe that they share the same value system with a company, it can be concluded that the idea of sustainability can be a value, which is common for customers and a company. However, to achieve this, it is necessary to, after the implementation of the concept of sustainability in the strategic orientation of the company, improve or develop a marketing mix that will also consistently support and transmit the idea of sustainability. The specific role of sustainable marketing in individual companies will vary in relation to the industry, size, corporate culture, as well as marketing management model, which can be customer-focused, technology-focused or communication-focused.

Within the implementation of the concept of sustainable marketing, the first objective is to create and increase the market for sustainable products and services, and identify and stimulate demand for sustainable products (Meler&Magas, 2014). Also, one of the important steps in the implementation of strategies for sustainable marketing is segmentation of sustainable market. This is followed by the implementation of the concept of sustainability into a company's marketing mix. In this regard, it is necessary to adapt products to the needs and desires of consumers, as well as to the criteria of environmental protection and sustainability. The prices of products must be formed on the correct level, which must be ethically suitable and acceptable both to a seller and a buyer. The distribution, as well as the price should be in line with good practice while respecting the principles of sustainability, transparency and accountability. Finally, the promotion should be

based on sound ethical and moral codes, providing wide, reliable, unambiguous and creatively adapted publicity related to environmental protection and sustainability (Meler&Magas, 2014).

All this points to the need for marketing to get out of the current framework and involve a wider concept of management which is focused on the production and delivery of sustainable solutions which would profitably meet the needs of consumers and other stakeholders.

4. CONCLUSION

Bearing in mind all that has been said so far, it can be concluded that the application of the concept of sustainable development in companies is becoming an increasingly important topic and one of the key strategic goals of business of an increasing number of companies. They do not question whether it is necessary to integrate the concept of sustainable development in business any more, but how this can be achieved. Although there are many good examples of applying the concept of sustainable development, it is impossible to make a universal model of its implementation. Each company, depending on the market in which it operates, its size, industrial sector, must develop an adequate strategy, whose leading aim will be to preserve the ecological environment and take care of the interests of society with the achievement of adequate economic results. Such sustainable strategy is focused on the future by meeting the needs of consumers and at the same time by achieving profitability for investors.

Based on current marketing theory and practice and specificity of the concept of sustainability and sustainable development, it can be concluded that the role of marketing in the implementation of the concept of sustainable development is important and versatile. First, marketing as a business segment that is closely connected to customers through market analysis, as well as through the creation of offers of values, must take into account the principles of sustainability when designing a marketing mix, as well as when building relationships with consumers. Also, marketing, with its extensive knowledge and experience regarding the customer behaviour and promotion of new ideas can significantly help to spread the idea of sustainable development and increase sustainable market. Finally, sustainable marketing, with its focus on social and environmental issues, can be considered one of the drivers of sustainable development because of its enormous potential initiating cultural change in society.

SUSTAINABLE DEVELOPMENT OF STRATEGIC BRAND PARTNERSHIP

Slobodan Vasilic*[1], Dejana Milosev[1],
[1]Faculty of Organizational Sciences, Neoplanta a.d.
* Corresponding author, e-mail: milosevdejana88@gmail.com

Abstract: *Sustainability in marketing strategy not only helps in competitive advantage but also opens door for cost savings and innovation. When company achieve a brand partnership regarding sustainable development, that is a very good strategy for future. This paper presents a theoretical overview of strategical brand partnership and sustainable development. Also, this paper deals with understanding the concept of brand partnership and with understanding the process of building the strategic position and image of brands through the implementation of the concept of brand partnership within the strategy of integrated marketing communications. There are also two examples from practice and they presents sustainable development of strategic brand partnership. The first example is the example of strategic brand partnership of the companies TOTAL and Peugeot and the other one is the example of strategic brand partnership of the companies Unilever, PepsiCo and Coca-Cola. Both of these examples show their great cooperation where the companies combine their ideas and insights regarding main global challenges.*

Key words: *sustainability; development; strategic brand partnership; marketing; brand value*

1. INTRODUCTION

Strategic brand partnerships can be a very successful way to build serious business, boost brand awareness and walk into new attractive markets. Companies have been making partnerships for many times and for a variety of reasons and the whole point is that success of one brand will bring success to the other brand, its partner too. Brands partner for the visibility lift, increased exposure, attachment to other brand values, the anticipated revenue boost. Partnership can help or either hurt brand and brands in partnerships must be very cautious so they can access new targeted audiences and grow net new revenue. For good working partnership, it has to be a win-win game for all players in the game so target audiences, prices, value perceptions and promotion channels need to fit.

Successful brand partnership should bring measurable and high value to both companies, but they must combine each other value and deliver similar customer profiles. Also, the partnership must sit within the lifestyle and user experience of the customer.

The main advantage of strategic brand partnerships is in chance to produce the product that ensures to be at exclusive and powerful positions through the use of one or more other brands in the campaign. Partnerships can create more compelling points of differentiation and - or points equal to the brand, than would be possible without the partnership. As a result, partnership can generate higher sales than the existing target groups and to provide additional opportunities with new customers and sales channels. When we add responsibility for sustainable development in partnerships, that became a gold solution of modern world business.

2. WHEN TWO BECOME ONE: THE POWER OF STRATEGIC BRAND PARTNERSHIP

Consumers aren't looking so much for new brand thanks to brand loyality. They are on social networks that allow them to act „behind the scene" (i.e. Twitter, Facebook, Skype etc.). Consumers are creating brand stereotypes beacuse they like what others like on social networks without individuality. So brands reach new customers using other brands through partnership.

Today, brands may be linked to other entities in the minds of consumers have their own knowledge structure. Thanks to these connections, customers can assume or conclude that some associations that are characteristic of other entities may also be true for himself a brand that is associated with an entity. In other words, the brand "borrows" a brand knowledge and, depending on the nature of the association, a certain part of the brand values of the other entity.

This indirect approach to building brand value is called the use of secondary brand associations. Secondary brand associations can be important in creating a strong, appealing and associations of unique and positive customer response, if the existing association in some way insufficient. Also, the use of secondary brand associations can be an effective tool for strengthening the existing brand associations and responses of customers in a new and creative way. Connecting brands with another entity can create a new set of brand associations, but also could affect existing brand associations.

Creating a new brand associations: creating a link between the brand and the other entity, customers can form a mental connection from the brand to the other entity, and consequently to all associations, attitudes, feelings and likes that are related to that entity. This is important in situations where customers feel they do not have adequate knowledge to choose the brand or they do not care at all of that. In such situations, it is likely that the brand selection device based on consideration of secondary associations such as: what they think, feel or know the country of origin where the product / brand to come, stores in which the brand sales on behalf of the company that produces the brand or other characteristics.

Effects on existing brand knowledge: Linking the brand to another entities can affect the formation of new brand associations through the transfer from the entities to the same brand and also may affect the existing brand associations. Impact process is very ordinary. If consumers have some knowledge of the brand when the brand identify that is tied to another entity, customers can conclude that some specific associations, attitudes and emotions that characterize an entity also feature the brand. In other words, in the minds of consumers form an opinion that what is true for the property must be true for the brand.

The basic question to be answered, which is crucial for the success of the brand partnership and transfer of secondary association of other entities:
▪ What do customers know about the other entity?;
▪ Do you have the knowledge that the other entity in any way affects how will think of the brand when the brand in some way be connected to this entity?

Keller and Kotller (2012) point out that entities for which brands can bind with the aim of building the secondary brand associations:
• Company (through branding strategy);
• Member or other geographic areas (origin of the product);
• Distribution channels (through channel distribution strategy);
• Other brands (through co-brand);
• Characters (through licensing);
• Speakers (the recommendations);
• Events (through sponsorship);
• Other sources.

Best elements of brands are mixed into a partnerships. But there is also a risk where both parts need to solve a potential problems with negative attention. Because of the internal logistics not all partnerships are a good combination. It is estimated that about 80% of partnerships don't work successfully.
With the right partnership, the positive sides are obvious, starting with the access to an all new target audience, what is very important for both partners. Expectations of partnerships are to achieve:
▪ Better value proposition;
▪ Better visibility;
▪ Increased exposure to values (in partnerships with nonprofits);
▪ Solution to create exclusive products.

Keller and Kotller (2012) point out that three key important factors in predicting the degree of importance of linking the brand to the other entity are:

- Recognition and knowledge of the entity: If the entity is not well recognized and buyers have no knowledge of him, then the entity does not have anything that could be transferred to the brand. Ideally, customers should be aware of the existence of the entity; to have a strong, appealing and of unique assemblages related entities; to have positive attitudes and feelings related entities;
- What knowledge they have on the entity: If an entity causes some positive associations, attitudes and feelings, to be seen whether this knowledge is relevant and important for the brand. Some associations, attitudes or feelings may seem relevant and valued for the brand, while the other may have little to do with the brand;

- Portability knowledge of the entity: Refers to the question of how much of an association, attitudes or feelings that wears polarized entity (which could potentially be transferred to the brand) could strongly bind to the brand.

3. EVOLUTION OF SUSTAINABILITY IN MARKETING

Despite the different interpretations that can be found in the literature,this concept today has a central place in the consideration long-term prospects of survival and progress of mankind. Sustainability, or sustainable development, occurs both as an essential precondition, as well as the ultimate objective of efficient organization of numerous human activity on Earth.

Sustainable development is a concept where lives the idea that social, environmental, and economic growth are all achievable within the limits of our earth's natural resources.

It is important to meet all needs of the businesses and people but in the way of saving nature and life on our planet. One of many goals of sustainable development is to achieve business and social progress regarding saving natural resources. We owe to future generations to find a way of development that is good also for environments.

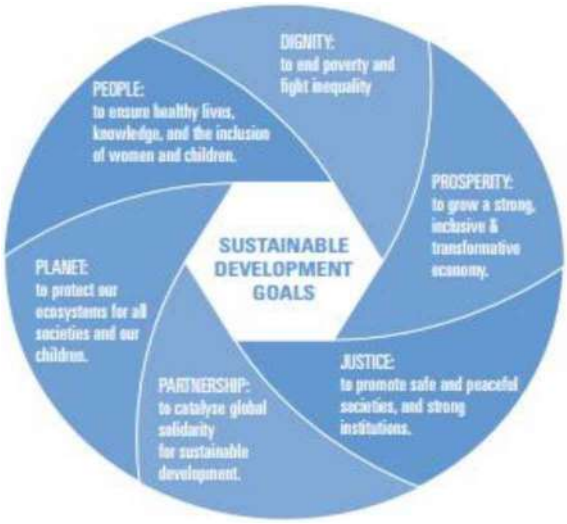

Figure 1: Six main parts for achieving the sustainable development goals (Charter, Peattie, Ottman and Polonsky, 2006)

In the past, it was believed that marketing and sustainability were almost opposite terms, since marketing was usually perceived as the promotion of more consumption while on the other side sustainability promoted less consumption. Marketers have to brake their traditional frame of reference to include sustainability in their marketing strategy. In some markets and companies sustainability issues have become highly important and a competitive factor influencing marketing strategies. Sustainability have three dimensions: environmental, social and economic and all three are very important.

Based on the above mentioned, companies needs to formulate the strategy so they can earned profits even after reduced impact on our society and environment.

Charter, Peattie, Ottman and Polonsky (2006) point out that the same is the case with sustainability marketing strategies i.e., if someone finds solutions for one environmental or social problem which is economically profitable, then a new set of problems also can arise out of that and this cycle goes on and on. Sustainability in marketing strategy not only helps in competitive advantage but also opens door for cost savings and innovation. It is rightly said that companies cannot stay for longer in the market if they will not become truly sustainable. But, there are limited companies which are trying to adopt sustainability in their marketing strategy. Moreover they are also having unsustainable products in the market.

In addition to this, Vinor, K., Zillur, M., Kazmi, A.,A., and Praaven, G. (2012) point out that the future goal of sustainability marketing strategy should be focused on segmentation, targeting and positioning customer on

the basis of sustainability criteria along with designing sustainability marketing mix for better products and services, better prices, better distribution and better promotion (p. 487).

4. SUSTAINABLE DEVELOPMENT OF STRATEGIC BRAND PARTNERSHIP

Companies are increasingly careful with whom they operate, so that in conditions of maximum transparency preserve its reputation. Therefore, as much as 95 percent of the 250 largest companies providing regular public reports on sustainable development.

Not all partnerships are well planned and successful but they has grown exponentially. There is many motives within companies for connecting with other company to achieve sustainability goals. Corporate social responsibility (CSR) is very important for all companies and they are looking at it as a chance to win and make a good brand with reducing their environmental footprint. Many researchers have proposed typologies or continua to capture differing levels of commitment by businesses to Sustainability or to partnerships designed to promote those ends.

Most continua had four levels, although some only had three, and a few had five. Austin and Seitanidi's (2012) proposal represented a synthesis of the four-part models, ranging from philanthropic to transactional to integrative to transformational.

Austin and Seitanidi's (2012) explained that achieving successful partnerships at the upper right of the continuum, in Figure 2, requires that partners learn to capitalize on the creative tensions inherent in the partnership. The different levels also help to distinguish partnership outcomes, with those focused on reputation and image in the bottom left and those with wider societal impact in the top right.

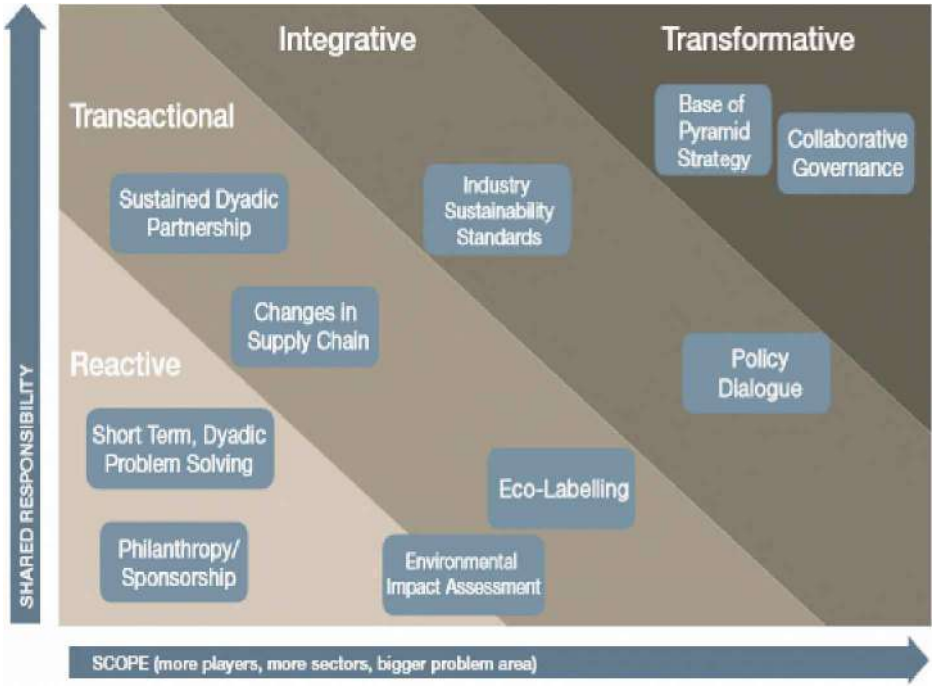

Figure 2: Sustainability Continuum (Austin and Seitanidi's ,2012)

Marrewijk and Werre (2003) explained that partnerships in the lower left-hand corner largely represent threat-induced, compliance or charity-driven responses. In this level of response, sustainability activities involve providing welfare to society by responding to government regulations or by providing charitable giving (p. 132).

The second level shows largely transactional sustainability partnerships, where the main reason for business is to make higher profit or better market share. The 3rd level captures integrative sustainability partnerships where businesses consider how to balance considerations with social and ecological concerns.

At the end, partnerships in the upper-right part in the Figure 2 shoes a final type in which other key stakeholders are involved in sustained interactions.

Young and Utting (2005) suggests that some do little, if anything, to advance the cause of sustainable development. Certain initiatives that are a form of eco-regulations can play, potentially, an important role in

promoting corporate social and environmental responsibility. Some so-called negotiated agreements, where government and business work together to design and implement programmes that retain the element of state sanction in case of non-compliance, have proved fairly effective. (p. 139-142).

5. SUSTAINABLE DEVELOPMENT OF STRATEGIC BRAND PARTNERSHIP IN PRACTICE - PEUGEOT AND TOTAL

TOTAL oils protects the engine from wear, transmit power and facilitate changing the transmission. Reaffirming its desire to be a leader in the domain of lubricants with high content of technology, innovative products Total brand are specially designed to save fuel (oil saving in fuel) , for the protection of the environment and improve the performance of every engine.

Oil products of brand TOTAL around the world tried out, tested and recommended by most manufacturers of cars - people who know what they're saying. In the United Kingdom, the company Total for Partners in the field of lubricants have chosen the leading car manufacturers like Peugeot, Citroen and Renault (it's Elf brand lubricants). They are perfect partners, because they all share a common ambition to be the best at all fields.

TOTAL and PEUGEOT are partners since 1995 and they renewed their partnership agreements recently. This renewal is not surprising , because the TOTAL lubricants are only brand to the French car manufacturer accepted at all, because they share the same goals. Researchers in companies TOTAL and PEUGEOT develop tomorrow's lubricants: oils which leads to less fuel consumption and thereby protect the environment and take fuel efficiency to better level. To further reduce their global CO2 footprint, their oil was developed with bio-sourced bases.

Main area of this partnership according sustainable development is: developing new engine lubricants and gearboxes, Total significantly contributed to reducing the TCO (Total Cost of Ownership), CO2 emissions, and fuel consumption by more than 7%.

TOTAL and PEUGEOT worked on an innovative project where the main theme was to secure future generations mobility that will be comfortable and energy efficient. They conceived lower CO_2 emissions (49 g/km).

This technological concept model uses the latest Peugeot and Total innovations in aerodynamics, weight saving and operating system. The performance of this concept can be achieved without the use of the main sources of energy, taking its base for highly energy-efficient production car model Peugeot 208. Achieving emissions of just 49 g/km and acceleration to 100 km/h in 8 seconds, then halved emissions at current most economical petrol engine, while at the same time receives motion of a small sports car that is fun and efficient. Accepting this technological challenge, the company Peugeot and Total as combining their research and development capacity to develop mobility solutions for future generations of cars. This car will have a special thermo-cycle management and improved fuel combustion, reducing friction engine components.

The result of engagement of company Peugeot is very positive, as the company has models with the lowest emissions in Europe, with an average reduction in emissions by 7 g/km on average 121 g/km in 2012. Total Group companies with their production parts (Lubricants, Fuels, Hutchinson, CCP Composites, Total Global Polymers) is actively involved in a number of Peugeot R&D projects to the production of new environmentally friendly vehicles.

6. SUSTAINABLE DEVELOPMENT OF STRATEGIC BRAND PARTNERSHIP IN PRACTICE - UNILEVER, PEPSICO AND COCA-COLA

Two months ago Unilever, PepsiCo, Coca-Cola and few more brands announced the cooperation where they combine their ideas and insights regarding main global challenges. This group performs under the name Paragon Partnerships, and wants to achieve the Sustainable Development Goals (SDG) through their collaboration and active market research.

With the United Nations Global Goals agreed and in motion, industry, governments and individuals can all play their part in contributing to the 17 point plan which aims to end poverty, combat climate change and fight injustice and inequality.

With no one single body or organisation able to find a solution to all of these challenges, Paragon has been created to be a single information source together with research bodies and industry.Launching in May this year, the vision for Paragon is to generate and provide access to quality insights on the issues that the world is facing which will help governments, academics and NGOs around the world. All insights hosted on the site will be linked to the Global Goals for Sustainable Development and will be available for Paragon partners to formulate fact-based programmes.Partners signed-up for launch include PepsiCo, Coca-Cola, Kantar, Nielsen, MetrixLab, GfK, Flamingo, Save The Children, The Market Research Society (MRS), Esomar and Sapient Nitro.Stan Sthanunathan, Senior Vice President, Consumer & Market Insights (2016, May 15).

Country clusters will segment the questions and it will be added to research conducted by the agencies for their clients during that quarter. The data will be hosted on a single platform to democratize the information and facilitate easy access; anyone signed up to the initiative Paragon will be able to access the company data.Through its research partners and their clients, Paragon expects to provide quality insights on the issues that the world is facing to allow governments, non-governmental organizations (NGOs) and academics to access and leverage that knowledge to help advance their work.

“In a rapidly-changing world, we cannot operate in silos. The past year has set the precedent with highly ambitious goals and frameworks created to address the global sustainability and development challenges that we all face. It is time to accelerate efforts to move towards achieving these goals and Paragon will allow us to share learning, data and insight, and encourages other businesses and industries to address these critical challenges affecting us all. By building a network of partners and working together, we can look for solutions which have greater scale and impact globally to address development and societal challenges”, said Stan Sthanunathan, Senior Vice President, Consumer & Market Insights at Unilever.

7. CONCLUSION

The strategic brand management have a main role in process of implementation sustainability in a company's main strategy and integration of the sustainability principles into all corporate parts. The imperative of sustainable business is not just a matter of altruism. It is primarily a question of the physical survival of companies in the world of limited resources. Adoption of a sustainable business model, together with other companies as partners, will enable them not only to survive in conditions of limited resources and more to long-term development.

Knowing that companies are increasingly careful with whom they operate, two cases from this paper showed great solution of modern world business and their partnership between some companies.

The first case showed the positive result of combining the research and development capacity to develop mobility solutions for future generations of cars. Peugeot has models with the lowest emissions in Europe, with an average reduction in emissions by 7 g/km on average 121 g/km in 2012. Total Group companies with their production parts (Lubricants, Fuels, Hutchinson, CCP Composites, Total Global Polymers) is actively involved in a number of Peugeot R&D projects to the production of new environmentally friendly vehicles. This case showed the great example of sustainable development of strategic brand partnership.

The second case testifies the definitive development of awareness and the importance of sustainable development of strategic brand partnership. The future will hopefully show the success fro of this network of partners under the name Paragon Partnership.

SPONSORSHIP OF SPORTS EVENTS AS A MARKETING TOOL

Mila Petrović*[1], Jelena Vučinić[1]
[1]Faculty of Organizational Sciences
* Corresponding author, e-mail: mila.m.petrovic@gmail.com

Abstract: *The focus of this paper is the concept of sponsorship of sports events as a marketing tool of the sponsoring company. The areas which will be explored through the research are commercialization and development factors of the sports industry, as well as the concept of sports sponsorship and its main goals. The aim of this paper is to contribute to the scientific perspective of the sport event sponsorship, as well as to the quality of future sponsorships between the organizers and the companies.*

Keywords*: sponsorship, sport, event, sports events, marketing, marketing tool, communications*

1. INTRODUCTION

The development of modern technologies, digitalization and rapid exchange of information are just some of the trends that cause many changes in the way businesses and access to target groups with regard to the corporate sector. In recent years the increasing convergence of the sports and entertainment industry is noted, and thanks to new technologies, the sports events are getting more and more publicity. This further promotes not only certain sporting disciplines, but also organizations and companies that have supported and provided sports events to happen. The goal of this paper is to present the concept of sponsorship of sports events as a marketing tool by analyzing existing literature and modern marketing trends. In the beginning, the role of the marketing in the spots industry is explained, followed by analysis of the concept of sport events sponsorship.

2. ROLE OF THE MARKETING IN THE SPORT INDUSTRY

2.1. The commercialization of sports industry

The commercialization component is present in the sport for many years – even before the modern era, Greek athletes were receiving cash prizes for achieved sport results. However, not a single historical period is more characterized by rapid growth of commercialization in sport, as it is the case with the previous three decades. Today sport is a serious business where large companies take a great part and have influence on the development of the sports industry. Prominent athletes have become a product of this industry, sports teams and individuals are exchanged on the market, sponsorship of sports events cost millions of Euros and TV companies pay large sums of money in order to receive the right to broadcast these events. Furthermore, multinational component of sports industry makes it more challenging and appealing to the corporate sector. The importance of the marketing function in sport organizations is proved by the fact that more and more sports organizations employ marketing experts in order to design and organize specific campaigns. Commercialization of sport allows sports organizations to gain financial benefit for training and entertainment activities and this has become crucial for both development and survival of the sports industry.

2.2. Sports industry products

A product can be described as "*something that meets a need or desire while using*". Gerber-Nel (2004) says that product is a solution to the problem as its purchase provides some kind of a benefit. With that said, consumers actually buy the benefit, not the product. Sports products can be extremely complex, which is obvious when you take into account the different types of sports disciplines and events. Sports products are diverse and complex due to additional, mental and physical dimensions – some sports products affect consumer's mind (like in the case of a sports event), while others affect the body (like participating at the event itself). A sports game can be classified as a pure product, while the activities related to the game (food and beverages, merchandise, entertainment during half-time, video walls), can be classified as additional component to the product. Lately there are more experts who advocate that primary product (like football

match) is not the most important, and that marketing professionals need to focus on the positive experience of the consumer, rather than the outcome of a match.

2.3. Development factors of sports industry

According to a report published by the consulting company PricewaterhouseCoopers (2011), some factors that greatly influence the development of sports industry are:

- Sport and entertainment converge;
- Social media;
- Commercial challenges;
- Compensation for sports persons;
- Internationalization;
- Broadcast rights.

Every day we see an increasing **convergence of sports and entertainment industries** and their development that go along the development of modern technologies. Sponsorship and media rights have become the main sources of profit, putting into question the traditional ways of earning from sporting events. Event organizers are under pressure because poor organization of the event as a consequence has the abandonment of nowadays extremely important stakeholders – the media and the corporate sector. Sport and entertainment events are increasingly being staged together, as a way to enhance the overall experience and extend the length of events − and therefore the time that supporters and viewers stay. With an average US audience of 111 million viewers, the 2011 Super Bowl became the most-watched program of any kind in the history of American television. In addition to the sports game this event includes performances of the world's biggest music stars (PricewaterhouseCoopers, 2011).

The increased usage of **social media** is one more factor that has the great impact on the industry of sport. Social networking continues to create opportunities and challenges for traditional broadcasters, as well as to the faithful followers who are more interested to accept new ways of communication. Partly as a result of this open personal interaction, social media allows fans to get closer to athletes and sports personalities, and provides sponsors with an opportunity for two way communication, thus enabling them both to embed their brand, and also to understand and manage how fans perceive the brand. According to research conducted by Burst Media (2012), 45% of viewers aged between 18 and 35 years follow their favorite teams and athletes on social networks, and 35% of them regularly use social networks to find out or share sports facilities. Perhaps the most important effect of these networks, however, has been greater audience empowerment: individuals use technologies to become actual participants in the sport communication process. According to Newman (2013) it is important to note that social media have an impact on the visitor in various phases. Sports event marketing can begin before the visitor decide to attend, may be continued during the event and after the event ends. Sporting events are promoted ahead of time to build enthusiasm for the event. Promotion during and after the event are designed to encourage repeat consumption of rather sport, or the products of the sponsor"s company. Every aspect should be considered and planned for by sport professional. Furthermore, the use of social media at each point should be considered to maximize the number of “personal touches” the sport consumer experiences in relation to the event.

Sports industry today faces challenges when it comes to financial and **commercial aspects**. Organizers are under pressure to maintain and increase the value of the event in accordance to the ticket price increase. If viewers are paying more money, they expect an extra value in return. The same principle applies in case of gaining right to broadcast certain event. The balance between price and value is further complicated by the deep sense of ownership that many sports fans feel for their club or sport. Again reflecting trends in entertainment such as brand and product placement, sports sponsors want to be embedded within the product, rather than just being a name on a shirt. Naming rights remain a popular investment for sponsors, both for new and established sport and entertainment venues. Examples include Barcelona Football Club"s five and-a-half year, €171 million shirt sponsorship deal with the not for profit Qatar Foundation. (Barcelona considers ending Qatar sponsorship deal over 'social issues', 2015). However, this type of open commercialism does not always go down well with paying customers, and thousands of Barcelona fans signed a petition demanding the agreement be dropped.

In many professional sports, the focus on providing the most entertaining and successful product is driving rapid inflation in **player costs**. This leads to two types of risks when it comes to the sustainability of sport organizations. First of all, large payments are putting at risk the long-term survival of an organization whose core business is not fun, but professional sport. On the other hand, branch associations and organizations strive to keep good athletes with significant results, thus restricting their ability to monetize their work and glory. This problem can lead to shift of activities: for example, the start of the 2011–12 National Basketball

Association (NBA) season was delayed by a lockout caused by a standoff between players and NBA owners over revenue sharing and the structure of the salary cap (PricewaterhouseCoopers, 2011).

A further challenge for governing bodies is the increasing pressure to grow their sports in new **international markets**, while at the same time maintaining the local support base and the integrity of their competitions. The English Premier League has been widely criticized by fans and media worldwide for proposing a „39th game" in an overseas location (Chelsea fans oppose FAs Premier League proposal of staging a round of matches overseas, 2014). Yet some fans in other sports and countries are more welcoming of international expansion. Most notably, decisions have been taken to hold the FIFA World Cup in two emerging sports markets − Russia in 2018 and Qatar in 2022 (FIFA World Cup, n.d).

While **media rights** revenues are continuing on a generally upward path, the size of the market remains volatile year on year, depending on the presence or absence of major events such as World Cups and Olympics. What is more, the value of broadcast rights for international tournaments varies depending on local screening times in regions around the world. On purchase influences time zone of the event, and even the day of the week (PricewaterhouseCoopers, 2011).

2.4. Marketing of sports events

Goldblatt (2010) points out that in planning, preparation and maintenance of special events, marketing function is certainly of great importance for defining goals, build partnerships and promotional activities for the event itself. For example, in the preparation phase of the external events marketing has the task to provide sufficient financial and material sponsorship, or the number of tickets, to allow the prompt maintenance. Promotional activities of a special event can include: advertising, public relations, establishment of partnerships, physical promotion, guerilla marketing and direct, personal contact. If it comes to development of an internal, closed event for which there is defined and sufficient budget, the function of marketing is unloaded in terms of proving the financial justification or approval for certain actions. In this case, marketing is responsible for ensuring the appropriate number of guests/visitors. In both cases, the function of marketing carries the greatest responsibility when it comes to creating promotional materials and communication with stakeholders. The essence of the existence of the marketing campaign for the event is to ensure that every decision made in the planning and preparation of events brings added value to the overall outcome of the event. For this reason it is extremely important to choose a good strategy for the proper maintenance objectives, test all the ideas and use feedback to improve and develop creative solutions that will highlight the value of the event that visitors expect in exchange for a ticket or time invested.

3. SPONSORSHIP OF SPORT EVENTS

3.1. The concept a sport sponsorship

First ever sponsorships were noticed in a form of patronage, when patrons supported talented individuals who were building a career in culture or arts. Even in the early stage, the patrons expected something in return. During the Roman Empire, patronages were rulers and distinguished military representatives, and this role was later passed to authority representatives and aristocrats. Queen Elizabeth and King James I supported the work of Shakespeare (Shakespeare's Patron - Queen Elizabeth, n.d), while Roman Popes and other church figures supported Michelangelo and Leonardo Da Vinchi. In seventeenth century, the concept of sponsorship hadn't existed, but certain benefits for patronages, such as advertising, were introduced. This was one big step in building the modern concept of sponsorship.

Further development of the concept was noticed in twentieth century. In 1924, The Eveready Hour became the first ever commercially sponsored radio show (Biographical Dictionary of Radio, 2011). Golf, motor racing events and tennis matches were roots of the modern sponsored events. Companies from automotive, tobacco and alcohol industry were the first ones that were sponsoring events. In 1958, The Kentucky Derby Festival became the first ever event that had one of its activities named after a sponsor: Philip Morris Festival of Stars. The most important growth of this concept happened between 1970 and 1990. Even though many organizers were skeptical about losing their audience, they started to accept corporate sponsors more and more often. In that time, sponsorships still couldn't show any financial benefit – only advertising and publicity. The 1984 Olympic Games in L.A. were saved by corporate sponsorships and this was an important milestone in the development of the sponsorship concept. During the next 10 years, more than 40.000 events were organized only thanks to corporate sponsorships, which also caused companies to study the importance and effects of event sponsorships.

3.2. Global sponsorship market

Corporate sponsorships in Europe have drastically increased during the last years. In 1980s, when the concept was established in the USA, many European event organizers wanted to avoid having corporate sponsors, but after realizing that they are missing financial support, they skeptically started to cooperate with large companies. Thanks to a careful choice of the corporate partners, many events have established strong cooperation with the corporate world that gives them much more possibilities than they had before (Skinner, B. E, Rukavina, V, 2003). During the 1990s, the change in the way that cultural events were enabling the financial support was one of the biggest trends of the modern world, and many researches show that this trend is going to grow in the future. Corporate sector is seeing more and more different ways of participating in various events, not only cultural, but any events that have a positive contribution on the society. In 2014, the global sponsorship spending resulted a total of 55,3 billion USD, and it grew to a 57,5 billion in 2015. The forecast for 2016 is 60,2 billion, which means the market is growing year by year (Sponsorship spending worldwide by region 2009-2016 | Statistic, n.d). One of the reasons for this growth is an increase of the athletes and coaches paycheck. In the end of 2014, the number of companies that are investing over 15 million USD in sponsorships grew to 107. Among them, the leader is PepsiCo, whose yearly spending is between 355 and 360 million USD. The second and the third place go to Anheuser-Busch InBev and The Coca-Cola Company with yearly spending of approximately 300 million USD.

Sponsorship as a concept became an important item in strategic corporate planning and it is very likely that soon it will be an inevitable tool in companies" integrated marketing communications plans. This tool will allow companies to use the possibilities of traditional advertising, as well as emotional and experience benefits built through sponsoring a sports, cultural, art, educational or social event. What used to be a sponsorship with a minimal budget tends to grow into an important part of integrated communication channels, where sponsorship itself is just one element, and many other players have important roles in its success.

3.3. Goals of sport sponsorship

The International Events Group defines sponsorship as "*financial contribution to sports, art, entertainment or other industry entities that allows sponsors to use the commercial potential of these entities*". (Skinner, B. E., Rukavina, V, 2003). According to various researches, companies sponsor events mainly for their own interest. However, reasons that can influence corporate and employer brand, such as raising awareness about a certain social problem or community contribution, are also present. The definition of sports sponsorship in the words of Shank (2009) is "*Investing in a sports entity (athlete, league, team or event) to support overall organizational objectives, marketing goals and/or promotional strategies*." Amis, Slack and Berrett (1999) believe that "*sport sponsorship should be considered an important resource which can help companies to secure a position of competitive advantage*". They presented the results of an analysis of 28 national and multi-national Canadian firms that had been involved in sport sponsorships at the national or international levels and they "*tried to demonstrate that sponsorship can be an extremely valuable resource with great utility in a firm's quest for a sustainable competitive advantage. For this to be achieved, however, the firm must approach any sponsorship agreement as a potentially valuable resource worth spending time and effort on developing.*"

One of the biggest benefits of sports sponsorships is raising the brand awareness. Miloch and Lambrecht (2006) conducted a research regarding consumer awareness of sponsorship at grassroots sport events. Generally, the recall and recognition rates in this study were slightly lower but comparable to sponsorship awareness studies, particularly those focusing on large sports events. This suggests that when compared to mega-event sport consumers, participants and spectators at grassroots and niche sport events may not possess the same level of sponsorship awareness. However, according to authors "*sponsorship of grassroots and niche sports has proven effective in generating a return on investment for sponsors at this level*". Another study (Biscaia, Correia, Rosado, Ross, Maroco, 2013) examined the relationships between both attitudinal and behavioral loyalty with sponsorship awareness, attitude toward two actual sponsors, and purchase intentions. Results indicated that *"although fans may be aware of a great amount of team sponsors, their intentions to purchase sponsors' products will only increase if they develop a favorable attitude toward those sponsors"*. Therefore, this study *"highlights the role of focusing on actual sponsors, rather than generic sponsors, given that the relationships between the team loyalty constructs and sponsors' outcomes differed according to each of the sponsors".* The main reason for including sponsorships into a marketing mix of the company is the overall presence of sports in everyday lives of people of different age and lifestyles. Polonsky and Speed (2001) reckon that management of the sponsor company firstly should answer the following questions: What type of consumer is targeted (existing or new)? What type of customer

action is required (purchase or purchase and secondary action)? What is the firm's financial commitment (unlimited or capped)? What leveraging activities are required?

Just like advertising, the goals of sports sponsorship can be direct and indirect. Direct goals are connected to short-term buyers" behavior and sales incensement. When it comes to indirect goals, it can be intent to build a corporate image, or a specific brand promise. All goals can be grouped in a following way:

- **Raising the awareness about the company.** When sponsoring a sports event, a company is being exposed to a large audience. This means the company is raising the awareness about its product, service, or corporate image. Various researches prove that sponsoring an event gives much better results when it comes to raising the awareness about the brand, than traditional advertising does. According to one respondent in the study that was conducted by Farrelly and Queste (2005) "*sponsorship value will always be evaluated in terms of contribution to the brand, and weighed up against what was spelled out in the original agreement such as the level of sales and gains in brand preference in select markets.*"
- **Market positioning.** Another goal can be to eliminate any kind of competitor threat and increase the position on the market. In other words, if a company decides not to sponsor an event, it is very likely that its competitor might decide to do so.
- **Reaching the target groups.** If target group of the company matches the target group of the event, a company can benefit of the sponsorship much more than of traditional advertising activities. Sports industry is a great example for this. For example, if a company that produces sports goods sponsors a marathon, the company is automatically targeting its potential buyers.
- **Relationship marketing.** Building the relationship with the customers could be another motivation for companies to sponsor an event. If a company representative participates in the event, he can get in touch with current and potential clients, establish cooperation and help in building their business. VIP lounges are a typical practice when it comes to sports events that prove this goal. Tsiotsou and Alexandris (2009) believe that "*highly attached fans are more likely to develop positive image about their team's sponsor and consequently express positive intentions to say good things and buy the sponsor's products.* They propose marketers to *"work on the development of team attachment and the creation of positive sponsor image, in order to increase sponsorship effectiveness*".
- **Building the corporate image.** Many companies are investing a lot into creating a unique public presentation. For many companies that are doing B2B business, sponsorships are a way to communicate their internal values externally. Events that these companies sponsor should be chosen carefully, as the whole image depends on the success and publicity of the event, and the message it sends to public. For example, message that is being sent by the organizers of Formula 1 events – fast, dangerous, courageous, exciting and risky – can fit many organizations that want to present themselves as dynamic. However, it would not be an appropriate event for companies that want to position by communicating different values: calmness, safety, security, stability – for example, insurance companies. Every sponsored event should be aligned with company"s corporate values. One study has put things in perspective for many sport marketers in that "*logo placement, along with myriad of other sponsored activities at the venue, is just a small fraction of what the spectator visually records and assigns meaning to. In order to transcend the illusion of effectiveness and elevate sport sponsorship activation to another level, sport managers today must provide an experience that is more than a simple, one-dimensional logo viewing*" (Choi, 2006).
- **Sales increase.** This is a common goal for all companies that sponsor sport events - usually the ones selling sports goods or services. It happens often that events are being created especially for the sponsor in order to achieve sales goals and increase the profit. Without sponsors, some sports events today would not be possible, which give the right to companies to have a certain financial benefit.
- **Relationships with the local community.** When companies sponsor a sports event, they are sending a message that says they support sports and physical activity. Consumers connect these companies to a positive contribution on the society. In some countries where the government does not invest in sports a lot, corporate sector holds the key role when it comes to building a healthy society environment and contributing to sports activities.

3.4. Measuring the effects of sports sponsorship

When it comes to measuring the success of sponsorship investment, it is important to measure it from signing the contract until the end of follow-up activities. Meenaghan (1991) suggests the following methods of measurement:

- **Measuring media coverage.** Sponsors are often using media coverage as an indicator of success. Evaluation of this kind could be measured in the following ways: time of media stream, number of viewers or printing amount. It is very important to note that this method measures only the coverage

without its actual effect. Apart from traditional media channels, the big influence is now related to social media and web portals.

- **Measuring communication odds of sponsorship investment.** Sponsors tend to measure communication success of the event, since sponsorship is used to achieve communication results such as raising and increasing brand awareness, etc. Some sponsor companies are measuring the sponsorship success by conducting surveys to find out how many are people connecting the event with their company.
- **Measuring sales efficiency of the sponsorship.** Sponsorship is facing similar problems as traditional advertising or other communication activities, when it comes to relationship between sales results and sponsorship investment. This happens for many reasons and some of them are usage of different marketing tools at the same time, previous marketing activities and competition behavior. However, many sponsors are often using sales results to prove the success of sponsorship investment, even when it is very difficult to measure results.
- **Monitoring attendees' feedback.** In some cases, when relationship with the attendees is one of the goals of sponsorship, monitoring their feedback can be a good way to measure the effect. This feedback can also be useful when it comes to evaluating event organizers.
- **Cost-benefit analysis.** When a company has more philanthropic than commercial reasons to sponsor an event, that company should conduct other ways of measuring the effects, different than traditional ways. In this case, the most important activity in the process of measuring is to research and define the stand of top management which will be used as a base for measuring.

3.5. Good case practice – "Thank You, Mom" campaign by Procter and Gamble

P&G, the largest Consumer Packaged Goods company in the world was a mid-tier sponsor of the 2010 Winter Olympic Games. This impactful investment led to an "Official Olympic Sponsor" of the Summer Games in London. The idea of their „100-day phased plan" across creative, media, PR, and shopper marketing outlets, was to create a global "Thank You Mom" movement and celebrate mothers who inspired, sacrificed and supported each athlete in their quest for Olympic glory. Through moms of the Olympians, they connected to all mothers, P&G"s core consumers. The company used social media to debut the emotionally powerful "Best Job" video that introduced "Thank You, Mom" and "Proud Sponsor of Mom" messaging. Within three weeks, "Best Job" became a digital sensation, and that was just the beginning. The plan allowed P&G to control the level of connection to the Olympics, growing more prominent as the Games drew nearer.

This was the most successful campaign in P&G"s 175 year history that delivered $200MM+ incremental sales (USA) and record-setting P&G ROI results. It increased brand portfolio linkage to P&G for 11% and recall of P&G"s ads was +38% higher than other US Olympic sponsors. Other important results include 33.6 billion earned media impressions, 17 million views on YouTube, 65% increase in number of Facebook fans and 20 time more in Twitter followers (Medaling In Media: P&G Proud Sponsor of Mom, n.d).

4. CONCLUSION

Year by year, sports industry marks a significant growth and the some investments top GDPs of many countries. Sports industry is coming closer to entertainment, which means possibilities for commercial activities are growing. A modern consumer does not want only a product that will fulfill his basic needs. He wants a product that he will be able to identify with, a brand whose values he could live every day. Sports industry is getting in touch with a large audience, with people of different age, location or lifestyle, which means it is a perfect ecosystem for reaching a wide audience, as well as specific targeted groups. However, it is important to note that sponsorship of sports events now days go far beyond a one-dimensional logo viewing. Generic sponsors do not add specific value to an event – and along with that, they cannot expect a lot in return either. When making a decision about sponsoring an event, sponsors should focus on their customer and its needs. Together with the organizer, they should aim to provide an extraordinary experience to their customer – through brand activation and other, specific company-related activities, which will allow them to fully utilize and maximize the investment of the sponsorship. As technology is in a fast progress, there can be more ways to both track, measure and evaluate sponsorship investment, as well as to engage the spectators and a specific target group more deeply during the sponsored event.

INNOVATIVE APPROACH TO ONLINE MARKETING FOR BOOK PUBLISHERS

Milan Prtenjak
Klett Publishing House Ltd. – Belgrade
*Corresponding author, e-mail: milan@klett.rs

Abstract: *Books and publishing business have undergone tremendous changes since 1980s. The causes of these changes are numerous, however the main cause can be stated as being digitization, which has brought novelties in all business processes of publishing houses.*

Publishing houses are faced with great challenges and books, as both commodity and cultural asset, don't have the same status in the society as once did. Book publishers need to find ways to remain profitable in new circumstances. If online marketing is implemented appropriately in the business of publishing houses, it can be more efficient and much more cost effective than traditional marketing.

The paper shows a digital marketing model that can be applied for the realisation of business and marketing objectives of publishing houses. The model will be reviewed through a product policy, electronic customer relationship management (eCRM) and communication policy.

Keywords*: book publishing, online marketing, eCRM, website, social media*

1. INTRODUCTION

Book publishing is a centuries-old business and cultural activity. Since release of the programming language PostScript (1984) and the program for desktop publishing PageMaker (1985) book publishers have been dealing with numerous changes in all aspects of their business. It can be contended that today's numerous and intensive changes were primarily caused by technology (Tat Keh, 1998). The application of digital technologies has caused that only traditional, printed books remain analog (MacRitchie, 2009). Although it is impossible to predict the further development of book publishing, it may be presupposed that many changes are still to come (Hughes, 2014) and book publishing will hereafter be very active and unpredictable activity.

Book publishers face considerable challenges and as a threat to their success may be listed the following issues (Hughes, 2014):

- Publishers and authors consider all books as potential bestsellers.
- According to the information from the people in the publishing business, 60–80% of all titles do not bring money or they are unprofitable in the first year.
- Traditional models of success prediction cause high risk of unprofitability.

Regardless of their size and history, publishing houses cannot focus only on their primary activity ignoring the changes that affect the market, readers and society as a whole. Every publishing house which wants a long-term success should be aware of global and market-specific changes and needs to respond quickly to all new factors. One of the ways to respond to modern requirements is the application of appropriate business strategies which would include online marketing.

2. MARKETING STRATEGY FOR BOOK PUBLISHERS

Today's media are being consumed in digital form, while users expect to access online content very easily. This applies to all traditional media – newspapers, television, radio, music, film. Due to the large amount of online content that is being offered without a charge, users expect to pay only for exclusive content. Media companies and content creators decide whether to create free content for the mass market or exclusive content that will be charged. Many news websites and cable television networks charge for the access to their content because of the quality they offer. Book publishers do not have a possibility to choose whether they will create free or exclusive content. Despite the form of the final product (printed book, ebook, audio book) book publishers need to create the content of premium quality which will be charged.

Book publishing has traditionally been product-oriented and marketing activities have been primarly focused on the promotion of new titles (Clark, 2014; Vulf, 2011). The user is becoming even more important in the competitive enviroment but also more demanding and less loyal. Book publishers need to break a long tradition and focus on their customers. Although some authors have enormous success which can affect the

profitability of their publishers for a long time, all publishing houses actually serve niche markets (Clark, 2014). It is very important for every publishing house to define the target group, its size and potential value. Book publishers should build long-term and direct relationships with their customers in accordance with their business and marketing strategy. As a result, the production of new books needs to be aligned with the customers' needs.

This paper describes how book publishers can use online marketing as an integral part of their business strategy, enabling them long-term profitability. The proposed method includes three components which should be applied together:

1. Product policy
2. eCRM
3. Communication policy

2.1. Product policy

The book as a product is the basis of every publishing house (Then & Schmidt-Stölting, 2009). In order to be profitable, it is essential for a publishing house to publish every year a sufficient number of new titles which will be successful in the market. The commercial success of a book can be affected by many factors, but the most common reason for book purchasing is its topic (Vulf, 2011). However, a high percentage of fruitless titles is typical for book publishin.

Every published book starts from the manuscript which a publishing house acquires from its author. The acquisition of the manuscripts has traditionally been left to the editors who don't know neither the market nor the readers. The marketing strategy of publishing houses should include the acquisition of the manuscripts in agreement with the marketing department.

The acquisition of new manuscripts can occurre in two ways: (1) The book publisher can invite the authors over the website to apply following the given instructions, and (2) The book publisher can actively seek the authors in accordance with the publishing plan. The Internet can be very helpful for finding new authors, especially blogs and social media. Successful bloggers prove that they know how to write about a particular topic in a way that attracts the audience and the visitors of their blogs represent at the same time the future readers of the book. Social media allow individuals to become popular avoiding traditional media and book publishers can assess their potential for writing a book.

The customers from the target group can be involved in the book production after the acquisition of a manuscript. The reasons for this are: (1) Customer feedback during the editing and designing process and (2) Establishment of the direct contact with the target group. In the case of less demanding activies such as choice of cover, title, etc. the publishing house can use social media and emails to invite the customers to participate. If users are expected to do more demanding tasks such as reading and commenting the manuscript, the publishing house can invite a certain number of users to a long-term cooperation with financial compensation. Such users could be the promoters of the published books, especially it they have their own blog or are active users of social media.

Through the process of book publishing, publishing houses add value to the manuscript in order to sell it at a higher price than the total costs of its production (Clark, 2014). The Internet allows publishers to add value to the already published books. While the website of the publishers of fiction can contain videos, audio recordings, press releases, etc. textbook or non-fictional publishers can provide additional materials such as files for exercises, online tests, learning management systems, webinars, etc.

2.2. eCRM

Successful online marketing strategy in today's competitive environment should include the implementation of CRM (customer relationship management). CRM is a strategy in an organization that is widely implemented to manage and promote the company's interactions with customers (Arab, Selamat & M. Zamani, 2010). It involves managing detailed information about individual users. The application of technologies that support CRM is the key element of online business (Chaffey, 2015) and the task of eCRM (electronic customer relationship management) is to establish and maintain long-term relationships with clients. Today CRM cannot be separated from eCRM (Chaffey, 2015).

While traditional marketing represents the mass marketing, the Internet has enabled a user-oriented marketing that helps establishing long-term relationships with customers. Monitoring of former and current user behavior enables better planning and implementation of future marketing activities.

Book publishers are still inert when it comes to user data and their use. The reason for this may be the lack of experience because the contact with customers is usually being established indirectly over bookstores. There are no available data about the use of eCRM among book publishers, but all those who want to build direct relationships with their customers should use them in the future.

eCRM includes creating user profiles, tracking their purchase history and buying habits which allows better understanding of users' needs and builds the fundament for communication with them. It is essential that publishing houses collect data from every touchpoint with their customers – website visits, shopping, contacts with sales representatives, phone calls and emails received from customers, communication via social media, etc. After establishing of direct contact with the customers, book publishers enhance understanding of users' needs and can create books which will have a superior value for them. The decision on new titles should also be based on the information about the customers which could increase chances for market success and at the same time can win a loyal customer.

2.3. Communication policy

The Internet and especially Web 2.0 represents the Copernican revolution in communication between users and organizations. Users are no longer passive recipients of messages, but they are able to initiate communication with publishing houses or other users, primarily using social media. While the communication in traditional marketing can be personal (book promotions, book fairs, etc.), such contacts are short and superficial. Online communication allows establishing and maintaining direct and long-term contacts with customers.

Every book publisher can choose tools for online communication in accordance with its resources and marketing objectives. The available online tools can be the following:

- Website
- Blog
- Search engine marketing (SEM)
- Email marketing
- Social media marketing
- Online PR.

In order to use online tools for communication with their customers, book publishers should conduct analysis, planning, implementation and control.

A **website** is the key marketing tool for publishing houses (Baverstock, 2015). It is the core of the entire online communication for an organisation (Olbrich, Schultz & Holsing, 2015). The building of a website is a long-term process that never ends. The website of a publishing house is the hub which connects offline and online communication since the instruments of traditional marketing (catalogues, brochures, etc.) need to guide users to the website. A website can have an informative role but also can offer an online shop with payment system. Regardless of the funcionality of the website, particular attention should be payed to its information architecture, usability principles and user-centered design. However, the website design should be in accordance with the profile of the publishing house and its target group. A website of the academic publisher is expected to be significantly different then the one of a publishing house for children's books.

Every published book should have its own web page which can be reached with links from other web pages or easily found using the search. Such web pages can contain detailed the data about the book with clearly highlighted title, author's name, year when it was published, format, synopsis, sample pages and the list of other books written by the same author.

The books on the website should be grouped into specific categories in order to help visitors to find them. The same categorisation can be used for creating of user groups in the eCRM system. The publishers of fiction can classify their titles by genre (thrillers, romance novels, historical novels, classic literature, etc.), while textbooks can be classified by school subjects.

A website of publishing houses can be used for creating additional value to the books with additional materials for the visitors (video materials, online exercises, software, files for download, etc.). Some books can have their own websites if the publisher expects them to be very successful. In the case of book series such websites can be popular for a long time.

If we assume that book consumers like to read, a **blog** could be an effective communication tool. Blog posts can be written by employees or the authors who operate with the publishing house. The topics and format of the blog posts depends on the profile of the publishing house and their target group. In some cases a blog can be launched only for one book as a promotion tool.

Search engine marketing (SEM) is a set of measures which aim is a better position of a specific web page in the search results of the web search engines. As their goal is expected more visits of the web page. SEM consists of SEO (search engine optimisation) and search engine advertising. The factors which affect the position of the web page in the search results can be external and internal. One of the most important external factors is popularity of the links, ie. number and quality of inbound hyperlinks. The internal factors can comprise the structure and the content of the web pages. The obtained results are called organic search results. Search engine advertisement turn on advertisements on the web pages with the search results. Everyone who is responsible for SEM in the publishing house should focus on the keywords which are expected to be used by consumers. Book publishers may use experts for SEM, but much can be done with good structure of the website and web pages.

Email marketing involves systematically sending of emails with the information which correspond to marketing objectives (Olbrich, Schultz & Holsing, 2015). Although it was believed that social media would decrease the popularity of email marketing, it is still important for business purposes. Email can be used for the communication with customers and their retention. Email is also an efficient way of direct marketing and can be useful as a sales channel.

The main prerequisite for an effective email marketing is a list of recipients. Email addresses can be collected through the website, but book publishers should every opportunity to collect them asking the visitors to give their email addresses if they want to be kept informed.

Newsletter is a special kind of emails that are sent to a specific schedule (usually once a week or once a month). If the publihshing house have different publishing programs for different consumers, the recepients of newsletters can be classified by genres. Email marketing offers insight into the success of the campaigns and book publishers can analyze the percentage of delivered emails (delivery rate), percentage of open mails (open rate) and the percentage of clicks on the link (clickthrough rate).

Since **social media** are popular all age groups, their application is indispensable in online marketing. Although there are many papers dealing with the theory of social media, there is still no universal definition of the term. For the first time in history all social strata have powerful instruments to affect the public opinion and inititate communication with organizations. Social media enable their users to be content crators.

All social media share the same characteristics (Olbrich, Schultz & Holsing, 2015):

- topicality
- virality
- multimedia
- spatial and temporal availability
- interactivity
- price/quality ratio.

Facebook is the biggest opportunity for book publishers because it is the most widely used marketing tool (Baverstock, 2015). Its advantage is the large number of users and a book publisher can find his targer group among them. In comparison with the Facebook profile, book publishers should create the Facebook page. This means that users don't need to send friend requests and there is no limit of 5,000 friends. In addition, the Facebook page provides analytics that tracks the performance of the posts. Posts can represent different kind of materials which are supposed to be interesting for users (text, images, links, videos). The publishing house should have the strategy of post publishing and needs to resond quickly to user comments.

According to official data, there are 380,000 Twitter users in Serbia. From this reason, Twitter can also be used as a part of the online marketing strategy. The Twitter timeline also enables posts of different content and it is particularly suitable for sharing links that lead to other relevant content. It is recommended for publishers to post news, opinions, interesting stories, links to interesting content, daily tips, links to the website or blog and links to the competition (Baverstock, 2015).

The popularity of YouTube and low cost of video production can be used for video content. A publishing house can have its YouTube channel with relevant videos about books and their authors.

The focus of the PR activities should be positive relations between organization and its environment. PR in publishing business involve creating free publicity and enhancing the brand using authors and media (Clark,

2014). Traditional PR instruments in book publishing are press conferences, book presentations, book fairs, interviews with book publishers or authors, telephone interviews with media representatives, PR ads, etc.

Online PR have the same function as traditional PR, but their key element is maximizing of positive references to organizations, brands, products or websites of third parties which are online and can be follow by the target group (Chaffey, 2015). Since some individuals can be influental online, it is important to build long-term relations with them. It can be bloggers, tweeters, Instagram users with a large number of followers, admins of online forums, etc. As tools for online PR activities can be used corporate website, social media and blogs which can transmit important information. Since the social media enable a two-way communication, they can be used for asking questions, commenting or expressing of complaints. Fast responding is very important in such situations, but the book publisher needs to analyse the reasons for customer complaints in order to improve the quality of products or services. Mistakes in books, especially in textbooks, can cause attention of the social media users and journalists as well, which could bring negative publicity to book publishers.

3. CONCLUSION

Tremendeous changes in book publishing primarily caused by new technlogies require from publishers to change their centuries-old way of doing business. Regardless of the tradition and a cultural role that book publishing has, it is essental for book publishers to create bussines and marketing strategies which will include online marketing. The focus of the strategy should be the customer and his needs. Choosing the target group and serving it with online marketing can be the basis for profitability of a publishing house. The model proposed in this paper can be applied to publishing houses in Serbia and abroad.

Abstract: *The purpose of this paper is to introduce the importance of putting Key Performance Indicators (KPI) into the holistic view of Continuous improvement methodology in modern manufacturing enterprises. The research was based on the continuous tracking of the OEE (Overall Equipment Effectiveness) indicator using the common tool of Lean approach – control charts. The simulation has consisted of two different types of control charts. Adopted conclusion expresses that fluctuation of OEE, and functioning of the fictive company itself, are susceptible to a positive influence of Lean management models. This study could be valuable, both for the academic and practical purpose, due to its structure which contains the practical method for measuring and continuous improvement of the production process, as well as the obtained business result itself.*

Keywords*: KPI, continuous improvement, lean manufacturing, OEE, control charts, simulation*

1. INTRODUCTION

In the modern business environment, there is the essential need to be constantly aware of extremely fluctuated market trends. After the commonly followed Western approach in business philosophy, today's importance of cost reduction principle caused the huge percentage of successful enterprises that base their business processes on Japanese Lean manufacturing model. Furthermore, the lean approach doesn't only mean the lower costs and money saving, but also the focus on involving all process participants in the venture of developing every single part of it.

Sources of knowledge which were being used during the research were the academic database of scientific papers (Science Direct, JSTOR, etc.). These sources were combined with the several case studies that were the basis for executed simulation. Using this kind of method, it has been tried to present how the appropriately established process of tracking and "attacking" the deviations, could lead to their reduction and bringing the business parameters into the zone of conformity.

The rest of the paper is organized as follow: Section 2 introduces the concept of KPIs and their definition and purpose. Section 3 describes how previously mentioned indicators could be involved in arranged system of continuous improvement, where management could derive the real meaning conclusions from indicators´ quantitative structure. After the section 4, which is related to the concept of control charts, section 5 is written to explain OEE indicator, as well as the simulation process carried out by using both mentioned tools. Section 6 concludes the paper with the review of the presented study and future research intentions.

2. KPIs – DEFINITION AND PURPOSE

In spite of growing importance of controlling and monitoring different business activities and results, putting performance measurement in place has always been a daunting task. Reasons such as the lack of incentives and top management support, as well as an organizational culture unfavourable to performance measurement, often make the development of performance measurement tool complicated and very challenging for ordinary businesses (Lindberg et al., 2015).

Cyclic management systems provide the basic concept, on which performance measurement system is based. This system is carried out by monitoring performance indicators, whose values indicate the results of certain management actions. Performance measures are system parameters or the method for quantitatively defining the process to be considered following the procedures of measurement and evaluation of performance. The main advantage achieved by the application of this kind of business approach is the possibility to provide information on potential quality improvements of company's performance.

In today's world economy, KPIs are an important tool to manage companies. In the first place, KPIs are used to divide important from unimportant information, simplify complex subject matters and create transparency. KPIs represent a set of measures focusing on those aspects of organizational performances that are the most critical for the current and future success of the organization (Parmenter, 2007).

In almost all modern business, we can always identify existence of time gap between the planning and execution. Because of this reason, different, unexpected events often occur during the execution. Consequently, there is always a gap between what was planned and what is actually done. In accordance with this problem, all of modern, competitive companies and their members need to make continuous efforts (or adaptations) to close the gap.

Performance metrics or KPIs offer the overall visibility of all company's processes and help to assess the accuracy of all plans (e.g. forecast accuracy), and the execution performance (e.g. actual sales versus forecast plan). KPIs reveal the gap between plan and execution and offer opportunities to identify, analyse and correct potential problems. Therefore, carefully selected KPIs precisely show where to take action in order to improve performance. KPIs help an organization to define and measure progress towards selected goals. If an organization has defined its goals, then it is more important for them to measure the progress of those goals (Jevgeni & Eduard & Roman, 2015).

Based on extensive analysis and discussions with over 1,500 participants in KPI workshops, covering most organization types in the public and private sectors, some of the basic KPI characteristics were defined. As examples, it can be highlighted that they are nonfinancial measures, which are frequently measured, and also make a significant impact on all company's processes (Parmenter, 2007).

One of the crucial tasks that refer to KPIs is a challenge of choosing number of KPIs that will be defined and monitored for a particular company. Unlike a general perception that more is better, in area of performance measurement "less is better". It is recommended to companies to start with a small number of KPIs which are absolutely necessary to monitor the multilevel processes (*plan, source, make, and deliver*) which they can successfully manage and operate. Another step that would undoubtedly make better review and understanding of KPIs by companies can also be hierarchical organization of those selected KPIs.

3. IMPLEMENTATION OF KPIs IN CONTINUOUS IMPROVEMENT PROCESS

If KPIs are mentioned as one of the crucial tools for process measuring, it is necessary to put them into the larger frame, where the results of the feedback would be significantly more valuable. The main purpose of this article is to introduce and explain the key role of combining mathematics with analysing processes, presented through KPIs, and continuous improvement way of thinking, which allows managers to understand processes and draw essential observations from quantitative data. Process improvement is the continuous methodology with aim, not only to eliminate deviations and non-value added activities, but also to fill in the performance gaps and level all kinds of activities and resources inside the production system (Sutari, 2015).

Approach to Continuous Improvement (CI), as the part of famous Japanese business philosophy, has spawned many various tools which are nowadays the foundations of modern industry world. As initial argument, unavoidable prerequisite for full implementation of CI process is the establishment of self-learning factory. As the concept, it stands for action-oriented approach in which employees (especially shop floor operators which are specialists for line or process stage they are responsible for) are encouraged in development of their own competencies in order to achieve improvements in production methods, reduction of all excessiveness and establishment of Lean production (Cachay & Abele, 2012). Therefore, only fundamental and multi-level system approach, where every single participant, in each company activity, has to leave his mark and impact along the way to some improvement, means that future prosperity lies on the reliable source – developed people. Essential importance of involvement of employees from every company department, and with different professions, will be further explained through particular case.

In theoretic concept of Lean manufacturing, there is present a huge pile of defined tools. Whether we are speaking of quality improvement tools like *Six Sigma* and *Poka-Yoke*, or methods related to time savings like *SMED* (Single Minute Exchange of Dies) or other scheduling methods like bottleneck analysis, all of them have the same unified goal – optimal process (Sundar, Balaji & Kumar, 2014). Even if it is clear that the word "optimum" is just a true north, commitment of every single participant in achieving it, is the promising way for company development. On the other side, repetitive return to the significance of the human role in case of this kind of production is necessity. Success of every senior Lean factory relies on the dedication and perceptions of their workers, no matter if they are called white or blue-collar. Due to that, suggestions,

opinions and ideas of people who are in tight, everyday contact with process itself, are invaluable assets for managers and other decision makers.

All previously presented systematics naturally strive to be composited in some type of process entirety, which, according to the rule of closed circle, need to have iteratively and cyclically type of flow. Similar to the Deming´s PDCA (*Plan-Do-Check-Act*) approach, some theoreticians define DMAIC (*Define, Measure, Analyse, Improve and Control*) model, which is tightly related to Six-Sigma quality concept. According to Gejdoš (2015), DMAIC is "*extended model which refers to a data-driven improvement cycle used for improving, optimizing and stabilizing business processes and designs*". According to both previously mentioned models, it is clearly notable that every sustainable improvement of any performance or process, first need to be decomposed to the exact points which then have to be evaluated, and then every part should be analysed as independent process with own specific characteristics and deviations. In order to minutely present and explain the whole, or some part of the process, there are several commonly used methods. One of the most frequently used is VSM (*Value Stream Mapping*), which relies on wide set of symbols and rules used for their networking (Rohani & Zahraee, 2015). In this way, every deviation would be entirely understandable and therefore attacked straight to the root cause. This kind of approach is one of the basic elements of the Lean production.

After the activities with purpose to define the nature of deviation, and evaluation of its influence on the holistic system picture after that, measuring is the phase which is mostly connected with some kind of calculations. Due to that, crucial point of this task is to segregate the appropriate method or model, which would express the most accurate current state. The most commonly used tool for this purpose, and one way to carry out the monitoring of the production process appropriately, is a control chart. How different types of control charts could be used to monitor different aspects of the production process, will be treated in the following section.

4. DEFINITION AND IMPORTANCE OF CONTROL CHART TOOL

According to the theory, control chart is significantly important tool stem from the wider concept of Statistical process control (SPC). SPC itself is a part of the comprehensive concept of Statistic Quality control (SQC), and its main purpose is analysing and inspecting if the randomly chosen outputs from particular process are within a predetermined range (Reid & Sanders, 2005). Based on the previous phase, management can evaluate stability and performance of the measured process.

Control charts are forms used to gather and describe values, statistical quantities, or production outputs for comparison, with previously established control limits. Initially, control charts are just graphical representation of measured results. Moreover, if the pile of collected observations is recorded over the long period, characteristics and behaviour of the process begin to be recognizable. These kinds of charts are the most frequently used tool in the statistical regulation of processes. Besides the fact that their ability to make impact on process quality, they are considered as a valuable tool for distinguishing random from systematic deviation causes. Due to significantly larger consequences after the special kind of reasons, and their practice to change the attributes of a process, they would be their most important object for measuring. Functioning of the chart systematic is based on samples taken from the process, which is usually taken on the fixed time interspace (Gejdoš, 2015).

The main aim of control charts is to be used in processes of monitoring and performance control. From the moment when deviation appeared, corrective actions are a must, to achieve a better mean value of the process, or to reduce variability of indicators. Visually, chart is presented as a histogram on which, the horizontal axis contains the terms when samplings were noticed, differently from the vertical axis which represents calculated values of the appropriate variables. Also, one of the greatest advantages of control charts is the easiness of use, even to the employees without advanced knowledge and skills in statistics and business analysis (Humble, 1998). Concreteness, time saving, and width of use, make this tool powerful for Continuous improvement methodology in every company.

5. TYPES OF CONTROL CHARTS

Considering dispersion of process variability as a base for analysing reliability of functioning, Range charts (R-charts) are used to secure the reduction of oscillations to the defined scope. For appropriate monitoring and process tracking, it is essential to establish upper and lower control limits, which could signal and separate special from the common deviation causes. Keeping indicator values within the defined scope will lead company to the crucial business stability. As an illustration, situation when there is at least one measured range outside the upper control limit, or there is specific upward trend of indicator within the

control limits, process variability then has increasing trend. The fundament of continuous improvement methodology lies into the constant and iterative reduction of the variance.

As the main characteristic of R chart, difference between the maximum and minimum value of the measures in each period, should be calculated and divided to the number of observations. Consequently, the aim of every company is to stabilize each part of the process, and that stabilization is expressed through narrower interval of limits. Only when the company reaches the moment when process flow is stable enough and stated between the limits, it is suitable for them to apply another type of control chart.

The second type used during analysis is based on the mean of the gathered data. Therefore, theoretical titles for this kind of charts are "mean" or "X-bar" charts. Initial step of developing this methodology is based on calculating mean value of all measured observations. Then, for the purpose of accessing to a holistic view of organization process, average value is drawn from all individual mean values related to different moments in time (1).

$$\bar{\bar{x}} = \frac{\bar{x}_1 + \bar{x}_2 + \cdots + \bar{x}_N}{N} \tag{1}$$

Similar to the R-charts, it is important step to set both limits (2) as a border in which, process variables must be integrated. In this type of chart, they are calculated in the following way:

$$\begin{aligned} \text{Upper control limit (UCL)} &= \bar{\bar{x}} + z\delta_{\bar{x}} \\ \text{Lower control limit (LCL)} &= \bar{\bar{x}} - z\delta_{\bar{x}} \end{aligned} \tag{2}$$

If symbol *z* is representing standard normal variable, which could lead to the specific level of certainty (2 for 95.44% confidence, 3 for 99.74%), variable δ stands for standard deviation of the distribution of sample means. Otherwise, usually practical way of calculating limits is based on multiplying $\bar{\bar{x}}$ with 0.9 or 1.1, that expresses increasing or reducing it by 10%.

It is crucial to emphasize that this type of chart should be used only when the fluctuations of the process variables are within the defined limits. This trait derives from the nature of mean method, which is quite unreliable in cases of often oscillations.

6. CASE OF OEE INDICATOR

Overall Equipment Effectiveness (OEE) represents a metric that is used to identify the percentage of planned production time that company exploits during the shifts. OEE score which is equal to 100% is considered as the true north state with manufacturing only good parts, as fast as possible, with no time losses. Three essential factors that constitutes OEE indicator are: Availability, Performance, and Quality. Each of them expresses different view on the types of deviations, which can be solved in order to close gaps and improve process (Puvanasvaran, Mei & Alagendran, 2013).

Availability as a parameter of OEE indicator refers to the percentage number that presents time availability of machine when there is production need for it. Difference in time between total production time and time shown by this parameter, is caused by breakdowns, setups and adjustments. Calculation (4) is given in following:

$$\text{Availability} = \frac{\text{Actual Production Time}}{\text{Planned Production Time}} \tag{4}$$

Performance efficiency (5), as sub-indicator, is used to express decreases of availability time by different causes of small disruptions (cleaning, checking, and jam) and reduced production speed (equipment wear, operator inefficiency). It takes in consideration actual and ideal run rate in order to show real equipment efficiency.

$$\text{Performance} = \frac{\text{Current Run Rate}}{\text{Ideal Run Rate}} \tag{5}$$

The quality rate (6) defines the accuracy of the process. It is used to show, how many of total production pieces, are in accordance with quality standards and principles. It is extremely important to reduce scrap and inappropriate parts by setting continuous improvement tools (e.g. Poka-Yoke). These results will have crucial impact, first on quality parameter, and the whole OEE indicator, too.

$$\text{Quality} = \frac{\text{Good Pieces}}{\text{Total Pieces}} \tag{6}$$

Combining these three previously mentioned variables, OEE indicator (7) would be the result of the following calculation:

$$OEE = \text{Availability} * \text{Performance} * \text{Quality} \tag{7}$$

For the purpose of this analysis, example of the fictive, manufacturing-oriented company is used to accurately represent importance and expediency of OEE implementation and tracking. Period that has been considered for making analysis and conclusions derived in this paper, is defined as one-year monthly based period.

Elements of production that were involved in the calculation include shift length, breaks, downtime, ideal cycle time, total parts and scraped parts. Combining these several variables, it is aimed to present how appropriate implementation and usage of control charts, will provide company with stability and improvement impacts on all its processes.

In the following table will be presented the calculation of OEE for one-month period:

Table 1: Input data for OEE calculation

Item	Data
Shift Length	8 hours
Breaks	1 hours
Down Time	1.25 hours
Ideal Cycle Time	12 seconds
Total Count	1580 pc
Reject Count	110 pc

According to the inputs in Table 1, and presented formulas (4,5,6 and 7) for individual indicators, achieved results are presented below in Table 2:

Table 2: OEE calculation

Item	Data
Availability	82.14%
Performance	91.59%
Quality	93.03%
OEE	**69.98%**

As the conclusion of the highlighted example, it could be noticed that only one parameter below the target level could cut down the holistic score regarding OEE. In this case, huge influence is observed by the variable availability score, which is caused by increased participation of breakdown time in total production time. Therefore, the first advice that could be given to the company is to work continuously on productivity and time usage improvement.

By application of the same method as above, calculation lead to the overall OEE results for all further months of the particular year. For the purpose of this paper, two types of control charts were used (X-bar chart and R-chart) within the simulation algorithm to properly analyse impacts of different production elements on the value of OEE indicator and process itself.

Simulation conclusions would be analysed in two different ways. First one is presented on the R-chart and refers to the diversity of different samples that were noticed during one month. As it was highlighted before, the main significance of the R-chart is to show if differences in measurement result in each period are within the set target scope.

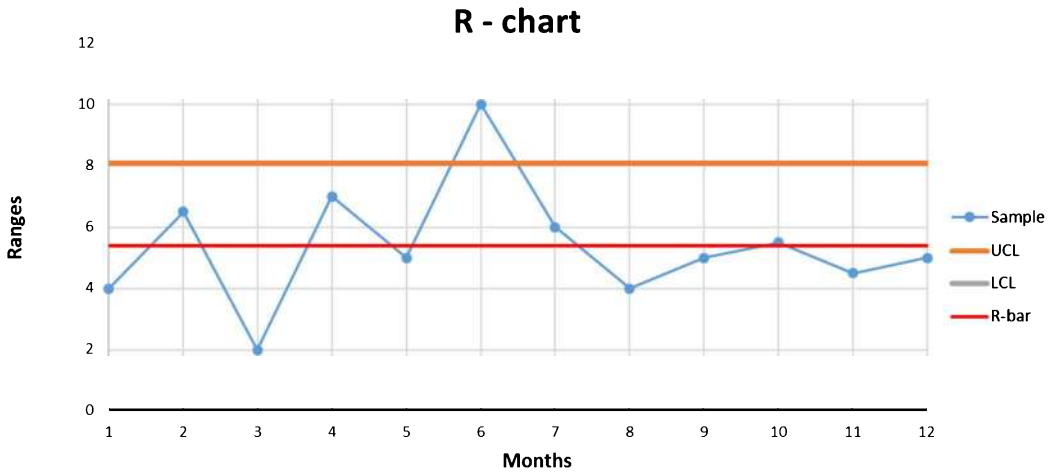

Figure 1: R - chart on example of OEE indicator

The graph above shows importance of accurate control and adequate influence on production process according to the OEE oscillations. As it is noticed in the first six months, there are huge variations in gathered data values between consecutive months. In the sixth month, value of the indicator is rocketed high and above the set upper limit. That signals that the production process of the company faced unusual special cause, which must lead to the investigation, analysis, and corrective actions.

It is important to emphasize that every company department and all employees of all levels of hierarchy, must be completely involved in the process of monitoring and stabilization of this essential process traits. For the reduction of the OEE within the framework defined by the control limits, all of its parameters must be thoroughly analysed. Seeing that the OEE is a too complex and comprehensive variable, it must be "attacked" from the several different aspects. For this purpose, suggested way for improving the whole results is to track and constantly improve the individual values of availability, performance, and quality of the "tools" to make a bigger impact on the future stability of the compound OEE variable.

As the responsible department for working on the boosting the performance sub-indicator, could be mentioned the production department itself, which has to secure appropriate ergonomic conditions, in order to reduce the ideal cycle time per part/product. In this task, they must have support from the company's technicians.

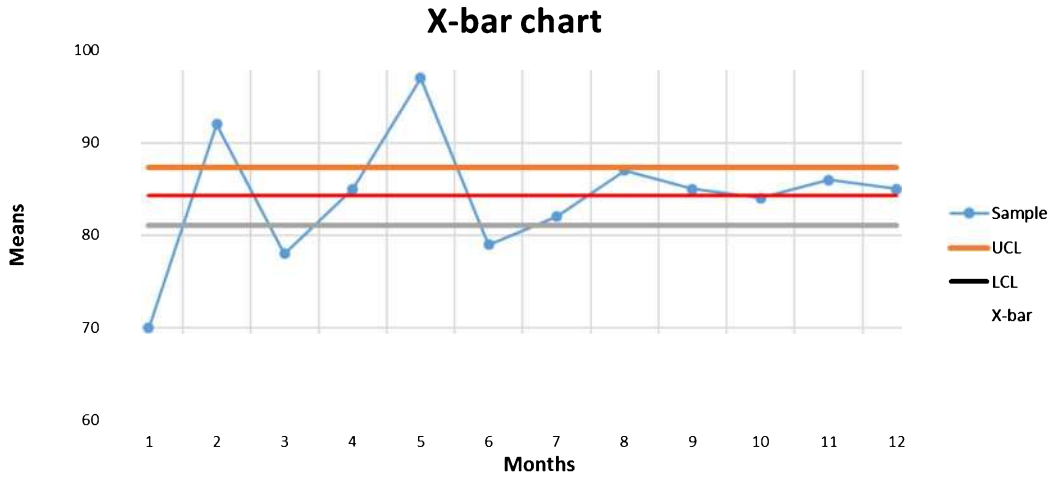

Figure 2: X-bar chart

Quality sub-indicator refers to the reducing of scrap and inappropriate production parts, as well as the early revealing of the damaged parts delivered from the suppliers. With the previous, quality department fulfils all necessary standards for deviations prevention in order to secure smooth process flow.

Availability is connected with organizational harmoniousness and it is responsibility of every company's department to work on it. With more minutes or seconds for value added activities, company has a good base to be stronger competitive in the market race.

As the previously highlighted measures and required approach were implemented, variations of observed variable are reducing. For every company, this is a precondition for a timely application of X-bar chart. It distinctly presents variations between monthly measured averages of taken samples, and represent the basis for stability of variable first, and then of the whole process, too.

In the graph above, impact of corrective actions by different company's departments could be clearly identified. In first half of the year, value of OEE indicator is almost always outside defined limits, and during this period, application of X-bar chart is worthless. When impacts on process are made, X-bar chart becomes a powerful tool, which, if it is used properly, provides crucial process consistency and gives significant benefits to the whole company's business.

Finally, it is important to emphasize that stable and precisely defined process provides significant certainty to all departments, referring to every process performance, and consequently, to all tasks that they should accomplish.

7. CONCLUSION

As has been noted, the present research aimed at investigating and emphasizing of essential impact that continuous improvement tools have on the frame of production process performances. In addition, it is presented how crucial is the appropriate usage of the key performance indicators in order to extract maximum utilizable information from its rigidly quantitative essence. For this purpose, simulation was conducted over the data of the fictive manufacturing company with combined methodology based on X-bar and R control charts.

The results of this study could be used in further research, both for operations managers in companies and scholars, due to its wide applicability in field of industrial engineering. Besides the limitation of the study caused by its basing on the simulation and data of the fictive company, all implemented tools, management advice and conclusions are derived from the analyses of the many real company case studies. Taking into account common causes of inappropriate asset utilization and all other deviations, this paper was attempted to explain methods, which could be easily used even by the non-engineers.

Further research in this field of study should focus deeper on developing and combining new types of control charts, as well as on possibilities for its application in other areas of production and operations management. Consequently, many other production losses could be deeply investigated and reduced, taking into account the reliable support provided by statistical methods and models.

A NOVEL ALGORITHM FOR COMBINATORIAL PROBLEM IN MANUFACTURING CELL FORMATION

Miloš Danilović*[1], Oliver Ilić[1],
[1]Faculty of Organizational Sciences, Belgrade, Serbia
*Corresponding author, e-mail: danilovicm@fon.bg.ac.rs

Abstract: *In this paper we consider machine and part family grouping for cell formation. Manufacturing cell formation is the first and foremost issue in designing cellular manufacturing systems. The primary objective of this step is to cluster machines into machine cells and parts into part families so that the minimum of intercell trips will be achieved. For this purpose, the Generalized Constructive Algorithm is applied for solving the combinatorial optimization problem in manufacturing cell formation. The objective is to maximize the sum of similarity coefficients between machine/part pairs. This formulation is suitable for effective narrowing of the feasible solution set. A parameter determining the precision of the search of the feasible solution set is introduced. The Generalized Constructive Algorithm constructs a solution population from the feasible set. The initialization phase of the Generalized Constructive Algorithm utilizes the advantages provided by the definition of the objective function. Experimental evaluation confirms the advantages of the proposed approach regarding known results.*

Keywords: *group technology, similarity measure, constructive algorithm, cluster analysis*

1. INTRODUCTION

Group technology is an approach that identifies attributes of the population suitable for grouping its members into groups, or families (Ilić 2015). Cellular manufacturing is an application of group technology in manufacturing in which all, or a portion, of a firm's manufacturing system has been converted into cells. The layout of a facility contributes significantly to the speed of product throughput achieved by the facility. Cell formation can be defined as grouping the parts into part families, and the machines into machine cells, and then assigning the part families into corresponding machine cells. Thus, the Cell Formation Problem (CFP) can be defined as a problem of grouping machines into groups that minimizes the number of parts to be processed on machines from different groups. CFP is known as an NP-hard problem, due to its computational complexity.

This paper proposes a method based on the definition of the problem in Ilić (2014), where the optimization procedure is carried out by applying the Generalized Constructive Algorithm (GCA), shown in (Danilović and Ilić 2013, 2016). In Ilić (2014), the proposed objective function takes into account only the neighbor elements in the permutation of machines and parts. Thus defined objective function opens up great possibilities for the implementation of the optimization process. Limiting the mutual influence only to neighbor elements in the permutation allows defining the rules that significantly reduce the feasible solution set. These rules are formulated through five lemmas, presented in the Section 4.

The research, presented in this paper, is focused to the improvement of the procedure of determining the optimal arrangement of machines and parts, assuming that the cell formation is conducted in the same manner as in Ilić (2014). The suitability of the formulation of the problem in Ilić (2014) allows that the initial arrangement, *i.e.* the first phase of GCA, is applied after narrowing the feasible solution set (Danilović and Ilić 2016a). This significantly increases the efficiency of the process, what's more, in that way specific instances can be solved using exact procedures.

The paper is organized as follows. After the introduction, Section 2 presents related works. The problem formulation is given in Section 3. In Section 4 five lemmas are proven which enable narrowing of the feasible solution set. The hypothesis that defines the precision of the search of the feasible solution set is stated. The proposed procedure is presented in Section 5, while the comparison of the proposed approach with the program PFAST is given in Section 6. Concluding remarks and directions of future research are given at the end of the paper.

2. LITERATURE REVIEW

Due to its importance in the design of cellular manufacturing systems, the CFP has been given considerable attention in literature. There have been many different approaches and practical researches conducted on the CFP (Yin et al. 2005; Hachicha et al. 2008; Pattanaik and Sharma 2009). A comprehensive review of CFP approaches is given in Singh (1993). Extended reviews of the various approaches are available in the literature (Reisman et al. 1997; Selim et al. 1998; Papaioannou and Wilson 2010).

Most CFP methods in the literature assume that parts have only a unique process routing. Also, in most of the studies, cell formation is performed assuming all machines to be reliable (Jabal-Ameli and Akart 2008). Machine-component Group Analysis (MCGA) is based on Production Flow Analysis (Burbidge 1977). In MCGA-based methods, machine-component groups are formed by permuting rows and columns of the machine-component chart in the form of a zero-one matrix. Rank Order Clustering (ROC) (King 1980) is a simple algorithm used to form a machine-part group. The algorithm is based on the sorting rows and columns of the machine-part incidence matrix. A Direct Clustering Algorithm (Chan and Milner 1982) sorts the total number of 1's in each row and column in increasing and decreasing order to form the clusters. MODROC algorithm, developed by Chandrasekharan and Rajagopalan (1986) offers improvements over ROC.

Similarity coefficient-based approaches are distinguished from the other approaches by their flexibility in incorporating various types of manufacturing data into the CFP, and suitability for development software tools. A number of similarity coefficients have been analyzed and proposed in literature (Yin and Yasuda, 2005; Yin and Yasuda, 2006). Among various similarity coefficients, Jaccard similarity coefficient was the most used in literature and the most stable similarity coefficient (Yin and Yasuda, 2005). Oliveira, et al. (2008) reviewed 8 different similarity coefficients. Four of them are Jaccardian and the rest are non-Jaccardian coefficients. They concluded that the one similarity coefficient can be chosen over others according to the preference of the cell formation. For example, if the fewest intercell flows is the main focus, McAuley's Jaccardian coefficient should be used. Also, McAuley's Jaccardian coefficient is preferred when the strength of clustering is the key factor of judging the quality of a solution. Similarity coefficient-based approaches have been widely used since McAuley (1972) for the first time combining the Jaccard similarity coefficient with the Single Linkage Cluster analysis, which was resulted in construction of a tree called a dendrogram. This was followed by development of other similarity coefficient-based approaches. Recently, the Cluster Analysis (CA) was discussed and attention was drawn to the main decisional step of CA based on similarity coefficient methods (Manzini, et al., 2010). One group of researchers used similarity coefficient-based method for generating a good initial solution for CFP (Wu, et al., 2009; Chung, et al., 2011). An e-Learning tool considering similarity measures is presented by Ilić (2014).

3. PROBLEM FORMULATION

Similarity coefficient represents a measure of similarity between machines/parts which is used to group them together. The value of the similarity coefficient usually ranges from 0 to 1. If this value is equal to 0, there is no similarity between two machines/parts. Conversely, as this value is closer to 1, the two machines/parts are more similar.

The similarity coefficient between machine *i* and machine *j* is defined as the ratio of the number of parts visiting both machines and the number of parts visiting one of the two machines as follows:

$$s_{ij}^{M} = \frac{a_{ij}^{P}}{a_{ij}^{P} + b_{ij}^{P} + c_{ij}^{P}}; \quad 0 \le s_{ij}^{M} \le 1 \tag{1}$$

where a_{ij}^{P} is the number of parts that visit both machines *i* and *j*; b_{ij}^{P} is the number of parts that visit machine *i* but not *j*; c_{ij}^{P} is the number of parts that visit machine *j* but not *i*.

The similarity coefficient between part *k* and part *l* is:

$$s_{kl}^{P} = \frac{a_{kl}^{M}}{a_{kl}^{M} + b_{kl}^{M} + c_{kl}^{M}}; \quad 0 \le s_{kl}^{P} \le 1 \tag{2}$$

where a_{kl}^M is the number of machines used by both parts *k* and *l*; b_{kl}^M is the number of machines used by part *k* but not *l*; c_{kl}^M is the number of machines used by part *l* but not *k*.

The optimisation procedure for machines finds the permutation $(\pi_1,...,\pi_m)$ of machine labels (1,..,*m*), which maximizes value $\sum_{i=1}^{m-1} s_{\pi_i\pi_{i+1}}^M$.

The optimisation procedure for parts finds the permutation $(\Pi_1,...,\Pi_n)$ of part labels (1,..,*n*), which maximizes value $\sum_{k=1}^{n-1} s_{\Pi_k\Pi_{k+1}}^P$.

A deterministic combinatorial optimization problem may be formulated as a quadruple (*I*, *F*, *C*, *g*), where:

- *I* is a given instance of the combinatorial optimisation problem;
- *F*(*I*) is the finite set of feasible solutions for a given instance *I*;
- *C*(*x*), $x \in F(I)$, denotes a real-valued objective function, which is a measure of the feasible solution *x*;
- *g* is the goal function, and is usually "min" or "max".

The goal is then to find, for a given instance *I*, an *optimal solution*, that is, a feasible solution *x* with:
$C(x) = g\{C(x') \mid x' \in F(I)\}$

In the significant number of combinatorial optimisation problems (scheduling problems, routing problems, assignment problems) $I = O^n = \{o_1,...,o_n\}$ is a set of *n* objects, each having defined properties and $F(O^n)$ can be formalized by different sequences of these objects. The selection of objects and the order of objects in a sequence determine the corresponding *C* value. Let $PR^n = \{pr_1,...,pr_n\}$ denote a set of object properties (pr_i are properties of object o_i). The set of given objects O^n can be defined formally, without loss of generality, as a bijection from the set S^n={1, 2,..., *n*} to O^n. In that way, *I* can be represented by PR^n, and $F(O^n)$ can be represented by permutations π^n of S^n. Heuristics for solving these problems differ only by the manner in which they form the permutations and the criteria for the selection of desirable permutations.

Constructive search techniques work by constructing a solution step by step, evaluating that solution for feasibility and objective function. Insertion based constructive heuristics typically have common structures, comprising the *initialization* phase and the loop in the *insertion* phase. In the initialization phase, the selection function $f_1(PR^n)$ determines an integer e_1 from S^n, that will be included into the solution *x*. The insertion phase has *n*-1 iterations, such that, at the beginning of the *k*-th iteration, S^n is partitioned into two subsets: $PRT^2(S^n) = (PRT_1^k(S^n), PRT_2^{n-k}(S^n)) = (A_1^k, A_2^{n-k})$.

At each iteration *k* of the insertion phase, two types of selections are performed: a selection $f_2(PR^n, k, A_2^{n-k})$ of the integer e_{k+1} from A_2^{n-k} to be removed from A_2^{n-k} and the selection $f_3(PR^n, k, e_{k+1}, \rho^k[A_1^k])$ of the position *l* in $\rho^k[A_1^k]$ where e_{k+1} will be inserted. Performed insertion uniquely determines the arrangement of integers in $\rho^{k+1}[A_1^{k+1}]$.

GCA may be defined as a function $x \leftarrow CA(PR^n, F, C, g, f_1, f_2, f_3, ARG)$, where $ARG = \{\boldsymbol{arg}_1,...,\boldsymbol{arg}_7\}$ is the set of seven optional arguments. In this research, only $\boldsymbol{arg}_4$ having value R_1 is considered, *i.e.* algorithm tracks simultaneously all partial permutations that result in current optimal value of the objective function.

4. NARROWING THE FEASIBLE SET

The proposed similarity coefficient objective function takes into account only the neighbor elements in the permutation of machines and parts. Limiting the mutual influence only on neighbor elements in the permutation allows defining the rules that significantly reduce the feasible solution set. These rules are formulated through five lemmas, stated in this Section. As there is a direct analogy between the optimization

of machine arrangement and arrangement of parts, the remainder of this paper considers only the optimization for machines.

Lemma 1 (Symmetric solution): Each optimal solution has its symmetric solution that is also optimal; symmetric solution is obtained by reversing the original permutation.

The proof of this Lemma is obvious. Since the value of the objective function is obtained summing similarity coefficients of the neighbor elements in the permutation, same value is obtained if the summands are reversed.

Lemma 2 (Complete matching): If $s_{ij}^{M} = 1$, the position of machine *i* in the optimal permutation is next to the position of machine *j*.

Lemma 3 (Transition): If $s_{ij}^{M} = 1$ and $s_{jk}^{M} = 1$, then $s_{ik}^{M} = 1$.

Lemma 4 (Group matching): If a subset of machines has mutual similarity coefficient equal to 1, every permutation of these machines within the entire permutation results in the same value of the objective function.

The proof of these Lemmas can be derived as follows: The value of the objective function is obtained by summing only the similarity coefficients of neighboring machines in the permutation. Suppose, without loss of generality, that the machines *i* and *j* have a similarity coefficient equal to 1, and that all other coefficients are less than one. Suppose that, in the first case, the optimal partial sequence of machines is *k i j l,* and in the second case *k i q j l.* The similarity coefficient for machines *i* and *q* is less or equal than the similarity coefficient for machines *i* and *k*, otherwise *k i j l* is not the optimal permutation. In the same way, the similarity coefficient for machines *j* and *q* is less or equal to the similarity coefficient for machines *j* and *l*. Thus, the summand, having value 1, is in the second case replaced with the summand with the value less than 1; the added summand in the second case is less or equal to the corresponding summand in the first case. This completes the proof of the Lemma 2. Accordingly, proofs of Lemma 3 and Lemma 4 are straightforward.

The conclusions of these Lemmas can be extended to the cases where the similarity coefficients are not equal to one.

Lemma 5 (Clustering): If the subset of machines has all of their mutual similarity coefficients greater than x, and if all the other similarity coefficients are less than x, in the optimal permutation all those machines belong to the same compact group. Mutual arrangement of machines within this group will match the permutation of the group that has the largest partial value of the objective function.

The proof of this Lemma is analogous to the previous proof.

It is clear that the obtained conclusions may define the procedures which significantly reduce the feasible solution set. While the first four lemmas imply exact reduction of the feasible set, Lemma 5 implies the possibilities for the near optimal reduction of the feasible set. Figure 1 presents an agglomerative cluster dendrogram representing similarity of machines A, B, C, D, E, F and G.

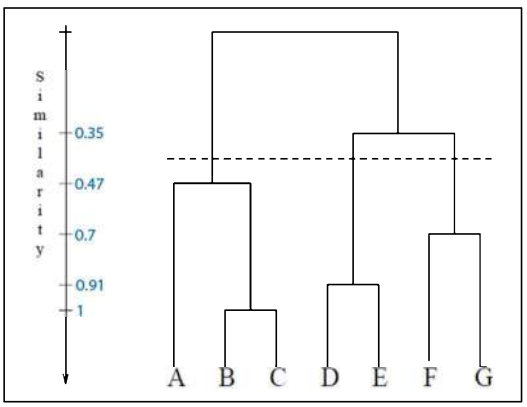

Figure 1: Agglomerative cluster dendrogram

According to Lemma 2, machines B and C, having similarity coefficient equal to 1, are always neighbors in optimal permutations. According to Lemma 5, if the precision parameter is 0.8, two clusters, {B,C} and {D,E} are constructed (D and E have the similarity coefficient 0.91 which is greater than 0.8). If the precision parameter is 0.5, three clusters, {A,B,C}, {D,E} and {F,G} can be constructed.

5. THE NOVEL ALGORITHM

The adopted objective functions and the pre-defined level of clustering are the ideal conditions to define the arrangement that provides the initial phase of the GCA. Since the GCA can simultaneously track multiple initial permutations, it can be formally defined as:

$$x \leftarrow CA(PR^n, F, C, g, f_1, f_2, f_3, \boldsymbol{arg}_4 = R_1). \tag{3}$$

This definition also allows a trivial application of parallel programming, because the individuals in the initial population can be treated completely independently of each other. The initial grouping and arrangement can be summarized through five steps:

Step 1. Each group of machines having all similarity coefficients equal to 1 are replaced with a single, arbitrarily selected machine from the group.
Step 2. Define the parameter $p \leq 1$.
Step 3. Apply the cluster algorithm so that the lowest similarity coefficient in each of the clusters is greater than or equal to *p*. Let y_q denote the lowest similarity coefficient in the *q*-th cluster (if the machine does not belong to any cluster, the corresponding value is equal to its largest similarity coefficient).
Step 4. Sort clusters according to non-increasing values of y_q.
Step 5. Determine the permutations of machines in each cluster that provide the greatest values of the objective function. Let z_q denote the optimal number of partial permutations within the *q*-th cluster. Any combination of the obtained optimal partial permutations determines an initial arrangement for the GCA. In the insertion phase of GCA, each cluster is treated as one element in the permutation. When the *k*-th iteration determines the permutation of length *k*, each cluster in the permutation is replaced with its elements.

Even before the experimental verification of the proposed approach, certain benefits are obvious. Although the proposed approach does not guarantee the optimal value of the objective function, it enables an efficient processing, due to an important fact: the number of steps of the algorithm is predefined with only two variables, *m* and *p*, so the user is informed in advance precisely what will be the consumption of CPU time. In this way, the user can adjust the search precision to the available computer time, *i.e.* to choose the greatest possible value for p.

6. EXPERIMENTAL RESULTS

The quality and efficiency of the proposed procedure are verified on the example, which is discussed in Ilić (2014), and Ilić and Cvetić (2014). In these researches, the results are compared with the results of Irani, *et al.* (2000), Irani and Huang (2005), and Irani (2012), obtained by the software package PFAST. Table 1 illustrates the process paths for 19 parts on 12 machines.

Table 1: Routing sheet

1	1	4	8	9			
2	1	4	7	4	8	7	
3	1	2	4	7	8	9	
4	1	4	7	9			
5	1	6	10	7	9		
6	6	10	7	8	9		
7	6	4	8	9			
8	3	5	2	6	4	8	9
9	3	5	6	4	8	9	
10	4	7	4	8			
11	6						
12	11	7	12				
13	11	12					
14	11	7	10				
15	1	7	11	10	11	12	

16	1	7	11	10	11	12	
17	11	7	12				
18	6	7	10				
19	12						

Based on the above routing sheet, similarity matrices for machines and parts are shown in Table 2 and Table 3 respectively. The diagonal elements are marked in grey, indicating the only elements that contribute to the value of the objective function. The bold marked elements of the matrix are the elements having the value above the stated threshold, which is 0.7 for both, machines and parts.

19	0	0	0	0	0	0	0	0	0	0	0	0.333	0.5	0	0.2	0.2	0.333	0	

The values of the objective functions for these arrangements of machines and parts are 3.496 for machines and 8.632 for parts. For the stated tresholds of 0.7, three clusters are identified for machines and four clusters for parts. Clusters for machines are {3,5}, {4,8} and {11,12}, clusters for parts are {15,16}, {12,17}, {8,9} and {2,10}. These clusters narrow feasible sets: from 12! to 2!2!2!9! for machines, and from 19! to 2!2!2!2!15! for parts. Thus, total search can be applied to obtain solution for machines, while GCA should be

applied to obtain results for parts. Total search for machines results in four (2 symmetric) optimal arrangements, having 5.87 as the value of the objective function. These arrangements are shown in Table 4.

Table 4: Optimal arrangements of machines

	1	2	3	4	5	6	7	8	9	10	11	12
1	12	11	10	7	1	4	8	9	6	3	5	2
2	2	3	5	6	9	8	4	1	7	10	11	12
3	12	11	10	7	1	4	8	9	6	5	3	2
4	2	5	3	6	9	8	4	1	7	10	11	12

Arrangement 4 is symmetric to arrangement 1, while arrangement 3 is symmetric to arrangement 2. When GCA is applied for parts, 16 (8 symmetric) optimal arrangements are obtained, with 11.418 as the value of the objective function. These arrangements are shown in Table 5.

Table 5: Optimal arrangements of parts

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19
1	11	8	9	7	1	3	4	2	10	6	5	18	14	15	16	12	17	13	19
2	11	8	9	7	1	4	3	2	10	6	5	18	14	15	16	12	17	13	19
3	11	8	9	7	1	3	4	2	10	6	5	18	14	16	15	12	17	13	19
4	11	8	9	7	1	4	3	2	10	6	5	18	14	16	15	12	17	13	19
5	11	8	9	7	1	3	4	2	10	6	5	18	14	15	16	17	12	13	19
6	11	8	9	7	1	4	3	2	10	6	5	18	14	15	16	17	12	13	19
7	11	8	9	7	1	3	4	2	10	6	5	18	14	16	15	17	12	13	19
8	11	8	9	7	1	4	3	2	10	6	5	18	14	16	15	17	12	13	19

The lower threshold implies reduced processing time with the possibility of worse objective function values. To investigate that, the threshold of 0.66 is stated for the optimization of the arrangement of parts. Five clusters are obtained: {14,15}, {16,17,18}, {2,3,4}, {5,6,7,8,9} and {10,11}. This grouping reduces the size of the feasible solution set from 19! to 2! 3! 3! 5! 2! 9!. It is interesting that despite the significant reduction in the feasible solution set, and significant savings in CPU time, GCA provides optimal results identical to the previous experiment, when the threshold was 0.7.

7. CONCLUDING REMARKS

This paper presents a procedure for arrangement of machines and parts in the process of cell formation. The objective is to determine the arrangements that maximize the objective function, proposed in Ilić (2014). It is shown that GCA is extremely suitable as an optimization heuristic because its initialization phase can utilize the advantages provided by such a defined objective function with some modifications in the cluster process. Specifically, applied definition of objective function allows simple clustering of machines and parts and the introduction of the precision parameter for the GCA search. Experimental results clearly show that such a defined GCA provides optimal results on the observed test instances with significant saving of the CPU time.

Future research should be directed towards the application of the obtained results when objective functions, extended from the definition in Ilić (2014), are applied. Namely, it is possible that a certain problem requires the involvement of the influence of non-adjacent elements in the permutation on the value of the objective function. However, also in these cases, the former results should be unavoidably used. Information obtained by using the objective function in Ilić (2014) is valuable for narrowing the feasible solution set for any objective function applied.

APPLICATION OF MODERN CONTROL THEORY TO INVENTORY CONTROL IN PHARMACEUTICAL DISTRIBUTION COMPANY

Lena Đorđević *[1], Slobodan Antić [1]
[1]Faculty of Organizational Sciences, University of Belgrade
*Corresponding author, e-mail: lena.djordjevic@fon.bg.ac.rs

Abstract: *Modern Control Theory (MCT) is an interdisciplinary area, which combines different mathematical concepts and methods in order to produce body of applied mathematics. This paper presents MCT as efficient tool for inventory control in pharmaceutical distribution companies. Inventory system of the pharmaceutical distribution company, which is considered as an example in this paper, has continuously changing state of sales. States of inventories are registered at the ends of the defined time period. Considered time horizon is one year. Structure of inventory system is generally known and represents sales forecast per months. The system was modelled based on the feedback control systems methodology. During the model creation, all elements of a feedback loop (reference, system, sensor, comparator, and controller) are created. When one or more output variables of a system have to follow a certain reference over time, a controller manipulates the inputs to a system in goal of obtaining the desired effect on the output of the system. Inventory control problem, modelled in accordance with MCT concept, is developed in spreadsheet. Spreadsheet is used for creation of decision making model. The results obtained from the model are used for procurement planning for more than 50 products per country, for five countries from East-Central Europe in year 2016.*

Keywords*: control theory, feedback loop, inventory control, pharmaceutical company, decision making model, spreadsheet*

1. INTRODUCTION

Pharmaceutical is one of the most sensitive and major industry that deals with human life. Quality and security are the most important to maintain. Inventory management of the industry is a difficult job. A pharmaceutical companies handle 500-600 types of products that includes huge amount of raw materials movement, packaging, secondary packaging of the finished products and delivering to the customers. Planning and scheduling in the pharmaceutical companies is a critical activity.

The primary distribution management goal is to maintain a steady supply of pharmaceuticals and supplies to facilities where they are needed, while costs of distribution should be the lowest. Distribution costs include costs related to storage, transport, customs and analysis etc. Designing a system for storing and distributing pharmaceuticals and medical supplies is complex and important.

Effective pharmaceutical distribution relies on good system design and good management. A well designed and well managed distribution system should (Managing distribution, 2012):

- Maintain a constant supply of medicines;
- Keep medicines in good condition throughout the distribution process;
- Minimize medicine losses caused by spoilage and expiry;
- Rationalize pharmaceutical storage points;
- Use available transport resources as efficiently as possible;
- Reduce theft and fraud;
- Provide information for forecasting medication needs;
- Incorporate a quality assurance program.

Centralized distribution is one option for pharmaceutical producer companies. Some countries procure and distribute medicines regionally, and some use commercial supply systems, which often exist in parallel with public systems. Collaboration between private and public systems may occur at any level. Private distribution companies can provide cost-effective alternatives for the storage and distribution of medicines, especially at the national and regional levels.

This paper presents simulation model, created to analyze the pharmaceutical distribution process and to determine ordering periods, in private pharmaceutical distribution company from Serbia. Model is aimed to

help the pharmaceutical distribution company to determine the reorder point for products and to reduce wastage in time and money. Model is designed based on MCT concepts.

2. MODERN CONTROL THEORY

The modern control theory is a discipline dealing with formal foundations of the analysis and design of computer control and management systems. Its basic scope contains problems and methods of control algorithms design, where the control algorithms are understood as formal prescriptions (formulas, procedures, programs) for the determination of control decisions, which may be executed by technical devices able to the information processing and decision making. The problems and methods of the control theory are common for different executors of the control algorithms. The control theory deals with the foundations, methods and decision making algorithms needed for developing computer programs in such systems. The problems and methods of the control theory are common not only for different executors of the control algorithms but also, which is perhaps more important, for various applications. In the first period, the control theory has been developing mainly for the automatic control of technical processes and devices. This area of applications is still important and developing, and the development of the information technology has created new possibilities and on the other hand new problems. The full automatization of the control contains also the automatization of manipulation operations, the control of executing mechanisms, intelligent tools and robots which may be objects of the external control and should contain inner controlling devices and systems. Taking into account the needs connected with the control of various technical processes, with the management of projects and complex plants as well as with the control and management of computer systems has led to forming foundations of modern control science dealing in a uniform and systematic way with problems concerning the different applications mentioned here. The scope of this area significantly exceeds the framework of so called traditional (or classical) control theory. The needs and applications mentioned above determine also new directions and perspectives of the future development of the modern control theory (Bubnicki, 2002).

Summarizing the above remarks one can say that the control theory (or wider − control science) is a basic discipline for the automatic control and robotics and one of basic disciplines for the information technology and management. It provides the methods necessary to a rational design and effective use of computer tools in the decision support systems and in particular, in the largest class of such systems, namely in control and management systems (Bubnicki, 2002).

The process of designing a control system generally involves many steps. A typical scenario can be presented as follows (Antic et al. 2012):

- Study the system to be controlled and decide what types of sensors and actuators will be used and where they will be placed;
- Model the resulting system to be controlled;
- Simplify the model if necessary so that it is tractable;
- Analyze the resulting model and determine its properties;
- Decide on performance specifications;
- Decide on the type of controller to be used;
- Design a controller to meet the specs, if possible. if not, modify the specs or generalize the type of controller sought;
- Simulate the resulting controlled system, either on a computer or in a pilot plant;
- Repeat from the first step, if necessary;
- Choose hardware and software and implement the controller;
- Tune the controller on-line, if necessary.

Control systems are most often based on the principle of feedback, whereby the signal to be controlled is compared to a desired reference signal and the discrepancy used to compute corrective control action, (Doyle et al. *1990).* The most elementary feedback control system has three components (Figure 1):

- a system (the object to be controlled, no matter what it is, is always called the system or plant),
- a sensor to measure the output of the plant, and
- a controller to generate the plant's input.

External input of a system is called the reference. When one or more output variables of a system need to follow a certain reference over time, a controller manipulates the inputs to a system to obtain the desired effect on the output of the system. The usual objective of control theory is to calculate solutions for the proper corrective action from the controller that result in system stability, that is, the system will hold the set point and not oscillate around it. The concept of the feedback loop to control the dynamic behaviour of the

system: this is negative feedback, because the sensed value by sensor is subtracted from the desired value to create the error signal, which is amplified by the controller (Doyle et al. 1990).

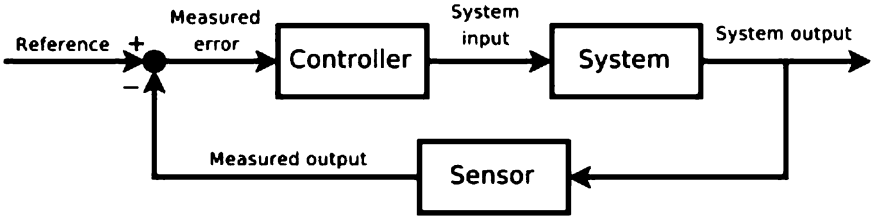

Figure 1: Concept of the feedback loop

Sensor can be define as device that converts a physical stimulus or input into a readable output, which today would preferably be electronic, but which can also be communicated via other means, such as visual and acoustic. As perhaps the simplest example, consider the sensor on keyboard switch actuator - which provides a signal when the associated key is pressed. The role of a sensor in a simple automation system is depicted in Figure 2. The detection and measurement of some physical effect provides information to the control system regarding a related property of the system under control, which we are interested in regulating to within some "set point" range. The controller outputs a command to an actuator (a valve, for example) to correct for measured deviations from the set point, and the control loop is thereby closed. Because of the simplicity of example in Figure 2 control system, it represents a fair number of practical control systems. In especially simple systems, a distinct controller may not be immediately evident (for example, thermostat), (Zook et al. 2008).

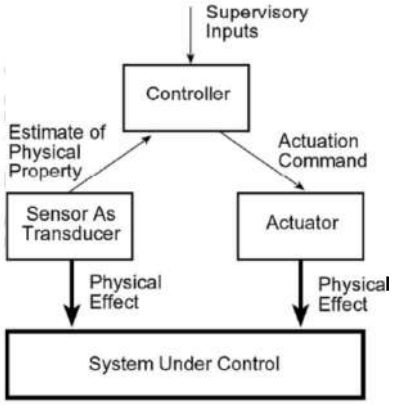

Figure 2: Example of a simple control system

A dynamical system is a system whose behaviour changes over time, often in response to external stimulation or forcing. The term feedback refers to a situation in which two or more dynamical systems are connected together such that each system influences the other and their dynamics are thus strongly coupled. Simple causal reasoning about a feedback system is difficult because the first system influences the second and the second system influences the first, leading to a circular argument. This makes reasoning based on cause and effect tricky, and it is necessary to analyze whole systems. A consequence of this is that the behaviour of feedback systems is often counter intuitive, and it is therefore necessary to resort to formal methods to understand them. In Figure 3 (a) the output of system 1 is used as the input of system 2, and the output of system 2 becomes the input of system 1, creating a closed loop system. In Figure 3 (b) the interconnection between system 2 and system 1 is removed, and the system is said to be open loop. A system is said to be a closed loop system if the systems are interconnected in a cycle, as shown in Figure 2 (Åström & Murray, 2009).

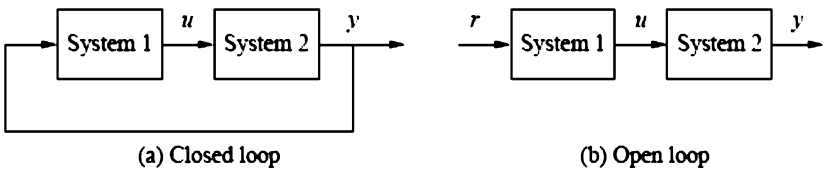

Figure 3: Open and closed loop systems

Feedback is an active concept in practically all area of activity. A feedback process is one in which the state of the system, or its output, determines the way in which the control has to be computed at any time instant (Neculai, 2005). Feedback has potential disadvantages as well. It can create dynamic instabilities in a system, causing oscillations or even runaway behaviour. Another drawback, especially in engineering systems, is that feedback can introduce unwanted sensor noise into the system, requiring careful filtering of signals. It is for these reasons that a substantial portion of the study of feedback systems is devoted to developing an understanding of dynamics and a mastery of techniques in dynamical systems. Feedback systems are ubiquitous in both natural and engineered systems. Control systems maintain the environment, lighting and power in our buildings and factories; they regulate the operation of our cars, consumer electronics and manufacturing processes; they enable our transportation and communications systems; and they are critical elements in our military and space systems. For the most part, they are hidden from view, buried within the code of embedded microprocessors, executing their functions accurately and reliably. The term control has many meanings and often varies between communities. We define control to be the use of algorithms and feedback in engineered systems. For example, the thermostat, in particular, is a simple example of feedback control that everyone is familiar with. The device measures the temperature in a building, compares that temperature to a desired set point and uses the feedback error between the two to operate the heating plant, e.g., to turn heat on when the temperature is too low and to turn it off when the temperature is too high (Åström & Murray, 2009). Another representation of feedback loops is optimal control and estimation in feedback loops.

3. INVENTORY CONTROL MODEL FOR PHARMACEUTICAL DISTRIBUTION

Pharma 4U gmbh is Swiss company, established in 2013. Main activity of this company is production and sale of innovative pharmaceutical products. 4U Pharma d.o.o. (http://4youpharma.com) is a branch in Serbia, aimed at pharmaceutical distribution for Balkan and neighbourhood countries. This company supplies wholesalers and pharmacies from Serbia, Macedonia, Montenegro, Bosnia and Herzegovina, Slovenia, Croatia, Albania, Rumania and Bulgaria. The company is constantly expanding, thanks to constant investment in development and monitoring of recent trends in the global pharmaceutical market.

Inventory management is an especially important for 4U Pharma d.o.o., as it is core activity of the company. At the end of every year company's logistics manager creates monthly sales forecast for next year. This forecast is based on historical data from previous years and manager's experience. At the beginning of every month customers from all countries deliver their stock reports. Ordering quantities and ordering periods are calculated in accordance with Fixed Order Quantity (FOQ), defined by supplier for each product (brand). There are more than one FOQ for each product and unit price depends on the ordered quantity. Order quantities are based on cumulative sales forecast for products of the same brand for different countries. Logistics manager orders articles of the same brand in total quantity for all countries, with remark about language for packaging and instruction. The company does not hold stocks and products are immediately transported to the clients, after customs and analysis. Production lead time is between 90 and 120 days, transportation lead time is up to 7 and custom and analysis 21 days. Total lead time, from order to delivery, is between 118 and 148. Additionally, manager negotiates about shortening of deadlines and price.

Ordering problem can be defined as follows: it is necessary to determine order quantities and ordering periods for each product (brand) for all countries, in accordance with FOQ, in order to provide enough inventories to cover monthly sales forecast, and to minimize distribution costs. Inventory management system is modelled in order to solve this problem. The system is modelled based on the feedback control methodology. During the model creation, all elements of a feedback loop are created (Figure 4).

Model is implemented in spreadsheet and procedures are automated through Visual Basic for Application (VBA). Spreadsheets are inexpensive and run on machines of modest specification. Due to ease of learning, usage and a great possibility for complex analyzing, spreadsheets have been accepted by many users at all levels, from beginners to experts (Lawson et al. 2009). Spreadsheets can be effectively used for analyzing logistics and supply chains issues. Usage of spreadsheets as logistics decision making software tool has exploded in the last two decades, driven by the need to optimize and integrate the supply chain. These tools are extremely effective in determining the optimum number of distribution locations, the appropriate mix of transportation modes, production scheduling, inventory optimization, product rationalization and strategic planning exercises (Smith, 2003). Spreadsheet software, notably Microsoft Excel, allows analysis from many different perspectives and can be modified and enhanced to reflect new situations and options. Moulder develops a baseline model according to current operations, creates alternative scenarios and compares those scenarios to the baseline. Non-quantifiable factors and soft costs are also considered to develop a complete analysis. Using spreadsheet, moulder can analyze the impact of business decisions on any

number of variables, such as: logistics strategies, flow planning, inventory control, allocation and aggregate planning and network design and planning. Also, spreadsheet charts and graphs are excellent tools to provide visual impact to the logistics problems analysis. The effective use of graphs can aid in understanding the models' results. Contrary to the traditional logistics software, that may not always provide the flexibility required, spreadsheet allow analysis from many different perspectives and can be continually modified and enhanced, to reflect new situations and options. The user can add complexity to the model, in compliance with the increase of experience and knowledge about the process. Spreadsheet models can be used for strategic, operations or logistics planning and in many cases can be used simultaneously for all cases (Djordjevic & Vasiljevic, 2013).

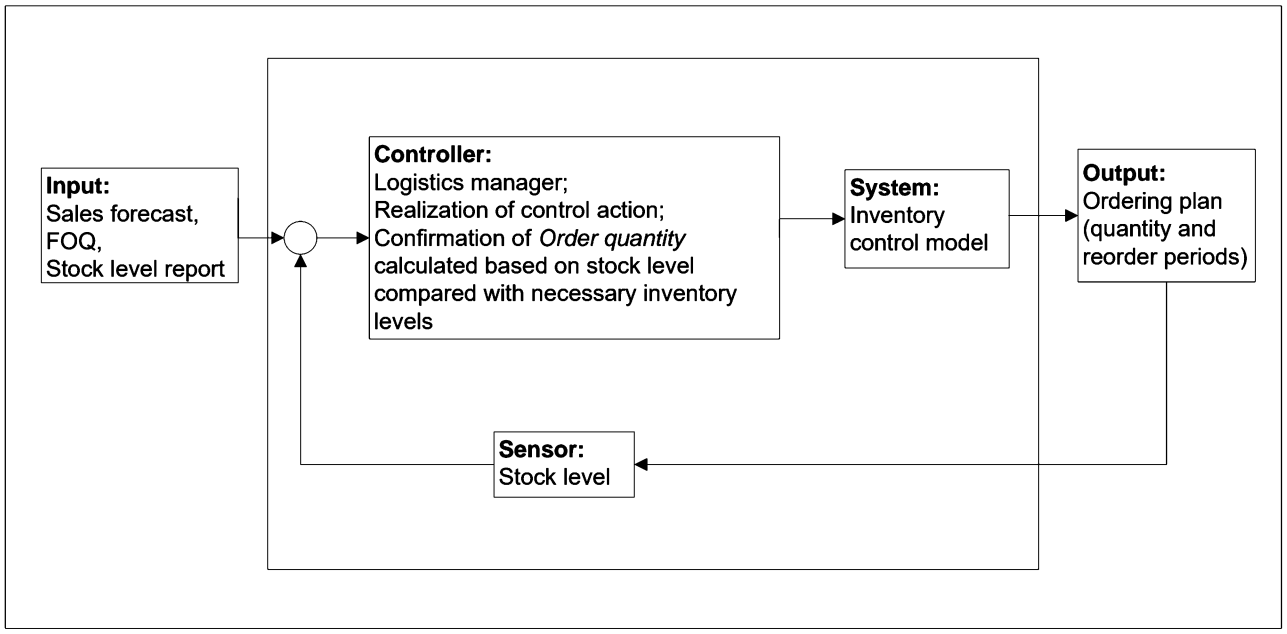

Figure 4: Elements of a feedback loop for inventory control model

Input elements for feedback control systems model are sales forecast, FOQ and stock level report (Figure 5). Monthly sales forecast is created at the beginning of year for entire next year, based on historical data from previous years and manager's experience. FOQ is defined by supplier. There are more than one FOQ for each product and unit price depends on the ordered quantity. At the beginning of every month, each wholesaler and pharmacy (customers from all countries) sends a report about stock level status to 4U Pharma's logistics manager. This report is prescribed form and format in Excel spreadsheet.

No.	Month	Sales forecast	FOQ	Stock level report	Stock level
0				1.508	1.508
1	January	10.900	32.000	2.000	2.000
2	February	12.100	32.000	5.000	5.000

12	Decemb	18.600	32.000	0	15.800

Figure 5: Input elements of inventory control model

In addition, monthly stock level has to be calculated. As stock level report is received at the beginning of month, it corresponds to the level at the end of previous month. Stock level for current month is calculated as

sum of stock level quantity at the end of previous month and planned input and reduced for forecasted sale. In that way model covers whole year, even future months, where stock level is calculated based on planned delivery (input) and forecasted sale (output). Column *Stock level* (Figure 5) represents stock levels for all months in observation period at one place, which are calculated in described way. In this way, we define the sensor function of model, which prepares data for comparison in the model comparator.

Figure 6: Spreadsheet inventory control model

Unusually long lead time (LT) indicates that order quantity has to be calculated based on inventory levels and sales forecast for all months between current period (t) and delivery period (t+LT). Comparator is used to determine the difference between necessary inventory levels for observed months and actual state of stock. Defined differences in the output of comparator are used for making final decisions about quantities of items that will be ordered and delivered to each wholesaler and pharmacy and time periods when orderings have to be realized (reorder periods). According to comparison algorithm (Figure 8), stock levels are compared with necessary inventory levels. Necessary inventory levels consider that demand should always be satisfied. Based on these differences, order quantity and reorder periods are calculated and presented in column *Order quantity* (Figure 6), which now realizes function of the model controller.

12	Decembe	18.600	32.000	0	35.200	0	0	

Figure 7: Input realized earlier then it is planned

Column *Realized input* is used in cases when order arrives earlier or later than expected. In those cases, whole model is recalculated automatically. For example, if ordering is realized in January and LT=5 months, then ordered quantity is delivered after five months, in June (Figure 6). However, if delivery of articles ordered in January is realized earlier, in May, then stock level is increased and ordering plan has to be changed (Figure 7), in accordance with comparison algorithm (Figure 8).

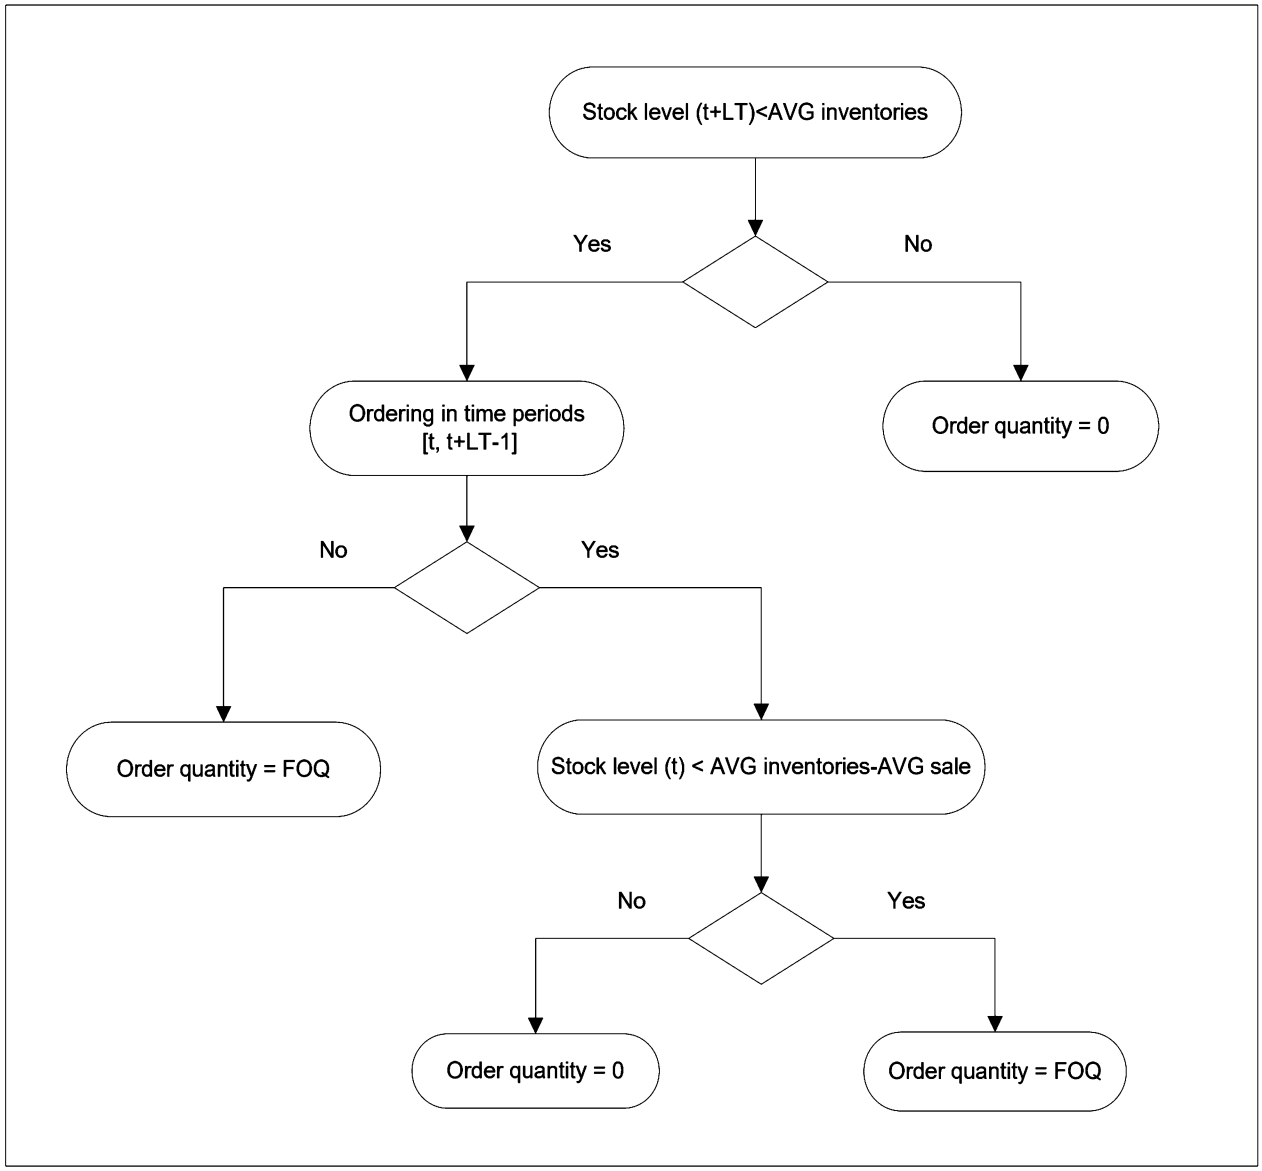

Figure 8: *Comparison algorithm

Model controller function is realized in position of logistics manager. His control role is to confirm order quantity for each product and if it is necessary to make a change of order, in accordance with FOQ, in order to get a lower price. Manager compares and control calculated order quantities in compliance with stocks level, prices, sale forecast, etc.

When quantities are approved, order is realized and sent to production, to 4U pharma gmbh. These actions as an effect has inventories planned level filling for all clients, wholesalers and pharmacies from different countries. Additionally, when order quantity and delivery is confirmed from production plant, whole quantity (FOQ) is assigned to the countries and clients (Figure 9). In this manner, logistics manager controls distribution of ordered quantity, which provides articles necessary for customer requirements fulfilment.

* AVG inventories - average inventories = (AVG sale * LT)/2 AVG sale - average sale for one year

4. CONCLUSION

Many professionals, as well as beginners, from different fields make important decisions based on spreadsheet analysis, and organizations rely on them in record keeping, forecasting, analysing, decision making etc. Spreadsheets are an indispensable tool for simple, quick and easy processing and data analysis for activities of planning, modelling and control of inventories. Apart from logistics, spreadsheet models have a great importance in many other disciplines and fields such as finance, quality management, human resources, quantitative methods and etc. Spreadsheet modelling can be very simple or very complicated and prone to errors and consequently cause of bed decisions, in dependency of how much is moulder familiar with model developing methodology and data organizing in control models. Modern control theory and feedback control system provide basic concepts and elements that can be used for model creation.

Management of pharmaceutical inventory and pharmaceutical distribution have become a major challenge for pharmaceutical companies, as they simultaneously try to reduce costs and improve customer service level in an increasingly competitive business environment. Implementation of modern control theory and feedback control system logic can make inventory control of pharmaceutical articles easy and effective.

Focal point of this paper is inventory control in pharmaceutical distribution company, with an emphasis on order quantities and reorder periods, which have to satisfied specific constraints, described in the paper. As it is presented, inventory control system with feedback is implemented in spreadsheet. This spreadsheet model allows analysis from many different perspectives and can be modified and enhanced to reflect new situations and options. We have developed baseline model that enables alternative scenarios creation and compares those scenarios to the baseline. The results obtained from the model are used for procurement planning for more than 50 products per country for several countries from East-Central Europe for the year 2016.

STATIC CODE ANALYSIS AND REPORTS BASED APPROACHES FOR SPREADSHEET ERRORS DETECTION

Miloš Živić*[1], Lena Đorđević[1], Danica Lečić-Cvetković[1]
[1]Faculty of Organizational Sciences, University of Belgrade
*Corresponding author, e-mail: mzlosmi@gmail.com

Abstract: *Spreadsheet programs represent one of the most successful end-user software development tools, used for a variety of purposes. Professionals from different fields make important decisions based on spreadsheet models, simulation, analysis and organizations rely on them in record keeping, forecasting, analysing, planning etc., although, the statistics say that there are many errors in spreadsheets. Considering that the quality of business decision makes difference between success and failure, one must be sure that a spreadsheet doesn't contain an error that could get the decision maker to think of a problem in a wrong way. Consequently, spreadsheet risk awareness has been significantly increased over the last two decades and researchers have proposed a number of approaches, techniques and automated tools aimed at supporting end-users in error detection and debugging. In this paper focal points are spreadsheet error detection approaches from category static code analysis and reports. Four different approaches are presented and the gap that enables existing errors not to be found is discovered, which leaves space for future research in order to narrow the gap, especially in database manipulation field. Some of the approaches mentioned are concerned with units and types of the data, some are dealing with dimensions of the data and some of them are dealing with both. Since most of them are very specialized, not any of them can be marked as the best, since each one of them is used in a special area. Correspondingly, the goal of this paper is to recognize positive aspects of existing approaches and combine them into universal method applicable on more groups of error detection problems.*

Keywords*: spreadsheet errors, error detection, static code analysis, reports*

1. INTRODUCTION

Spreadsheet applications represent the most successful example of developing applications by the end user. The great advantage of spreadsheets is that they allow professionals from non-programming areas to create their own tools to support their business and to apply their domain expertise. The tools developed in this way are often available very soon, unlike many other applications used in business and that have to be developed by special IT departments. However, even if spreadsheets have many advantages as an environment that provides fast development of business applications, it leaves a lot of space for errors. Some more recent papers about spreadsheet errors, like the one by Jannach, Schmitz, Hofer and Wotawa (2014), show that there was at least one error found in every single spreadsheet they have tested. Sometimes, these errors don't affect the business, and on the other hand, there are spreadsheets used for decision making in very important situations, so every error of any type could make a difference between survival and disaster of a company, or even greater consequences.

A feature of developing their own tools that was given to end users has certain advantages, like flexibility, independence, development speed, lower risk of communication problems. But, there are also some flaws, and the greatest of all of them is possibility to create spreadsheet tools with errors, as described by Luckey, Erwig and Engels (2012) and Cunha, Erwig and Saraiva (2010). As the total number of spreadsheet users is a lot greater than the number of programmers, and as their needs for applications are great, the number of spreadsheet applications created every day is very great too. However, end users are not trained enough to check their applications for errors and that causes development and usage of their applications even on real data, even if they have errors. In order to minimize risks, spreadsheet experts have developed various approaches for avoiding, detecting and correcting errors in spreadsheets. It is possible to lower the risk by investing into education and training of end users, then, by creating organizational procedures for evaluation and development of spreadsheet applications, and, finally, by developing support to end users that will help them to identify errors while creating the spreadsheet tool (Jannach et al., 2014).

This paper highlights static code analysis and reports. The main goal of this paper is to present available solutions for analysis and to reveal the gap for further research and development of an approach that would

enable, if not eliminating, then at least narrowing the gap between the errors that occur and the ones that can be found by using some of existing methods.

2. TYPES OF SPREADSHEET ERRORS

Errors in spreadsheets can be classified based on various criteria. Differing error types is important because each error type demands another method for detection. Errors can be divided into two main groups: qualitative and quantitative. Quantitative errors most often come as a result of a numerical error that could lead to wrong end results. On the other side, qualitative errors occur because of wrong spreadsheet design, for example double entries or few entries in one cell.

According to Teo and Tan (1999), quantitative errors can be mechanical, logical and omission errors. Mechanical errors are those that occur because of simple things like wrong number entry, watching the wrong cell address or selection of the wrong area of cells. The main reason why users make these mistakes is lack of attention, stress, work overload or bad work environment. Logical mistakes are more complex and they occur because of wrong formula. Wrong formula comes as a result of wrong algorithms caused by the lack of domain expertise. For example, it is possible to determine price only by adding variable costs, while forgetting about fixed ones. The consequence is very clear, the product might be sold at a price that doesn't cover total costs for its production. For detecting spreadsheet errors it is required to have more experience than for detecting mechanical errors because it requires, except knowing spreadsheet technique well, also knowing the business process. Finally, there are omission errors. They are caused by not including some important element in the model. As with logical errors, they are not easy to find and it requires both, knowing the spreadsheet techniques well, but also understanding the business processes.

On the other side, according to Rajalingham, Chadwick and Knight (2008), spreadsheet errors can be divided into few groups. System generated errors are those generated by spreadsheet tool or a bug in software. Their creation is above users' control, but, if users are aware of them, they can perform steps to avoid them. Errors generated by end users can be prevented, detected and corrected. They can be qualitative and quantitative. Quantitative errors can be accidental, as errors and omissions created by lack of attention, like typing errors. They can be caused by spreadsheet designers or end users. Designer could select a wrong field, double some entry or create an omission error. When it comes to end user, they can be divided into two groups: those who enter the data and those who read the data. Both groups can create errors of the same type as the developer. The second type of quantitative errors is a reasoning error that could be an error caused by not knowing the domain enough, like not understanding the business process or mathematical way of displaying. Quantitative errors include errors during implementation process, that can be syntax and logical errors. The other group of spreadsheet errors is qualitative errors. They can be semantic and errors for future maintenance. Semantic errors are those with wrong structure and time – entering data that is not up-to-date, while maintenance errors are those that make data entry more difficult, but also other types of upgrades.

3. CATEGORIES OF APPROACHES FOR SPREADSHEET ERRORS DETECTION

For identifying errors in spreadsheets, many approaches and tools were primarily developed and used for the same cause in software engineering. However, as it was mentioned above, the feature of spreadsheet error detection is in immediately visible results, the user gets visual feedback as a result of applying function on some data. Spreadsheets are different than common program languages because all the calculus is done within the cells that contain formula and they are performed with data contained in other cells. Also, in spreadsheet, every datum has its physical position, but also its semantic of calculus. Potential errors can be found based on sign in data header that puts every single datum into some context and then it is possible to make conclusions about characteristics of results of certain formula.

The technology of spreadsheets enables users who come from different areas and levels of spreadsheet knowledge to create their own models. Most of the users don't know even the basics of spreadsheet model quality assurance. Because of that, this process has to be done in a way that requires minimal or no end-user participation in a way that doesn't depend on the level of expertise of the user.

Approaches to software quality assurance (QA), applicable to spreadsheets, are categorized in two major groups (Đorđević and Lečić-Cvetković, 2015):

- Identifying and correcting errors – techniques and tools designed to help users to detect errors, identify its cause and suggest correction. These tools are used by spreadsheet creators, auditors and reviewers, during or after development of spreadsheet model.

- Avoiding errors – contains techniques and tools that support spreadsheet development without errors. They are applied during the spreadsheet model development process.

Finer-grained categorization of the existing approaches to automated spreadsheet quality assurance can be seen in the Table 1.

Table 1: Automatic spreadsheet quality assurance approaches categorization (Đorđević and Lečić-Cvetković, 2015):

N°	Spreadsheet QA approaches	Identifying errors	Avoiding errors
1.	Visualization based	x	X
2.	Static code analysis and reports	x	X
3.	Testing	x	
4.	Automatic localization and correction	x	
5.	Model based development		X
6.	Design and maintenance support		X

Categories 1 and 2 can be used for identifying and avoiding errors. For example, good visualization of dependencies among cells helps users to identify the problem, but also to identify cells that have high chances of creating errors. Static code analysis discovers existing errors like a reference to an empty cell or listing formulas that are too complex. On the other side, 3 and 4 are used for identifying and localization of already made errors. Methods 5 and 6 are made for avoiding errors, for example, by refactoring or adding levels of abstraction.

4. STATIC CODE ANALYSIS AND REPORTS

Static code analysis is the spreadsheet QA area that has major usage options and can be divided into three subgroups: unit and type inference, spreadsheet "smells", static analysis and commercial tools, as it is explained by Đorđević and Lečić-Cvetković (2015). However, these approaches are often combined in order to discover more errors.

Static code analysis and reports based approaches analyze formula in spreadsheets and show potential errors or wrong spreadsheet design that could lead to future errors. This approach doesn't analyze cell values. The approach is based on formula and their dependencies, their static labels and other structural characteristics of the spreadsheet.

Unit and type inference is an approach that belongs to static code analysis and report based approaches, and the main idea of this method is getting information about cell units and using them in order to make a conclusion if the calculation makes sense or not. In order to get information about units, headers are used. Erwig and Burnett (2002), in their first papers from this field, were only telling about ways how to get information based on header, and later they developed procedures how to actually perform that without user efforts. The newer papers of these authors are directed to label analysis and attempts to get them down to known units and to decide on calculations based on that. Some of them require user to enter units, while the newest of them even have systems for unit recognition based on the label.

The group of spreadsheet "smells" methods is contained by methods that don't "say" that in some spreadsheet there is an error nor that there will definitely be some error in future. They are designed in a way to recognize spreadsheet parts where there is too much space for errors, because of spreadsheet design: long formula, too many references to another spreadsheet, constant values in a formula, etc.

Finally, techniques of static code analysis are often used as a part of commercial tools. Many of them can be seen in MS Excel in order to mark "suspicious" formula that maybe shouldn't be where they are, or they could be made in some other way, as it was presented by Jannach, Schmitz, Hofer and Wotawa (2014). In the next section of this paper, methods developed by spreadsheet engineering experts are presented, by highlighting virtues and flaws of their methods, in order to identify directions for future development.

5. STATIC CODE ANALYSIS AND REPORTS APPROACHES OVERVIEW

The basic principles of identifying errors in spreadsheets based on unit and type inference are presented in Erwig and Burnett (2002). This approach presents one of the basic methods for spreadsheet errors detection from static methods and is based on an idea of identifying errors related to forbidden combinations of units. The goal of this paper was to discover errors in system if they occur during entry, at the moment of data

entry. Errors are identified based on units, where unit is a label entered in table header. There is an acknowledgement of the existing need for functions of higher level, but it is limited only to first level functions. These functions are the ones that make a result some value that is in the unit of same level and it doesn't include option of using functions where a new dimension is created as a result of applying function on existing values. Because of the striving to achieve greatest functionality possible, the authors made four limitations set (Erwig and Burnett, 2002):

- The first one includes inference mechanism that provides immediate feedback of visual type in order to know if the formula is error-free.
- The second limitation is that inference system uses labels and functions that users use.
- The third limitation is related to formal unit labelling. An additional limitation is a mechanism of inference that does it function without need to predefine formal units.
- The fourth one defines a mechanism that is applied to real spreadsheets created by users and doesn't include assumption that users will use the right formula in a right way.

Headers are labels that assign units to a group of cells. A cell can have few headers. A header is explicit information about cells to which it belongs and based on its units are checked. Header can be defined by expected entry information, based on formatting and position in spreadsheet. Headers and cells can have different relations. Dependable units are present on few levels. For example, higher level unit – a car, can be a limousine, roadster, a sports-utility vehicle etc. Relations "and" and "or" refer if a cell can have one or both units. The logic of this model is based on defining well-formed units and differing them from those that are not.

Well-formed unit is 1, as an universal unit, then, unit that doesn't have a header. If a cell has value *v* and a header *z*, then, *z(v)* is a well-formed unit. One example includes "and" operations that combine values without common predecessors. Also, well-formed unit is a unit that comes as a result of "or" operation when two units have common predecessors. According to Erwig and Burnett (2002), rules for unit inference are:

- If a cell doesn't have header, the unit is 1;
- If cell a has header b that contains value v and has a well-formed unit u, then *u(v)* is a unit of a;
- If a cell has a reference to some other cell, it will also have the cell's unit;
- Each mathematical operation has its own definition of combining units.

In accordance with rules and limitations, an algorithm for unit inference was created, based on units and the operation that are used in formula. It is logical that adding and reducing are done over data of same units and that result has the same unit. The complete algorithm is based on an idea to get well-formed units from operations. If it is not possible, the system will report error.

Unlike the previously presented paper, Ahmad, Antoniu, Goldwater and Krishnamurthi (2003), based their paper on an idea that spreadsheets are made of cell locations, values and expressions. Header is a common unit for a group of cells. The presumption is that all headers are known. There are two types of relations "is-a" and "has-a". "Is-a" is used for belonging to a type, for example "apple is a fruit", and, "has-a" tells that header has some characteristic "apple has an attribute colour". Units are defined in the same way as in the previous model. In order to use the method, the authors have defined four rules for "calculating" units in the model (Ahmad, Antoniu, Goldwater and Krishnamurthi, 2003):

- The first rule is that each cell has one or zero "is-a" relations. If no, then it is "top" and the unit is the header label. Otherwise, it is a concatenation of header label and its cell label.
- The second rule says that cells that contain values and are not in header get units from their headers. Each cell containing user data must have at least one "is-a" header. Except that, there must be at least one "is-a" header with "has-a" relation. If there is only one "is-a" header, unit of a cell is formed by concatenating header unit and the header label to get "is-a" part and by adding existing attribute in the end. If there are few "is-a" headers, every "is-a" has its own hierarchy, and results are combined.
- The third rule explains that cells that contain only references are taking units of referenced cells.
- The fourth rule explains that cells that contain formula get unit based on rules of mathematical operation.

Adding is defined in situations when there is an "is-a" operation with common "has-a" relation, adding and reducing with common "is-a" with different "has-a" part. The defined didn't include the case when both "is-a" and "has-a" are different. Based on functioning of adding and reducing, it can be said that any binary operator calculates units correctly in two cases – common "is-a" part – result of the operation is combination of two different "has-a" parts, also defined for common "has-a" parts. The authors also defined the "&" operation. The spreadsheet has an error if it comes between two units with common header ("top" not included). Examples of these rules, according to Ahmad, Antoniu, Goldwater and Krishnamurthi (2003), are given below (the mark for "has-a" part is "{}", and for "is-a" part - "[]"):

$$Fruit[Apples]\{Quantity\}+Fruit[Oranges]\{Quantity\}=Fruit\{Quantity\}$$

In other words, adding quantities of apples and oranges results as a quantity of fruit.

$$Fruit[Apples]\{Costs\}+Fruit[Apples]\{Profit\}=Fruit[Apples]\{Costs\circ Profit\}$$

If costs of apples are added to their profit, there will be a new unit – result of operation ◦ on cost and profit. A situation not covered with this model can be presented as:

$$Fruit[Apples]\{Costs\}+Fruit[Oranges]\{Profit\}$$

This method also covers a case with multiple relations of subtype:

$$Fruit[Apples][Bad]+Fruit[Oranges][Bad]=Fruit[Bad]$$

"Bad" is a subtype, and not an attribute. The result of adding is "Bad Fruit". Reducing is defined in the example below:

$$Fruit[Apples[Total]]\{Quantity\}+Fruit[Apples[Bad]]\{Quantity\}=Fruit[Apples]\{Quantity\}$$

Reducing "bad apples" from total quantity will result with quantity of "good apples", but, it is impossible to conclude that unless it is predefined that only two subtypes of apples are "good" and "bad". The authors also defined the case with common subtype, but different attribute:

$$Fruit[Apples]\{Revenue\}-Fruit[Apples]\{Costs\}= Fruit[Apples]\{Revenue\circ Costs\}$$

The result is a common type-subtype part with an attribute received as a result of operation over two different attributes. In case of multiplication, a situation simplest described on shapes is defined:

$$Shape[Square]\{Width\}xShape[Square]\{Height\}=Shape[Square]\{Width\bullet Height\}$$

The result is a common subtype part, and it gets a combination of different attributes. The case of different subtypes and same attributes is not defined, but, the system won't report error in this case. The concatenation operation, often used in spreadsheets can be used only for elements with headers that are not common and at most one of them has an attribute.

A different approach is given by Chambers and Erwig (2009), where error identification is performed on three levels:

- headers;
- labels that simplify units and search for already known units and inferring based on it;
- inference on dimensions, by checking all the cells with formula and getting final dimensions by rules described in the paper.

The authors defined dimensions for many operations that can be performed in spreadsheets: adding, multiplication, "if" function, count, reference and "regular" cell's dimensions (Figure 1).

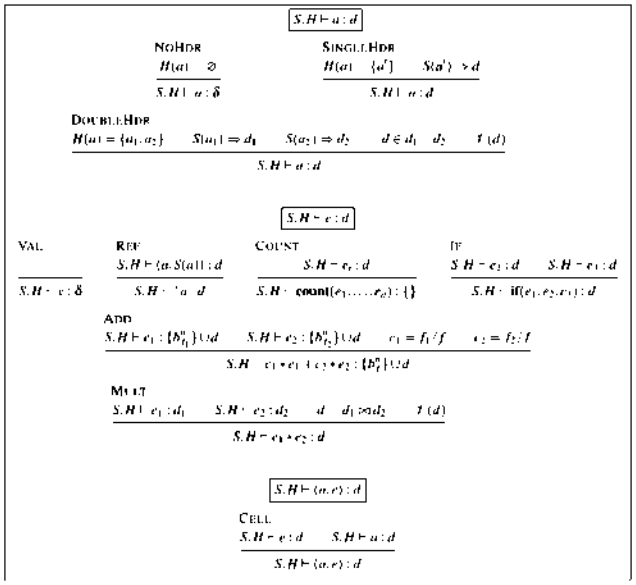

Figure 1: Inference rules (Chambers and Erwig, 2009)

In case that the dimension cannot be defined, the system reports an error. Also, exponents of existing dimensions are included. The logic of the approach on the example is presented in Figure 2.

F5 =B5+MAX(F2*60-C5,0)*D5

	A	B	C	D	E	F	G
1							
2				Hours of use	15	25	35
3							
4	Plan	Base Fee	Plan Minutes	Usage Charge	Total		
5	Verizon	39	1000	0.025	39.00	51.50	66.50
6	Quest	49	1500	0.021	49.00	49.00	61.60
7	Xingular	29	500	0.026	39.40	55.00	70.60
8	IBN	0	0	0.034	30.60	51.00	71.40

Figure 1: Example of the approach used on spreadsheet (Chambers and Erwig, 2010)

In the Figure 2, cell F5 contains a formula "=B5+MAX(F2*60-C5,0)*D5". Authors applied the rule given in the Figure 1, labelled "CELL". The value has dimension based on formula it contains and its header. Header "Total" can represent a sum of different units, however, since these spreadsheets are from finance area, the guess is that it is $. The conclusion is that F5 should have $ unit, but it is not confirmed that the result of the formula will be in $. Because of that, addition rule is applied, but after the reference rule. Based on that, B5 part has dimension $, like in original formula.

The other part of formula uses rule for unit inference in multiplication. Field D5 doesn't have a unit, and dimension of second factor is received from addition rule and it can be also applied to "max" function. If the operation is watched, it is clear that it has few parts. In F2, there are hours, and, it is logical that multiplied by 60, the result is in minutes. Then, it is reduced by minutes. Then, by the rule of multiplication, in order to get $, it must be in $/min, so it can be said that D5 has $/min unit, which is acceptable, if the logic of the model is had in mind. Finally, adding of two values in $ will result in $. In this case, no errors are reported.

Another example for showing functionality that is not contained by previous example, is an example of adding values that have common basic unit, but their factors are different (centimetres and meters). Centimetres require multiplication with 0.01, so the system will report error, but it will be able to suggest a correction.

In a paper about identifying errors, Chambers and Erwig (2010) use a combination of mentioned methods, for example, there is an approach of integration of dimension and unit inference. First, header inference, then, understanding labels, identifying dimensions and label axis, then, combined inference based on labels and dimensions. Header inference analyzes structure of spreadsheet and returns a set of headers for each cell. Header represents an address of other cell. One cell can be a header for many cells, and any cell can have zero, one or more headers. In this paper, headers can be vertical and horizontal. Header inference is

performed by analyzing spatial relations between the formulas. Label inference relates to a situation when dimensions are derived based on its header's label. Labels are separated into words that are translated into dimensions and then all of them are combined into one dimension.

When identifying labels and dimensions, there are three different cases (Chambers and Erwig, 2010):

- no dimensions,
- one dimension and
- two dimensions.

In the first case, only labels are watched. The second case represents a combination of label and dimension inference. An axis is determined for each dimension and label. A cell has a combination of characteristics received as a result of separate use of mentioned methods. The third case is the same, but for both of them, dimension inference is used.

The combination of labels and dimensions inference has many levels: value inference, header inference, expression inference and cell inference. The advantage is that it checks only if units are the same. This is easier because dimensions are combined into one, so it is easier to determine units for multiplication, where it is the only condition to have matching units.

The last feature of this method is finding primal dimension, it enables to, if possible, to find different units for same dimension and to express one through another. If impossible, the system will report error.

6. ADVANTAGES AND DISADVANTAGES OF STATIC CODE ANALYSIS AND REPORTS APPROACHES

Approaches described in this paper have virtues and flaws which make them more or less convenient for certain situations. Erwig and Burnett (2002) presented the base of this whole category. Based on header, unit inference is performed and then, errors are reported if no rule of well-formed units can be applied. The good side is that errors are reported immediately after entry. The main flaw is a narrow scope of different spreadsheet and formula that can be checked.

In paper Ahmad, Antoniu, Goldwater and Krishnamurthi (2003), authors proposed approach, with relations “is-a” and “has-a”, and based on them, rules for unit inference based on operations are used. There are different cases, depending on which characteristics of formula elements are common and which are not, and based on that, resulting units are defined. Errors are reported in case that there is no combination of common characteristics and operations found. Advantage of this method is that it can be applied in many fields, without knowing much about the area where spreadsheet is used. It doesn’t require predefining units and it is not restricted to only one or small number of areas. The main flaw of this approach is the lack of header inference, it is necessary to write dimensions in the same way every time. Also, small number of operations is defined: adding, reducing, multiplication and dividing, but also concatenation.

According to Chambers and Erwig (2009), the analysis is performed in three steps. First, on header level, the second is based on labels, which are analyzed by parsing and finding known units that are used. The third level is based on formula in cells which have rules defined. The approach has three levels and it makes it more efficient than each of them separately. Shortcoming is that it includes assumptions, as it is shown in the example “Total” header where it is guessed that it is $. The positive is that values of same dimensions can be compared even if indifferent dimensions.

The approach shown by Chambers and Erwig (2010) can be characterized as the most complete. This approach presents a combination of different methods and contains the previous methods. Except mentioned, approach has two new features: it doesn't detect errors based on well-formed units, but it combines all units into one, and all it takes is these dimensions to match and the cell will be considered correct. Dimensions are inferred in three situations: horizontally and vertically, horizontally or vertically, or no dimensions at all.

All the approaches are used for simple spreadsheet models and simple calculus in maximum two dimensions. Calculus is checked and cells that might contain errors are reported. They are used for only one table in a spreadsheet, while they cannot be used for putting few tables into one. Also, there are no checks if there are all the elements required in the formula. As it can be concluded based on the approaches presented, there is enough room for improvement of these methods that will enable discovery of errors that occur often.

7. CONCLUSION AND FUTURE RESEARCH

Analysing existing approaches and methods for error detection and potential types of errors that might occur, future research should be pointed to approaches that will enable finding errors that are not included in mentioned methods and on implementing existing methods in new situations, aiming to improve spreadsheet models' reliability.

Existing approaches were tested on a small number of spreadsheets and mainly require more or less efforts from end users in order to test the spreadsheet. The goal of future research is to minimize user efforts required in spreadsheet error detection process and lower dependence of data form in spreadsheet.

Future research directions also consider development of approach that will identify errors on many levels, especially those that were made during database manipulation. In case of database with many columns, each column represents a new dimension where the datum is located depending on its value. In existing models, one or two dimensions are checked, while in case of database, error check would have to be done in a large number of dimensions in order to check if some operation makes sense. If some operation over some data will get a result that is meaningful to the user. To be more precise, it is checked if it is possible to relate the result with some existing or a new dimension that represents a combination of the existing ones.

Another functionality of spreadsheets that is not checked enough, but yet, used very often, is "VLOOKUP" function, used for transferring data from one database to another by using common parts. Often, users skip some data in the formula which results in not finding a value that exists. Also, different formats in the database cause "VLOOKUP" not to find some value, even if it exists in the spreadsheet. The idea is to create an application that will check the type and scope of formula data, and in case of data in the same column, but not of the same format, it should report potential error.

Another potential improvement might be improving existing Excel methods for checking values and formats of adjacent cells. Potential options will be considered in the future, in order to add some new functionality that will lead to lowering error probability.

AN OPTIMIZATION-SIMULATION APPROACH TO ADVERTISEMENT PLACEMENT PROBLEM

Stefan Marković*[1], Mirko Vujošević[1]
[1]Faculty of organizational sciences, Belgrade, Serbia

Abstract: *A stochastic programming problem with a number of random parameters in the set of constraints is considered. An iterative optimization-simulation approach is applied as solving method. It consists of two phases: optimization phase, which includes solving a deterministic counterpart of the original chance-constrained problem, and a simulation phase in which the original constraints are checked using Monte Carlo simulation. One iteration corresponds to one scenario. If the decision maker is not satisfied with results, new scenario is generated in which the deterministic values of stochastic parameters are changed in the direction that will provide a more robust solution. Deterministic counterpart in the new scenario is formulated depending on the result of previous iteration. For that purpose, different heuristics are considered. The main goal is to provide a good insight on the optimization problem under uncertainty by performing relatively small number of iterations. General approach and results of the proposed framework will be illustrated on an advertisement placement example.*

Keywords: *Stochastic programming, Simulation, Chance constraints, Linear programming*

1. INTRODUCTION

Application of operational research techniques in marketing started with the famous theorem for marketing mix optimization in 1954 (Dorfman & Steiner, 1954). That pretty much opened the path for OR techniques implementation to marketing problems. Linear programming and goal programming became the first choices when talking about OR in marketing, and Markov models and various simulation techniques, as well as game theory, were applied in the 1960's and 70's (Montgomery, 1970). Even in these early days of interaction between OR and marketing, researchers observed the stochastic nature of marketing problems, through utilizing the theory of decision making under uncertainty (Pratt, Raiffa, & Schlaifer, 1995). Not much was done in the upcoming years on this field, but recently, due to substantially increased computational capacities of computers, modeling uncertainty through various estimation techniques has found its place in OR applications in marketing (Rossi & Allenby, 2003).

Consequently, stochastic programming is not new to marketing, but generally wasn't the main focus of the researchers at the beginning. Nevertheless, it has sprung a new interest among researchers in various fields of marketing problems.

Even with the abundance of research material and the long history of marketing models, it is an observed fact that these models are rarely used for decision making in practice. Advertising, as a part of the marketing mix, was particularly researched, and researchers deemed its effects on sales and market share to be doubtful. This particular opinion was created due to concerns that advertising might have no effect on sales at all, but since (Clarke, 1976), (Leone & Schultz, 1980) and (Vidale & Wolfe, 1957) confirmed that advertising has a positive influence on sales, all suspicions on effectiveness of these models and its application in decision making could be dismissed. Naturally, a lot of effort was put into developing models that could optimize the allocation of an advertising budget, which is also the task at hand of this paper.

Still, because of the stochastic nature of marketing problems, many of them will remain intractable to ordinary mathematical solution (Kotler, 1963). But, complying with the saying: "When all else fails, simulate!" an optimization-simulation approach is put forward and applied to the advertising placement problem.

Stochastic programming allows decision makers to incorporate a measurable uncertainty in a model, which means e.g. that uncertainty can be expressed through appropriate distribution of data or in some other way.

Stochastic programming has applications in a great number of areas and classes of problems, and in this paper, a class of marketing models is considered, namely the marketing campaign model. The reason why the field of marketing is chosen, is due to stochastic nature of the marketing problems. Thus, the observed

problem is a perfect match for the use of a new approach to stochastic programming that is being proposed. The task at hand will be to minimize the cost for a marketing campaign by placing advertisements in various newspapers, which is done exclusively through printed editions of newspapers and magazines, while reaching the needed views and scores both in total population, and within target groups.

As for the solving method, an original approach is proposed, an iterative optimization-simulation approach to stochastic programming.

The paper is organized as follows. Section 2 gives a short overview of stochastic and robust programming and shows how both of them fit into the proposed solving method. Section 3 is the part of paper where the model is formulated, i.e. mathematical model and its notation and a short explanation of the optimization task. Section 4 is reserved for detailed description of the proposed optimization-simulation approach. All the steps of the iterative process are presented, both in words and graphically. The results of research are presented in the Section 5. Concise results are given through tables and diagrams for every scenario used. Section 6 summarizes the conclusions.

2. STOCHASTIC AND ROBUST OPTIMIZATION

Every attempt of modeling a real life problem means facing an uncertain, incomplete or erroneous data. One can differentiate between stochastic and robust optimization when handling uncertainty in models. Robust optimization consists of several approaches for which common goal is to protect the decision maker from any uncertainty in the parameters and from stochastic uncertainty (Gabrel, Murat, & Thiele, 2014). The basic presumption of robust optimization is the existence of such constraints that must always be satisfied, no matter what the realization of the uncertain parameters are (Gorissen, Yanıkoğlu, & den Hertog, 2015). In addition, every uncertain parameter has to get its value from a predefined set.

Stochastic linear programming was first defined in 1955 (Tintner, 1955), and the same year, (Beale, 1955), (Dantzig, 1955) developed an approach that was based on recourse costs and the method was named linear programming with uncertainty. Several years later, (Charnes & Cooper, 1959) defined a new approach in stochastic programming called the chance constrained programming, which differed greatly from the previous two approaches.

There are different methods to incorporate uncertainty in a mathematical model. Theory suggests that most of them are based on defining a new deterministic counterpart, or deterministic replacement, of the original problem. As for solving these models, there is an approach of simplifying the real problem so it can be solved with standard mathematical methods; while on the other hand, there are simulation and optimization techniques that are commonly used in practice (Beyer & Sendhoff, 2007).

Nevertheless, stochastic programming is less conservative compared to robust approach, which is generally orientated on the worst-case scenario when creating a deterministic equivalent of the original problem. The previous statement is valid only on the condition that distributions of random variables in the model are known, or can be calculated. If that's not the case, there are a lot of problems to be expected in solving the deterministic counterpart of the original problem, and often one won't even be able to find any solution for such uncertain parameters. Still, as (Ben-Tal, El Ghaoui, & Nemirovski, 2009) state in their book, stochastic and robust programming are complementary approaches for optimization under uncertainty, which is the approach that will be used in this paper.

3. PROBLEM FORMULATION

The problem of selecting the optimal number of advertisements to be placed in different newspapers is considered. Besides the obvious task of determining the number of advertisements, their positions and size for every newspaper has to be determined as well, while reaching the needed views and scores both in total population, and within target groups. The goal is to achieve all these with the minimum cost possible. Daily, weekly and monthly newspapers, their total views, as well as rating for each newspaper for the targeted group are considered. Ratings are data with a stochastic nature, and are assumed to have a Gaussian distribution. The cost of advertising is set in accordance with real life data. The problem is formulated as a linear stochastic programming model.

Notation
I - Set of newspapers (daily, weekly and monthly)
J - Set of possible positions in all newspapers
P - Set of possible positions for every single newspaper

T - Set of target groups

S - Minimum number of unique advertisement views
c_{ij} - Price for each position in every newspaper
v_i - Number of newspaper views
r_{ik} - Newspaper rating for every target group
p_j - Visibility percentage for every advertisement position
t_k - Wanted rating for a target group
m - Minimum number of advertisement in i newspaper
h - Maximum number of advertisement in i newspaper
g - Minimum number of advertisement on j position
d - Maximum number of advertisement on j position

x_{ij} - Number of j advertisement in i newspaper

Mathematical model

With reference to introduced notation, the advertisement placement model is presented:

Minimize

$$f(x) = \sum_i \sum_{j \in P} c_{ij} x_{ij} \tag{1}$$

subject to constraints

$$\sum_i v_i \sum_{j \in P} p_j \sum_i \sum_{j \in P} x_{ij} \geq S \tag{2}$$

$$\sum_i \sum_{k \in T} r_{ik} \sum_i \sum_{j \in P} x_{ij} \geq t_k \tag{3}$$

$$\sum_{j \in P} x_{ij} \geq m_i \tag{4}$$

$$\sum_{j \in P} x_{ij} \leq h_i \tag{5}$$

$$\sum_i x_{ij} \geq g_j \tag{6}$$

$$\sum_i x_{ij} \leq d_j \tag{7}$$

Constraint (2) sets the minimum wanted total advertisement views; constraint (3) sets the wanted rating for every target group; constraints (4) and (5) set the minimum and maximum number of possible advertisement for every newspaper, respectively; and constraints (6) and (7) set the minimum and maximum number of possible advertisement that can be placed on the assigned positions for every newspaper, respectively.

4. OPTIMIZATION-SIMULATION APPROACH

The proposed solving method is an iterative optimization-simulation approach. It consists of two phases, the optimization phase, where scenarios are generated and the deterministic model is solved, and a simulation phase where the validity of scenario is checked.

Applying the robust approach to creating a deterministic counterpart of the original model will result in a model that is immune to uncertainty. Obtained solution will always be admissible despite any realizations of uncertain parameters. An obvious downside of this approach is that the value of the criterion function is the worst possible. This is why this approach is also called the pessimistic approach, or the worst-case scenario approach. In reality, realizations of uncertain parameters that result in a worst-case scenario are highly unlikely. The goal isn't to model an extreme case, but to handle general uncertainty and that is why the chance-constrained approach is used and combined with robust approach in the solving method.

This approach is about replacing an original problem with a new, deterministic model that will provide the best solution under the condition that constraints are satisfied with a predefined probability. Generating a new deterministic counterpart of the original model corresponds to one scenario. Obviously, this approach will require defining a considerable amount of scenarios that need to be checked, in order to find a scenario

that will achieve the wanted probability of satisfying the constraints. The upside is that one's able to better understand the original problem with every iteration.

The second phase of the method uses the power of simulation to check the generated scenario.

Upon solving the deterministic counterpart of the original problem in the first phase, optimal solution is obtained, which is needed in order to determine the probability of satisfying the stochastic constraints. Next, a random deterministic value for every uncertain parameter from its predefined set with assigned distribution is selected. This way a matrix of random deterministic values of uncertain parameters is generated, or in other words, the randomness of stochastic data is simulated. The constraints are checked if they are satisfied or not by taking into account the deterministic values and optimal solutions of the scenario generated in the first phase.

These simulations are repeated N times, generating N of these matrices, inserting the numbers into the constraints and then calculating if they are satisfied or not. By counting the times when constraints were satisfied, the probability for satisfying stochastic constraints can be calculated, with the following formulae: (Number of cases when constraint was satisfied/Total number of cases N) *100. This is done for every constraint in model.

This approach works under the presumption that the decision maker is willing to accept a certain risk that the constraints won't be satisfied. In return, the value of the criterion function will be better than if the decision maker was to remove all uncertainty and accept the robust approach. If the decision maker is not satisfied with the results, a new scenario will be created, i.e. a new deterministic counterpart of the original problem, and the whole procedure will be repeated again. New scenario will be formulated depending on the results of the previous one, and the goal will be to find such a scenario that meets the minimum criteria set by the decision maker in terms of chance that constraints are satisfied, while trying the find the best possible value of the criterion function.

The main issue of the whole procedure is scenario generation and how to define a new deterministic counterpart of the original problem. There is no iron rule in scenario generation, and it is strongly suggested to use different heuristics. Particular heuristics used will depend on the nature of the problem that is considered, the assumed distribution of the random data, past data available, experience of the decision maker and of the specific problem that is being considered.

For every heuristic to be meaningful, a general target goal must be known, or set. Decision makers usually require a high percentage of constraints satisfaction. Therefore, stochastic constraints are usually divided into two groups. The first group is the so-called "hard" constraints group, and decision maker demands that these constraints must have p_i levels that are 100%. The second group is the "soft" constraints group and decision maker accepts a certain risk that these constraints won't be satisfied. Usual p_i levels for these set of constraints are above 90 - 95%. The idea of dividing constraints in LP model to hard and soft ones was first introduced in (Kendall, 1975) and is used in this paper as well. One can make further groups of constraints, but these are the general guidelines of how this specific problem was modeled in this paper.

Two starting scenarios should be the scenario with the expected values, and a robust scenario. Using these two scenarios as border cases provides the initial insight in the nature of the problem and stochastic data. The only thing that's left is to test different scenarios, and that is why iterative approach is very handy. If facing the usual problem of high p_i levels (above 90%), then sticking close to robust scenario provides the greatest possibility that constraints will be satisfied. Have in mind though that not getting to close to the robust scenario is also a prerequisite, because getting to close to this scenario will translate in a worse criterion function. Therefore, the general approach will be to make a tradeoff between the robustness of the model and the value of its criterion function.

The whole approach is summarized in Figure 1.

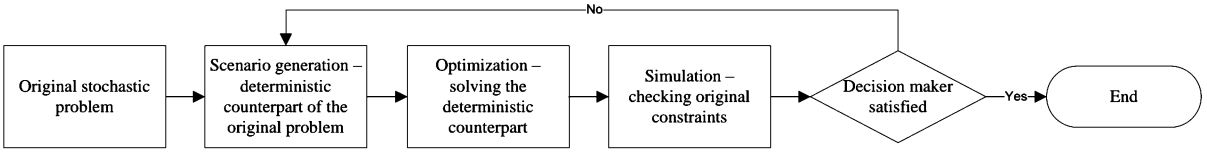

Figure 1: Optimization-simulation approach

The proposed solving method will be applied, namely optimization-simulation approach to stochastic programming, to the advertisement placement model presented in Section 3 and the results will be presented in the following chapter.

5. COMPUTATIONAL TESTING AND RESULTS

Let's take another look at the model presented in the section 3. The stochastic nature of the model is reflected in equation (3), and its set of constraints. The obvious reason is the stochastic parameter r_{ik}, which represents the newspaper rating for target groups. The reason why these parameters are stochastic is that these ratings represent the evaluation of the observed newspaper ratings. These ratings are calculated based on the number of copies printed, newspaper reputation and tradition and the assumed ratings for the position of advertisement placed in those newspapers. The method that is used to calculate these parameters is not in the focus of this paper, but what's important here is that these parameters are calculated monthly and adjusted on a six month period. For the purpose of the model, a case where uncertain parameters have a Gaussian distribution with expected value - μ and variance - σ is considered.

There are fourteen different target groups, which gives us a set of 14 stochastic constraints to be considered in total. This set of constraint is denoted as "soft" constraints, while all the other constraints are viewed as "hard" constraints. Since "hard" constraints must always be satisfied, they won't be considered in the optimization-simulation approach.

These target groups, and consequently the set of stochastic constraints, can be classified in four groups:

- Gender: the first two constraints define the minimum wanted rating achieved within male and female population,
- Age: there are six different age categories that are considered, and consequently the same number of constraints that define minimum wanted ratings within every age group,
- Geographic location: the model differentiates between three geographic locations where newspapers are sold, hence the minimum ratings that need to be achieved within the assigned geographic region are set,
- Education: three education levels are considered, and minimum ratings are assigned for them.

The set of 14 stochastic constraints become chance constraints with a predefined probability level of satisfaction in the following manner:

$$\left[\sum_{i}\sum_{k\in T} r_{ik}\sum_{i}\sum_{j\in P} x_{ij} \geq t_k\right] \geq p_i, i = 1,...m$$

Decision maker sets the p_i level for every constraint.

Decision maker owns a chain of supermarkets and therefore wants to target a specific group through advertising. His focus and target group are women that are between 40 and 49 years old, from the geographical region G1 and have a university degree. This means that second, sixth, ninth and fourteenth constraint need to have the highest p_i level. Decision maker is willing to accept less than 0,5 percent risk that these constraints won't be satisfied, which means that p_i levels for these four constraints need to be higher than 99,5%. For all other constraints decision maker is willing to accept a 5% risk, namely, p_i levels are equal or higher than 95%. This is presented in the Table 1.

Table 1: Probability levels for soft constraints

Constraint	Gender		Age						Geographic region			Education		
	1	2	3	4	5	6	7	8	9	10	11	12	13	14
p_i (%)	≥95	**>99.5**	≥95	≥95	≥95	**>99.5**	≥95	≥95	**>99.5**	≥95	≥95	≥95	≥95	**>99.5**

Decision maker divided the set of soft constraints by selecting one constraint from each of the four groups of constraints, by accepting a minimal risk for these constraints not to be satisfied. In return, the decision maker demands at least 15% in currency spent less than if the robust approach was to be used on this model. So the tradeoff is described by accepting certain levels of risk in return for at least 15% better value of criterion function.

Having this in mind, the results of computational testing of proposed scenarios will be presented, as well as the general guidelines used for scenario generation.

Table 2: Computational results

f(x)	23.397.780		23.575.284		23.774.668		23.986.632		24.261.686		29.737.023	

In the two tables above, Table 2 and Table 3, the computational results of our scenario testing are presented. Scenario 1 and robust scenario are two border cases, and scenarios are generated between these two cases. In the first column, there is an indication to what the new deterministic equivalent is set to, and the following column presents the probability of satisfying the chance constraints of the scenario using the simulation approach described earlier. Each scenario is run through 10.000 simulations and appropriate probabilities are calculated and presented in the table. Value of the criterion function is presented accordingly for every scenario. Shaded cells indicate that there were changes made to the scenario for assigned constraint, relative to the previous scenario, meaning every change in creating a new scenario is marked in this fashion. This shows the approach, or heuristic, used to obtain wanted probabilities.

Now, a few words of the heuristic used. Starting from the expected values as the border case, deterministic realizations of the stochastic parameters are slowly moving towards a robust scenario that provides the highest probability of satisfying the constraints. However, three constraints were already satisfied with the probability over 95%, so it is decided not to change these stochastic values of parameter r_{ik}. Other constraints were not satisfying so scenarios were created towards the robust case by reducing the expected value by 0,1 σ in each scenario, keeping an eye on the p_i levels.

The basic presumption was that there is a strong positive correlation between constraints within their respective groups. Namely, in the set of constraints annotating the age a positive correlation between them was hypothesized. In terms of generating scenarios, this means that by satisfying one constraint of the group, the p_i levels of all the other constraints in that group will also be increased. Of course, it is assumed that these correlations are stronger between constraints that denote similar ages, like the age of 30-39 and the 40-49 years, than when there is a large age difference, like 12-19 and older than 66 years.

For the set of constraints that denote geographical regions, the same presumption is applied, as well as for the education. The only difference is on the set of constraints denoting gender. It is also assumed that there is a positive correlation between male and female population, but on a much lower level than in the other three set of constraints. This is to be expected considering different interests in newspapers for male and female population.

What this hypothesis actually means when generating a new scenario is that it won't be necessary to create a scenario that is getting closer to a robust one and one can still expect a certain increase in probability levels for a constraint if we have already decreased the value of a stochastic parameter in a constraint that is within the group of interest. For example, let's look at the constraints six and seven in scenarios S6 through S11. Stochastic parameter r_{ik} for these two constraints was set to μ-0.5σ in the scenario S6. Probability levels are 98,08% and 91,85% respectively. Our goal is to achieve probability level greater than 99.5%, and equal or greater than 95%. Yet, the value of stochastic parameters was kept the same, μ-0.5σ, all the way to the last scenario S11, and a steady increase in probability levels through every scenario afterwards is observed. This confirms the hypothesis of positive correlation within groups of constraints. The same pattern is used for other constraints, so the wanted probabilities in the last scenario were achieved.

The other very important advantage of this heuristic is that by keeping scenarios as far away as possible from the robust scenario, a better value of the criterion function is been generated. By applying this heuristic, both of the prerequisites for a good scenario are achieved: high probability levels for constraint satisfaction, and a better value of criterion function. Even though these two goals may seem opposed to each other, meaning that higher probability levels of satisfying constraints translates into an unfavorable value of a criterion function, the model still managed to achieve them both by applying the proposed heuristics and an iterative optimization-simulation approach.

Figure 2 shows the graphical results of the computational testing of scenarios:

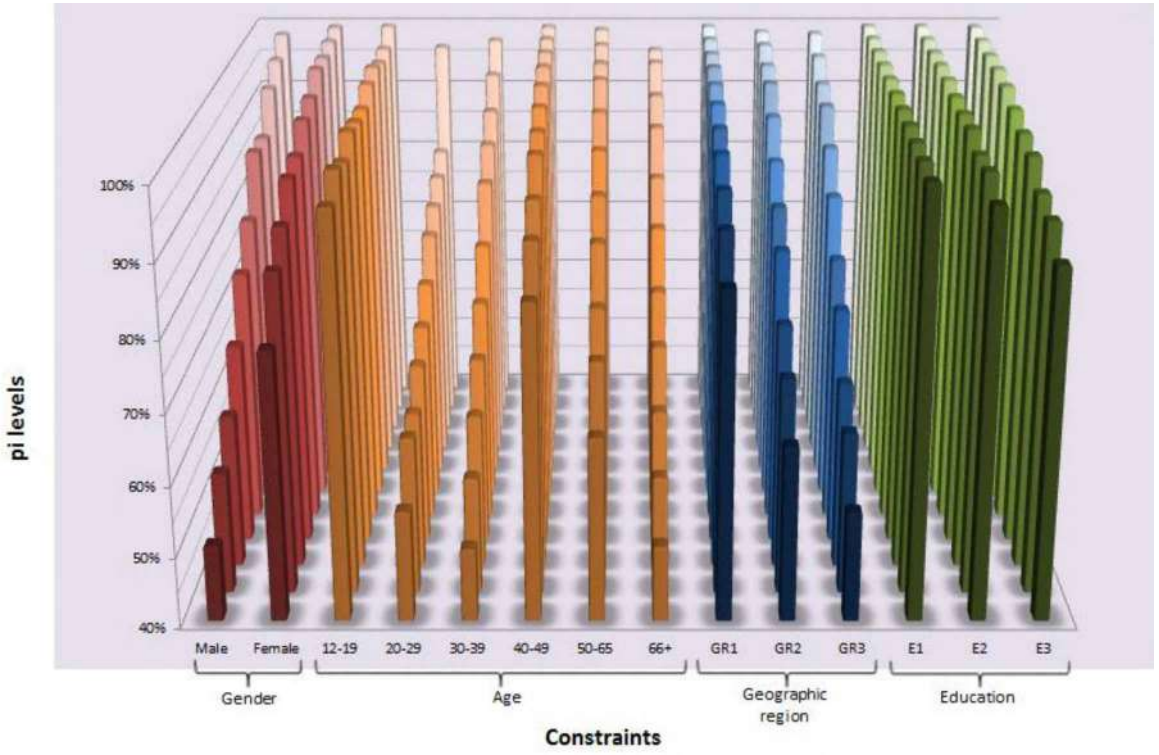

Figure 2: Graphical representation of computational results

Each group of constraints has its own color, and there are total of eleven scenarios presented here, all but the robust one. This chart shows how p_i levels increase with every new scenario.

6. CONCLUSION

In this paper, an original approach for tackling uncertainty in a model was put forward and general guidelines of how to use an optimization-simulation approach to stochastic linear programming in practice was given. Combining chance constraint approach and a robust approach to a problem with stochastic parameters is the foundation of the framework. In addition, using the power of simulation to check probabilities of chance constraints is the backbone of the approach. Advertisement placement model, which is by its nature a stochastic problem, is used to show how the optimization-simulation model works in practice. By using the proposed heuristics, one is able to generate valid scenarios to be optimized and checked through simulation. Understanding a specific problem is of essence when generating scenarios and applying the proposed framework. Incorporating the preferences of the decision maker is also an important part of the model.

Numerical and graphical results of the proposed approach on an advertisement placement model are also provided. The approach is intuitive and easy to understand and apply to real life problems.

RATIONALIZATION OF STORAGE COSTS BY APPLICATION OF MODIFIED SMED METHOD

Abstract: *In modern business, the flexibility of production, i.e. the possibility of production of a large number of various products, with minimal storage costs of the material, is one of key factors of the success. This is mostly important in automotive industry where the production is based on Just in Time production and every loss of capacity due to frequent and insufficiently fast changes of tools/forms can easily cause failure to fulfil the daily plan of production. This can caused very big effect, stopping of the production line of the customer. This paper reviews the modified SMED (Single Minutes of Exchange of Die) method by whose application the flexibility and competitiveness of some company can be significantly improved by reducing of the operating costs i.e. for the same spent time it's possible to change production program more time, give us possibility to reduce batch size and space needed to store the goods. This modified SMED method is different from others because for the process of data analyze is used statistical method, t-test, which caused big cost reduction for testing and time needed to performed it. Except that, in the paper is present the significant correlation between results of SMED and way of production planning, with the goal to reduce and stabilize the stock. Multiple benefits of using of SMED method is reflected in the fact that in addition to saving storage space, also getting the flexibility of the production system which enables faster response and adaptation to daily customer's requests.*

Keywords: *SMED method, stock reduction, automotive, flexibility, batch size*

1. INTRODUCTION

In circumstances of adapting to changing requirements of users, one of the problems in the production is appropriate preparation of the machines, and/or preparatory - final time. The duration of the preparation of the machine for the second operation is very frequently very long, which in small quantities in the series, and that is the case when we adapt to changing requirements of users, burdens the production unit by additional time and costs. In an effort to enable as greater adaptability as possible within the observed company, the significant attention is devoted to rationalization of activities within the preparatory - final complex of actions with the aim of their shortening.

The basic idea in realizing the shortening of preparatory - final time is in implementing of all necessary actions while the machine is running, so that the machine would stop only while performing of those activities which cannot be performed while the machine is in motion. Likewise, the duration of all activities on the machine while it is not in motion should be shortened by all available methods and rationalization techniques. Separation of these activities is a key and starting basis for all further efforts, because thus the research is expediently directed in the field of those activities that determine duration of preparatory - final activities.

Globalization of the market has created the need for the production in small batches, by which the increase in the number of machine setting and equipment is conditioned, as well as the reducing of production time of a batch. For these reasons, it is necessary that the replacement of production be faster so that the flexibility does not influence on the speed of the response to a request (Mcintosh et al, 2007).

Goubergen and Landeghem (Goubergen and Landeghem, 2002) have divided various reasons into three main groups:

1. Flexibility : Due to a large number of various products and reduction in their quantities, the company must be able to respond quickly to customer's demand. That is, if it is necessary to produce in small batches, it is of great importance to be able to perform the change of tools in the shortest possible time,
2. Lack of capacity: Every loss, especially in these conditions, even of one minute while changing the tool is a huge loss. Every reduction of time of tool change is directly reflected on the increase in capacity,

3. Reduction in costs: cost of production and storage is in direct conjunction with the machine performances,

According to Haron and Peterson (Harmon & Peterson, 1991) reduction in time necessary for setting is important for three reasons:

- Great expense during a complicated change of tools and setting of the process causes the increase in production series, by which the investing in stocks,
- Rapid and simple technique for tool change reduces the possibility of errors during the equipment setting,
- Reduction and simplification of setting increase the operating time of the machine.

Also, one of key factors for improvement of the process of production change, and it has not been mentioned in any of the above-mentioned analyses, is the production plan. Its importance is great because of adequate and timely preparation of the operators that work on the change, and so that the process be adequately prepared and all external operations done in accordance with the standard. One of the key external operations, for which the exact time of tool change is very important, is pre-heating of tools for the sake of reducing of the time of waiting for warm-up while the tool is in the machine.

Frequent changes of product range on request of the market cause significant percentage of preparatory-final time in the machine running and cannot be eliminated but it only can be minimized by application of appropriate methods.

Since SMED method that Shigeo Shingo has improved is one of the basic, and the others are based on it, in the following, we will deal with its analysis and the results of its application, i.e. its influence on the factors which Harmon and Peterson have singled out, primarily on the inventory levels.

Shingo defends the idea that SMED method is composed of various techniques by which the setting is possibly reduced to less than 10 minutes, or that even the number of necessary minutes for change be reduced to a single digit (Shingo, 1989).

2. THE PREPARATION OF THE EXPERIMENT

The process of tool change is carried out in five steps which are conditioned by one another:

- Stopping of the machine
- Removing of tool
- Inserting of new tool
- Tool change
- Starting of the machine

and duration of tool change counts from the last good part of the last batch to the first good part of the next batch (figure 1).

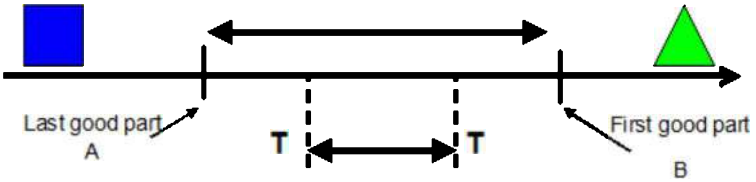

Figure 1: Diagram of the time of tool change (Changeover of Production and Lot sizing, Toll GPE 0097, 11.2010, Mecaplast, Monaco)

The focus in this paper will be on the analysis of the activities that is necessary to be made during one SMED, and their redistribution with the aim that the number of internal operations be as small as possible.
For this purpose it is not necessary to analyse every machine individually, because it has been established by the analysis that the schedule of steps that should be performed on the machines is the same, only the duration of performance of certain steps differs, which can statistically be proved. (Ana Sofia Alves et al, 2009).

For the purpose of this proving we will use t-test, known as "Student's" t-test. There are 3 types of t-test and these are:

- One sample t-test that is commonly used for the comparison of the mean value of one group of data with target mean value,
- Two sample t-test when the mean value of one group of data should be compared with the mean value of the other,
- Paired t-test when we want to compare the values before and after a particular treatment.

Before the application of t-test it is necessary to determine the normality of data of the population of samples with which it is handled. If the distribution of population values of samples is normal, either F-test (if σ levels are compared) or 2 samples t-test (if the mean population values are compared) are used for the comparison. If the distribution of data does not give a normal distribution, the test that is used for the comparison is Levene's test.

The results of data normality test during the tool change on the machines of small tonnage (200t - 550t), and for the data for the machines of large tonnage (550t - 1300t) are represented in the following diagrams (figure 4). As the distribution is normal in both cases, P>0.05, one could continue with the application of some of t-tests which have aimed at proving that two groups of results of 30 samples per each for the machine of 200t and for the machine of 500t, are statistically the same.

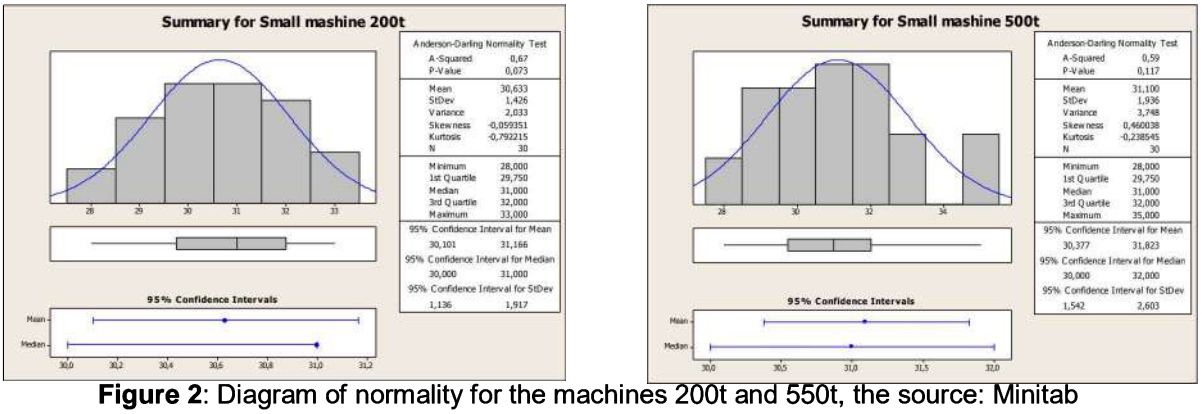

Figure 2: Diagram of normality for the machines 200t and 550t, the source: Minitab

When it comes to the two data populations, and as the mean value of those populations is compared, 2-t test has been chosen as relevant for proving the statistical equality of the two populations.

2 sample t-test consists of the confirmation of null hypothesis (equation 1) and alternative hypothesis (equation 2):

$$H_0 = \mu_1 - \mu_2 = 0 \tag{1}$$

$$\mathrm{H}_1 = \mu_1 - \mu_2 \neq 0 \tag{2}$$

By the confirmation of null hypothesis, if the value is P > α=0.05, where α represents the coefficient of risk (significance level) and its value is usually 5% or 0.05, it is confirmed that the mean values of populations are equal, i.e. that there is no difference between the populations. Otherwise, the null hypothesis is rejected and the alternative hypothesis is accepted. The value P, as well as the other values can be seen in the statement of Minitab, software for statistical data processing (figure 3).

Two-Sample T-Test and CI: Small mashine 200t; Small mashine 500t

```
Two-sample T for Small mashine 200t vs Small mashine 500t

                     N   Mean  StDev  SE Mean
Small mashine 200t  30  30,63   1,43     0,26
Small mashine 500t  30  31,10   1,94     0,35

Difference = mu (Small mashine 200t) - mu (Small mashine 500t)
Estimate for difference:  -0,467
95% CI for difference:  (-1,347; 0,414)
T-Test of difference = 0 (vs not =): T-Value = -1,06  P-Value = 0,293  DF = 53
```

Figure 3: The statement of the results of 2 Sample t-Tests, Minitab

where N represents the number of samples per population, Mean - the mean value for the population, StDev-standard deviation, DF - number of degrees of freedom.
As the value P = 0.293> of the given α=0.05, it means that the null hypothesis is accepted, by which it is confirmed that in the further review, the conclusions that have been drawn for one machine refer to all machines from this group. The identical conclusion has been drawn also for the group of machines over 500t, by which the range of research and number of experiments have significantly reduced, i.e. the number of observations has reduced from 11 to only 2 representative samples from 2 populations of machines. The results of this test have significantly influenced on the reduction in the costs of further analysis.

3. THE PRACTICAL APPLICATION SMED METHOD AND ITS EFFECTS

The method of observation, collection and processing of data in the example of group of machines from 200t to 500t will be shown in the following, with the proviso that at the end the results from both groups of machines and common conclusions will be shown.

Observation, collection, analysis and control have been done on the basis of Shingo's division and distribution of operations (figure 4).

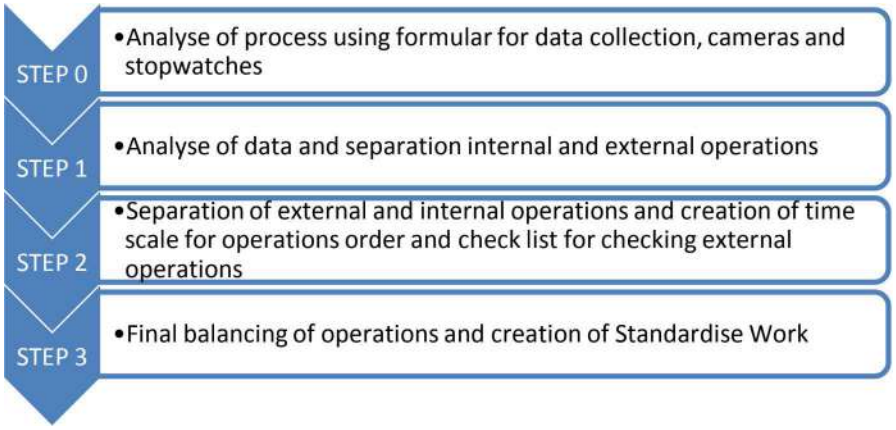

Figure 4: Diagram review of Shingo's method

Step 0 (Internal and External setup): In this step we cannot distinguish what the internal operations are and what the external operations are. It is necessary here to perform the analysis of existing production process with the presence of the operators that are normally engaged in tool change and process setting. It is necessary to analyse the time of every single activity, and by recommendation of Shingo, during this analysis one should use stopwatch, as well as make a movie during the production change.

Observation has been done by synchronous monitoring of two operators, wherein their every activity, its duration, the manner of operator's movement and distance that he has going while performing every single activity have been recorded in the form. As a result, at the end of this form one can see the total duration of all activities, as well as the total distance that each of the operators have gone.

Step 1 (Separation of internal and external operations): In this step it is necessary to separate internal and external operations by the analysis. According to Shingo, this step is extremely important in the implementation of SMED. He claims that, in this step, the total time of setting can be reduced 30% to 50%.

By the analysis of comparative time diagram of operations (figure 5) is the most important in this step, where the duration of every operation has been presented by the line whose length indicates the duration of the operation. Here, in addition to the duration, it can also be seen which activities are mutually ovelapping, or where exists certain waiting at interdependent operations. Based on this and the next diagram (figure 10) it can also be concluded which operations can be performed before stopping of the machine.

Step 2 (Transforming of internal into external operations): in this step it is the most important that the separated internal operations transform into external, i.e. to perform them while the machine still operates.
This involves the activities such as: preparation, check and preheating of tool before the starting of the change itself, i.e. stopping of the machine. Also, check and change of material can be done as external operation. The important precondition for correct performing of the operation of tool preheating as an external operation is the existence of precise plan of production. With precise plan, i.e. precisely defined time of completion of the previous batch, the operator that performs the preparation of tool can start the

preheating of tool on time so that it can be completed by the time when the tool has to be placed in the machine. None of the previous authors has taken this detail into their examination as an important factor in the duration of change. In the case that the tool has not been set on the counter for preheating on time, it happens that the tool, which is insufficiently heated, is inserted into the machine, whereby the time of its heating for the start of production in the machine itself is extended, which directly increases the time of change.

In the checklist of external operations there are the following items that are necessary to be checked before the stopping of the machine: raw material – whether it is appropriate, on the marked place and prepared for production according to the standard, the presence and state of hand tool, presence and state of peripheral equipment for production, the state of connectors and the state of preheating of tool that is prepared for change, documentation on the workplace etc.
By the examination of comparative diagram (figure 6), it can be concluded that the time required for performing the work of the first and second operator is not balanced, and that one should check the possibility of switching of some of the operations, which is performed one of the operators, to the other operator and vice versa, and in order to equate their time and to reduce the total time.

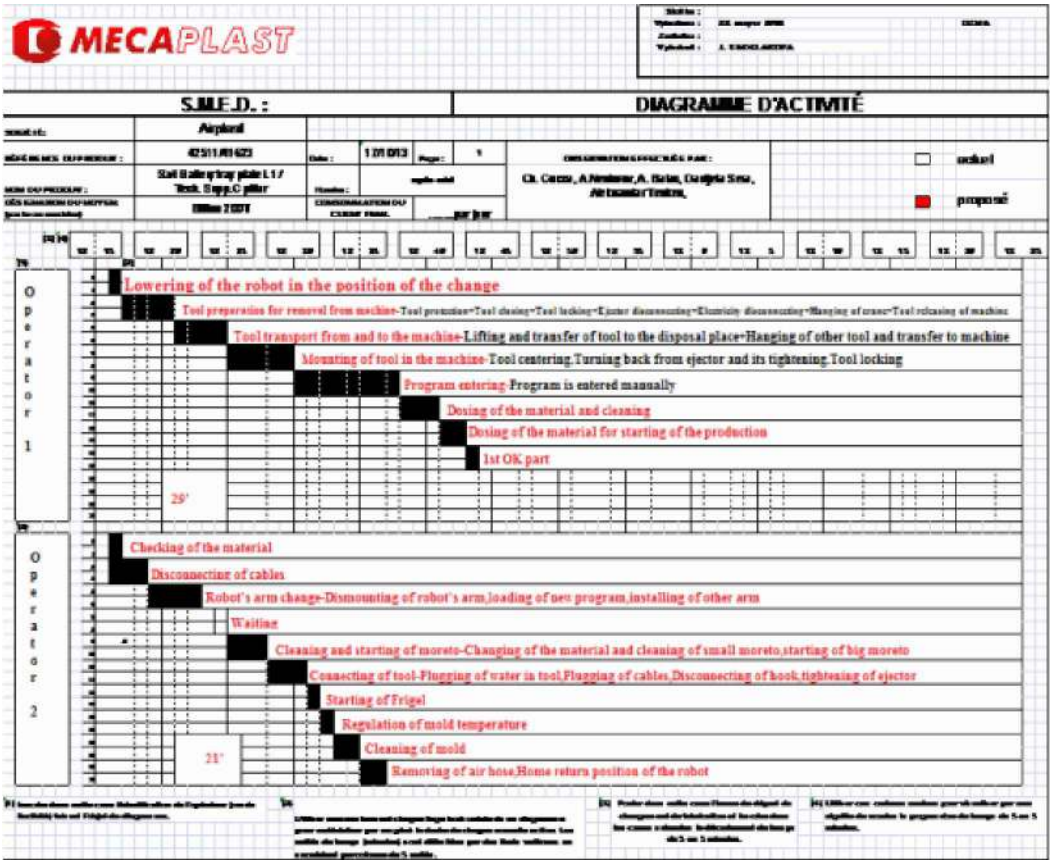

Figure 5: The diagram man - machine, the comparative display of the schedule and duration of operations (Changeover of Production and Lot sizing, Toll GPE 0097, 11.2010, Mecaplast, Monaco

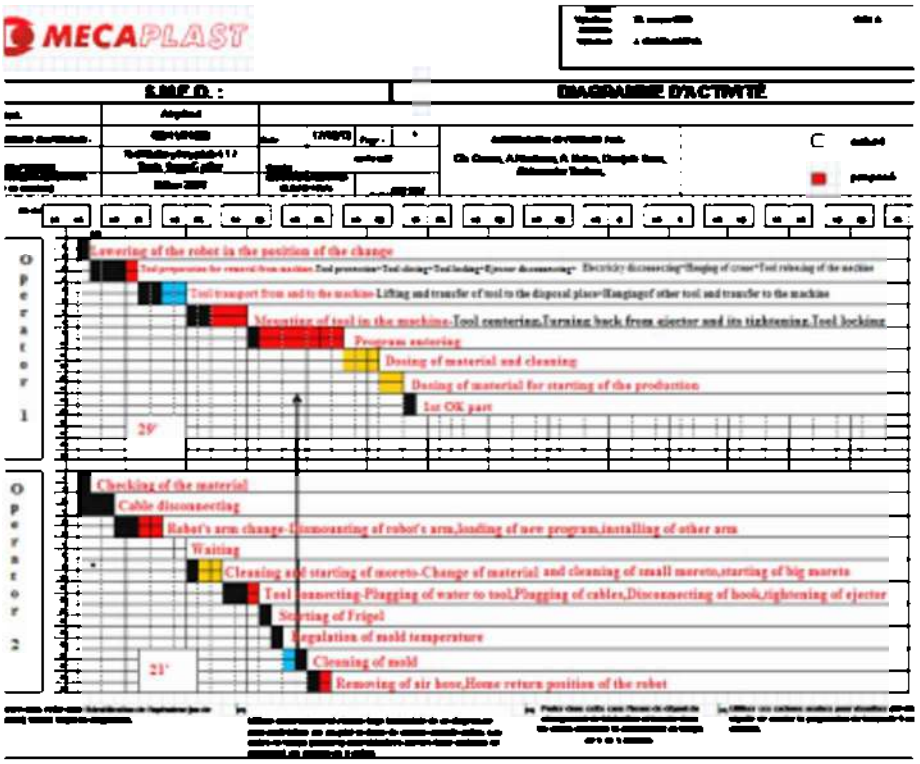

Figure 6: The diagram man - machine, separate external operations and the operations that can be eliminated (Changeover of Production and Lot sizing, Toll GPE 0097, 11.2010, Mecaplast, Monaco

The operations highlighted in yellow (figure 6) are the operations that refer to the material change and cleaning of the dryer of material, and they have been identified as the operations before the machine stops, i.e. they can become the external operations, and they have been placed in the checklist (figure 7). This move would save 5 minutes of the time of the operator 1., and 2 minutes of the operator 2.

As it can be seen in diagram (figure 7), by the application of the first two steps (0,1,2) of Shingo's methodology, the time of the tool change at the operator 1 has been reduced for 62%, i.e. from initial 29 minutes the time of change has reduced to 11 minutes, while at the operator 2 that percentage is 38% (from 21 minutes we have reduced to 13 minutes).

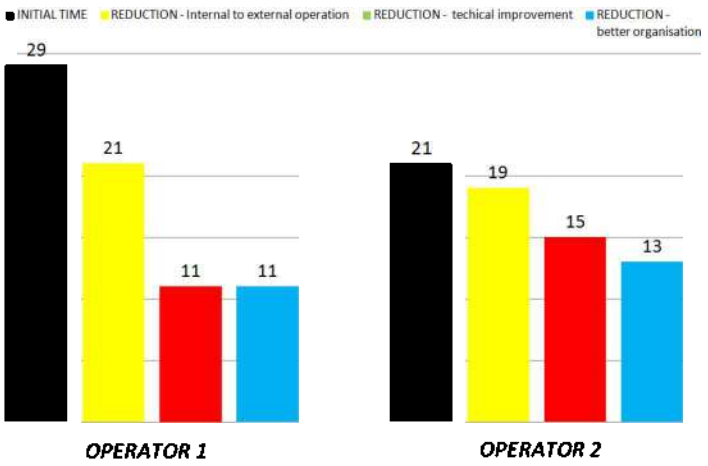

Figure 7: The comparative display of the improvement of SMED by the application of Shingo methodology

Step 3 (final balancing of operations) - By the application of this third step, the final balancing of operations are performed, as well as final reducing and eliminating of unnecessary activities. As it is shown, our 2 operators do not have balanced time of performing of their operations, i.e. the operator 1 finishes his work for 2 minutes earlier than the operator 2. As those 2 minutes, during which the operator 1 does not perform any activity, influence on the extension of total time of tool change, the assignment is to find appropriate activity that lasts 1 minute which performs the operator 2, and shift it to the list of activities of the first operator.

Cleaning of mold, one of last operations of the second operator, has been identified as a potential activity for assigning to the first operator.

After final balancing, both operators have the same final time of 11 minutes, and by which the total time of change has been reduced for yet additional 7,7 %.

Final display of the schedule of the operations is shown in diagram of operations (figure 8).

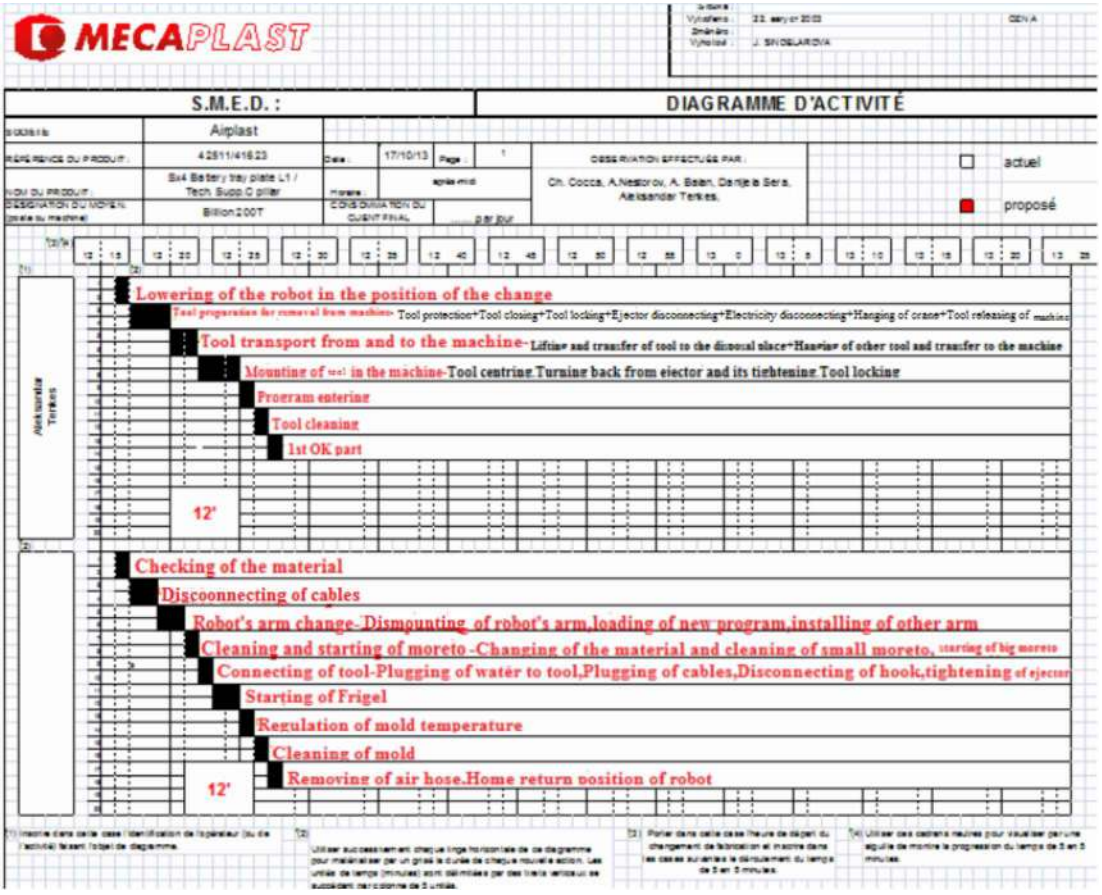

Figure 8: Diagram man-machine, the final display of the schedule of the operations (Changeover of Production and Lot sizing, Toll GPE 0097, 11.2010, Mecaplast, Monaco

The final result of the application of SMED method to both groups of machines is presented in table (table 2) as follows.

Table 1: Comparative display of reducing of tool change by *the application of SMED method*

Group	Initial time average	External set-up operation	Improvement %	Techical improvement	Improvement %	Better organisation	Improvement %	Final balance of operations	Improvement %
Small mashines (200t - 550t)	30	21	***30***	16	***47***	13	***57***	12	*60*
Big mashines (550t - 1300t)	45	35	***22***	32	***29***	30	***33***	27	*40*

As it can be seen from the presented table, by the application of SMED method to these two groups of machines, total time that is necessary for tool replacement has reduced for 60% for the group of small machines, and/or 40% for the group of the machines over 550t.

Reducing of total time of change has influenced on:

- reducing of storage costs,
- increasing of production flexibility,
- increasing of the capacity of production equipment.

Quantity of goods that is in stock depends on several factors, and one of the most important is the size of the production batch. As the size of the production batch is directly related to the time of tool change, hence the indirect connection of the time of tool change to the quantity of stored goods.

For calculation of the size of batch, as well as for the quantity of stored product (semi-product / final product) KANBAN calculation has been used, and one of key factors in that calculation is the time of tool change, as well as the number of replacements during the day.

During the calculation of the batch size, the influential factors that are taken into consideration are:
Available time of the machine for production during the day, cyclical time of action, the number of tool changes which it is possible to be performed on the machine on which the product that is the subject of the analysis is produced, the duration of tool change.
The batch size (LE) is one of the factors in the calculation of the time required for renewal of one card - lead time (TA), minimum stock that can endure the fluctuation - pool stock (SM), the values of Kanban card= 36 parts (Vk, 1Vk = 1 transport trolley = 36 parts), the request of the buyer per day (CMJ), which is presented by the equation (equation 3):

$$N_k = \frac{((\mathrm{TA+SM})\mathrm{xCMJ})+\mathrm{LE}}{V_k} \tag{3}$$

In the example of one referential number, the number of required Kanban cards is calculated in the following way:

TA = 2 h, SM = 8 h, CMJ = 600 pieces/day = 25 pieces/h, LE = 450 pieces, Vk = 36 pieces

$$N_k = \frac{\left(((2\mathrm{h}+8\mathrm{h})\mathrm{x}25\frac{\mathrm{kom}}{\mathrm{h}}\right)+450}{36\ kom} = 20\ cards \tag{4}$$

Using of the results of the equation 3, i.e. by multiplying the maximum number of Kanban cards required for every single product with the surface required for placing of one kanban unit, one obtains required size of space for placing of every single reference. Of course, in this one should also take care of the information on the method of packing of kanban units in the warehouse (possibility of packing in more), which can significantly influence on the final result.

Speeding up the process of tool change influences on reducing of production batch which also entails reducing of required number of Kanban units in every moment. Table (table 2) shows the relation of old and new value of stock by groups, preoccupied space as well as released capacity for both groups of machines after the application of SMED method in the production plant of the company "Mecaplast".

Table 2: Display of benefit of SMED method application

Group	Old stock value €	Old stock occupation m2	New stock value €	New stock occupation m2	Free capacity h/day
Small mashines (200t - 550t)	*5760*	*85,4*	*2220*	*26,6*	*2,7*
Big mashines (550t - 1300t)	*98880*	*324*	*47064*	*104*	*4,8*

Total freed capital by this action is 55,300 € by reducing of stored quantity, 280 m2 of space that has been used for storage, as well as 2,7h and/or 4,8h of released capacity in both groups of machines per day.

As the part of the production plant is used for the storage of semi-products, it can be concluded that by optimization, i.e. by reducing of preparatory time on all machines, the space that can be used for placing of new production units would be significantly unloaded, and without additional expansion of the existing facility, i.e. additional investments.

4. CONCLUSION

On a practical example in the paper it is shown how the application of Shingo's SMED method can influence very efficiently on very important factors, identified by many authors from the beginning, with a large impact on operating of one system. Some of those factors are the costs of storage, the capacity of equipment, flexibility of production etc.

The importance of this paper also represents the display of successful combining of SMED method with other methods, primarily with statistical analysis, and in order to conduct the experiment as efficiently and economically as possible. As it is shown in the paper, after the statistical confirmation that the group of 11 machines for vertical injection is possible to be divided into only 2 groups, the experiment has been conducted on 2 representative samples, one representative from each of the two populations. The conclusions that have been obtained based on the analysis of the results of representatives are implicated on the entire group, whereby the total number of experiments (11) has been reduced to only 2, which has significantly reduced the duration and cost of the complete analysis.

The difference of application of SMED method shown in this paper and other described SMED methods is that the production plan has been also considered here as an influential factor on the duration of change. It has been explained how imprecise and incompletely defined production plan can influence on the total extension of the time of tool change. In support of this, the way of calculation of Kanban system that has been used in the combination with SMED method is presented so that required needs for quantities, capacities and space be determined more rationally. Also, Kanban gives us the possibility of work without classical production plan with constant batch size, whereby the determination of the end of the production batch is ensured, and thereby of the beginning of the preparation of tool change. The result of that is more efficient SMED.

By the analysis of the results and by the implementation of SMED standard on all machines, the saving has been achieved of 55,000 € in freed goods and 200 m2 of storage space.
As the freed space is within production space, it could be used for placing of 4 new machines, whereby the potential investment in the expansion of the facility in the value of 200,000 € is avoided. This proves that the benefit of the application of SMED method is not insignificant.

The importance of this research is reflected in the fact that all tools that have been shown belong to LEAN philosophy that is increasingly current by the change in business climate in our country, primarily after the arrival of a large number of foreign companies. Owners and managers increasingly look for the concrete solutions and concrete and visible results.

KEY PERFORMANCE INDICATORS AND PRICING STRATEGIES PLANNING IN RETAIL INDUSTRY

Milenko Radonić*[1], Vedrana Đorđević[1], Jasmina Omerbegović-Bijelović[1]
[1]University of Belgrade, Faculty of Organizational Sciences
*Corresponding author, e-mail: milenko.radonic@yahoo.com

Abstract: *Choosing and using key performance indicators is necessary for each part of the economy. Retail market is one of the most dynamic fields in economy, and choosing and analyzing the right indicators could be crucial for decision making. This paper should provide guidelines for choosing adequate key performance indicators in retail industry, but also give a brief overview on the different aspects of interpreting those indicators. Modern retail is mostly focused on two main indicators: Turnover and Gross margin, which are directly affecting profitability of retailers. Mentioned indicators could be analyzed more detailed which is of special meaning for lower levels of management. Turnover and Gross margin are indicators that are the basics for many other indicators – Market share, EBIT/EBITDA/EBITDAR, for vertical and horizontal financial analysis, etc. Based on that fact, there are many factors which are dictating the potential turnover and gross margin. One of the main factors are prices and prices strategies. In retail, there are two main pricing strategies: EDLP (Every Day Low Prices) and Hi-Lo (High-Low). Since turnover could be calculated as quantity multiplied with prices, pricing strategies are in position to define planned level of turnover and gross margin. Managing prices successfully gives a good platform for managing key indicators and decision making.*

Keywords*: retail, turnover, gross margin, key performance indicators, pricing strategies planning*

1. INTRODUCTION

The idea of this paper is to present which indicators are relevant and how to choose them, focusing on the retail industry as one of the biggest industries. Also the idea is to make a differentiation between performance indicators and key performance indicators. Key performance indicators (KPIs) could be defined as points on which companies should pay attention the most, and based on which, companies can make decisions. There is a slight difference between KPI and PI (performance indicator). Key indicators are those indicators, which could help management to make strong decisions that will directly affect (positively) on the business results. On the other hand, performance indicators can also affect business results, but without direct impact on business results (for example: tracking employees satisfaction cannot give exact information, did it increase or decrease EBIT[1]/EBITDA[2], etc.). Based on the different levels of top management, key indicators are mostly tracked, analyzed and controlled by every level of management.

The purpose of the paper is to perceive pricing strategies as one of the important parts of all retail strategies, considering other parts of business and to show their impact on some of the key performance indicators. There are several pricing strategies, but two of them are mostly used. More about pricing strategies can be seen in the point 3 of this paper.

The idea of this paper will be presented, considering theoretical frame of key performance indicators, then the development of the retail industry and the use of key performance industry in retail. Afterword, there will be more about pricing strategies and their effect on key indicators. Generally, this paper should present the link between key indicators and pricing strategies and the way they are used to concept.

2. KEY PEROFORMANCE INDICATORS AND THEIR USE IN MODERN BUSINESS

Key performance indicators (KPIs) could be defined as points on which companies should pay attention the most, and based on which, companies can make decisions. There is a slight difference between KPI and PI (performance indicator). Key indicators are those indicators, which could help management to make strong decisions that will directly affect (positively) on the business results. On the other hand, performance indicators can also affect business results, but without direct impact on business results (for example: tracking employees satisfaction cannot give exact information, did it increase or decrease business results, etc.).

[1] Earnings Before Interest and Taxes
[2] Earnings Before Interest, Taxes, Depresiation and Amortization

The starting point for choosing the right performance indicators is to make a list of indicators which are of interest for the board. Those indicators are mostly considered as key ones. Financial performance indicators are mostly used by the top management to manage the business. On the other hand, non-financial indicators are becoming important as much as financial indicators. A challenge is whether the KPIs currently presented to the board are those that allow them to assess progress against stated strategies, and when reported externally, allow readers to make a similar assessment.

Appropriate selection of indicators that will be used for measuring is of a greatest importance. Process organization of business is necessary to be constituted in order to realize such effective and efficient system or performance measuring via KPI. Process organization also implies customer orientation and necessary flexibility in nowadays condition of global competition (Velimirovic, 2010).

New business conditions where information is the most important resource impose new approaches in measuring performances of organizations, related to traditional performance measurement system which evolved just financial and accounting indicators. One of the newer approaches refer on measuring performances of organizations via KPI. KPI are financial and non- financial measures that organizations use to reveal how successful they were in accomplishing long lasting goals. In order to constitute effective system of performance measurement it is very important to have defined and standardized all processes within the organization (Velimirović D, 2010).

The overriding need is for the KPIs to be relevant to that particular company. Management should explain their choice in the context of the chosen strategies and objectives and provide sufficient detail on measurement methods to allow readers to make comparisons to other companies' choices where they want to (Price Water House Coopers, 2014, pp. 8-11).

However, it is the management's duty to suggest and make a portfolio of indicators which will be measured, tracked, analyzed and which will give a good basis for decision making. Considering business conditions, Kaplan and Norton recommended not to use more than 20 key performance indicators. Hope and Fraser suggested even less than 10 KPIs. Even though, the focus in this paper is on key performance indicators, performance indicators (PIs) and key result indicators (KRIs) are important as well. The 10/80/10 rule could be considered as a good proportion and segmentation of the number of tracked KPI/PI/KRIs[3]. It suggests using about 10 KRIs, up to 80 PIs, and 10 KPIs in an organization. For many organizations 80 PIs will at first appear totally inadequate.

Table 1: 10/80/10 Rule
Source: Permanter D, (2007) *Key performance indicators - Developing, Implementing and Using Winning KPIs,* p. 9

TYPE OF INDICATORS	GUIDANCE
Key result indicators (10)	Give information how have organization done in perspective
Performance indicators (80)	Give information and guidance what to do
Key performance indicators (80)	Give information what to do to increase performance dramatically

Many organizations will probably find tracking only 10 KPIs restrictive and may wish to increase the number of KPIs. That could be acceptable and rational if organization is made up from businesses from different sectors, in which case the 10/80/10 rule can apply to each diverse business. In that point, it is normal to increase KPI rollout (Parmanter D, 2007, pp. 8 - 10).

Retail is one of the most important parts of the global economy. Modification of retail from traditional retail to modern retail (online shopping/shopping with entertainment, etc.) has certainly changed KPIs that are tracked (from simple tracking of turnover, retail is now tracking some more advanced KPIs which will be considered in this paper). According to that fact, it is important to perceive the development of retail industry as well.

3. DEVELOPMENT OF THE RETAIL INDUSTRY AND INNOVATION AS THE INCENTIVE FOR TURNOVER

The retail industry has undergone drastic changes in the 80s of the last century. "Modern trade "and the development of large retail chains which could compete with their low-cost products have made a new standard of retailing. It all started with the sale of goods at predetermined locations where buyers would buy the goods

[3] KRIs (Key Results Indicators) mostly cover a longer period of time than KPIs. They are reviewed on monthly/quarterly cycles (not on a daily/weekly basis as KPIs). Separating KRIs from other measures has a profound impact on reporting, resulting in a separation of performance measures into those impacting governance and those impacting management.

they want at a given time and in a given location. Today, retail centers, beside grocery stores, include many specialized sales facilities - bookstores, boutiques and the others (which could be presented as shop-in-shop[4]).

During the 1980s and 1990s, retail industry started changing to modern-retail, under the influence of new technologies. Mass usage of bar codes and development of the internet has reconstructed the traditional ways of retail. Thus, the primary focus during the 80s and 90s was on inventory management, tracking billing and payment methods. Nowadays, CRM is even more changing the retail industry in the terms of specialized offers and connecting the customers with retailers (Dunković D, 2010).

During the 20th century, loyalty programs created a new sphere of retailing – making special offers and analyzing the needs of a customer in order to keep the existing customers, but also to attract the new ones and increase total turnover. Retailers who are leaders in innovation are moving faster in the terms of earning more, attracting more customers and having higher rates of growth. In the table 1, there is a data of top grocery retailers from 2013th year, according to the net sales.

Walmart is the world's biggest retail chain, considering net sales of 467 billion $, earned in 28 countries worldwide. Such as in every other industry, leading retail chains are dictating the tempo and trend of retail. In the previous past years, there is a trend of quick buying, in the lack of time.

However, online retail is getting more popular, and this kind of retail gives a lot to both – customer and a retailer. To a customer it gives more time to spend free, with the delivery on the wanted address, and to a retailer it gives better chances to operate more successfully with supplies.

Table 2: World greatest grocery retail chains
Source: Delloite, Report 2015: *Global Power of Retailing*, pp. 11-16

Rang	Name	Net sales in mil $ (2013.)	No. of countries	Country of orgin	2008-2013 average rate of growth
1	Walmart Stores Ltd.	476.294	28	America	3,30%
3	Carrefour S.A.	98.688	9	France	7,70%
5	Tesco PLC	98.631	18	Great Britain	2,90%

71	S Group	13,233	5	Finland	6,20%
73	Whole Food Market Inc.	12.917	3	America	10,20%
78	China Resources Enterprise, Limited	12,258	5	China (Hong Kong)	22,40%
222	Agrokor d.d.	4,011	3	Croatia	/
226	Axfood AB	3,989	1	Sweden	2,40%
234	Heiwado Co, Ltd.	3,863	2	Japan	-0,40%
241	SMU S.A.	3,823	2	Chile	29,80%
250	Overwaitea Food Group	3,700	1	Canada	6,50%

As the retail industry is considered one of the most dynamic and fastest growing industries, innovation are essential for the survival and development of the market. Innovation in this industry does not necessarily refer

[4] Shop in shop stores are stores specialized for selling a specific group of goods within bigger shopping markets. For example, in Roda Megamarkets, there are specialized shop-in-shop objects for selling equipment of Basketball Assosiation of Serbia.

only to the technology, a new billing system, the system of price reductions, but can also refer to innovations in marketing campaigns, which is the most common example of innovation in this industry.

So, speaking of innovation, it is important in the terms of overall growth and growth of the turnover of a retailer. Generally, there are two main types of innovation in retail: operational and strategic innovation. Operational innovation is related to operational improvements, while strategic innovation is related to radical changes within the retail network. The purpose of innovation in the retail network is approximation of consumer needs, with critical requirements in terms of quality and price. From the standpoint of the company, the time of implementing some innovation is a key factor, due the dynamic of the retail market.

4. KEY PERFORMANCE INDICATORS IN RETAIL INDUSTRY

There are several indicators, which could be considered as key indicators in retail. One of the most basic key performance indicators is total turnover. Turnover in retail could be defined as the quantity of goods sold to customers, or as a total value of those goods. So, it could be presented as both, quantity and value.

Turnover is an input for many other indicators, such as:

- Market share,
- Margins of cost,
- Result (EBIT/EBITDA/EBITDAR),
- Turnover per (m^2, employee),
- etc.

Turnover as itself is the basics for calculating other indicators. Every position in income statement start with total turnover. Table 2 (below) shows the structure of P&L statement (*Income statement*), with total turnover as starting position.

Table 3: Structure of income statement in retail with total turnover as the starting position

TOTAL TURNOVER
-
VALUE ADDED TAX
SALES REVENUES – DISCOUNTS = NET SALES
-

FINANCIAL COSTS
EBIT (EARNINGS BEFORE INTEREST AND TAX)
EBITDAR (EARNINGS BEFORE INTEREST, TAX, AMORTIZATION, DEPRECIATION AND RENT)

Both, turnover and gross margin are contributing to the profitability of a company. However, turnover with low margin rates is not enough for a sustainable profitability. On the picture bellow (Figure 2), it is explained how turnover and gross margin are connected.

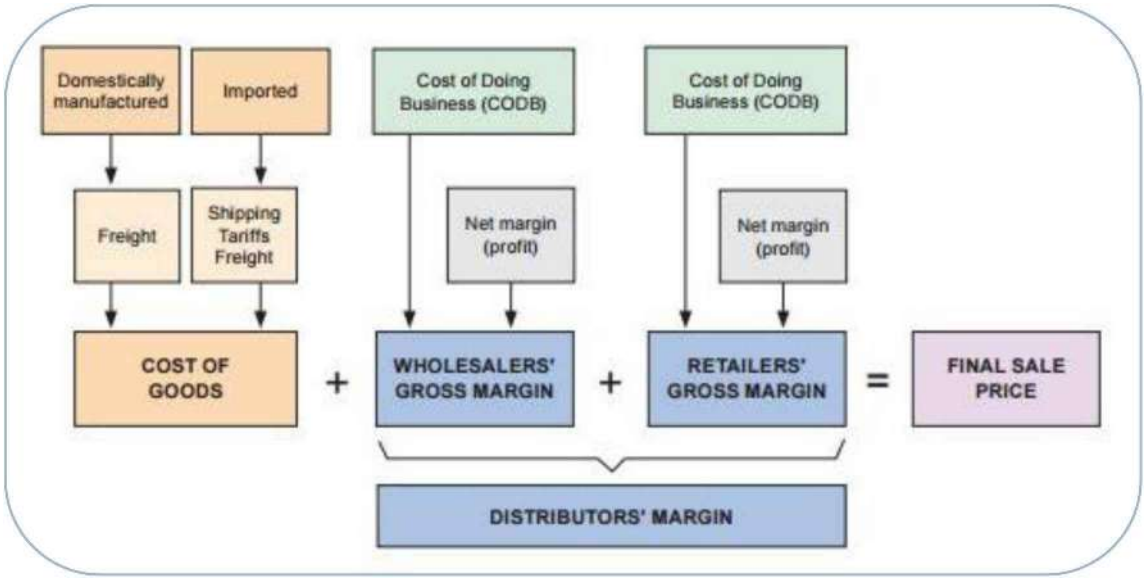

Figure 1: Price calculation structure
Source: D'Arcy P, Norman D, Shan S, *Costs and Margin in the Retail Chain* (2012), p. 15

Price sales is calculated as a cost of goods sold, plus net margin and cost of doing business (which is not necessarily included into final sale price). On the picture above, gross margin form wholesalers is also included, since this model includes wholesaler as one part of the supply chain.

Cost of goods sold can also be reviewed and analyzed as KPI. **The Cost of Goods Sold KPI** measures the actual profit margin on products and services by analyzing how costs such as labor or shipping affect your profit margin. This KPI is instrumental in determining the markup percentage for products and can be a key component in a pricing war with your competition. It's important to remember that even if product is flying off the shelves, you still need to make profit on all that product (Klipfolio, 2016).

Price of the goods is directly linked with the turnover of a retailer, so it is of great interest that a company has a competitive prices. Retailers seek for lowest possible costs of goods, and for the highest possible margins. In that case, the price can be highly competitive in comparison to other retailers.

Seeing the income statement, there is a notion that every position which is presented as a business result (EBIT/EBITDA/EBITDAR) is directly linked with total turnover. In theory, sales is mostly considered as starting position in income statement, but, sales comes from the deference between turnover and VAT (Value Added Tax[5]).

As mentioned before, beside total turnover, turnover could be analyzed as **turnover per employee** (which shows the efficiency of workers) and **turnover per m^2 of shopping space** (which shows the efficiency of used space and it is mostly compared to the cost of rent if that space is not the property of the company).

Total turnover per m^2 (or as it is also called – *Sales per Square Foot*) could be calculated as total net sales divided by net floor space. Net floor space includes only the shopping space (without warehouse and offices if they are integrated within shopping space).

In Table 3, there is a scenario analysis of decision making based on average grocery stores of two biggest retail chains in Serbia: Mercator-S and Delhaize Serbia (considering indicators for three month period including different banners[6]).

On the other hand, turnover per employee is calculated as a quotient between total net sales and FTE (*Full Time Employees*) for a specific grocery store. Top retailers in Serbia, such as Mercator-S and Delhaize Serbia, have the share of rent costs in total turnover 4-5%, which is considered as normal share on this market. For bigger market shops, this percentage could go a little bit higher.

[5] In the Republic of Serbia, VAT has two tax rates: 20% and 10%.
[6] Banners in modern retail include different brands of grocery stores. For example, Mercator-S consists of two banners – Idea and Roda, and both of them include different formats (Small Idea stores, Super Idea, Hypermarkets, etc.). Idea stands for neighbor stores, while Roda has a perception of a family stores, so the banners are percept differently among customers.

Table 4: Turnover per m^2 / Rent costs per m^2

Name of the shop	m^2	Total turnover in RSD	Turnover per m^2 in RSD	Rent costs in RSD per m^2	% Rent costs per m^2	Opinion
Retail shop 1	592	**30.204.000**	**51.020**	**8.300**	**16.26%**	Retail shop 1 is in comparison to other two shops the worst. Margin of renting costs is 16.26% which is above the average % of rent. This shop is ineffective, considering turnover and rent per m^2.
Retail shop 2	1401	**132.308.000**	**94.438**	**4.583**	**4.85%**	Retail shop 2 is the best in balance between renting costs and turnover with 4.85% of share in turnover per m^2. The space of 1401 m^2 is efficiently used.
Retail shop 3	8924	**802.270.000**	**89.870**	**5.350**	**5.95%**	Retail shop 3 has the biggest quadrature, but still it has a relative good balance between rent cost and turnover per m^2.

According to analysis in Table 4, retail shop no. 2 is the most efficient in doing business, while retail shop no. 1 is the worst.

Table 5: Turnover per employee

Name of the shop	No. of employees	Total turnover in RSD	Turnover per employee	Average salary in RSD	% Earning costs in turnover	Opinion
Retail shop 1	14	**30.204.000**	**2.157.428**	**269.333**	**12.48%**	Normal share of salary costs in total turnover are moving in the scale 3-6%. According to that fact, retail shop 1 is not so efficient in the use of the workforce.
Retail shop 2	25	**132.308.000**	**5.292.320**	**292.266**	**5.52%**	Retail shop 2 has a good balance between salary costs and turnover per employee and it is the representative of some bigger supermarkets, such as Idea Super or Maxi stores in Serbia.
Retail shop 3	85	**802.270.000**	**8.438.470**	**235.262**	**2.78%**	Retail shop no. 3 is the most efficient with the 2.78% share of salary costs in total turnover. However, shops that size and with lot of employees, have other costs higher, so in the Republic of Serbia, but also in Europe and America, there is a new trend of quick buying.

Indicators such as turnover per m^2 or per employee are important for middle and lower parts of management in retail, so they are also considered as key performance indicators, based on which, management can make appropriate decisions.

5. THE IMPACT OF PRICING STRATEGIES ON TURNOVER AND GROSS MARGIN INDICATORS

If profit is reviewed as the equation *turnover = price x volume, than, there* are just three turnover drivers: price, volume and costs. Among these components, price is the most effective profit driver.

Profitability is a very important group of indicators in every industry, in retail especially. Without a profitable category of goods and grocery stores, modern retail couldn't exist. Speaking of grocery retailers, with a very low margins, profitability is crucial. Falling into price-promotion traps is hard to manage with both customers and competitors, affecting the terms on the retail market.

During the last few years, price wars has increased the impact on profitability of grocery retailers and has become more fatal for new retailers who enter the market. In the terms of dynamic market, it is really important for a retailer to have a successful and profitable pricing strategies.

There are many pricing strategies, but two of them are mostly used in retail. The first strategy is called "Every Day Low Price" (EDLP) which considers the lowest prices every day for their customers. This strategies is mostly focused on some specific group of products in order to differentiate retailer from its competitors. Wal-Mart is considered as pioneer of the EDLP pricing strategy. It started being popular in the 1990's, but today it is still one of the mostly used pricing strategies.

On the other hand, there is a "High-Low" (Hi-Lo) pricing strategy whereby the retailers set their prices on a higher every day level, but use price discounts and promotions to attract customers.

Researches has shown that the main motivation for using EDLP pricing strategies is cutting down advertising costs and reducing labor as a consequence of cutting back on promotions, but also improving inventory management. Speaking of Hi-Low pricing strategy, it is suggested that the motivation for retailers to use this strategy is to "generate excitement, attract shoppers, clear out time-sensitive merchandise and sell complementary, high-martin items (Voss and Seiders 2003, p. 37).

In theory, using just one pricing strategy doesn't function. Retailers not only use either a Hi-Lo or an EDLP pricing strategy, but follow a "hybrid" pricing strategy containing elements of both Hi-Lo and EDLP. For example, in the German retail market, Rewe is seen as a Hi-Lo retailer, but Rewe also has EDLP elements with its private label brands. On the other hand, for example Aldi and the drugstore chain DM are pursuing an EDLP strategy, but also offer some products on promotion.

An increase in price – holding the volume constant – has a 100% impact on profit, whereas an increase in volume – holding the price constant – just influences the profit to the amount of the additional turnover minus the marginal costs (Husseini, 2015).

Nowadays, there are several methods by which a pricing strategy could be presented to a customers. The mostly used method is loyalty program method. Running a loyalty programs is a huge managerial task. Affecting on the customer perception of loyalty program – coupons, loyalty cards, bonus points, etc. are just the top of the iceberg. Behind that, there are many activities – logistics activities, involving and card issuing, call centers, involving card issuing, negotiation with partners in the scheme and suppliers of bonus merchandise, and so on (Stone, 2004, p. 308).

Tracking the competitor's activities through usage of pricing strategies can be done using different models and methods. One of them is the competitive matrix for pricing strategies (Table 5).

Table 6: Price index matrix - pricing strategies
Source: Blazek A, Deyhle A, Eiselmayer K. (2011), Controlling System, p. 114

Factors	Weight	Scale					Total
		1	2	3	4	5	
In-Store pleasantness	30%					x	150
Online shop	5%			x			15
Assortment	30%				x		120
Loyalty programs	5%				x		20
Time spend queuing	30%		x				60
Total	**100%**						**365**

The matrix consists of factors whose importance is determined by the sum of weighting to give 100%. It also contains the scale of 1-5, which is estimated ratio compared to competitor (1- much worse, 2 - worse, 3 - the same, 4 - better 5 - much better). Multiplying the scale of weights we get the total amount. The competitor automatically has a total amount of 300 (by multiplying the sum of all weights - 100 with the number 3).

Comparing the ratio obtained by our company and the number 300, we get a percentage which shows should the company increase or decrease the prices in comparison to the main competitor. If that ratio is higher than 1, than the company has the potential to increase the prices of its goods, and in opposite, to decrease prices.

For the analysis of the factors and assessing whether the factor determined by the company is better than a competitor, it is necessary to do more detailed quantitative analysis, and even seek the help of consultants and research agencies. If we compare company X with company Y – main competitor, on the given example in table above, the calculation has given the sum for company X of 365. If that amount is divided with 300 (competitors score), the comparing ratio is the number 1,215. That means that for the company X it is justified to increase prices by 21.5%.

6. CONCLUSION

Managing key performance indicators is crucial for all retailers. There are two main types of indicators which are mostly used in every business. Key performance indicators (KPI's) doesn't necessarily have to include only financial indicators (sales, EBIT, EBITDA, etc.), but could also include some non-financial indicators as well. Choosing the proper indicators is crucial for every business. But, it is important to put the accent on the different aspects of reviewing selected indicators. Top management and other lower parts of management doesn't consider every KPI with the same importance. Turnover and gross margin are two basic indicators in grocery retail. They are tracked by every level of management, but there are some more specialized indicators such as sales per square foot or turnover per employee which are more interested to lower levels of management (for example managers of grocery stores) than to the top management. With low margin levels, grocery retailers must establish higher turnovers in order to have a profit and to do business with a certain level of sustainability. However, there are several factors directly affecting on gross margin and total turnover. Two of them are prices and the quantity of goods sold. Speaking of prices, grocery retailers are mostly using two pricing strategies: EDLP (*Every Day Low Prices*) and Hi Lo (*High-Low*). Nowadays, retailers use hybrid pricing strategies – combining both mentioned pricing strategies with a planned combination for different groups of goods. It is up to category managers to plan those strategies carefully and to track changes on the retail market in order to establish target. Having a strong and consistent pricing strategies will provide to a retailer a competitive advantage on the long terms. All in all, with the proper analysis, use of key performance indicators and proper mix with adequate pricing strategies, retail chains can run toward leading positions on the retail market. Customers are mostly attracted by location of the grocery store and by the kindness of employees (GfK Market Research, 2015). Considering that fact, there is still enough space for additional research of turnover, and the impact of employee's satisfaction and efficiency of selling space on total turnover.

OPEN SOURCE ENTERPRISE RESOURCE PLANNING: SOLUTION FOR PRODUCTION PLANNING IN SMEs

Zoran Rakićević*[1], Jasmina Omerbegović-Bijelović[1], Danica Lečić-Cvetković[1]
[1]Faculty of Organisational Sciences, University of Belgrade
*Corresponding author, e-mail: zoran.rakicevic@fon.bg.ac.rs

Abstract: *This paper presents the study on open source Enterprise Resource Planning (ERP) software from the perspective of their production module. The study was based on the survey of five open source ERP software. The survey method was content analysis. The observed ERP solutions were evaluated, in a qualitative way, regarding important functionalities and analysis tools of their production module. Besides that, the paper is also focused on capabilities, advantages, and shortcomings of open source ERP solutions for small and medium-sized enterprises. The purpose of this paper is to further present information and knowledge about reasons for SMEs to adopt open source ERP. One of the goals is also to promote alternative ways of supplying SMEs with adequate management and IT solutions. In this paper, analysed and presented open source ERPs (Oddo, WebErp, OpenBravo, Compiere, and NextERP) have proved to be very useful and equipped solutions for SMEs production planning. The findings of this paper are interesting both for scholars and practitioners (including SMEs) as well as for ERP developers.*

Keywords*: Enterprise resource planning (ERP), small and medium-sized enterprises (SMEs), production planning, open source ERP*

1. INTRODUCTION

Contemporary planning and management cannot be imagined without the usage of information and communication technology (ICT). According to the American Production and Inventory Control Society - APICS (Cox & Blackstone, 2005), Enterprise resource planning (ERP) is defined as a „*method for the effective planning and controlling of all resources needed to take, make, ship and account for customer orders in a manufacturing, distribution or service organization*". ERPs are often defined as standardized packaged software designed to integrate an organisation's entire value chain (Johansson & Sudzina, 2008). According to Heizer and Render (2011), Enterprise Resource Planning is software that allows companies to: (1) automate and integrate many of their business processes through planning of enterprises resources; (2) share a common database and business practices throughout the enterprise; (3) produce information in a real time. At the strategic level, ERP system presents an application programme that integrates all business functions and processes (Loh & Koh, 2004). At the operational level, ERP is the system for planning and monitoring resources of manufacturing, i.e. manufacturing resource planning system (Loh & Koh, 2004).

The roots of ERP system originated in the manufacturing industry in the 1980s, through the development of Materials Requirement Planning (MRP) method and Manufacturing Resource Planning (MRP II) concept (Kilic et al., 2015). Later it evolves in the integral information system with different modules for resource planning and management of production, service and commerce. The core modules included in ERP are (Zhang et al., 2005; Madanhire & Mbohwa, 2016): *Production planning* module with the primary purpose to optimize the utilization of manufacturing capacity and material resources using historical production data and sales forecasting; *Purchasing module* facilitates procurement of required raw materials, and automates the process of placing orders to suppliers; *Inventory control module* enhance the process of maintaining appropriate stock level and identifying inventory requirements; *Sales module* helps in order placement and scheduling, shipping and invoicing; *Marketing module supports* marketing activity and campaign; *Financial module,* as the core module, collect and integrate financial data from every department and generate financial reports and statements; *Human resources module* retains a complete database with information about employees. Thus, ERP software system is a comprehensive system which consolidates all departments from purchasing via production to distribution in one integrated system and manages it (Madanhire & Mbohwa, 2016). Furthermore, according to Ruivo, Oliveira, and Neto (2015), ERP system provides process-oriented business management view which is more effective and organised

way of executing business operations then the functions-oriented. So, one of the main advantages generated by the implementation of the ERP system is integration between enterprise's departments and processes throughout the ERP modules, with achieving different operational performances such as: improved productivity, lowered costs, more reliable performances, reduced paperwork, and saved time (Antoniadis, Tsiakiris, & Tsopogloy, 2015). In the last ten years, besides the conventional ERP systems, the focus is on the open source, cloud and mobile ERP systems, especially their application in small and medium-sized enterprises (SMEs). A comprehensive literature review in ERP field is presented in Huang & Yasuda (2016).

The development of ERP for SMEs rose from two sources: the first is the business needs of SMEs, which become more complex in global business and supply chain environment; and the second is saturation of large companies' market demand. In that situation, ERP producers introduce solutions for small business. Corresponding to Ruivo, Oliveira & Neto (2015) the most literature studies are about ERP comparisons regarding the selection process and, implementation duration and costs. However, little studies examined ERP implementation in SMEs and even less described the comparison of different ERP products. Besides that, Huang and Yasuda (2016) deduced that research on SMEs and ERP will continuously increase, mainly because many new ERP producers provide different solutions that can be easily implemented and maintained by SMEs. Several years before, Johansson and Sudzina (2008) stated that there is tremendous interest in free and open source ERP systems. Due to previous, the authors of this paper consider Open Source ERP in the context of SMEs as a very actual research topic.

In this paper, we will analyse and compare five Open Source ERPs software observing their production planning module. Our main research question was: Are the Open Source ERPs software appropriate for SMEs? The rest of the paper is organised as follows: Section 2 introduces the concept of production planning. Section 3 describes ERP through SMEs point of view. Section 4 presents the qualitative evaluation of observed software concerning their production module. Section 5 concludes the paper.

2. ENTERPRISE PRODUCTION PLANNING

Planning as a management phase includes defining the objectives, as well as activities and resources which are necessary for achieving the proposed objectives, taking into account all constraints (Omerbegović-Bijelović, 2006, p. 36). Broadly observed in business operations of every enterprise, planning is concerned with the adjustment between what the market requires and what the operation's resources can deliver (Slack, Chambers, & Johnston, 2007, p. 290). The domain of production and service planning are the defined goals and activities which are conducted with appropriate resource usage, in order to obtain efficient and effective production and servicing process.

The process of operations planning (production and service delivery) initially start from the demand forecasting of product and services. On the basis of anticipated demand, long-term needs for capacities of production and service provision are planned. Long-term capacity planning decisions are a framework for planning capacity and demand on mid-term – which is the information input in the process of aggregate planning. Aggregate planning includes defining the strategy on a mid-term (3 to 18 months) for engagement of human resources, production capacities, quantities of different categories of product and services, inventories, overtime work and subcontracting, all with the aim of cost minimization. After aggregate planning, next phase is master production scheduling. Master Production Schedule (MPS) defines planned quantities of different product and service varieties in planned time for its realisation. MSP is the result of aggregate plan decomposition. MPS together with bill of material present the basis for the next phases of production planning: *Material Requirements Planning (MRP),* negotiating and selections of suppliers, contracting of supplies, raw material and components ordering, time scheduling of production activities on different machines and workers, production orders launching, dispatching material in the production process (Omerbegović-Bijelović, 2010). Presented concept of production planning doesn't have to refer to only one company. The modern trend in management involves the orientation on the networks of production and service enterprises which are in customer to supplier relation, known as supply chain or value chain (Omerbegović-Bijelović, Atanasov & Rakićević, 2014). The task of planning is more complicated at enterprises that are in the supply chain because it is necessary to define plan for all of the enterprises which are connected to each other.

According to the authors (Schut, 2004, p. 219; Gansterer, 2015), production planning (including whole Supply Chain) covers the following areas: Sales forecasting, quantitative support for sales and operations planning, integrated supply chain tactical planning, production requirements calculation from distribution network requirements, master production scheduling, detailed scheduling of production, inventory deployment planning in a distribution network and short-range transportation planning.

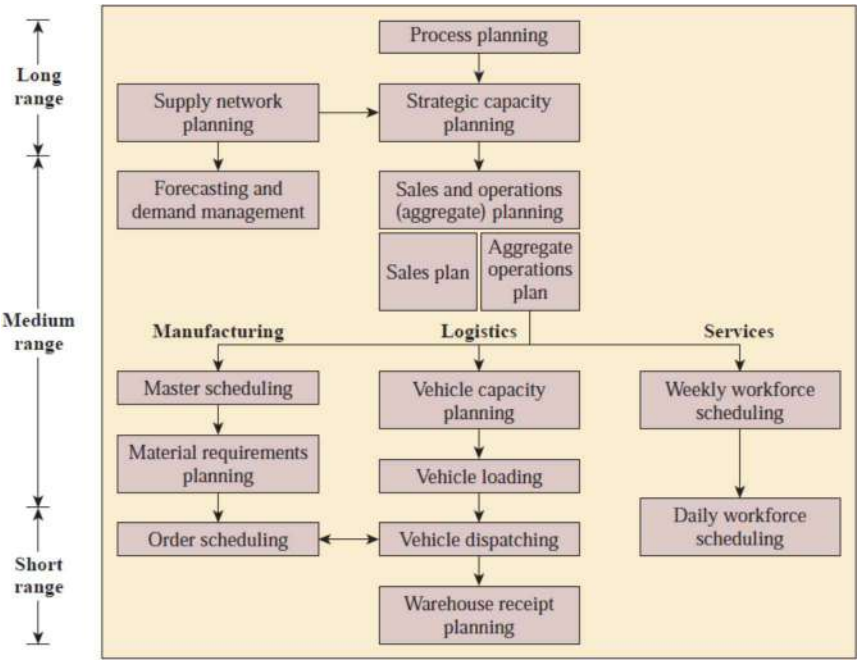

Figure 1: Main activities in planning of production and servicing operations
Source: Jacobs & Chase (2010, p. 286)

Junior & Filho (2012) in their paper defined next production planning activities: product demand forecast, aggregate planning, determining of the master production schedule, inventories planning, capacities planning, determining production order quantities, scheduling of production activities.

3. SMALL AND MEDIUM-SIZED ENTERPRISES AND ENTERPRISE RESOURCE PLANNING

Surveys and studies relating to the implementation of enterprise resource planning (ERP) systems in small and medium-sized enterprises (SMEs) has been rapidly increasing in recent years (Loh & Koh, 2004). Mabert et al. (2003), presented the difference between large and small and medium-sized enterprises in their implementation of ERP software. They approved that large companies customize ERP software more often while small enterprises adopt business processes within ERP systems. Besides that, large companies reported greater benefits in the financial areas, while small companies report more benefits in manufacturing from their ERP implementations. SMEs, which are in a supply chain, that deals with large enterprises and have an ERP system with production planning module will provide better performances in manufacturing, like *productivity*, *customer services*, *inventory turns* and *reduction in material cost* (Mabert et al. 2003; Loh & Koh, 2004).

Antoniadis, Tsiakiris & Tsopogloy (2015), in their survey based on respondents' opinions, identified the following key benefits of ERP utilization in the SMEs: data integration from different departments, reliability of information, saving time by automating procedures, controlling activities and flexible decision making. However, the cost reduction was the less important advantage of implementing the ERP system in the company, despite the fact that during crisis periods, reducing cost is essence for SMEs. The same authors present the main disadvantages and deterrents for ERP systems adoption: cost of initial setup and support and, the cost and time required for training the personnel to handle the new ERP system. Ruivo, Oliveira & Neto (2015), also defined benefits of using ERPs: ERP systems allow information to flow transparently in a firm's ecosystem, benefiting its supply chain efficiency; ERP systems can bring operational excellence and competitive advantages to firms.

Obvious benefits of ERP software can be achieved if its implementation was successful. Antoniadis, Tsiakiris & Tsopogloy (2015) presented the most important factors for successful implementation of ERP in SMEs: Appropriate ERP provider support, ERP customization and parameterization, ability of communication and cooperation between all the involved enterprise departments, personnel's training and education, level of quality service in external technical support for the ERP. Beside this, in comprehensive analysis Upadhyay et al. (2010), identified several critical factors: 1) Education and training to enhance SMEs employees knowledge and proficiency; 2) Clearly defined goal and scope of ERP implementation; 3) Top management support through providing necessary resources and providing leadership; 4) Proper project planning due to constrained SMEs' resources; 5) Minimal customization (fit the organisational needs to the functionality of ERP); 6) Proper implementation strategy ("Big bang" or "vanilla" approach).

Resource constraints of small business are huge obstacle for purchasing of ERP system. One of the possible options for SMEs is to implement Open Source ERP software. Johansson and Sudzina (2008) presented initial literature review about open source ERP and SMEs. They also identified the lack of studies about why SMEs choose open source ERPs instead of proprietary ERPs and try to bridge it within their survey.

The SMEs present backbone of the Serbian and European economy. Every study about improving SMEs' competitive advantages as well as their further development has vital importance. Adoption of ERP system is one of the most important technological and organizational innovations in modern SMEs, since it promotes knowledge diffusion, and accelerates their business decision-making processes. Therefore, a good consideration and multi-criteria analysis should be applied in a selection process (Kilic et al., 2015).

4. COMPARATION OF THE OPEN SOURCE ERP SOLUTIONS

Before the comparison among Open Source ERPs will be presented, it is necessary to remark that three best-known ERP vendors (SAP, Oracle, and Microsoft Dynamic) take about 55% of the market share. The commercial prices of mention proprietary ERP solutions are among 5.000 up to 250.000 $. (Top ten ERP vendors in 2016, https://www.top10erp.org). The result of this fact is that SMEs, especially those that are micro and small, can't afford proprietary ERPs, and they turn to open source solutions.

The term "open source" refers to something that can be modified and shared because its design is publicly accessible (https://opensource.com/resources/what-open-source). While it originated in the context of computer software development, today the term "open source" designates a set of values - what we call *the open source way*. Open source projects, products, or initiatives are those that embrace and celebrate open exchange, collaborative participation, rapid prototyping, transparency, meritocracy, and community development. Open source software is software which source code is available for modification or enhancement by anyone. Open source software is partially free and comes with the open source code that has possibilities to be adjusted and changed according to users' needs (Riehle, 2007). Sometimes open source software licenses provide users possibilities to redistribute the software.

There are two types of open source software: *Community open source* is software where broad community of volunteers are developers; *Commercial open source* is software that a for-profit entity owns and develops. The owner company maintains the copyright policy and determines what can be changed and implemented in software code (Riehle, 2007). Commercial open source software is usually available for free to non-profit users. Sometimes, for commercial users, it is free as well. In that situation companies make money by providing support services and selling software upgrades. Really interesting businesses are companies and individuals (known as committers) that provide IT services for different open source software.

Even though that open source software are initially free, they could have cost related to the usage (cost of learning, cost of adjustment and cost of maintenance). The main implementation problem of ERP software, both proprietary or those that are open source, is unsuitability between ERP functionality and company requirements (Johansson & Sudzina, 2008). Project of ERP implementation requests that organization changes processes or adjusted ERP solution according to them. However, in the case of process changes, one of the big advantages for SMEs is their small scale and,

consequently, flexibility and adaptability. Besides that, in the case of ERP customization, the great characteristics of open source solutions is that they present: process delivery model (that can be implemented) and, development model that need to be tailored.

Decision process for implementation open source ERP in SME may include the evaluation of different ERP characteristics: usability, compatibility, features, support cost and, software reliability (Johansson & Sudzina, 2008). Kilic et al. (2015) defined three groups of evaluation criteria: Business criteria (brand image and market position), Cost criteria (purchasing cost, implementation cost, and support cost) and technical criteria (functionality, reliability, compatibility). Business criteria are brand image and market position; cost criteria are purchasing cost, implementation cost and support cost; while technical criteria are functionality, reliability and, compatibility.

In analysis, which will be presented underneath (Table 1), ERPs' production module features will be observed. First, every analysed open source ERP (Odoo, WebERP, OpenBravo, Compiere and ERPNext) will be described in a few sentences.

Odoo ERP (previously titled TinyERP) is partially free open source ERP for all size-companies. For two users when the system is hosted online, it is free. For the off-line version intended for larger number of users, it is not. Besides that, Odoo is totally free for in-house maintenance. This software covers all standard modules and functionalities (the application suite includes: billing, accounting, manufacturing, purchasing, warehouse management, and project management) and is perfect for managing small business lower than 50 employees (http://www.odoo.com).

WebERP is an open source ERP system for SMEs. WebERP is a complete web based business management system that requires only a web-browser and .pdf reader to be used. It has a wide range of modules and features suitable for many businesses particularly distributed businesses in wholesale, distribution and manufacturing. Due to its on-line hosted nature, it is less hardware demanding than others off-line solutions (http://www.weberp.org).

OpenBravo ERP is a commercial on-line ERP based on a modular system for small and medium-sized companies. The software comes in three editions depending on the needs of particular organization. OpenBravo Community Edition is the free of charge that offers reduced functionalities in compare to payable versions (Enterprise and Professional edition). These editions include some premium, commercial modules — like financial management and inventory management — that many businesses find necessary. This program is among the top ten most active projects on *SourceForge* - centralized Web-based service for control and management of free and open-source software projects (http://www.openbravo.com/).

Compiere is the open source and cloud-ready ERP solution for SMEs in distribution, retail, manufacturing and service industries. Compiere automates accounting, supply chain, inventory and sales orders. It is one of the successful open source projects with more than 1.8 million downloads till nowadays. Compiere includes wide range of modules and encourages enterprises to customize and match Compiere towards they business needs (http://www.compiere.com/).

ERPNext is the on-line open source ERP solution designed for small and medium businesses and is presented as a series of applications. ERPNext covers many business functions including accounting, inventory management, Customer Relationship Management (CRM), purchasing, project and task management, human resource management and manufacturing. ERPNext is very easy to set up, using simple forms to enter information about business in typical setup wizard style. This solution very quickly becomes familiar as the ERPNext is very user-friendly (https://erpnext.com/).

Table 1 shows evaluation of observed open source ERP solutions from perspective of their manufacturing module with contained production planning tools: Manufacturing order, Bill of material, Production costs, Order planning, Aggregate planning, Master production schedule, Gantt chart planning, Quality control planning and reports, MRP (Material requirements planning), Sales and production forecasting, Traceability of products, Product manufacturing routings, Inventory management (receipts, internal transfers, delivery orders), Automated purchase orders, ABC inventory analysis, Inventory algorithms, Production scheduling, Production and inventory reports, Capacity requirements planning, Product lifecycle management, Maintenance planning. Besides that, we examine: ERP solutions' connectivity with other applications and programs; whether solution is

available for online/cloud usage; is there option for multilingual customization (particularly for the Serbian language); what is the initial price in the form of licence fee for obtaining observed ERP solutions.

Table 1: The evaluation of Open source ERP solutions

Tools of manufacturing module:	Open source ERP solutions				
	odoo	webERP	openbravo	Compiere	ERPNext
Manufacturing order	✓	✓	✓	✓	✓
Bill of material	✓	✓	✓	✓	✓
Production costs	✓	✓	✓	✓	✓
Order planning	✓	✓	✓	✓	✓
Aggregate planning	x	x	x	x	x
Master production schedule	✓	✓	✓	✓	x
Gantt chart	✓	x	x	x	✓
Quality control planning	✓	✓	x	x	✓
MRP	✓	✓	✓	✓	✓
Sales & Prod. forecasting	✓	✓	✓	✓	x
Traceability of products	✓	x	x	✓	✓
Product manufacturing routings	✓	x	x	✓	x
Inventory management	✓	✓	✓	✓	✓
Automated purchase orders	✓	✓	✓	✓	✓
ABC inventory analysis	x	x	✓	✓	x
Inventory algorithms	x	x	✓	x	x
Production scheduling	x	x	x	✓	x
Prod. & inventory reports	✓	✓	✓	✓	x
Capacity requirements planning	x	x	x	✓	✓
Product lifecycle management	x	x	x	x	x
Maintenance planning	x	✓	✓	x	✓
Manufacturing type	Discrete	Discrete	Discrete	Discrete	Discrete
Connectivity	CSV/XLS/ XML/ODS	PHP/ CSV	XML	CSV/XML/XLS DOC/PDF	CSV/XLS
On-line/cloud	✓	✓	✓	✓	✓
Multilingual	✓	✓	✓	✓	✓
The Serbian language	✓	x	x	x	x
Licence fee	240$ per user per year	0$	4.500$ for professional edition	0$	300$ per user per year

According to the analysis in Table 1, all solutions are well equipped. Although presented solutions are generally among each other's, still some solutions that dominate in particular features:

- Aggregate planning is not possible with observed ERPs;
- Planning with Gantt chart is present in Odoo and ERPNext;
- Quality control planning are available in Odoo, WebERP, and ERPNext;
- Sales and production forecasting are part of all observed open source solutions, except for ErpNext;
- Traceability of products is available in Odoo, Compiere and ERPNext;
- Manufacturing routings are available in Odoo and Compiere;
- ABC inventory analysis is only present in OpenBravo and Compiere;
- Inventory algorithms are only present in OpenBravo;
- Production scheduling is part of Compiere, though advanced production scheduling and optimization in not part of any observed software in Table 1. This functionality is still unreachable for this softwares;
- Capacity requirements planning is available in Compiere and ERPNext;
- Product lifecycle management is unavailable in all observed solutions;
- Maintenance planning is included in WebERP, OpenBravo and ERPNext;
- All analysed open source ERPs are intended for discrete type of manufacturing;
- Comprehensive ability for connection with other software and platforms have Odoo and Compiere (CSV/XLS/XML/ODS/PDF);
- Every observed ERPs are available in on-line/cloud version;

- Language of platform: all software are multilingual. The Serbian language is only available for Odoo;
- Licence fee: WebErp and Compiere are free of licence cost.

Although every analysed software has one or more omitted tools and features for production planning, the authors of this paper believe that they are excellent and very economical choice for SMEs. This attitude is also strengthened with fact that open source ERPs have possibilities for adjustment and upgrade in accordance with their open source code.

5. CONCLUSION

The study presented in this paper aimed at investigating the capabilities of production module of open source ERP software for small and medium-sized enterprises. The analysed sample was consisted of five open source ERP solutions, which were compared with set of common features of their production module. The analysis showed that open source ERP have wide range of possibilities, as well as that there are dominated open source ERP solutions for particular features: a) Zero licence cost (for WebErp and Compiere software); b) Excellent language customization (especially Odoo for the Serbian language); c) Connectivity with other software for data export and import (Odoo and Compiere); d) Modern planning methods and tools: Gantt chart (Odoo and ERPNext), sales and production forecasting (Odoo, WebERP, OpenBravo, and Compiere), traceability of products (Odoo, Compiere, and ERPNext), product manufacturing routes (Odoo and Compiere), ABC inventory analysis (OpenBravo and Compiere), inventory algorithms (OpenBravo), production scheduling (Compiere), capacity requirements planning (Compiere and ERPNext), maintenance planning (WebERP, OpenBravo, and ERPNext);

Open source ERP software present great opportunity for small business due to their initial cost and adaptable nature. Serrano and Sarriegi (2006) stated that benefit of applying open source ERP solutions are greater than for other applications. This is reflected in: 1) Increased adaptability of ERP solutions due to full access to source code; 2) Decrease dependency on single supplier – companies that purchase a proprietary ERP are highly dependent on the software producers or distributors; and 3) Reduced costs – open source ERP usually avoid licence costs, and if the consultant charge for customization is not high it will result in lower cost of implementation.

The results of this study can be used for the practical and theoretical purpose. Regarding the practical, implications it can be useful for owners and managers of SMEs to support a technological and organizational development of their small businesses. Theoretical implications are reflected in knowledge contribution to scientific fields of production planning and management of SMEs. Further research will be focus on detailed analysis of the wider group of open source ERPs as well as surveys of SMEs, their management problems and detail needs for ERPs implementation.

GPI PROCESS PERFORMANCE MEASUREMENT MODEL

Barbara Simeunović*[1], Dragoslav Slović[1], Milić Radović[1]
[1]University of Belgrade, Faculty of organizational sciences
*Corresponding author, e-mail: tisma@fon.bg.ac.rs

Abstract: *This paper investigates the possibility of developing flexible process performance measurement model. The results of comparative analysis of existing process performance measurement models suggest that they lack flexibility, ie the ability to use model in a wide and varying range of companies, with no significant changes in the model. New GPI process performance measurement model (in the narrow version) is proposed, that has improved flexibility compared to existing process performance measurement models. Results of case study show that proposed model can create basis for effective performance management, and also for further research in this area.*

Keywords*: process performance measurement, goals, key processes, process performance indicators, flexibility*

1. INTRODUCTION

In order to achieve sustainable performance of business system, it is crucial for companies to manage its processes, and process management requires the continuous measurement of their performances. In the literature, as in practice, there are number of models and frameworks that provide guidelines for the performance measurement system development and review performance measurement problems from different perspectives. Besides tendency to link operations and processes to strategic goals, they integrate financial and non-financial measures, and focus all business activities on customer requirements (Lynch & Cross, 1995, p.6). Nevertheless, these different approaches have led to numerous definitions of a performance measurement system, but still, there is little consensus regarding its main components and characteristics. (Dumond, 1994, p.17).

Since the environment in which the organizations operate is dynamic and success depends upon meeting the changing needs of all stakeholders, it is necessary for organizations to evaluate performance from an external perspective, listening to customers, suppliers and other stakeholders (Striteska & Spickova, 2012, p.1). Also, the organization goals need to be changed over time and when goals change, some performance measures (indicators) must be changed too. According to Franceschini et al. (2007, p.55), one of the most critical aspects in operations management is “translating” a company’s goals into performance indicators.

Nowadays, there are a number of performance measurement (PM) models that include or strongly rely on performance planning, job design, performance measures determination and monitoring, and on the reward system definition (Sikavica & Hernaus, 2011, p.433). Those frameworks assist in this performance measurement system building process by clarifying boundaries, specifying dimensions or views and may also provide initial intuitions into relationships among the performance dimensions (Rouse & Putterill, 2003, p.792). Various PM models consider performance from different perspectives, and they are designed for different purposes. Majority of them takes into account the strategy or goals while determining performance, but none of analysed models link directly organizational goals and performance indicators, in other words, they don’t specify their interdependence, which would allow model flexibility. There is, therefore a need for improving the flexibility in the performance measurement models.

The development of PM model, that starts from the strategic objectives defined in accordance with the stakeholders' requirements, and translates them on the goals of lower hierarchical levels, and then connects them with key performance indicators processes (which realize defined objectives), will allow the connection of strategic objectives and key process performance indicators. By this, the flexibility of the model, ie its simple and easy applicability in the various organizations, can be increased.

In the paper, after the brief literature review about process performance indicators and PM models, research hypothesis is proposed. After that, the methodology of research is described. Then, the initial model was proposed, and the case study research was described. Based on the study findings, previously

conceptualized model is improved. At the end, some conclusions are drawn, as well as the directions of future research.

2. LITERATURE REVIEW AND HYPOTHESES

2.1. Process performance indicators

A process performance indicator is a measure that reflects the critical success factors of a business process defined within an organisation, in which its target value reflects the objectives pursued by the organisation with that business process (Del-Río-Ortega, Resinas & Ruiz-Cortés, 2010, p. 555). Key performance indicators (KPIs) provide a valuable source for the translation of strategic objectives to process-specific goals and facilitate effective process control (Rosemann & vom Brocke, 2010, p.115).

Although most authors agree that the performance indicators have to be linked to the organization's strategy and objectives, there is no unique and universal approach to determining performance indicators. Turajlić et al. (2009) proposed Strategic Alignment Pyramid for ilustration the process of KPI determination. Parmenter (2010) proposed the 12-step model for development and usage of KPIs. Franceschini et al. (2007) sugesst 5-step approach that contributes to improved organization for measurement performnse system development.

Many authors defined the specific lists of performance indicators for certain types of organizations or business areas (Sikavica & Hernaus, 2011; Parmenter, 2010; Supply-Chain Council, 2010; Addison et al, 2009). Besides Parmenter's list (Parmenter, 2010), which can be considered as universal, all other examples of performance indicators' lists are limited to a specific area or performance perspective.

2.2. Process performance measurement models

In the literature, as in practice, there are number of models and frameworks that provide guidelines for the performance measurement system development. The objective for such models is to help organizations to define a set of measures that reflects their objectives and assesses their performance appropriately (Kennerly & Neely, 2002, p. 146). Besides tendency to link operations and processes to strategic goals, they integrate financial and non-financial measures, and focus all business activities on customer requirements (Lynch & Cross, 1995, p.6). Nevertheless, these different approaches have led to numerous definitions of a performance measurement system, but still, there is little consensus regarding its main components and characteristics (Dumond, 1994, p.17).

Some of the most common models in the literature are: Tableau de Bord - TB (de Guerny et al, 1990; Neely et al, 2007), Activity based costing – ABC method (Budd, 2010), Data Envelopment Analysis - DEA (Berg, 2010; Savić, 2012), Theory of Constraints - TOC (Goldratt, 1984), Performance measurement matrix (Keegan et al, 1989; Neely et al, 2007), Performance pyramid (Lynch & Cross, 1991), Framework of results and determinants (Fitzgerald et al, 1991; Neely et al, 2007), Balanced Scorecard - BSC (Kaplan & Norton, 1993), EFQM model (Neely et al, 2007; EFQM, 2009), DOE/NV model (Bellman et al, 1994; Franceschini et al, 2007), TQM performance measurement model (Sinclair & Zairi, 1995; Sinclair & Chang, 2002), Brown's performance measurement concept (Brown, 1996;), Supply Chain Operations Reference (SCOR) model (Supply-Chain Council, 2010), Demand to measure model - DtM (Ljungberg, 2002), Kanji Business Excellence Measurement System - KBEMS (Kanji, 2002; Naghavi et al, 2012); Business System Design Decomposition framework - BSDD (Taticchi et al, 2010).

2.3. Comparative analisys of PPM models

Those models were according to twelve criteria (Simeunović, 2015). One of the criteria was model flexibility, which implies the ability to use models in a wide and varying range of companies, ie model applicability in a number of companies, with no significant changes in the model. For research purposes, model flexibility is defined on the four levels, as shown in Table 1.

The results of comparative analysis show that five models are applicable to all organizations without major changes, but these models are limited to the level of processes, ie do not consider organization as a whole. Six models can be applied in different type of organizations, but only to a certain level, ie performance indicators must be defined again for each organization, and that's time consuming, so they can not be considered as fully flexible models. Only two models (EFQM, TOC), according to the results of the analysis, have sufficient flexibility.

However, EFQM model is not recommended to be used in developing countries, because of high demands on achieving business performance, so it is not suitable for use in the companies in Serbia. From the other hand, Theory of constraints is far from being a complete performance measuring system (Striteska & Spickova, 2012, p.9), and it is difficult for applying in changing environment. Based on previous, it can be concluded that the flexibility of analyzed PM models is not satisfactory.

Table 1: PM model classification - model flexibility asspect (Simeunovic et al, 2015)

Level	Description of level	Model
1	Model is not flexible, ie it is defined only for specific type of organizations	Framework of results and determinants, TQM, SCOR
2	Model is flexible to some extent, ie, it is applicable in all types of organizations, but with significant changes in the model	TB, PM matrix, Performance pyramid, BSC, DOE/NV, BSDD
3	Model is flexible, ie, it is applicable in a wide and varying range of companies, but only at process level (not at whole organization level)	ABC, DEA, Brown's model, DtM, KBEMS
4	Model is fully flexible, ie it is it is applicable in a wide and varying range of companies, with no significant changes in the model	TOC, EFQM

Therefore, there is the need for rapid adjustment of PM system to changing business environment. The development of PM model, that starts from the strategic objectives defined in accordance with the stakeholders' requirements, and translates them on the goals of lower hierarchical levels, and then connects them with key performance indicators processes (which realize defined objectives), will allow the connection of strategic objectives and key process performance indicators. By this, the flexibility of the model, i.e. its simple and easy applicability in the various organizations, can be increased.

2.4. Hypotheses

Based on previous, the following general research hypothesis is proposed:

H0. By defining a universal set of goals at the highest level of the organization, a universal set of goals of organizational units and the universal set of process performance indicators, the PM system flexibility could be improved.

To examine this general hypothesis more thoroughly, it is separated into five smaller sub-hypotheses:

H1: By applying the process management based PM model is possible to define the higest level goals of organization in accordance with the stakeholders' requirements.

H2: The highest level goals of organization can be generalized (the universal set of highest level goals can be defined).

H3: By decomposing the highest level goals to the goals of organizational units, key processes can be identified.

H4: By applying the process management based PM model is possible to identify proces performance indicators.

H5: It is possible to identify the universal set of process performance indicators, which can be measured and monitored in each process-orientied bussines system.

3. RESEARCH METHODOLOGY

In order to test the proposed hypotheses, it was decided to conduct case studiy research on the domestic market. Although geographical area wasn't significant, due to the possibility of data collection, research was limited to Serbia. Case study was conducted according to guidelines for case study research proposed by Eisenhardt (1989).

During planning research, intention was to test initial process management based PM model in process-oriented organizations, and then, to analyse decomposition of stretegic goals of organization onto the organizational units' goals, as well as their conection with key process performance indicators.

The unit of analisys for the case study was bussines system, i.e. organization. Selection criteria were designed process model in the organization, and data availability (possibility of data collection). Research was conducted from October 2011 to February 2013. Proposed model was tested at 31 cases, i.e. in 31 organization.

During the research, detailed examination of the documentation on the strategic goals and organizational processes was performed. In order to obtain insight about selected organizations, available documentation from the organizations' web-sites, as well as information on the current PM practice were thoroughly reviewed. The proposed PM model was tested in all selected organizations, and the obtained results were further used for testing hypotheses, as well as for the model improvement.

4. CASE STUDY RESEARCH

4.1. Description of initial PM model

The first step in establishing process-oriented performance measurement system is the development of mission and vision statement. The mission can be seen as the far goal that may never be reached. It should describe what the organization is in business to do. The vision is where the company wants to go, the ideal future state of the organization. Well-defined mission statement should facilitate product/service identification, on the one hand, and identification of stakeholders, and their requirements, on the other hand. Vision statement, along with identified stakeholders, are the basis for defining those product/service quality features by which the organization meets the requirements of stakeholders. Considering the importance of stakeholders for the success of the organization, their requirements should be than incorporated into the strategy and translated into measurable organizational goals. Furthermore, company should decompose those organizational goals to lower level goals of organizational units. At the same time, according to mission, the basic product/service (or more basic products/services) should be identified, and the product/service catalogue should be created, which is the basis for business process identification, i.e process model design. Next step is to identify those processes and activities that (from process model) lead to achievement of organizational goals, and whose performance indicators should be measured. However, since it is impossible to simultaneously improve all processes, or to measure performances of all processes, due to limited resources and time, considering that all performances are not equally important, efforts should be focused on measuring the performances of those processes whose execution contributes to achievement of the organizational goals or stakeholders requirements. So, the list of prior, critical and key processes should be created, whereby the key processes are those processes through which the specificity of business system can be recognized and which contribute to business system goals realization. Given the above mentioned, it is necessary to select the key processes that will be measured and managed. The next step is to translate the top level goals into key process performance indicators which lead to the achievement of these goals. The degree to which goals, as a mission, are met is determined by measuring and comparing process performance with a defined goal (Simeunović et al, 2014).

Translation process is performed as follows. The strategic goals of the organization, aligned with the requirements of stakeholders, are decomposed into the lower level objectives, i.e. objectives of the business system units. If an organization achieves goals of its organizational units, the highest level goals will be achieved too. In this step, it's necessary to define the units of measurement, reference values (values that are required for goal achieving), the method of measuring these goals, and to describe how (in which interval) the trend of achieving these goals will be followed. Next step is to determine which processes in organization should be performed in order to achieve those second level goals. Then, for each of these processes, performance indicators which will be measured and monitored, have to be defined. In this way, process performance indicators are directly linked with organizational units' goals, but also, indirectly, with the highest level goals of organization. The logic and procedure for translating the business system's goals in process performance indicators are shown in Figure 1.

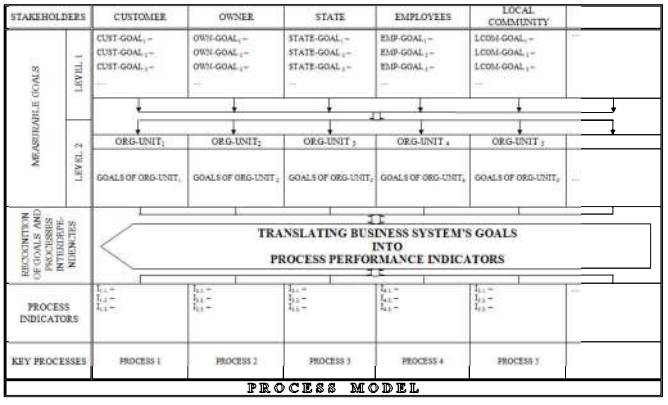

Figure 1. Procedure for translating the business system's goals in process performance indicators (Radović at al, 2012, p.129)

4.2. Results

The proposed model has been applied in 31 companies, which have been the subject of case study. Among 31 companies, 9 were small companies (29%) with less than 50 employees, 12 were medium companies (38,7%) and 10 (32,3%) were large companies (with more then 250 employees) . When it comes to business field that the company is operating in, 13 (41,9%) were service oriented, 14 (45,2%) were manufacturing companies, while only 4 (12,9%) were operating both in service and manufacturing industry.

The stakeholders, that are recognized in those companies are: customers, owner, state, local community, employees and suppliers.

Detailed overview of the companies as well as the results of applying the model in those companies are shown in (Simeunović, 2015).

5. DISCUSSION

Proposed model was applied in 31 companies in Serbia, and on the basis of the collected data, the universal list of the highest level goals (that are defined according to stakeholders' requirements) was obtained. The list include a total of 37 different goals that are defined (in the same or similar way) in these companies. Golas are given in a general form, and their quantification, ie closer specification is done for each organization in particular. Proposal of the list of goals, based on case studies, and the percentage of companies that defined these goals are given in (Simeunović, 2015).

Based on the abovementioned, the sub-hypotheses H1 and H2 were confirmed.

After defining the universal list of the highest level goals, these goals were, for each company, decomposed to the goals of the organizational units, which are responsible for accopmlishing the highest level goals. A total of 32 goals of organizational units were identified.

Furthermore, the key processes (that contribute to realization of these goals) were recognized in each company. All these key processes were then categorized, resulting in the list of 19 key processes (in general form). Performing those processes enables achievement of predefined goals in all companies (from case study). Detailed review of these processes can be found in (Simeunović, 2015).

Based on the abovementioned, the sub-hypothesis H3 was confirmed.

For each process, the process performance indicators (one or more), which will be measured and monitored, were defined. Based on data on process performance indicators collected in all the companies (which were the subject of case studiy), the universal list of process performance indicators was defined. Based of that list, each company, regardless of the activeness, form of ownership, size and form of organization, may select its own set of indicators, in order to monitor and assess the achievement of goals. The list includes 172 process performance indicators, shown in (Simeunović, 2015).

Based on the abovementioned, the sub-hypotheses H4 and H5 were confirmed.

Confirming sub-hypotheses H1-H5, the general research hypothesis is accepted:

H0. By defining a universal set of goals at the highest level of the organization, a universal set of goals of organizational units and the universal set of process performance indicators, the PM system flexibility could be improved.

6. GPI PROCESS PERFORMANSE MEASUREMENT MODEL

Based on research, the initial PM model was improved, and the improved version of model is named GPI process performance measurement model. The model was named as the acronym of three key words that form its structure: Goals, Processes and Indicators.

GPI model can be used in its narrower and broader version. Narrower version of GPI model allows application of model just as it is, without any changes (emphasizes flexibility), while broader version of the model implies its adaptation to the needs of concrete business system (emphasizes adaptability). Since the topic of the paper is PM models flexibility, the narrower version of GPI model will only be shown.

In the model, the highest level goals of the organization are predefined, as well as the goals of organization units, key processes and their performance indicators. The links between them are determined too. The model is specified based on case study research and it can be used (as such) in every business system, which means that it is extremely flexible.

Based on case study, the highest level goals of each company were analyzed, and the universal list of these goals, which contains a total of 12 different goals was defined. The list is shown in Table 2.

Table 2: Universal list of the highest levell goals, and theirs labels (Simeunović, 2015)

RB	Label	Goal
1	CKO_1	Improve/maintain product/service quality
2	CKO_2	Cut short/fulfill deadlines
3	CKO_3	Reduce/keep product/service price
4	CVL_1	Increase profit
5	CVL_2	Develop bussines
6	CZA_1	Increase wages
7	CZA_2	Improve work conditions
8	CZA_3	Provide training for staff
9	CDO_1	Regularly pay payables to suppliers
10	$CDR\text{-}LZ_1$	Regularly pay taxes and contributions
11	$CDR\text{-}LZ_2$	Increase employment/decrease unemploymenti
12	$CDR\text{-}LZ_3$	Protect environment/meet environmental requirements

It was also determined that the achievement of the defined goals can be monitored with a total of 20 process performance indicators. It is important to note that key processes should always be identified first, and then the indicators of these processes. But, considering that the final result (output) of model is the direct link betveen the highest level goals and process performance indicators, in Table 3, process performance indicators were first presented, and then the key processes in which these indicators should be measured.

Table 3: Process performance indicators, their labels and key processes (Simeunović, 2015)

RB	Code	Proces performance indicator	Key Process
1	IKV_2	The waste percentage	Product production / service provision
2	IKV_3	The percentage of non-compliant pieces	Product production / service provision
3	IKV_{21}	Percentage/number of (non)compliance with environmental requirements	Quality service provision / Quality Control
4	IKV_{24}	Number of corrective measures	Quality service provision / Quality Control
5	IKV_{31}	The complaint rate	Sales service provision; Collection and processing of complaints
6	IPR_1	(Annual) production volume	Product production / service provision
7	ITR_1	Total (annual) production costs	Product production / service provision
8	ITR_2	The cost per unit of product/service	Product production / service provision
9	IRO_{15}	The percentage of on-time deliveries	Product production / service provision; Providing services logistics / warehousing / transport; Providing services procurement
10	IRO_{16}	(Average) delivery time	Product production / service provision; Providing services logistics / warehousing / transport; Providing services procurement
11	IRZ_1	The number of new types of products or services (per year)	Product design and development; R&D service provision
12	IRD_1	The total number of employees of a particular profession (in a particular organizational unit)	HR services provision / training and professional development
13	IRD_7	The number of workers who have attended training/seminar/specialization	HR services provision / training and professional development
14	IRD_8	Number of organized seminars / trainings (per year / on a particular topic)	HR services provision / training and professional development
15	IRD_{15}	The rate of employee satisfaction with working conditions	HR services provision / training and professional development
16	IPD_2	(Annual) sales volume	Sales service provision
17	IMA_1	The market share (domestic or EU)	Marketing service provision/Market Research
18	IMA_{11}	(New) customer acquisition rate	Marketing service provision/Market Research
19	IFI_6	The amount of unpaid liabilities / unpaid net earnings	Financial service provision/ Payment process
20	IFI_7	Amount of (un)paid liabilities on time	Financial service provision/ Payment process

The names of key processes are generalized, and for operational usage of model, it is preferred to adapt their names to the specific company.

Interdependence of the the highest level goals and process performance indicators can be represented as follows (Simeunović, 2015):

CKO_1=f (IKV_{31}, IKV_2, IKV_{24}, IKV_3)
CKO_2=f (IRO_{16}, IRO_{15})
CKO_3=f (ITR_1, IKV_2, ITR_2)

CVL_1= f(all defined process performance indicators)
CVL_2 = f (IRZ_1, IMA_1, IPR_1, IPD_2, IMA_{11})

CZA_1=f(all defined process performance indicators)
CZA_2= f (IRD_8, IRD_{15})
CZA_3=f(IRD_8, IRD_7)

CDO_1=f(IFI_6, IFI_7)

CDR-LZ_1=f(all defined process performance indicators)
CDR-LZ_2 = f (IMA_1, IRD_1, IPR_1, IRZ_1)
CDR-LZ_3=f(IKV_{21})

7. CONCLUSION

Since a contemporary management of the organization involves management of its processes, the achievement of organization's goals depends on the success of its processes. The success of the process, ie their ability to meet organizational goals, is measured by using key performance indicators.

Analysis of the existing PM models showed that only a few of them has a certain flexibility, ie that is applicable to all organizations, without major changes. However, these models are applicable only at process level (not at whole organization level). Some PM models can be applied in different type of organizations, but only to a certain level, ie performance indicators must be defined again for each organization, and that's time consuming, so they can not be considered as fully flexible models.

Accordingly, the new GPI process performance measurement model is proposed, which is based on process management. This model starts from the highest level goals (that are defined according to stakeholders' requirements), decomposes them on the goals of organizational units and links them to the key processes performance indicators. In this way, GPI model allows specification of a universal set of the highest level goals and universal set of process performance indicators, thereby increasing the model flexibility.

In order to verify validity of the model, a case study research was done. Proposed model was tested at 31 cases, i.e. in 31 organization that manage their processes. Research was conducted from October 2011 to February 2013. Based on the study findings, previously conceptualized model is improved.

The narrower version of GPI model, which is presented in the paper, is applicable in each company, regardless of the activeness, form of ownership, size and form of organization. In the model, the highest level goals of the organization are predefined, as well as the goals of organization units, key processes and their performance indicators. The links between them are determined too. The model is specified based on case study research and it can be used (as such) in every business system, which means that it is extremely flexible.

Results of research and proposed GPI model create the basis for better and easier performance management, but also for further research in this area.

DETERMINATION OF FAILURE DISTRIBUTION PARAMETERS FOR BANBURY MACHINE

M. Şirin Aydın*[1], Baha Güney[1], Çağatay Teke[1]
[1]Sakarya University
*Corresponding author, e-mail: sirin.aydin@ogr.sakarya.edu.tr

Abstract: *Planning, conducting and control of maintenance activities enable to the highest level of availability of manufacturing machines. Maintenance is a set of activities that carry out to keep a system or equipment in operation. Maintenance activities are basically divided into two types as preventive maintenance and corrective maintenance. Failure distribution of machines and equipment has to be known for planning space parts, labor and tools. This can be determined by using failure data and suitable statistical method. In this study, failure distribution parameters of banbury machine were determined by using real failure data. Applied method was shown for the equipment which is vitally important.*

Keywords*: failure distribution parameters, maintenance, banbury machine, weibull distribution, maximum likelihood estimation*

1. INTRODUCTION

Tyre manufacturing process should be formed and managed properly in order to ensure completion of the process in time. The maintenance planning of Banbury machines used in tyre manufacturing should be arranged such that availability is always at a maximum level. In addition, spare part, labor and equipment planning should also be carried out properly so that maintenance activities can be carried out as planned. It is possible to do this for preventive maintenance activities since the times have already been scheduled. However, the same is not true for corrective maintenance activities. Because it is not known when there will be a failure. If the past failure data are available for the system or component for which corrective maintenance activities will be carried out, this uncertainty can be decreased significantly. Since past failure data will fit a certain statistical distribution and if the parameter values for this distribution are determined then it is possible to carry out spare part, labor and equipment planning based on the failure time estimations.

2. LITERATURE REVIEW

Zeytinoglu (2009) conducted a study to determine the weibull distribution parameters for a material that is being used as the printing unit of a photocopier. Graphic method, least squares method, maximum likelihood method and moment method were used for parameter estimation. At the end of the study, results of methods were compared. Kurban, Kantar and Hocaoglu (2009) used weibull distribution for analyzing wind speed and wind power. Moment method was used for parameter estimation. Razali and Al-Wakeel (2013) used mixture of two or three parameters Weibull distributions for fitting failure times. Maximum likelihood estimation method was used for estimating the parameters. Kurz, Lewitschnig and Pilz (2014) carried out a study to determine the weibull distribution parameters by using advanced Bayesian model. Time-to-failure and discrete failure count data belongs to burn in period were investigated for parameter estimation. Tan (2008) developed a new approach for two parameter weibull distribution parameter estimation to cope with interval data. Maximum likelihood estimation method was used for parameter estimation. Demonstration and validation of the approach were shown with data generated by Monte Carlo simulations. Zhang and Dwight (2013) performed a study for choosing an optimal model for failure data analysis by using graphical approach. Different shapes of plots on Weibull probability paper were created by using data. Selection of optimal model for failure data analysis is based on the shapes of the fitting plots. Abbasi, Jahromi, Arkat and Hosseinkouchack (2006) conducted a study to determine the weibull distribution parameters by using simulated annealing algorithm. Hung and Chang (2011) carried out a study for determining the mixed-weibull distribution parameters. Moment method and regularization type of fuzzy clustering algorithm were used for parameter estimation. Chu and Ke (2012) performed a study to determine the weibull distribution parameters. Least squares method and maximum likelihood estimation method were used for parameter estimation. Performance of two methods was evaluated via numerical simulation. Kaplan (2016) used weibull distribution and rayleigh distribution for analyzing wind energy potential of Osmaniye city. Moment method and graphical method were used for parameter estimation.

3. MAINTENANCE

Maintenance covers all the actions carried out to repair or to ensure that a unit, part or equipment continues to work under certain conditions (Dhillon, 2002). With regard to production systems, maintenance activities are those that are carried out so that all production systems or certain equipment are in working order. This definition shows that maintenance function covers not only intervention to a failure but also proactive tasks such as routine inspection, preventive maintenance, replacement and condition monitoring.
Various decisions related with specifications, purchasing, planning, operating, performance evaluation, development, replacement and scrapping are made for every stage of the life curves of various technical systems such as factories, machinery, equipment or plants within the scope of maintenance management. Maintenance management is thus the management of physical assets based on this wide perspective (Köksal, 2007).

3.1. Corrective Maintenance

It would be wiser to explain the concept of failure prior to corrective maintenance. Failure is the stopping of a system or the decrease in production rate and/or quality due to an unpreventable reason. In this method, intervention or repair is carried out after the failure. The machine or machines stop until repair. Maintenance crew and maintenance workshop strive to start the production system in the shortest possible time. Spare machines or spare parts are put into use if any so that the line continues working.
In corrective maintenance, a machine does not go through maintenance unless there is a failure. Other maintenance works are carried out with the repair when there is a failure. Most of the repairs are quick-fixes that are made to ensure that the failed part is repaired and that the machine continues to operate. These companies operate as minimum repair and work with professional maintenance companies for large maintenance-overhaul works. This is a management approach that minimizes maintenance crew and material costs (Köksal, 2007).
Corrective maintenance is observed most frequently in the following cases (Köksal, 2007):

- Small workshops with general purpose universal workbenches,
- Facilities that are planned to be sold out because they have become outdated or idle due to the changes in the market,
- In cases when there is more than one spare equipment in the facility (e.g. when there are three parallel connected equipment and one of them fails)
- Activities that support main production (forklift, compressor and similar equipment)

3.2. Preventive Maintenance

In this method, the machinery equipment, buildings or facilities go through inspection at certain periods and before any failure arises and protective activities such as machinery adjustment, cleaning, part replacement, painting and other minor repairs are carried out if necessary. It is a preventive activity (Köksal, 2007). Preventive maintenance should have the following properties (Köksal, 2007):

- Oiling: An oiling program should be included in all preventive maintenance policies. It should be carried out with trained personnel.
- Inspection: The condition of machinery equipment is under constant control with regular inspections. It should be decided to stop the machine for maintenance prior to the arising of any changes due to heat, vibration or wear.
- Programmed power off or maintenance: It is the planning of short or long term general maintenance or power off maintenance work. Transfer workbenches, heat treatment ovens, presses and reactors for short term.

The preventive maintenance activities listed above are generally carried out outside the production hours so that the operation is not stopped.

4. FAILURE DISTRIBUTIONS

When the failures in a system or component are recorded, it will be observed that the failure data fit a certain statistical distribution. When the current failure data are evaluated statistically, it will fit a distribution and the parameters of that distribution will take on values. The parameter values of the distribution will yield the

failure distribution of the related system or component. Based on this information, failure times will be estimated and maintenance planning will be made.
Even though there are many models used for failure distribution, the most widely used are weibull distribution, exponential distribution and normal distribution.

4.1. Weibull Distributions

Weibull distribution was put forth by Waloddi Weibull in 1951 in order to estimate the life times of machines. Today, it is used in the statistical models that are part of the science of engineering as well as in life data analysis. Weibull distribution is widely used in models that will be set up for the data set related with failure ratios which in some cases has a Rayleigh or exponential distribution based on the values that the shape parameter takes.
In general, the Weibull distribution is one that has a scale and shape parameter. The two parameter weibull probability density function is given below:

$$f(T) = \frac{\beta}{\eta}\left(\frac{T}{\eta}\right)^{\beta-1} exp\left[-\left(\frac{T}{\eta}\right)^{\beta}\right] \quad (1)$$

Here, f(T) ≥ 0, T ≥ 0, β > 0, η > 0 and β is the shape parameter, η is the scale parameter. The two parameter weibull cumulative distribution is given below:

$$F(T) = 1 - exp\left[-\left(\frac{T}{\eta}\right)^{\beta}\right] \quad (2)$$

One of the parameters of the Weibull distribution is the shape parameter and the reason for various different distributions is the value that the shape parameter takes. Failure rates increase over time when the slope value ranges between 0 and 1, that is when 0 < β <1. As a special case, when β =1, "f(T)=1/η exp(-T/η)" distribution is an exponential distribution. Here, "1/η =λ" represents the failure rate. When β = 2, it becomes the rayleigh distribution (Zeytinoğlu, 2009).

5. DETERMINING THE PARAMETER VALUES OF THE DISTRIBUTION

Statistical models mostly depend on data for estimations. The accuracy of any estimation depends on the completeness and quality of the data to be used. A good estimation can be made when a good data set is combined with the right model. The data that we will use when determining the parameter values of failure distribution may not be complete, they may include some uncertainties. Thus, we can classify the data used for analysis as complete data and censored data.

5.1. Complete Data

Complete data means that every sample unit has been observed and is known. For example, if we are testing five units and if all five of these units have failed during testing then it means we have complete data (http://reliawiki.org/index.php/Life_Data_Classification, 03.06.2013).

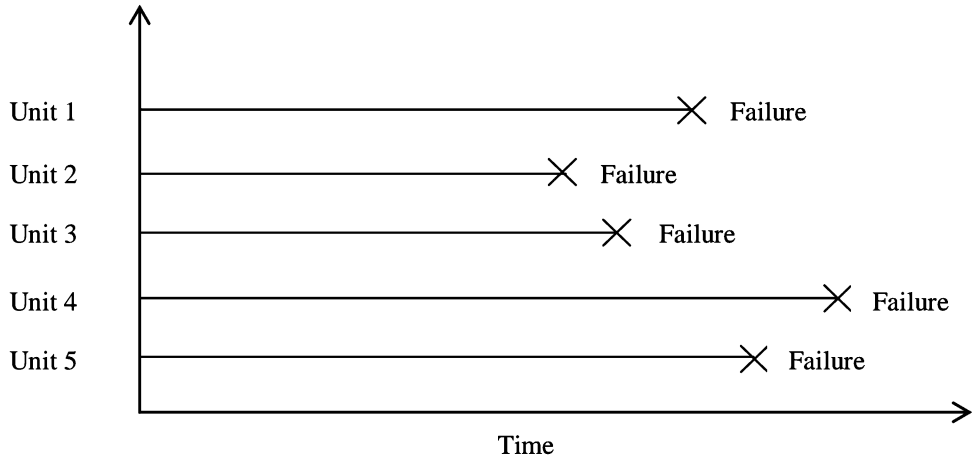

Figure 1: Complete Data

5.2. Censored Data

In many cases, not all sample units fail during testing or there may be instances when we cannot detect the exact time of failure. Such data are known as censored data. There are three types of censored data: right censored, interval censored and left censored (http://reliawiki.org/index.php/Life_Data_Classification, 03.06.2013).

5.2.1. Right Censored Data

It is the most common among censored data. For example, if we have tested five units and if only three of these units have failed until the end of the test, it means we have two right censored data (http://reliawiki.org/index.php/Life_Data_Classification, 03.06.2013).

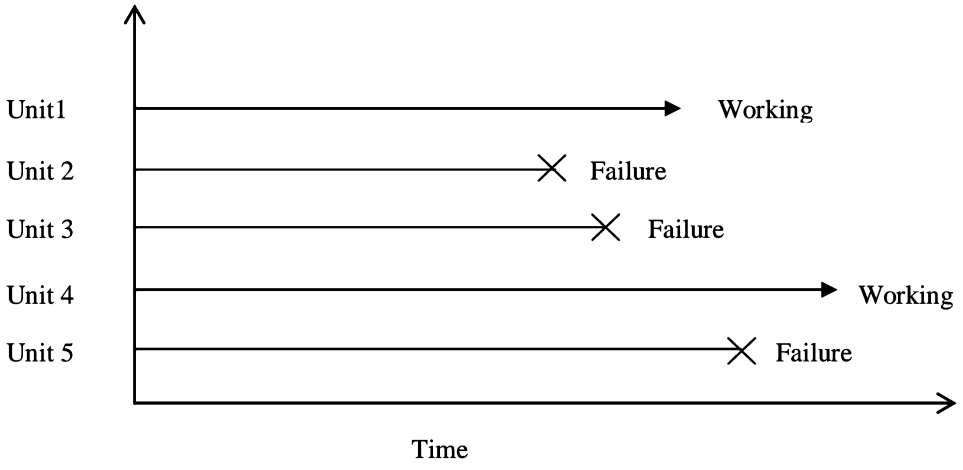

Figure 2: Right censored data

5.2.2. Interval Censored Data

Interval censored data represents the uncertainty regarding the time of failure of the tested unit. Thus, it is not certain when the unit has failed. This is observed in cases when the related unit is not under constant monitoring. For example, if we are testing 5 units and we observe these units every 100 hours, we can only know if the units failed between the observation times. If we are to give a more detailed explanation; if we observe that the unit is functioning at the end of the first 100 hours and that it has failed at the end of the second 100 hours, we can state that this unit has failed during 100-200 hours (http://reliawiki.org/index.php/Life_Data_Classification, 03.06.2013).

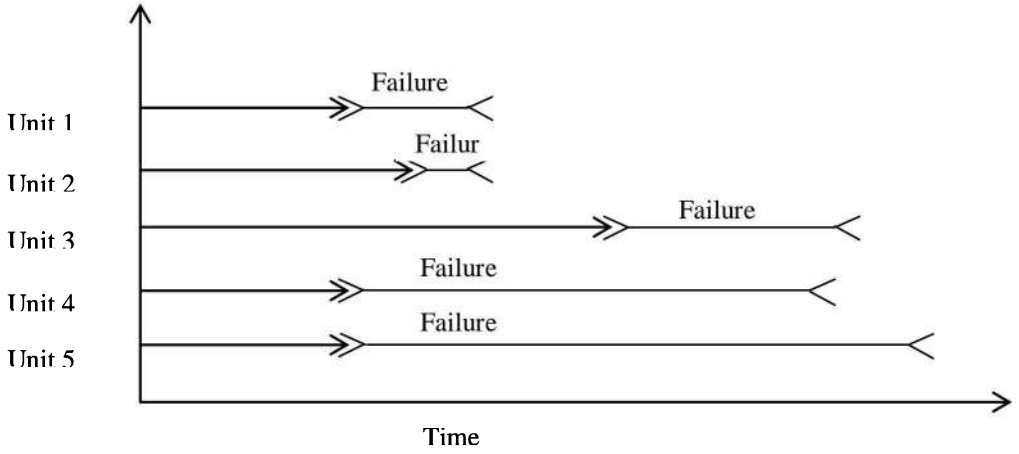

Figure 3: Interval censored data

5.2.3. Left Censored Data

For left censored data, we can know if the tested units have failed before a certain time or not. For example, we can state that the unit has failed before 100 hours, however we cannot give an exact time. In other words, this means that the unit has failed at some point in the 0-100 hour interval (http://reliawiki.org/index.php/Life_Data_Classification, 03.06.2013).

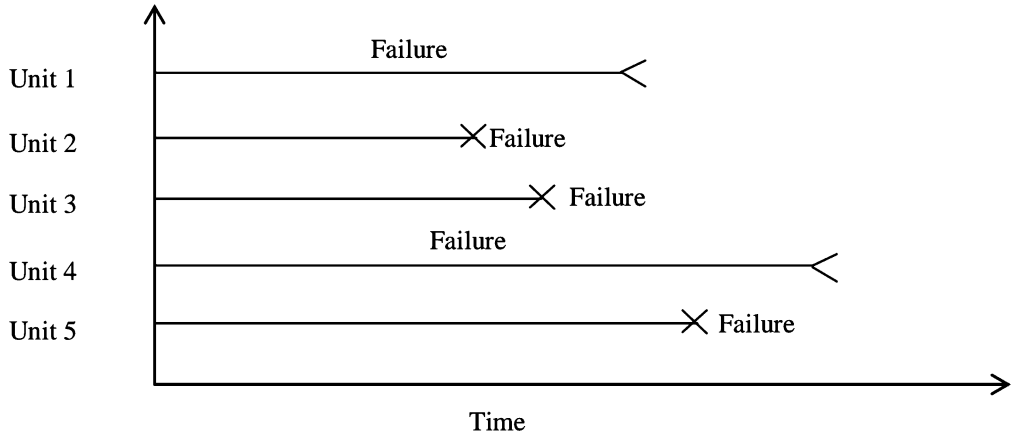

Figure 4: Left censored data

6. APPLICATION

Failures of banbury machines used in tyre manufacturing have been handled in the application. Banbury machines play an important role for tyre manufacturing process. Indeed, banbury machines failures significantly effect it.

Maximum likelihood estimation method, probability plotting, least squares method and moment method can be listed as methods used to estimate the parameter values of failure distribution. In this study, banbury machines failure data were used to calculate the weibull distribution parameter values using Minitab software in accordance with the maximum likelihood estimation method.

6.1. Maximum Likelihood Estimation Method

k and c are shape and scale parameters respectively in Weibull distribution. Maximum likelihood estimation is one of the methods used to calculate these parameters. Failure data comprise a set of n elements such as $v_1, v_2, \dots\dots\dots\dots v_n$ when using this method. The probability of $V = v_i$ in the observation is proportional with $f(v_i; k, c)$. Similarly, the probability of events occurring can be expressed as $V = v_1 \dots\dots V = v_n$. Since the events are independent of each other, the probability of events $L = \prod_1^n, \dots\dots V = v_n$ occurring can be written as such:

$$L = \prod_1^n f(v_i; k, c) \tag{3}$$

Scale parameter;

$$c = \left[\frac{\sum_{i=1}^n (v_i)^k}{n}\right]^{\frac{1}{k}} \tag{4}$$

Shape parameter;

$$k = \left[\frac{\sum_{i=1}^n v_i^k In(v_i)}{\sum_{i=1}^n v_i^k} - \frac{\sum_{i=1}^n In(v_i)}{n}\right]^{-1} \tag{5}$$

is obtained with these equations.
It is difficult to solve the equation since it is iterative. Hence, it is not a method used before modern technology (Akdag and Guler, 2008).

6.2. Determination of Failure Distribution Parameters

The analysis was conducted with dip tank failure data of banbury machine which is used in tyre manufacturing. Failures of dip tank are of crucial importance for banbury machine because they affect running of the system substantially. Banbury machine has a dip tank. Failure data of the dip tank was recorded for 365 days. 35 dip tank failures are available during the analysis period Thus; we have 35 complete data.

Failure data of the dip tank have been entered in the Minitab software and the weibull distribution parameters for it have been determined. “Failure” expression was used for complete data while entering the failure data into the software. Parameter values for the two parameter weibull distribution have been determined as β=0,287 and η=38,8481 in hours. In addition, the mean time to failure value for the dip tank has been determined approximately as 440 hours. In other words, the average life of it is 440 hours. The screenshot of the software used for analysis has been given below:

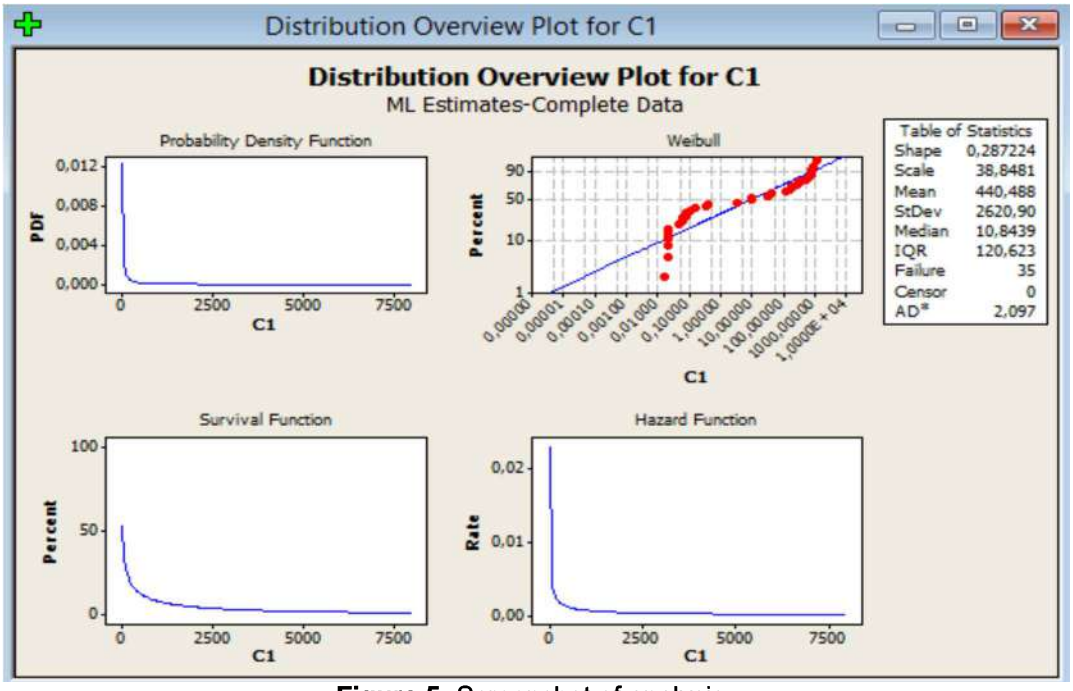

Figure 5: Screenshot of analysis

7. CONCLUSION

Planning of spare parts, labor and equipment to be used in maintenance activities has to be carried out accurately in order to ensure that the planning activities are executed in a planned manner. It is possible to do this for preventive maintenances, because the maintenance times are predetermined. However, the maintenance time is not certain for corrective maintenance activities since it is not known beforehand when a failure will arise.

In this study, failure data of banbury machine used in tyre manufacturing have been used to determine the failure distribution parameters via Minitab software in accordance with the maximum likelihood estimation method. In this way, failure times will be estimated and corrective maintenances will be carried out in proper manner. Since the spare part, labor and equipment planning will be carried out in accordance with this estimated value.

8. FUTURE WORK

While determining the failure distribution parameters, failure data can include some uncertainties. In other words, left censored data, interval censored data and right censored data can be available in data set. Therefore, effects of censored data for failure distribution parameters can be investigated in future works.

Abstract: *Most firms in the Western Balkans region manage only some portion of their performances due to the lack of understanding of the overall organizational performance concept. The result is an empty space that represents a potentially tremendous opportunity for managers wishing to fill the gap between their firms' current and desired level of performance. The paper starts with a theoretical background aimed to increase the practitioners' understanding of performance systems and management concept by integrating three levels of organizational performances into one comprehensive framework. This literature review sets the stage for empirical investigation conducted in 22 firms in the 5-years period that showed that, even though all the firms from the sample have some sort of performance system at strategic level, operational and individual level of performance are mainly not covered. Therefore, most of the firms are not in the position to effectively and systematically manage their performances, which is a necessary condition for their long term development. In order to remedy this situation, management will have to increase the awareness about the concept of the overall organizational performance in their firms, develop a proper performance management methodology, and bridge the gap in knowledge and skills related to performance management that resides in their employees.*

Keywords*: performance management, process, indicator, measurement, Western Balkans*

1. INTRODUCTION

Survival of firms depends on their overall performance. It is no longer viable to focus on some specific aspect of performance, such as production performance, financial performance, or sales performance. In order to stay competitive over the long run, firms must take a much broader view. They have to start tackling the performance issue holistically. More specifically, they need to grasp the complexity of their business, take a multidimensional perspective on performance, define various measures, conduct measurements, acquire and analyze the results, and perform specific actions accordingly. Thus, a lot of work is ahead of managers willing to manage the overall performance of their firms.

However, one must recognize the difficulties on this journey. One of the biggest roadblocks is the fact that it is not possible to measure social phenomena, such as those considering firms and their overall performances, with anything close to accuracy that characterizes the field of science. In line with this argument, Wholey (1996) states that performance is not an objective reality waiting to be measured and evaluated, but rather a socially constructed reality that exists in people's minds. Therefore, designing and implementing a performance management system within a firm is not an easy task. It is a very complex and time consuming effort that requires both imagination and analytical skills.

Considering these facts, it is no wonder Taticchi (2008) claims that interest in performance management has notably increased over the last 20 years (cited in Taticchi, Tonelli & Cagnazzo, 2010). Nevertheless, even though results of impact of this increased interest are mixed, it might be argued that its practical implications have not yet reached the benefits expected. For example, the results of a survey of 278 organizations from 15 countries, out of which about two-thirds are multinational corporations, showed that around 91% of them have established some form of performance management system. Survey findings revealed that organizations with formal and systematic performance management systems are 51% more likely to outperform their competitors regarding financial outcomes and 41% regarding additional outcomes including customer satisfaction, employee retention, and other important metrics (Casio, 2006). On the other hand, a public survey conducted recently by Deloitte revealed that more than half of the executives questioned (58%) believe that their current performance management approach drives neither employee engagement nor high performance (Buckingham & Goodall, 2015). These findings show that, even though some level of success with performance systems implementation is evident, current performance management systems have to be reexamined and modified in order to serve their purpose in a more holistic manner.

The purpose of this paper is to provide evidence to the managers in the Western Balkans about the existence of a wide gap between their practice (performance systems currently employed by their firms) and the overall organizational performance system. Therefore, its goal is twofold: (1) to depict the framework for overall organizational performance system in order to help managers understand this concept and benefits of its implementation (achieving this goal might be of interest to practitioners working worldwide), and (2) to set out to explore the current conditions of performance management in firms operating in Western Balkans region (the part of paper dedicated to this goal might be more interesting to practitioners working in Western Balkans). The paper starts with theoretical background in which the concept of performance management and overall organizational performance system is explained. The next part depicts the research conducted in firms operating in Serbia, FYR Macedonia, and Bosnia and Herzegovina between 2011 and 2015, as well as its results. The section considering practical guidelines regarding implementation of an overall organizational performance system in the firms follows. The paper ends with conclusion remarks.

2. THEORETICAL BACKGROUND

Firm performance indicates the quality of the firm's continuous co-alignment with the environment (Chakravarthy, 1986). On the other hand, performance management is seen as a tool that helps management improve organizational performance (Aguinis & Pierce, 2008) by providing them more control over a firm, which is in line with de Waal's (2010) argument that there is a clear and strong relation between organizational performance and the attention given to management control.

Performance management system may be regarded as a set of formal, information-based routines and procedures managers use to maintain or alter patterns in organizational activities (Simons, 2000). This system focuses on conveying financial and non-financial information that influence decision making and managerial action (de Wall, 2010). It is a balanced and dynamic system that enables support of decision-making processes by gathering, elaborating and analyzing information (Neely, Adams & Kennerley, 2002). The term "balance" refers to the need of using different perspectives and measures with both leading and lagging indicators that, tied together, provide a holistic view of an organization (Kaplan and Norton, 1992; Kaplan and Norton, 1996). On the other hand, "dynamicity" refers to the need of developing a system that continuously monitors the internal and external context and reviews objectives and priorities (Bititci et al., 2000).

Performance-based management includes developing a reasonable level of agreement on goals and strategies for achieving goals, as well as developing performance measurement systems that provide data that are sufficiently complete, accurate, and consistent to document performance and support decision making (Wholey, 1999). Performance may focus on inputs (money, assets, workforce, etc.), processes itself or some of their parts or activities (lead time, cycle time, etc.), or outputs (products or services delivered to the customers). It may focus on a variety of complex indicators that put different indicators in some sort of relations, such as efficiency or productivity which relate output to input. Performance may also focus on intermediate outcomes such as client satisfaction or end outcomes such as environmental quality or health status (Wholey, 1999). On the other hand, Simons (2000) argues that performance management systems cannot be designed without taking into consideration human behavior. Thus, it is not enough to observe only the hard elements of performances, i.e. what is being done, but also the soft components, i.e. the manner in which it is done.

That being said, no wonder that in the late 1980s and early 1990s dissatisfaction with traditional backward looking accounting based performance measurement systems led to the development of more complex, holistic and balanced measurement frameworks (Bourne et al., 2000). The need for an integrated approach to performance management based on systems thinking (Senge, 1990) was recognized. Instead of an isolated approach to one dimension of performance, the focal point became an integration of all components of the system and mapping the relationships between them (Brudan, 2010).

In order to secure its viability over the long run, the majority of firms need a management system based on overall organizational performance. Lawrence and Lorsch (1967) further elaborate this argument by stating that "it is clear that total organizational performance is... related to achieving the degree of integration between subsystems required for the overall organizational task of coping with the external environment." (p. 11) Therefore, the task of designing, implementing and managing overall organizational performance system seems quintessential for the success of any firm.

Overall organizational performance system is a very complex network of various indicators organized into three basic levels: strategic, operational and individual (cf. Brudan, 2010). At strategic level, performance management deals with the achievement of overall organizational goals. This level is crucial for the long term

adaptation to the environment, especially in situations in which management ought to pay attention to a large number of variables in the environment and their volatile dynamics (cf. Stefanović, Prokić & Vujović, 2012). Performance management at operational level covers end-to-end processes, i.e. the manner in which the value is being created for the end-users. This level acknowledges the processes as the driving force of any firm (Hammer & Champy, 1993), while adopting the customer's point of view (Davenport, 1994). The third level of performance is oriented on individuals. It covers the manner in which their day-to-day activities are being performed and the results achieved.

These three levels of performance ought to be seen as inextricably intertwined parts of the same system, even though in practice this is rarely the case. "Practice shows that communication and integration between the three levels of organizational performance is limited... Management does not see performance management as an integrated discipline used at various organizational levels, but as a subcomponent of strategic, operational and HR management respectively. An integrated approach, linking together all levels of performance management, becomes a necessity for both research and practice to facilitate the understanding and usage of performance management systems... This proposed integrated view to performance management has the potential to assist individuals and organizations to better understand and align these levels and create a complete, holistic picture of performance that outlines the relationship between organizational and individual performance." (Brudan, 2010, pp. 117-119). Having in mind the importance of having one integrated and overall performance system in place, we will elaborate on each of the three performance levels.

2.1. Strategic performance level

Strategic level emphasizes the firm's relationships with its environment and the basic "skeleton" of the major functions that comprise the firm (Rummler & Brache, 2013). In other words, strategic level is focused on strategic goals, i.e. the goals covering the whole firm as a part of its business strategy. These goals are then broken down to subgoals for each function. Only by taking a holistic stand and viewing the firm as a whole, its subgoals will not permit the optimization of the functional silos. Therefore, each subgoal ought to be derived from one of the strategic goals and be aligned with it.

The performances at this level are being measured by the percentage of achievement of strategic goals and subgoals. Only after the measurement results are obtained and analyzed, the discussion regarding further actions may start. Of course, this discussion must incorporate the results obtained from the other two levels of performance as well. Considering strategic level solely will not provide comprehensive information, which may jeopardize the effectiveness of further actions.

Strategic goals and accompanying functional subgoals may only be achieved through the hard work being done by every employee of the firm. In other words, strategic performance level needs to be integrated with other levels of performance in order to establish and manage the overall performance management system. Only in this way will strategic performance system gain its full relevance.

2.2. Operational performance level

Focusing on strategic level performance by itself will not provide a significant level of understanding of how the firm actually works. For this to happen, on must probe deeper into the firm's "skeleton". This deeper level will show the processes, which may be understood as the manner in which a firm does its work, i.e. the set of activities it pursues to accomplish a particular objective for a particular customer, either internal or external (Davenport, 2005). Operational performance level relates process performance and the customer satisfaction level resulting from it (Davenport, 1994). Taking the process standpoint in firms is likely to yield certain benefits in terms of the overall performance (Davenport & Stoddard, 1994).

Rummler and Brache (2013) argue that a firm is only as effective as its processes. Therefore, operational performance level shows whether the work is done effectively and efficiently enough. The first step on this level is to identify all the processes being run within a firm and the relevant process performance indicators. These indicators are derived either from process goals or from the means of achieving these goals, i.e. subgoals. Each of these goals ought to be congruent with enterprise wide goals, take into account the behavior of the competitors and, last but not least, be in line with process stakeholders' interests. It is very important to emphasize that process performance represents a degree of stakeholder satisfaction, which is why process performance measurement ought to be focused on those individuals who have an interest in the business process. In order to develop this stakeholder-driven performance measurement system, stakeholders of the process have to be identified and their process-relevant goals clarified. Each group of stakeholders needs to be represented by an aspect or dimension of performance (Kueng, 2000).

Measuring the process performance is critical for process improvement and excellent process management is based on suitable performance measures (cf. Chiou-Shuei, 2014; Crandon & Merchant, 2006). Once there is a reasonable level of agreement on the meaning of performance, managers can obtain information on key aspects of process performance through performance measurement, that is, the periodic measurement of specific inputs, activities, outputs, intermediate outcomes, or end outcomes. Performance measurement includes both the collection and analysis of numerical data and less formal assessment of performance such as narrative assessment of the extent of progress toward defined goals (Wholey, 1999). "The main objective of process performance management system is to provide comprehensive and timely information on the performance of business processes. This information can be used to communicate goals and current performance of a business process directly to the process team, to improve resource allocation and process output regarding quantity and quality, to give early warning signals, to make a diagnosis of the weaknesses of a business process, to decide whether corrective actions are needed and to assess the impact of actions taken." (Kueng, 2000, p. 72).

2.3. Individual performance level

Stopping at the operational level would hinder the understanding of performance on the most granular level: an employee and the work he or she performs. Rummler and Brache (2013) argue that "performance can be improved only if jobs and performers are analyzed in an overall performance context." (p. 62) Therefore, focusing on each individual within a firm is an essential task if one wants to gain a holistic view on performance.

Performance management system on the level of employees can be based on a consideration of behavior (how work is being done) or results (outcomes of work). Of course, combination of both is possible as well (Aguinis & Pierce, 2008). When it comes to work, Rummler and Brache (2013) advocate so-called "Human Performance System" (HPS), which may be one of the best approaches for managing the performance on individual level. TPS contains the following elements (Rummler & Brache, 2013): (1) input in terms of task support, (2) performer with its skills, knowledge and capacity, (3) output in terms of performance specifications, (4) consequences of reaching or not reaching the desired performance, and (5) feedback in terms of information about the performer's performance. Each of these elements is being permanently assessed for each employee within a firm.

TPS approach implicitly states that performance problems occurring at individual level may only sometimes be attributed to the employee. Rather, it supports the claim of W. Edwards Deming that employees are responsible for only 15 percent of the problems, and the system for the other 85 percent, which is the responsibility of management (Walton, 1986).

3. RESEARCH METHODOLOGY

The research question this paper is trying to answer is the following: Where do firms operating in the Western Balkans region stand on the road toward implementing the overall organizational performance system? The starting premise that helped authors embark on this journey is that most firms in Serbia and surrounding countries do not have an integrated, holistic system of measuring their performances on a regular basis. Instead, they usually rely on a set of financial measures based on traditional accounting systems. In other words, there is some sort of natural inclination to use the conventional financial data such as: profit, revenue, change in profits, change in revenues, percentage of new products in total sales, and so forth (cf. Lawrence & Lorsh, 1967, p. 25-26). This approach, besides measuring only one dimension of firm performance, focuses on lagging indicators and looks at the performance already achieved, i.e. retroactively. Non-financial aspects of firm performance, such as customer satisfaction or job satisfaction still play a modest role (cf. Eccles, 1991).

Authors' experience is that management tool mostly used in firms operating in Western Balkans is the quality management system certification according to ISO 9001 requirements, which somewhat guarantees that firms identify and execute their business processes in a specified and controlled way. Following this reasoning, the authors seized the opportunity to investigate the current state of the performance systems in firms operating in Western Balkans region during the time one of the authors spent as a management systems consultant and auditor. While running these consultancies and audits, this author acquired the relevant information on numerous firms, which make the majority of the sample collected. The other author has brought his own insights and relevant information from several other firms while working for them. Even though the sample of firms is selected on the "easy to obtain" criterion, thus resulting in the convenience

sample, authors believe it is still indicative for the current state of the whole population of firms in the region, which might be confirmed by some other research that would use the representative sample.

This research was carried out in the period between 2011 and 2015 on a sample of 22 firms operating in three countries of the Western Balkans region (Serbia, Bosnia and Herzegovina, and FYR Macedonia). All the firms in the sample have more than 250 employees, which classifies them in the group of large firms according to the current Accounting Law (Službeni glasnik, 2013). Only large firms have been taken into account because their scale allows them to recognize the need and have the necessary resources for implementing performance management systems.

The names of the firms in the sample will remain undisclosed due to confidentiality reasons. However, some details on the structure of the sample ought to be presented. First of all, the number of firms per country (Serbia, Bosnia and Herzegovina, and FYR Macedonia) ought to be revealed. Table 1 shows these numbers.

Table 1: Number of firms per country of their operations

Country of firm's operations	Serbia	Bosnia and Herzegovina	FYR Macedonia	Total number of firms
Number of firms per country	15	2	5	22

Secondly, the relevant data about each firm in the sample have been obtained in one year only during the period 2011-2015. Table 2 indicates from how many firms per year during this period the data have been obtained.

Table 2: Number of firms from which the data have been obtained per year

Year of data collection	2011	2012	2013	2014	2015	Total number of firms
Number of firms per year	5	4	6	1	6	22

Thirdly, there are differences in the number of employees per firm, which is why four categories have been identified and firms have been classified accordingly. This is shown in Table 3.

Table 3: Number of firms per their size in terms of employees

Number of employees	251-500	501-1000	1001-2000	≥2001	Total number of firms
Number of firms in the category	10	8	3	1	22

Finally, the firms in the sample operate in various industries and Table 4 indicates the number of firms per industry. For the purpose of industry classification, NACE classification of economic activities has been used (Eurostat, 2008). Even though some of the firms in the sample perform activities in more than one industry, which means they have more than one code, only the code for principal industry has been used.

Table 4: Number of firms per industry

Section	**Industry title**	**Number of firms**
B	Mining and quarrying	3
C	Manufacturing	10
F	Construction	3
H	Transportation and storage	1
J	Information and communication	2
K	Financial and insurance activities	1
N	Administrative and support services activities	1
P	Education	1
Total number of firms		22

After explaining the manner in which the sample has been obtained, as well as the structure of the sample, the criteria for assessing whether a firm has performance system implemented and at what level the performance is being managed ought to be depicted. In other words, what have the authors done with the collected data? How have they assessed if the firm has implemented performance system at some level?

The criteria for stating that a firm has some form of performance system have been defined as follows:

- Strategic performance level exists if at least 50% of the organizational units at the highest level of hierarchy (usually functions or divisions) have formally defined some sort of metrics (usually in the form of goals and objectives) and take obvious actions toward achieving it.
- Operational performance level exists if at least 50% of all the processes being run in the firm are formally identified and mapped, as well as have some sort of metrics established (usually in the form of KPIs with the associated targets) and obvious actions toward achieving it are being taken.
- Individual performance level exists if for at least 50% of positions (not employees/performers) there is some sort of metrics established that takes into account the performer with his/her behavior (how work is being done) and/or results (outcomes of work), as well as a system surrounding and influencing the performer's performance (adequate inputs, timely feedback, etc.) with the targets defined and obvious actions toward achieving them are being taken.

After depicting the firm sample details and explaining the criteria for identifying whether a firm has a performance system in place at some of the three levels, we will now turn to the results obtained and discuss their implications.

4. RESULTS AND DISCUSSION

Results obtained on the sample of 22 firms operating in three countries in the Western Balkans region are shown in the Table 5.

Table 5: Number of firms with established performance systems per three levels

The level of performance	Strategic	Operational	Individual
Number of firms with established performance system	22	12	1

Even though these results were somewhat expected, what came as a surprise was the fact that more than half of the firms in the sample had some sort of performance system on operational level. Based on their experience, both authors believe that the vast majority of firms operating in Serbia and surrounding countries have not yet completed a proper process identification and mapping, which is a necessary precondition for any kind of process performance system development. In other words, the results obtained at the operational level seemed misleading.

This is why further insights had to be developed. Since it was not possible to go back to the firms from the sample and conduct further investigations, authors have decided to interview some of the people working at those firms. Very quickly, a plausible explanation has been offered.

A number of firms for which the results showed they had operational performance systems in place were actually making those systems only for the purpose of the management systems certifications (e.g., ISO 9001, ISO 14001, BSI OHSAS 18001, etc.). Thus, these systems were actually nonexistent except on paper. Other firms from this sample had these systems in place, only not for the purpose of performance improvement, but rather merely for making more or less complex management reports, while the improvement actions would usually be omitted. It is interesting that the reason for making these reports was often unknown or found in some request from management in the past, but has not been assessed in the light of changing circumstances since then, which indicates the high level of organizational inertia (cf. Stefanović et al., 2014).

This kind of logic for making performance systems resulted in two more negative aspects. First, the performance indicators were not designed in order to reflect the needs of the customer and the accompanying process logic, which is why they were made static, i.e., they were not subjected to the changes in order to reflect the numerous shifts in the environment. Secondly, there was no alignment between the performance indicators on strategic and operational level (the results showed that only one firm had performance system established at individual level). There was not even an alignment between

performance indicators on the same level due to the fact that each organizational unit was usually developing its own indicators without taking the perspective of the whole firm or end-to-end processes.

This situation led the authors to the conclusion that true performance systems did not exist at operational level in majority of firms from the sample. Their processes were not being managed systematically through a set of performance indicators. Since performance systems did not exist at individual level either, it became clear that these firms had performance systems established only at the strategic level. On this level, performance indicators were being defined, measurements conducted and improvement actions taken.

5. RECOMMENDATIONS FOR PRACTITIONERS

The results from the investigation depicted in the previous sections show a low level of commitment in the firms operating in Western Balkans toward performance systems design and implementation. Taking this into account, authors can only assume this is attributed to the lack of general understanding of the performance system concept. Therefore, it is clear that something has to be done in order to remedy this situation if these firms are to thrive in the future marketplace.

The path toward designing and implementing the overall performance system is not an easy one. It must start with increasing the level of understanding of all key stakeholders about the concept of performance system and the benefits of its implementation. After all the stakeholders are acquainted with this and their approval is obtained, the work on designing the performance system may begin.

The design effort ought to start on the strategic level with the strategic goals. These goals are then broken down to subgoals for each function or division. After that, the subgoals are treated as targets that must be met by the processes being run within a firm. The processes are being mapped and performance indicators defined, starting from the process targets and moving backwards toward the upstream activities. Of course, each process performance indicator ought to have its own accompanying target in line with the process targets. The next step involves positions in charge of the activities comprising these processes. After identifying the responsibilities of each position within the processes in stake, performance indicators are being defined reflecting the performer's behavior and results, as well as a system surrounding and influencing the performer's performance (adequate inputs, timely feedback, etc.).

Only the performance system that links performance indicators from the top of a firm to its operating core and spreads throughout an entire organization may provide significant potential for radical performance improvement. Thus, every individual in a firm has to be fully covered by the performance system, which means that performance of every employee will be connected to the performance of every other employee. The resulting network of performances represents the system for measuring and improving the overall organizational performance.

Development, implementation and management of an overall performance system requires: (1) sound measures that ensure the right things are being monitored, (2) a total measurement system, not a collection of unrelated and potentially counterproductive measures, and (3) performance management process that converts the data provided by the measurement system into intelligent action (Rummler & Brache, 2013).

In line with this, it is useful to note that, while designing a performance system in a firm, one must take into account the concepts of business process management (BPM) and business intelligence (BI). BPM is focused on improving a firm performance by managing and optimizing its processes (cf. Panagacos, 2012), while BI brings value to managerial decisions by allowing them to easily identify, collect and interpret large volumes of data (cf. Rud, 2009). These concepts ought to be linked to performance management design from the start: BPM in the area of process identification and mapping, BI in the area of collecting the right data, their measurement and analysis, and BPM again in the process optimization phase. This is being emphasized due to the results of a research conducted in one of our neighboring countries by Vukšić, Bach and Popovič (2013). These results show that the usage of BPM and BI is not orchestrated within the framework of performance management.

5. CONCLUSION

Firms in Western Balkans region, specifically in Serbia, Bosnia and Herzegovina, and FYR Macedonia are on the very beginning of the road toward performance management. Even though some sporadic attempts have been made in this direction, there is a huge amount of work still left to be done. First of all, there is a need to increase the awareness about the concept of the overall organizational performance as a tool for achieving higher states of competitiveness. Secondly, a proper performance development and

implementation methodology has to be taken into account and tailored to suit the needs and possibilities of each individual firm. Finally, the gap between required and current level of the employees' knowledge and skills related to performance management ought to be identified and bridged.

Management in firms operating in Western Balkans must embrace the fact that if they wish their firms to continue to grow and develop in the long run, they will have to be able to manage the overall performance of their firms, not just some part of it as has been the case until now.

Abstract: *Lean applicability in ETO operations has been questioned by many authors. The results of recent research state that more empirical evidence is needed in order to rule in favor or against lean applicability in ETO environment. This paper presents results of action research, where efficiency of ETO company was improved through lean implementation. Lead times were reduced and delivery reliability was improved, thus adding to the fact that lean can be used for improving efficiency of ETO operations. Lean was implemented through tool-agnostic approach, where implementation was based on laws and principles that define lean, rather than specific tools. This approach provides implementation universality, and takes into account characteristics of specific manufacturing environment.*

Keywords*: engineer-to-order (ETO), lean, efficiency improvement, operational performance, empirical research*

1. INTRODUCTION

The emergence and popularization of lean is considered as one of the most important steps in the development of operations management (see e.g. Hines et al., 2004; Holweg, 2007). Lean can be defined as a continuous effort aimed at eliminating waste and sources of waste. Lean has helped many manufacturing companies around the world to realize significant gains in efficiency (see e.g. Womack et al., 1990; Womack & Jones, 1996; Slović et al., 2015). Still, most examples of efficiency improvement come from manufacturing environment similar to the one in which lean was originally developed in terms of product variety, volumes produced, and component assembly nature (i.e. repeated manufacturing of limited array of similar products in relatively high volumes). Some authors state that, in the future, lean research will abandon traditional manufacturing environment and focus more on areas such as high-mix/low-volume operations, thus moving from prescriptive application to contingency-led approach (Hines et al., 2004; White & Prybutok, 2001; Papadopoulou & Özbayrak, 2005). Engineer-to-order (ETO) operations represent high-mix/low-volume environment that is considered under-researched regarding lean implementation (Hines et al., 2004). Lean strategies have been proposed in ETO sector. However, characteristics of ETO sector might differ significantly from the ones typically found with low-mix/high-volume manufacturers, and extent to which lean practices are suitable for ETO operations has been questioned (Cooney, 2002). Empirical evidence in support of or against lean implementation in ETO operations are fairly limited, any contemporary research suggests that more empirical evidence is needed in order to test the applicability of lean principles in ETO environment (Gosling & Naim, 2009; Naim & Gosling, 2011).

This paper presents the results of empirical research, where lean has been implemented in a company that represent typical ETO manufacturer, supporting the stance that efficiency of ETO operations can be improved through lean implementation. The reminder of the paper is organized as follows: literature review regarding lean, peculiarities of ETO operations, and lean implementation in ETO operations is presented in Section 2; research design is presented in Section 3; the results of empirical research are presented in Section 4; discussion and conclusion follows in Section 5.

2. THEORETICAL BACKGROUND

2.1. Lean manufacturing

Lean manufacturing originated in Toyota after Second World War as a result of scarcity of resources and intense domestic competition on automobile market (Hines et al., 2004; Hopp & Spearman, 2008). Toyota developed a system (Toyota Production System – TPS) that was able to produce greater variety of products with lesser inventory, human effort, investments, and defects (Womack et al., 1990). TPS was developed as an alternative to Ford production system, and often has been seen as a counter-intuitive approach that

differs significantly from then dominant mass production (Womack et al., 1990). It was developed and applied under the leadership of Taiichi Ohno (1988), and additionally documented by the likes of Monden (1983) and Shingo (1989).

Monden (1983) is largely responsible for bringing TPS to western audience. His book described in details Just-In-Time (JIT) manufacturing as one of the pillars of TPS (the other one being autonomation, or *jidoka*). Term 'lean manufacturing' was coined during the International Motor Vehicle Program (IMVP) research, which was aimed at bridging the performance gap between Western and Japanese car manufacturers. Waste elimination was recognized as a central role of lean manufacturing (Bhamu & Sangwan, 2014), where waste is any system input (transformed resources, transforming resources) that is not transformed into a system output (fulfilled customer demand, this is neither unfulfilled nor exceeded) just-in-time. Womack & Jones (1996) described lean as an antidote for waste, and devised 5 lean principles aimed at eliminating waste: value, value stream, flow, pull, and perfection. Lean was deemed to be universally applicable to wide array of business environments (Womack & Jones, 1996). However, many authors criticize lean for its lack of applicability in operations that differ significantly from low-mix/high-volume environment that lean was developed in (Cusumano, 1994; Hines et al., 2004). Tool based implementation, car-manufacturing focus, and inability to handle variations in demand were recognizes as lean's main weaknesses (Hines et al., 2004).

2.2. Lean implementation in ETO operations

ETO operations are considered as operations where decoupling point (stock holding point that separates the part of the supply chain that responds directly to the customer from the part of the supply chain that uses forecast planning; see e.g. Portioli-Staudacher & Tantardini, 2012) is located early in the supply chain, typically at the design stage (Gosling & Naim, 2009). It refers to the type of operations where customer actively collaborates in product design, in order to develop and manufacture a product that meets functional requirements of the customer (Birkie & Trucco, 2016). The output of ETO operations is highly customized product that may be a result of modified past design or an entirely new design for every customer (Portioli-Staudacher & Tantardini, 2012). The demand is usually unstable and unpredictable. ETO operations might be associated with large, complex project environments such as construction and capital goods that require extremely high work content and low volumes (Gosling & Naim, 2009; Potrioli-Staudacher & Tantardini, 2012). However, large proportion of ETO operations is conducted by small machine shops, where customer requires design and production of highly customized products in relatively low volumes. These types of operations are often labeled as non-repetitive operations (see e.g. White & Prybutock, 2001). ETO operations are characterized by a high level of dynamism and complexity that create environment that is heterogeneous and unpredictable (Birkie & Trucco, 2016). Traditionally, short concept-to-delivery time and high delivery reliability are deemed to be key priorities for ETO companies, rendering them order winning characteristics in addition to quality (Amaro et al., 1999; Portioli-Staudacher & Tantardini, 2012). Price is considered to be of secondary importance, and is usually seen as order qualifying characteristic (Amaro et al., 1999; Birkie & Trucco, 2016).

Lean is often used to address problems with long lead times and unreliable delivery in repetitive manufacturing environment with stable and predictable demand. This is why there's a rising interest in lean implementation in ETO companies. Although lean has been suggested as a mean for efficiency improvement in non-repetitive manufacturing, evidence about lean implementation in ETO operations is scarce. Many authors state that lean implementation requires stable and predictable demand, which is unlikely situation in ETO operations (Hendry & Kingsman, 1989; Hüttmeir et al., 2009). Some of recognizable lean tools (such as work cells, takt time, supermarket pool, etc.) are deemed to be inapplicable or even undesirable in ETO environment (Hendry & Kingsman, 1989; Cooney, 2002; Hopp & Spearman, 2008).For example, straightforward and effective tool such as value stream map might be difficult to implement since product flows are often interlaced, resources are being shared, and cycle times differ between different products. Quality at the source might be hard to obtain, since products are highly customized, making it hard to learn from past mistakes. Demand variability, both in volume and mix, makes it hard to level the production in way it is done in environment with stable demand (Lander & Liker, 2007; Stump & Badurdeen, 2009). This might lead to ETO managers questioning the importance that lean might have for non-repetitive manufacturers (Jina et al., 1997). Difficulties in lean implementation might have several causes: (i) knowledge of lean implementation in ETO operations is not as structured and systematized as in repetitive manufacturing; (ii) managers fail to recognize contextual factors of ETO operations, and try to copy lean practice from repetitive manufacturing; (iii) managers fail in understanding underlying principles of lean, and focus on tools; and (iv) there is no unique framework that will guide lean implementation in ETO environment. Many researchers state that evidence on lean applicability in ETO environment is yet to be found, suggesting that more empirical research is needed to support the effects that lean might have on efficiency of ETO operations (Gosling & Naim, 2009; Birkie & Trucco, 2016).

3. RESEARCH DESIGN

The main research question in this paper is:

Can lean improve efficiency of ETO operations?
This section presents the research design established in order to answer the research question. Research design is presented in two subsections. First subsection gives a description of a case company, and discusses the rationale of using single case study approach. Second subsection discusses research approach and step taken in order to obtain the answer to the research question.

3.1. Case company: rationale and description

The research focuses on a single company. Using single company can be appropriate if it provides an opportunity to observe and analyze a phenomenon previously inaccessible to scientific investigation, and if longitudinal approach is taken, i.e. if functioning of case company is analyzed over a considerable period of time (Yin, 2013).

Company ALPHA (real name is obscured) is selected as a representative of ETO operations. The company produces Point-Of-Sale (POS) and Point-Of-Purchase (POP) products such as shelves, displays, overhand dispensers, kiosk displays etc. Most products are produced on an ETO basis, where company performs all steps of product realization, from design and engineering, prototyping, to manufacturing and delivery. The company serves a turbulent marking, and has to deal with demand variability both in production volume and mix. Demand is irregular and unpredictable, while products are mostly one of a kind in regard to design and characteristics. The company is subject to all kinds of external influences. Most of them are coming from customers, who are trying to enforce their orders as the most important ones. Product routings vary in sequence and length, although the flow of material is considered to be directed. Production volumes are relatively small, as are orders from suppliers, which makes company subject to supplier influence as well. During the initial interviews with managers and employees, it was concluded that company is not as efficient as it could be. Although there was a 'feel' that operations are not as efficient as they could be, the exact data were not collected or analyzed. For example, lead times were considered long, but precise data on average lead times were not readily available. In addition, the company had difficulties to adhere to promised due dates, but the data on percentage of lateness and average lateness was not available either.

3.2. Research approach and steps

To analyze the possibilities of efficiency improvement in ETO operations, a longitudinal case study was carried out. A considerable period of measurements was undertaken both before (baseline measurement) and during lean implementation (post-change measurement). The research involved cooperation between researchers, company managers and employees. Having that in mind, as well as the fact that research question 'relates to describing an unfolding series of actions over time in a given group, community or organization', the research can be further typified as action research, as a variant of case research (Coughlan and Coghlan, 2002). A process consultation model was chosen. Here, researchers help the clients inquire into their own issues, and actively participate in the design and implementation of the solution (Schein, 1999). A consistent approach was developed and well documented, so it can be followed by other researchers (Westbrook, 1995). Researchers' subjectivity was mitigated by including management and employee representatives in the research team. All decisions were made by consensus. In turn, employee subjectivity was mitigated by the presence of researchers. Research was conducted in three phases (Figure 1). First, base efficiency measurements were taken in order to enable researchers to understand the current situation, and to establish a baseline to which results obtained in later stages could be compared. Two types of measures were taken: (i) average lead time; and (ii) delivery reliability, measured through percentage of late orders and average lateness. Then, lean was introduced to the company. Afterwards, second set of efficiency measurements followed. Additional data were gathered from archival sources and semi-structured interviews with managers and employees.

Figure 1: Research phases

Baseline efficiency measurement

Baseline efficiency measurement was done based on an existing data collection system. During interviews with company management, lead time and delivery reliability were identified as order winners. This is why it was decided that lean implementation efforts should be aimed at shortening lead times and improving delivery reliability. Lead time was measured as the difference between the time when order left the company and the time when order entered the company. Delivery reliability was measured through percentage of late orders (number of orders delivered late divided by total number of orders), and average lateness (the difference between actual and promised delivery dates). Data was collected continuously, for each order. Collected data was later analyzed together with managers and employees of the company.

Lean implementation

A tool-agnostic approach to lean implementation was taken, meaning that focus was on underlying lean principles rather than on lean tools. Specific problems were analyzed in the light of lean principles, while tools were developed and used in accordance to identified problems. Lean implementation was guided by lean definition given by Hopp & Spearman (2004), where production of goods is considered lean if it is accomplished with minimal buffering costs. There are two sources of excess buffering. First source is obvious or big waste that has no rational reason for existence (Liker & Meier, 2006). This includes operations that are not needed, unreliable machines, rework, unnecessary waiting, excessive setup times, etc. This type of waste can be reduced without creating another form of waste is obvious waste. Second source of excessive buffering is variability that can take on many forms, including variability in process times, delivery times, yield rates, staffing levels, demand rates, etc. Variability can be external (irregular demand, product variety, changes in orders, etc.) or internal (excessive processing steps, unnecessary movements, setups, etc.). If variability exists it will be buffered with one of the following types of buffers: inventory, capacity or time. This is the type of waste that cannot be reduced without creating another waste (according to Little's law, changing one buffer without addressing the source of variability affects the size of other buffers, see e.g. Little, 1961).

Based on the lean definition presented in the text above, conceptual lean implementation model was designed and followed (Figure 2).

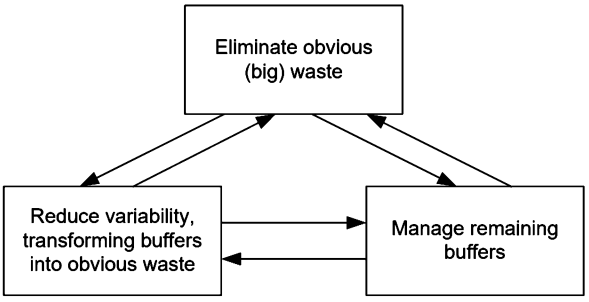

Figure 2: Lean implementation conceptual model

Eliminating obvious waste means removing everything that does not add value to the customer, and has no rational reason for existing. Reducing variability (both internal and external) decreases the requirements for buffers, thus transforming buffers to obvious waste (i.e. less variability removes reasons for buffers to exist). Variability that remains must be buffered or isolated in order to reduce the impact of variability on the entire value chain. The remaining buffers must be right-sized and balanced (i.e. by exchanging expensive buffer such as inventory for a less expensive one such as capacity) in order to improve flow and reduce the cost of buffering.

Over-processing and waiting were recognized as most significant obvious waste. Over-processing starts at engineering, where engineers thought that products that are more complicated then customer required had more value. In addition, engineers were pressured by short due dates, which prevented product refinement. This means that product manufacturability was rarely analyzed, which led to over-processing in manufacturing. Other obvious waste is waiting, where about two thirds of the entire lead time the order spends waiting. Uncontrolled order release was identified as main cause of waiting, since it leads to high levels of WIP and shop-floor congestion. This problem was resolved through controlled order release, based on input output control. Input control (releasing new orders based on the shop load) was deemed to be less feasible, because delaying order release was usually not possible, since due dates are usually tight. Shop-floor congestion was mainly resolved through output control, i.e. short-term capacity adjustments (overtime

or additional shifts) with the aim of increasing throughput. In addition to eliminating over-processing and waiting, operations were analyzed in order to identify and eliminate unnecessary activities and motion.

Variability was reduced mainly through standardization. Operations were analyzed and improved, and new standard operating procedures (SOP) were introduced. SOPs consist of three parts: (i) first part contains information about workplace preparation; (ii) second part contains information about performing operations on a workplace; and (iii) third part contains information regarding preventive maintenance of production resources and workplace. Greatest challenge was to create SOPs for assembly, since sequence and content of assembly operations might differ significantly from one order to another. This was resolved through division of assembly operations to smaller elements (different ways of putting elements together) which were standardized and written down to a SOP. SOP for an entire product is obtained by combining different SOPs for elements of operations. Special attention was given to setup reduction, where SMED (Single-digit Minute Exchange of Die) method was applied. Setup activities were analyzed and standardized, and new setup procedures were devised. Prototype production was a major source of variation. Engineers used to make requests for prototype production in an unstructured and erratic manner, thus interrupting production and introducing additional variability. This was resolved by introducing time slots (one hour at the beginning of each shift) which were used entirely for prototype production, while producing prototypes outside of this time slots was possible only by order of production manager.

Remaining variations were isolated through buffer introduction. First buffer was introduced at order acceptance phase in order to separate operations from demand variations. Orders were placed in an order pool, from which they were picked and released according to available capacities of engineering department. Engineering process is unstructured and unpredictable, and presents significant source of variation. In order to prevent transfer of variations to manufacturing, another buffer (pool) was introduced after engineering, and before manufacturing, so impact of variation could be isolated in engineering department. High WIP levels were used to buffer internal variability. They were used as a source of autonomy, where it was up to operators to select next order to be processed. The result was los of 'natural' flow of orders, shop-floor congestion, difficulties in tracking orders, orders getting lost, etc. this was resolved through 'swapping' one buffer for another, i.e. inventory (WIP) buffer for capacity buffer. As it was said earlier, controlled order release could not be obtained through input control, so it was obtained through output control, i.e. increase of throughput. Capacity slack was created through short-term capacity adjustments that were used when shop-floor was threatened to be congested. Work center load was used as a capacity adjustment trigger. Maximum allowed work center load was determined, and capacity was adjusted when it was estimated that maximum allowed load was to be violated. Lowering levels of WIP allowed for material to be moved through shop-floor in accordance to FIFO principle, thus lowering demand for order dispatching.

All actions aimed at waste elimination, variability reduction, and buffer management should be taken in accordance to scientific approach, i.e. through usage of PDCA cycle.

Post implementation efficiency measurement

Post implementation measures were taken during and after lean implementation. In order to facilitate gathering of data, new order tracking system was designed. New system facilitated information gathering and analysis, since data was collected in a way that enabled their use without significant amount of data processing (i.e. it was possible to analyze data in their 'raw' form). As was the case in baseline period, data was collected continuously, for each order. Data was gathered and analyzed together with managers and employees.

4. RESULTS

Data on lead times and delivery reliability were taken during 2015. The entire period was divided in two shorter periods, in order to track changes in lead times and delivery reliability before and after lean implementation: (i) period 1 – weeks 1 to 35, before lean implementation; and (ii) period 2 – weeks 36 to 52, after lean implementation. Figure 3 shows average lead time before and after lean implementation. Although measurements were taken per work order, the results are grouped per week, for the sake of better visibility.

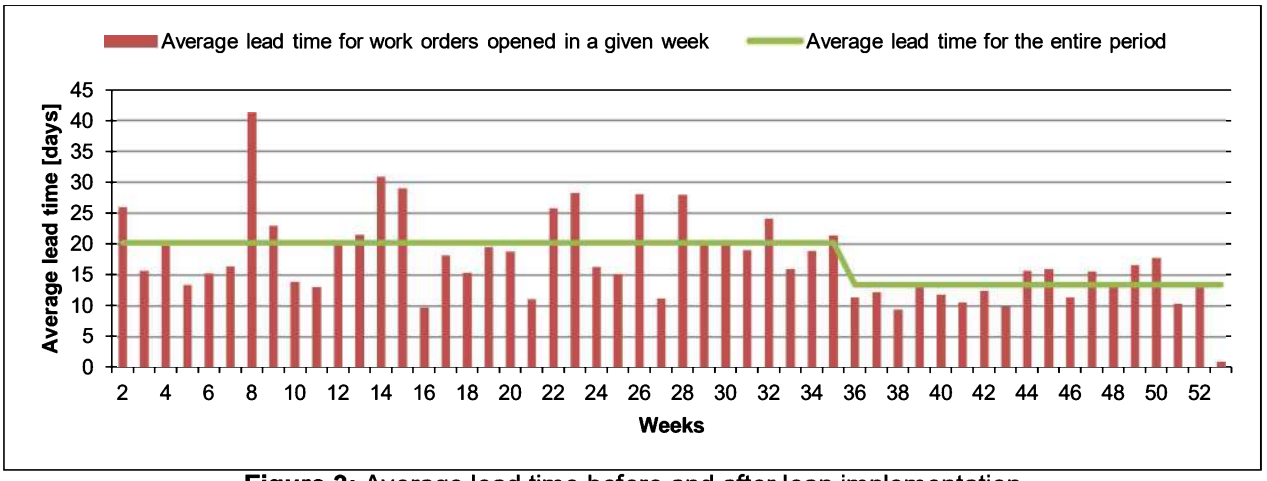

Figure 3: Average lead time before and after lean implementation

The results show that average lead time after lean implementation is shorter than the one before implementation. Before implementation, average lead time was 20.17 days, while after lean implementation it was reduced to 13.43 days. Standard deviation of lead times was also reduced, from 19.8 to 10. Decrease in lead times was obtained through two main courses of actions. First course of action was reducing and controlling variability, both in effective processing times and inter-arrival times. Reduction in processing times and inter-arrival times resulted in reduced wait time, which was estimated to 13 days before lean implementation (net time was estimated to be around 7 days). Processing time variability was reduced through waste elimination, standardized operating procedures, setup time reduction and standardization, and improved maintenance. Inter-arrival time variability was reduced through separation of demand and production, with introduction of two order pools in front of and right after engineering department, aimed at stabilizing the inflow of new orders, both in the company as a whole, and in manufacturing. These results support the claims presented by Kingman (1961) that waiting time in queue is directly influenced by variability. Second course of action was in accordance to Little's (1961) law, where lead time is affected by throughput rate and WIP. With tight due dates and constant pressure, it was hard to limit the amount of WIP on the shop floor, co congestion was managed through output control, i.e. short term capacity adjustments such as overtime and additional shifts.

Figure 4 shows the distribution of lead times before lean implementation and after lean implementation.

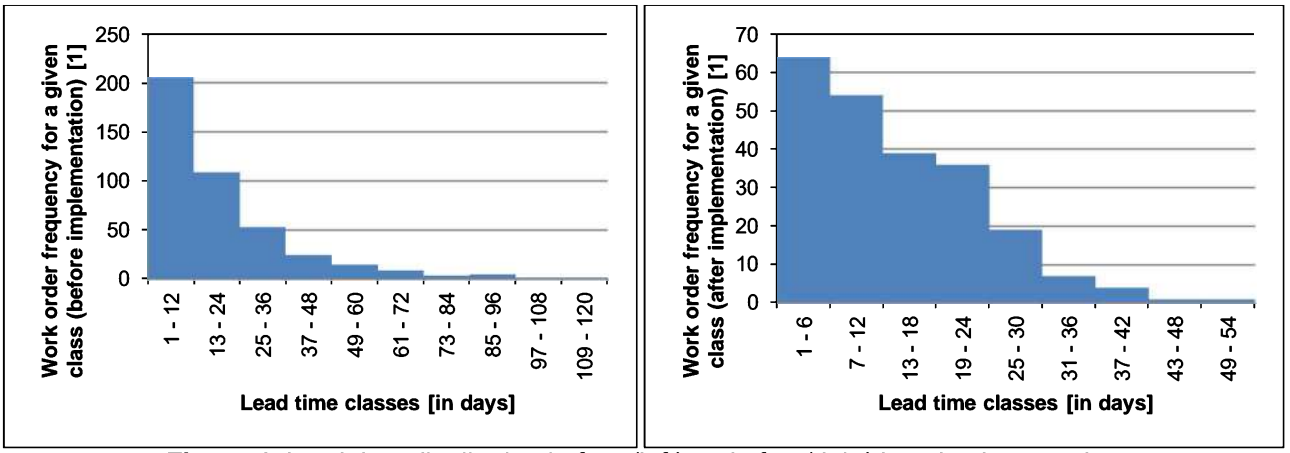

Figure 4: Lead time distribution before (left) and after (right) lean implementation

The results show that lead time range is significantly smaller after lean implementation, which effected the average lead time itself. In addition, more control of work orders was established through lean implementation, which is supported by the fact that lean implementation eliminated work orders with extremely long lead times. This led to less congestion on the shop floor, which reduced the opportunities to change order priorities, as well as the need for order dispatching. As a result, it became possible to use simple dispatching rules, such as FIFO, and to maintain the 'natural' flow of orders.

Figure 5 shows number of work orders completed before due date, on time, and after due date. As before, weeks 1 to 35 are before lean implementation, while weeks 36 to 52 are after lean implementation.

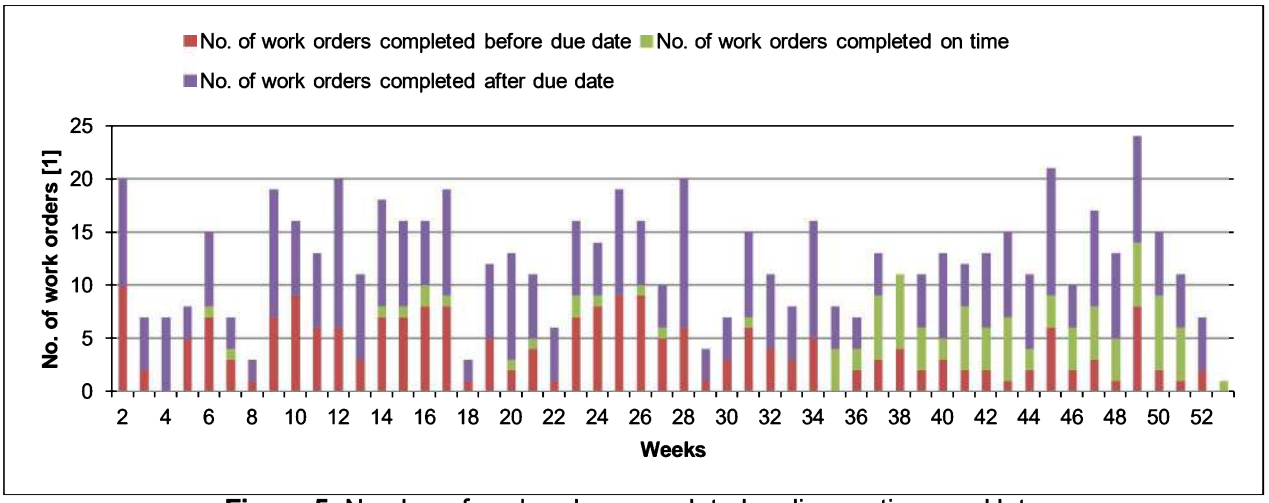

Figure 5: Number of work orders completed earlier, on time, and late

The results show that number of work orders completed late was lower after lean implementation. The percentage of late orders decreased from 55.5% to 46.7%. In addition, the number of work orders completed on time increased significantly, as shown on Figure 5. As a result, less work orders were completed late, as well as early, which increased service level of the company.

The distribution of lateness was also analyzed, as shown in Figure 6. The results show that, while lateness range stayed rather unchanged, distribution function became much narrower after lean implementation (right hand side if the figure). The results show that work orders are accumulated in a class that represents work order completion on time, or with a minimal earliness or lateness.

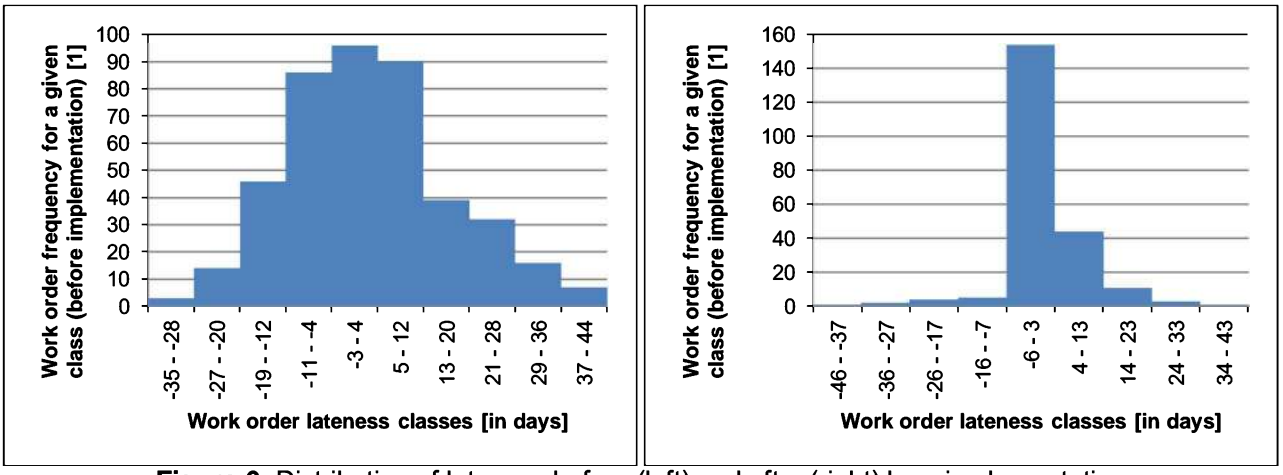

Figure 6: Distribution of lateness before (left) and after (right) lean implementation

Results presented in Figures 5 and 6 suggest that average lateness should have decreased after lean implantation. In order to test this hypothesis, average lateness before and after lean implementation was measured in details. The results are presented in Table 1.

Table 1: Average lateness before and after lean implementation

	Period	Sample size	Average	Standard deviation
Average lateness	Before	238	12.7269	9.83948
	After	105	7.1619	7.11056

The results show that average lateness decreased from 12.7 days to 7.2 days. In addition, standard deviation of lateness decreased from 9.8 to 7.1. Lead time reduction had a great impact on delivery reliability improvement, supporting the claim that improved delivery reliability can be a consequence of shorter lead times and/or lower standard deviation of lead times.

5. CONCLUSION

Evidence of lean being used from efficiency improvement in repetitive manufacturing are abundant. However, evidence of lean being used to improve efficiency of ETO operations are few and far between, thus raising the question of lean universality. This paper presents the results of an action research in efficiency improvement in an environment that is often considered as inappropriate for lean implementation. The results obtained through the research add to the fact that lean can be used for improving efficiency of ETO operations. ETO companies operate in turbulent environment, which is a fact they often use as an excuse for efficiencies. Variability is inherent to ETO operations, since ETO companies 'sell' variability, both in production mix and volume. So, rather than passively reacting to variability, ETO companies should take a more proactive stance, and put efforts to actively control variability. The fact that ETO companies 'sell' variability calls for caution. Some variability should be reduced, while some should be isolated and controlled. If there is no rational reason for variability to exist, then it is waste and it should be eliminated. If variability has to exist, it has to be managed as much as possible, and buffered in an effective way.

Production system introduced to company ALPHA was not a copy of TPS. This means that lean implementation was not formulaic, stripped down to mere tool implementation. Rather, it was TPS based production system, built on underlying lean principles that were used by Toyota to develop tools for specific problems. This approach reduces chance for failure, since it is advocates contextual approach that avoids prejudging solutions, but takes into account characteristics of a specific manufacturing environment and builds efficiency improvement on laws that define lean.

Abstract: *This paper aims to deepen and broaden the scientific fund of recently advocated paradigms that will significantly reshape operations management in banking industry in years to come. The purpose of this paper is to guide operations managers in banking towards economic sustainability by providing a conceptual architecture of digital platform for operations services to reduce complexity, time to market, and at the same time to visualize operations activities, i.e. to effectively support mass customized-lean-agile-fit operations strategies. Further, taking into account that the major challenge in mass customization paradigm is to determine product offerings, the paper provides a two-phase approach consisting of Total Unduplicated Reach and Frequency (TURF) analysis to facilitate a choice of new services imposed by market requirements and Analytic Network Process based on BOCR model (ANP-BOCR) to segregate a core from actual and augmented mass customized services. The study may be useful for operations managers in financial services, innovation, IT and business decision management.*

Keywords: *operations management, mass customization-lean-agile-fit operations strategy, banking industry, economic sustainability, conceptual architecture of digital platform, TURF analysis, ANP-BOCR method*

1. INTRODUCTION

The concept of sustainable development has been extensively studied from various aspects in the theoretical literature over the time. The analysis of hundreds definitions of sustainable development concept depicts that there is no unique and comprehensive formulation which provides clear understanding of the phenomenon due to its complex and multidimensional issue, which indicates that sustainable development should be considered as an integrated system of economic, ecological, social and institutional perspectives (Jiliberto, 2003; Ciegis et al., 2009).

In the face of an intense competition, comprehensive changes in technology, customers' demands, regulatory requirements and demographic changes into the volatile business environment, strategic managers worldwide understand sustainable business development not only as an option, but as a fully integrated paradigm into the strategy and operations of organizations. According to the Lacy et al. (2010), ninety-three percent (93%) of the 766 CEOs have stated that sustainability is significant issue to the organization's future success. Yet, businesses worldwide are rapidly digitizing, breaking down industry boundaries, building new opportunities, and at the same time harming long-successful business models (Weill & Woerner, 2015; Tornjanski et al., 2015). The phenomenon of digital disruption remarkably changes banking industry, indicating the considerable redesign of operating model in years to come. These underlying influences put sustainability in narrow focus of executives and at the same time create big pressure on banks to continuously evolve, by changing its strategic context and competitive dynamics (Propa et al., 2015; Weill & Woerner, 2015). In such circumstances, operations management as a central core function and its dynamic capabilities are of strategic importance to an organization (Brown et al., 2013), taking into account its significant role in overall organizational performances (Slack et al., 2004; Zangiski & da Costa, 2013). In the age of the third industrial revolution, adjusting complexity, harmonizing confronted requirements and dynamic processes with all accelerated changes under uncertainty, while effectively managing both internal and external interdependencies with various stakeholders that have different requirements and needs, have always represent challenge for operations management in banking. However, in the volatile times, it became challenge of key importance for organizational sustainability and business development (Slack, 2015; Sprogies & Schmidt, 2015).

Given that banking sector is undergoing significant transformation towards structure that follows principles of flexibility, openness and customer-centricity, sustainability from operations management aspect may be achieved if operations managers in banking industry understand what they have to provide and how to leverage resources and capabilities as an integrated system (Fasnacht, 2009; Huo & Hong, 2013; Tornjanski et al., 2015a).To this end, operations managers in banking industry have to develop the ability to tailor the appropriate strategies with clear long-term vision and strong short-term implementation capacities to effectively boost transformation of operating model from traditional "back-office" role toward "strategic" role with the possibility not only to support business strategies, but also to shape new ones for well-being of an organization on the long run (Henderson & Venkatraman, 1999).

With that in mind, this paper aims to extend and deepen the scientific fund of recently advocated paradigms that will significantly reshape operations management in banking industry in years to come. The purpose of this paper is to guide managers in banking to effectively support mass customized-lean-agile-fit operations strategies. Further, taking into account that the major challenge in mass customization paradigm is to determine product offerings, we aim to provide a framework to facilitate strategic decision making.

2. LITERATURE REVIEW

The field of operations management in service organizations has evolved tremendously over the years due to changes in market requirements (Gunasekaran & Ngai, 2012). The dynamic customer expectations, increased competition, advancements in information and communication technologies, development of knowledge-based economy (Kriščiūnas & Daugėlienė, 2015), financial market globalization and economic recession have forced service operations managers to approach the transition (Vinodh et al., 2014). The fundamental requirement in transition is change of operating models which implies an introduction and application of appropriate strategies and paradigms towards continuous operations improvements. As a result, service operations management has entered into the “mass customization-lean-agile-fit” era (Zhao & Lee, 2009; Gunasekaran & Ngai, 2012; Brownet al., 2013; Tseng & Hu, 2014; Vinodh et al., 2014), which significantly reshapes operations management in service sector today.

2.1. Mass customization

Mass customization has emerged as an important paradigm due to the heterogeneity of individual needs, competitive intensity and shortens product life cycles (Huang et al., 2008; Khalili-Araghi & Kolarevic, 2016).There is a wide variety of understandings of this phenomenon viewed from different perspectives. From a customer perspective, the paradigm enables superior customer value by providing products / services that meet individual needs (Tseng& Jiao, 2001). From the service operations management perspective, mass customization refers to the ability to quickly provide customized products in high volumes, with quality that will satisfy end user, minimal costs and time to market (MacCarthy et al., 2003). In other words, mass customization is a “paradigm that seeks, as its goal, to combine the value-added effectiveness associated with product customization with the cost-efficiency closely related to mass production” (Huang et al., 2008, p. 716). According to the Papathanassiou (2004), development of customized services is recognized as one of the top priorities in the service industry nowadays. However, customer driven business is both, an imperative and a potential threat. Gilmore & Pine (1997) pointed out that many companies have introduced new procedures and programs to meet every customer's requirement. Yet, such approach has caused additional costs and complexity to operations. In response to this issue, four unambiguous approaches to customization have been advocated, i.e. collaborative, adaptive, cosmetic and transparent customization. Pine et al. (1995) suggest that modular system, information availability to employees, incorporation of customers into an evaluation process for product / service development and creation of direct link with customers are elements that should be taken into account when companies embark development of mass customization strategies and architectures.

This concept shifts design, distribution and processes from "made-to-stock" to "made-to-order", which significantly challenges the conventional product development, process and supply chain management (Tseng & Hu, 2014).To effectively support mass customization strategy, organizations should reconsider the entire value chain from front to end, by efficiently adjusting economy of scale, variety and time to market (Tseng & Hu, 2014) and effectively managing the dynamics and trade-offs among product design, system design and supply chain design (Hoekstra & Nahmens, 2005).

2.2. Lean, agile and fit framework for service operations management

Lean philosophy advocates elimination of any kind of waste, including a reduction of non-value-added activities to continually improve company’s wealth creation capability (Droste, 2007; Lester, 2008; Womack & Jones, 2010). Although manufacturing organizations were the beginners of lean adoption (Hines et al., 2004), service organizations are increasingly inspired by lean management. Among all, financial services are

pressed to improve operational efficiency due to strict governmental regulations and intense competition determined by non-financial companies and changes in customers' behavior (Staikouras & Koutsomanoli-Fillipaki, 2006; Leyer & Moormann, 2014). Despite increased interest in the application of this paradigm, financial services often experience difficulties in successful adoption of lean. One of the reasons lies in an insufficiently explored phenomenon in financial services in both, the theory and practice. Leyer & Moormann (2014) have stated that only few case studies dealt with the applicability of lean in financial services. Prior theorists note that implementation of manufacturing lean principles in financial service organizations cannot be treated equally due to their contextual differences (De Treville & Antonakis, 2006), i.e. differences in nature of goods and services, operation processes and the way of customer integration in manufacturing and financial service organizations (Leyer & Moormann, 2014).

Early works on lean principles specify two fundamental criteria that characterize lean: just in time (JIT) and automation. Just in time represents a "pull" system in which production process starts only when it is signaled by the customer downstream, while the objective of automation is not to throw out production employees, but rather to shift them on those aspects of business which create the highest value (Womack & Jones, 1996; Ohno, 1988; Staats et al., 2011). Value, value stream, flow, pull, and excellence are five categories that refer to definite lean management concept (Womack & Jones, 1996). Value refers to a product / service that is offered to customers, along with the works backward to build an operation process. Value stream ensures that each step creates value in value chain. Flow reorganizes processes in order to have smooth delivery operation through the value-creation exercise, while pull represents a mechanism for limiting waste in operation processes (Hopp & Spearman, 2004). Finally, excellence requires continual striving to meet customer requirements, and at the same time to improve processes with zero defects (Staats et al., 2011). Mefford (1993) stated that just in time, high performance work systems and total quality management are management practices that characterize lean paradigm. However, Shah & Ward (2007) argue that these practices are not sufficient to adequately explain an entire idea of lean management (Leyer & Moormann, 2014). According to De Koning & De Mast (2006), lean represents an integrated system of principles, tools, techniques and practices aimed at waste reduction, synchronization and management of workflows in organization. In addition, Rother (2009) recognizes that employees' capability to think and act towards lean, i.e. to be focused on efficiency and value-creating processes in day-to-day business activities is equally important element in lean management. In accordance to that, a change in an organization's management system is perceived as an important element for sustainable implementation of lean management, too (Mann, 2014; Leyer & Moormann, 2014). A common denominator in all lean aspects is fundamental idea of optimization and continual improvement of operations processes (De Koning et al., 2008). The adoption of lean philosophy in organization is assumed to be in positive correlation with increased efficiency (Dahlgaard & Dahlgaard-Park, 2006), and in negative correlation with cycle time and costs, which results in more agile, customer-responsive and competitive organization (Alukaj, 2003).

Agile service operations management requires quick respond to changes in demand in terms of both volume and diversity (Christopher, 2000; Power et al., 2001). Naylor et al. (1999) defines agility as a usage of market knowledge and a virtual organization to bring about profitable solutions and alternatives in a volatile marketplace. According to the Power et al. (2001, p. 247) "The notion of agility is therefore recognized to be holistic rather than functional, and of strategic rather than tactical importance. The concept has also been extended beyond the traditional boundaries of the individual organization to encompass the operations of the supply chain within which the organization operates". It has been argued that organizations could thrive in rapid and unpredictable business environment by acting in an agile manner (Nagel & Dove, 1991; Bruce et al., 2004).

A holistic approach that integrates mass customization, lean and agility, i.e. fit framework is a new model for economically sustainable organization (Pham & Thomas 2011; Vinodh et al., 2014). Prior theories strengthen fit framework which combines these concepts and allow organizations to tune its operational and technological capabilities (Pham & Thomas 2005). Fit framework provides a new operations management perspective and new operations management strategy to accomplish dynamic strategic objectives. Innovative concept with holistic perspective, built upon the principles of these paradigms, is recognized as an effective strategy towards organizations' economic sustainability (Pham & Thomas 2005; Pham & Thomas 2011; Vinodh et al., 2014) and should be integral part of strategic and sustainable strategies in banking industry, too.

3. METHODOLOGY

For the purpose of this paper, the method of case study has been recognized as the most suitable research method to deeply understand the role and issues of operations management in banking, thus to ensure a holistic view on the researched phenomena in real life. Within the case study, we have incorporated a multi-method approach to strengthen the results on a given research problem.

To understand a specific problem, in-depth interviews were conducted with the senior managers in operations area of the bank under the study as a targeted sample of respondents for the sake of ensuring that the participants meet the requirements to be included in the study.

Thereafter, to answer "how" to effectively support mass customized-lean-agile-fit operations strategies in banking, we have developed a conceptual architecture of digital platform for operations services to reduce complexity, time to market, and at the same time to visualize operations activities. Further, taking into account that the major challenge in mass customization paradigm is to determine product offerings, i.e. in order to understand "what" operations management needs to provide to internal and external stakeholders to meet both strategic goals and end users' requirements, we propose a two-phase approach for selection process.

Phase I

First phase encompasses the selection of new services. The beginning of process is based on the principles of mass customization paradigm, which implies the inclusion of end users in the evaluation process. A survey method is carried out among experts of the bank under the study by conducting a web-based questionnaire as a survey instrument. Experts of the bank were asked to select the combination of proposed services with the aim to ensure that the possible introduction of new services would reach its maximum usage according to the business needs.
In other words, $y_i=\{1, end\ user\ i\ will\ use\ service; 0, end\ user\ i\ will\ not\ use\ service\}$. The results are derived using a Total Unduplicated Reach and Frequency (TURF) analysis that is substantiated by the equations (1) and (2) (Serra, 2013):

Equation 1 is used to reach maximum penetration of final combination of services, i.e. number of end users that are subjected to a limited number of varieties.

$$\max\ Z = \sum_{i=1}^{m} y_i \tag{1}$$

Equation 2 is used to reach maximum frequency of varieties, i.e. the highest number of selected services by each user.

$$\max\ Z = \sum_{i=1}^{m} f_i y_i \tag{2}$$

The results of TURF are analyzed in Excel spreadsheet with the advanced option for solving mathematical programming problems.

Phase II

Second phase implies final selection and segregation of core from actual and augmented mass customized operations services. In this phase, the Analytic Network Process (ANP) multi-criteria method is applied in modelling and quantitative analysis of service lines and their relative weights in regard to benefits, opportunities, costs and risks (BOCR) (Saaty & Vargas, 2001; Saaty & Ozdemir, 2005; Saaty, 2009; Tornjanski et al., 2014) to estimate all the effects when making decision. Final BOCR decision model is shown in Figure 1. Pair-comparisons is carried out by decision maker of the bank under the study using a nine-point Saaty's scale.

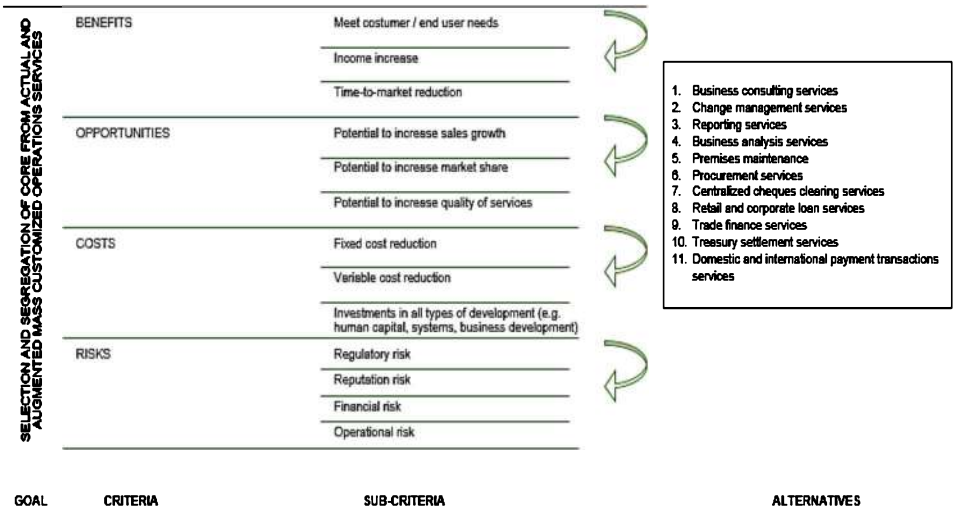

Figure 1: BOCR decision model (Source: Authors)

According to the pair-comparison matrix, local priority vector is obtained by solving (3) (Liang & Li, 2008):

$$A\omega = \lambda \max W \tag{3}$$

Where
A is the pair-comparison matrix
Λmax is its largest eigenvalue
W is the local priority vector.

Next, unweighted supermatrix, weighted supermatrix, cluster matrix and limit supermatrix are constructed. In order to obtain final results, the whole model is synthesized. To calculate the final rank of alternatives, Saaty proposes two ways of calculation. In this paper, the subtractive method is applied using the formula (4) (Saaty & Ozdemir, 2005; Saaty, 2008; Liang & Li, 2008; Tornjanski et al., 2014):

$$bB + oO - cC - Rr \tag{4}$$

Where
b, o, c, r are the priorities for BOCR merits in regard to strategic criteria (Liang & Li, 2008). The results are derived using Super Decisions software package for decision making.

4. RESULTS AND DISCUSSION

The bank under this study (hereafter: the bank) is a European bank which began operations in Serbia in 2003. Today it services more than 900.000 clients with 1.500 employees. With total market share of 4.61% it is ranked among the top 10 banks according to balance sheet assets in the banking sector of Serbia (NBS, 2015).

4.1. Understanding the problem

In an in-depth interview conducted in the bank, decision maker stated: "*Operations function in our bank represents an engine of the organization which simultaneously provides services, information and knowledge to numerous internal and external stakeholders that have different and often confronted requirements* (Figure 2). *Nevertheless, during the years of successful business in Serbia, Operations function has significantly contributed to the results of the bank, mainly due to established strategic alignment with business strategies and proper management of operations. These and many other efforts invested by the management and experts' team from the Operations function have resulted in an overall improvements of the bank's performances…*"

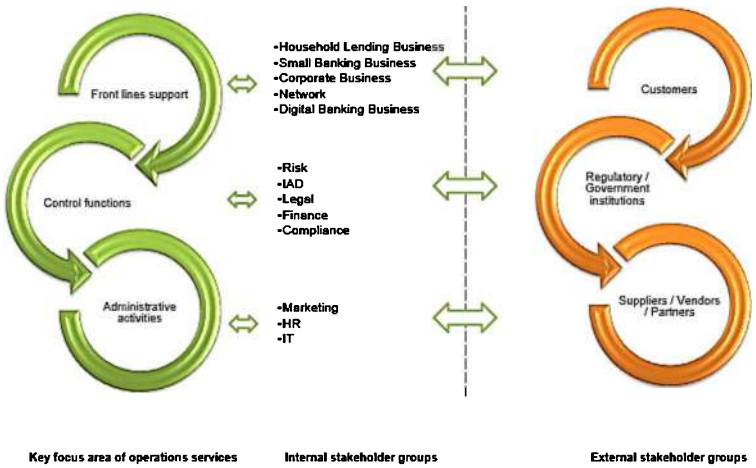

Figure 2: General overview of key focus area of operations services and stakeholders (Source: Authors)

However, decision maker emphasized that: "*Operations function should continue to evolve to ensure economic sustainability for the bank. To this end, we have recognized that it is of paramount significance to develop a model which will visualize operations activities, reduce complexity and time to market with the possibility to effectively support mass customized services and lean operations strategies into everyday business*".

Further, one of the senior managers of the bank has explained the role of operations management and pointed out issues that disrupt operations management today: "*Operations management faces multidimensional complexity when looking for ways in supporting all functions of the bank in achieving sustainability. Regardless of the organizational model followed by the bank, operations activities are placed at the core of the bank right in the crossroads of support to frontlines facing customers, managing administrative functions facing third party vendors and facilitating control functions facing regulatory bodies. Such position puts great challenge on operations managers to determine the right product and resources mix given that it needs to respond both to continuous changes in demand on all internal functions it supports and all external parties those functions are exposed to, in parallel ensuring that costs and resources are kept at optimum level and easily adjustable to changes. This clearly gives additional significance to question of achieving sustainability when operations managers are concerned. To this direction the first aspect which needs to be put in place is segregation between core and additional services which one operations manager needs to support. It is clearly dependent as priority by regulatory requirements as for such activities there is no alternative, but going further from those the variety of indicators coming from market needs (e.g. digitalization), top management strategic focuses (e.g. corporate vs. retail banking), external opportunities for collaboration (e.g. outsourcing) needs to be continuously evaluated in order to provide balanced operational support. Common denominator which always needs to be considered is available resources and how to keep them as flexible as the demand. This is where appropriate models will play the key role for operations managers. All operations managers inevitably will have available or even participate to design of variety of information influencing their activities such as market information, sales targets, product development plans, procurement plans, regulatory requirements, budget forecasts. Key challenge is how to filter all those data in order to identify key indicators which ought to shape operations manager strategy and how to monitor and have early alert on changes of those indicators in a way to efficiently adjust and prioritize operations services and resources".*

4.2. Towards mass customized-lean-agile-fit operations management

Conceptual architecture of digital platform for operations services aims to reduce complexity, time to market, and at the same time to visualize operations activities, i.e. to effectively support mass customized-lean-agile-fit operations strategies. Conceptual architecture of digital platform for operations services is shown in Figure 3 and aims to link value chain from front to end in order to provide mass customized services, information and knowledge, to enable continuous optimization, improvement of operations processes by eliminating waste and by allowing quick respond to changes in demand in terms of both, volume and diversity.

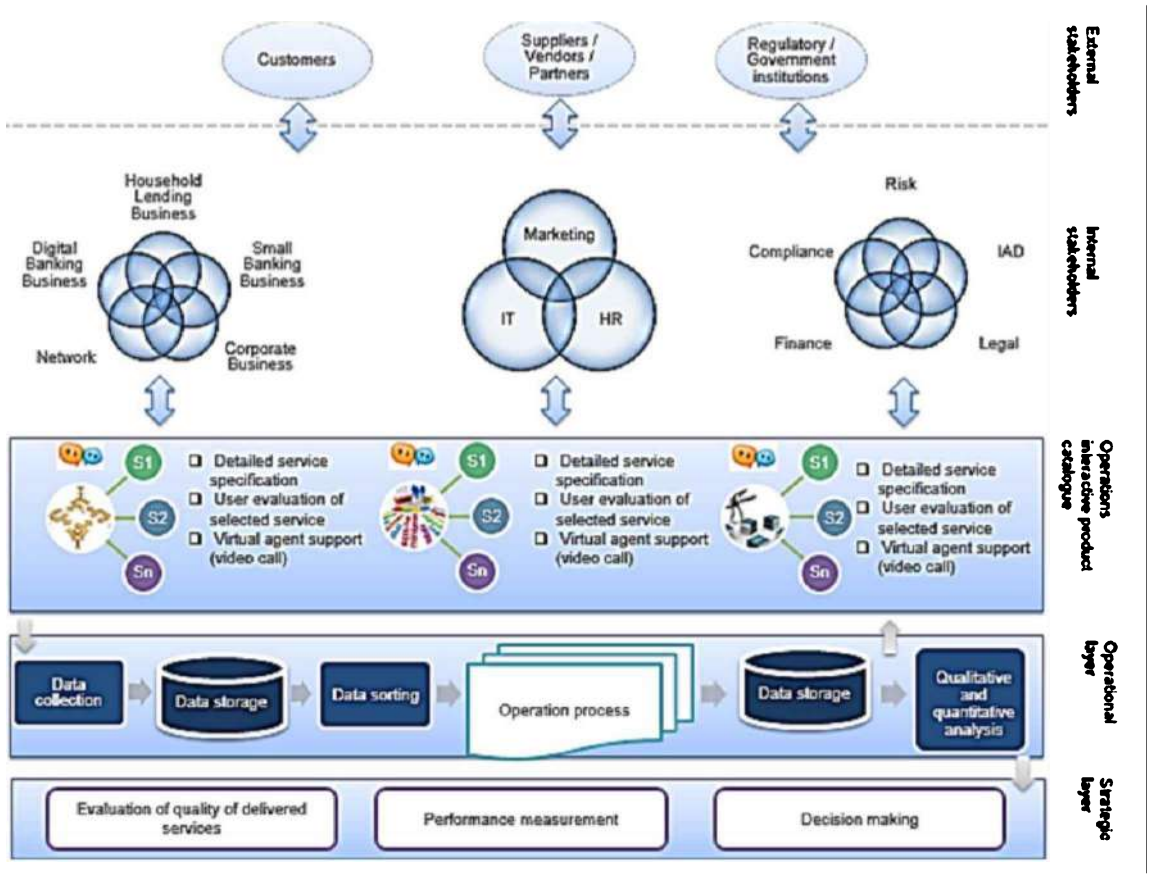

Figure 3: Conceptual architecture of digital platform for operations services (Source: Authors)

The platform consists of three layers. First layer of the architecture represents operations interactive product catalogue which allows users self-service by selecting multiple available services, in any combination, provided by operations function. Each service has a detailed specification to enable stakeholders sheer understanding of the offer in real time, and at the same time enables interactions with experts from the organizational part which delivers service by using on-line chat for instant support, and video call for deeper understanding of addressed issue. Besides, users at this level have possibility to evaluate quality of delivered services by particular organizational part of operations function.

Second layer of the architecture represents operational layer with the purpose of collecting, storing and sorting data of requested services, thus allows adequate allocation of selected service to particular organizational part that should deliver service. Furthermore, it enables storage data after delivered service for further control and analysis.

Third layer of the architecture represents strategic layer which aims to yield an insight into the quality level of delivered services, results of organizational performances, as well as to ensure effective support in decision making using qualitative and quantitative data.

4.3. Selection of new and segregation of core from actual and augmented mass customized services

4.3.1. TURF analysis results for selection of new service line

According to the market requirements, five new services are recognized as significant contributors to the sustainability and thus proposed by the authors of the paper to be further evaluated for operations division catalogue. The evaluation process was performed by 39 experts of the bank, who have selected a combination of proposed services based on the business needs. The results are presented in the following tables. Table 1 encompasses the frequencies at which the objective is achieved for each single service.

Table 1: Frequency table for each single proposed service

Proposed services	Frequency	Frequency (%)
Innovation and development management services	5	13
Strategic and operational planning services	2	5
Change management services	14	36
Reporting services	29	74
Business consulting services	30	77

The following table provides the best combinations obtained from experts' assessment, each time with the reach and the frequency obtained. The reach is the number of end users who intend to use at least one service, while the frequency represents the number of times a service received a maximum score. The results are shown in Table 2.

Table 2: The best combinations for introduction of new services

Service line	Reach	Frequency	Service 1	Service 2	Service 3
Line 1	37	73	Change management services	Reporting services	Business consulting services
Line 2	35	64	Innovation and development management services	Reporting services	Business consulting services
Line 3	35	61	Strategic and operational planning services	Reporting services	Business consulting services
Line 4	34	49	Innovation and development management services	Change management services	Business consulting services
Line 5	34	46	Strategic and operational planning services	Change management services	Business consulting services

Finally, Table 3 depicts a two-way TURF results, derived from the selected service lines.

Table 3: Two-way TURF results

	Line1	Line2	Line3	Line4	Line5	% X
Reach	37	35	35	34	34	
Reach (%)	94.87%	89.74%	89.74%	87.18%	87.18%	
Innovation and development management services		14.29		14.71		40.00
Strategic and operational planning services			5.71		5.88	40.00
Change management services	37.84			41.18	41.18	60.00
Reporting services	78.38	82.86	82.86			60.00
Business consulting services	81.08	85.71	85.71	88.24	88.24	100.00

According to the results from TURF analysis, business consulting services, reporting services and change management services, i.e. Line 1, has the highest score of 94.87%. Therefore, services in Line 1 represent candidates to be included in phase II of decision making for final selection and segregation of core from actual and augmented operations services.

4.3.2. ANP-BOCR results for segregation of core from actual and augmented services

In this phase, the authors of the paper have selected eight (8) existing and three (3) new services to be evaluated using ANP-BOCR multi-criteria method. Pair-comparison is carried out by decision maker of the bank under the study to segregate core from actual and augmented operations services. The results are shown in Table 4.

Table 4: Results from ANP-BOCR model

Name	Ideals	Normals	Raw	Segregation
Domestic and international payment transactions services	1.000	0.128	1.000	Core
Reporting services	1.000	0.128	1.000	Core
Business consulting services	0.800	0.103	0.800	Core
Centralized cheques clearing services	0.800	0.103	0.800	Core
Retail and corporate loan services	0.800	0.103	0.800	Core
Premises maintenance	0.800	0.103	0.800	Core
Trade finance services	0.800	0.103	0.800	Core
Business analysis services	0.600	0.077	0.600	Actual
Procurement services	0.600	0.077	0.600	Actual
Change management services	0.400	0.051	0.400	Augmented
Treasury settlement services	0.200	0.026	0.200	Augmented

According to the results, 64% of selected services are categorized as core, followed by 18% of actual services, while 18% of services are recognized as augmented. Besides, of the three new services from Line 1, which were the subject of evaluation, two have been identified as core services of the bank included in this study.

5. CONCLUSION AND RECOMMENDATIONS

This study aims to shed light the understanding of recently advocated paradigms that will substantially reshape operations management in banking industry in years to come, as a result of mainly external forces that are changing the market at high speed, and consequently put pressure on operations managers in

banking to continuously change its strategic context and competitive dynamics. The fundamental requirement in the evolution process is change of operating models, which imply an introduction and application of appropriate strategies, paradigms and tools towards economic sustainability of an organization. With that in mind, this paper presents an overview of innovative concepts with holistic perspective, i.e. mass customized-lean-agile-fit paradigms, provides a solution for effective support of mass customized-lean-agile-fit operations strategies, and answers on the question what operations management needs to provide to internal and external stakeholders to meet both strategic goals and end users' requirements.

To answer "how" to effectively support mass customized-lean-agile-fit operations strategies in banking, we have developed a conceptual architecture of digital platform for operations services. A conceptual architecture aims to visualize operations activities, reduce complexity and time to market, while links value chain from front to end, in order to effectively provide mass customized services, information and knowledge. The purpose of this platform is to enable continuous optimization, improvement of operations processes by eliminating waste and by allowing a quick respond to changes in demand in terms of both, volume and diversity. Further, taking into account that the major challenge in mass customization paradigm is to determine product offerings, we propose a two-phase approach consisting of Total Unduplicated Reach and Frequency (TURF) analysis to facilitate a choice of new services imposed by market requirements and Analytic Network Process based on BOCR model (ANP-BOCR) to segregate a core from actual and augmented mass customized services.

To sustain in today's highly dynamic and volatile business environment, based on the reviewed literature and the results obtained from the study, this paper draws some recommendations for managers in financial services: (a) Incorporation of integrated mass customization, lean and agile paradigms into the operations strategies, (b) Development of innovative and flexible solutions with established continuous monitoring and measuring of operations performances, (c) Development of smart processes focused simultaneously on the efficiency and effectiveness of banking operations, (d) Adoption of comprehensive, quantitative, and objective approach to decision-making with the development of a systematic, logical and ambidextrous view on the problem, and (e) The use of appropriate tools and decision support software solutions (Čupić & Suknović, 2010).

The study may be useful for operations managers in financial services, innovation, IT and business decision management.

APPLICATION OF THE GAMES IN TEACHING LOGISTICS AND SUPPLY CHAIN MANAGEMENT IN THE REPUBLIC OF SERBIA

Biljana Cvetić*[1], Nemanja Milenković[1]
[1]University of Belgrade, Faculty of Organizational Sciences
*Corresponding author, e-mail: cvetic.biljana@fon.bg.ac.rs

Abstract: *This research paper examines the current state of the application of the educational games in teaching logistics and supply chain management (SCM) in higher education institutions in the Republic of Serbia. The data for the study were collected from competent teaching staff through a questionnaire administered on-line using Qualtrics Research Suite. The results of the study show that educational games are not used to a great extent in teaching logistics and SCM at faculties in the Republic of Serbia. The most common reason for this lies in that teaching staff is not sufficiently familiar with the logistics and SCM games. At the same time, the results reveal the ubiquitous interest of the teaching staff for games introduction into the teaching of logistics and SCM. When it comes to the teaching scholars who use educational games, the results show that educational games are equally used at the state and private faculties and that the teachers are satisfied with the possibilities of improving students' competences with the use of games.*

Keywords*: logistics, supply chain management, educational games, application, questionnaire, faculties, Republic of Serbia*

1. INTRODUCTION

The application of educational games in synergy with other teaching methods is one of the perspective ways to enhance teaching and learning in the field of logistics and supply chain management. Most teachers of logistics and supply chain management from several leading institutions of higher education in the US use at least one game, simulation and/or interactive exercise in addition to other teaching methods such as lectures and case studies (according to Johnson and Pyke, 2000). Also, most teachers across the world who teach logistics and SCM would like to use business games/simulations in future (according to study by Rogers and Braziotis, 2016, p. 557). Much of the literature on logistics and SCM games is focused on the development and/or use of specific games; whereby the majority of papers is concerned with the most famous of them – Beer Game and their different versions (e.g. Sterman, 1989; Jacobs, 2000; Ngai et al., 2012; Lau, 2015). However, there is a little empirical evidence on the extent of the use of educational games in teaching logistics and SCM within the higher education institutions. The purpose of this paper is to examine the current state of the application of the educational games in teaching logistics and SCM in higher education institutions in the Republic of Serbia. The study is based on the findings of an on-line questionnaire sent to competent teaching staff working on faculties in Serbia.

2. THEORETICAL BACKGROUND

There are a number of educational games that can be employed in teaching logistics and SCM courses. They simulate the realities of a particular logistics or supply chain management problem, "allowing the students (players) to develop a thorough understanding of the problem and to design and test various solution strategies in an engaging environment" (according to Cambel et al., 2000, p. 68). These games allow students to learn through playing different roles, e.g. an inventory manager, a logistics engineer, a distribution network designer, a supply chain engineer, a supply chain manager, etc., in an environment 'without real risks' that consists of virtual entities (Cvetić et al., 2013, p. 1527). Students can compete individually and as a team memebers, with each other or against the standard, as in other games, and make learning and acquiring experience more interesting. The logistics and SCM educational games are very useful because they can enhance learning experience as they help connect learning theory with real-world dynamic situations; they improve students' active involvement in the learning process; increase students' motivation, and develop specific fundamental and professional competences (Pasin and Giroux, 2011). A brief historical background about these games and several ways of their classification are presented in Cvetić et al., 2013. When it comes to the empirical studies on their usage in teaching logistics and SCM in institutions of higher education, the available literature is almost scarce and slightly wider context should be considered i.e. the usage of business simulation games. Here, only two such studies are indicated. Faria and Wellington (2004) examine the game users, former-users, and never-users of businees simulation games in

higher education business schools in the US. Zoroja (2013) investigates the application of business simulation games at the economics departments of higher education institutions in Croatia.

3. METHODOLOGY

The study of the application of the educational games in teaching logistics and SCM at faculties in the Republic of Serbia was conducted during October and November of 2013. The main aim of the study was to determine and understand the level of application of the logistics and SCM games at faculties in the Republic of Serbia. Additionally, other important objectives were to identify the reasons why some teachers do not use these games, to determine the level of interest of teaching staff for games introduction into the teaching process, to determine which games are used in teaching, as well as to reveal the perceived possibility of improvement of students' competences by using the games.

Accordingly, the aim of the study was to test the following hypotheses:

- educational games are not used to a great extent in teaching logistics and SCM at faculties in the Republic of Serbia;
- the teachers that use games in teaching logistics and SCM are satisfied with the possibilities of improving students' competences with the use of the games;
- the teachers are not familiar with the logistics and SCM games; and
- the teachers are interested in the application of games in teaching logistics and SCM.

The study was conducted in the following seven phases:

1. Determination of population of teaching staff in the field of logistics and SCM at faculties in the Republic of Serbia;
2. Identification of risks related to the study and ways of their mitigation and/or overcoming;
3. Creation of Questionnaire on the application of educational games in teaching logistics and SCM at faculties in the Republic of Serbia;
4. Selection of method of sending the questionnaires and collecting the completed questionnaires;
5. Design of Questionnaire by selected tool;
6. Sending the invitations for participation in the survey and collecting the completed questionnaires; and
7. Analysis of results.

In the first phase, the data about the population of teaching staff in the field of logistics and SCM within the accredited study programs at universities and faculties in the Republic of Serbia were collected. In that sense, different documents and data were used, such as: "Guide through accredited study programs in the institutions of higher education in the Republic of Serbia" published by the Serbian Commission for Accreditation and Quality Assurance (CAQA) in 2013, "The list of accredited faculties and universities" published by the Ministry of Education, Science and Technological Development in 2013, the data from the official websites of higher education institutions and the data from direct contact with the representative of one faculty. The total of 16 accredited universities (8 state and 8 private universities), and within them 114 accredited faculties and 5 integrated universities, were considered. After consideration, it was determined that at 26 faculties there are courses in the field of logistics and SCM (15 state and 11 private faculties), with that the total of 70 teaching staff (44 teachers and 26 teaching assistants) are engaged in teaching these courses. Then, the data about teaching staff were collected (the title, the first and last name(s), and the official e-mail address).

In the second phase, the specific risks related to conducting the study were identified and named: distrust of respondents, the disinterest of respondents, the busyness of respondents, and disturbing of respondents (see Table 1). Next, the ways of mitigation and/or overcoming these risks were determined in order to provide a higher response rate.

In the third phase, the Questionnaire on the application of educational games in teaching logistics and SCM at faculties in the Republic of Serbia was created. The attention was given to the aims of the study and hypotheses; to the specific requirements about an appropriate number of relevant, clear, and short questions; to using open-ended response questions and fixed-alternative questions; to grouping questions, etc. The recommendations given in Zikmund et al, 2010, p. 337-352, were very useful during this phase of the study. The final version of Questionnaire was organized into the following five parts: 1. Introduction part; 2. The part called "Teaching in the field of logistics and SCM"; 3. "Educational games in teaching logistics and SCM"; 4. "Application of educational games in teaching logistics and SCM"; and 5. Final part of Questionnaire. At the end, the Questionnaire was technically and professionally checked.

In the fourth phase, the method of sending the questionnaires and collecting the completed questionnaires was chosen. First, it was decided to use an on-line questionnaire and accordingly to electronically collect the filled-in questionnaires. Then, several tools which enable the use of on-line questionnaires were considered, like Google Forms (https://docs.google.com/forms), SurveyMonkey (https://www.surveymonkey.com), SurveyGizmo (http://www.surveygizmo.com), Qualtrics Research Suite (http://www.qualtrics.com), etc. Finally, the Qualtrics Research Suite was selected based on good recommendations from several researchers (Zikmund, et al., 2010; Machado, 2012), price and attractiveness of different options (about 100 types of questions, the user can manage the activation of questionnaire, use of the Serbian language, redirection of questions based on answers, a possibility for respondents to take a break during the process of responding, use of visual indicator about completion of questionnaire, good options for visual design of questionnaire, easy collecting of data).

Table 1: Ways of overcoming risks related to conducting the study

Risks	Ways of overcoming risks
Distrust of respondents	– sending the personalized invitation for participation in the study with a carefully chosen subject of the e-mail – providing the highest possible level of anonymity of respondents
Disinterest of respondents	– providing a prize for respondents – sending the clear and short invitations for participation in the study – pointing out to the time required for completion of the questionnaire – making clear and short questions – using open-ended response questions at the beginning of the questionnaire in order to focus respondents on the questioning process (recommendation adopted from Zikmund et al, 2010, p. 338)
Busyness of respondents	– using on-line questionnaires – providing respondents to complete the questionnaire in a short period of time – providing respondents to take a break during the process of completion of the questionnaire – providing respondents the possibility to see the level of completion of the questionnaire, with a status bar or some other visual indicator of questionnaire length (recommendation adopted from Zikmund et al, 2010, p. 356-357) – making the appropriate number of relevant, clear and short questions – organizing the questions in several groups according to the topics – providing respondents to receive the invitations for participation in the study on Monday morning – limiting the horizontal visibility of questionnaire because of its display on different versions of the web browser – displaying the questionnaire page by page and avoiding that respondent need to scroll through the questionnaire (Zikmund et al, 2010, p. 356-357) – limiting the process of questioning to the previously defined number of days
Disturbing of respondents	– exclusively sending 1 invitation for participation in the survey by e-mail

In the fifth phase, the Questionnaire was designed and tested with the help of the Qualtrics Research Suite. One part of the Questionnaire is given in Figure 1.
