Abstract: *Cooperation with an external consultant, when certifying some of the management systems, is useful especially when the aim of the certification isn't the certificate itself, but quality improvement of the management system. Organizations are free when choosing a consultant, but his qualifications have to be carefully considered. This paper aims to found out which criteria for choosing a consultant are assessed as important by customers and therefore should be considered when certifying some of the management systems. We conducted the research among 49 randomly picked (small and medium-sized) organizations from the territory of Serbia (either in direct contact or by e-mail) on criteria considered important for choosing a consultant for management systems based on the directions for choosing a consultant (contained in ISO 10019:2005). Respondents assessed the importance of those criteria in cases when they choose a consultant for the first time. The research was repeated among the same respondents who evaluated the importance of the same criteria after the implementation of observed management system. The criteria considered in the research are divided into four categories: personal characteristics of the consultant, references of the consultant, consultant's offer and information on consulting organization.*

Key words: *differences, selection, management system consultant*

1. INTRODUCTION

Abraham (et al., 2000) presented reasons for an organization implementing management systems. They pointed out that, if the implementation is conducted in accordance with a valid strategy (when the goal of certification isn't certificate itself but improvement of quality of management system under observation), certificate can also guarantee high quality of outcome. This can be a reason why an organization would decide to implement quality management system or some other management system and, on that occasion, hire a consultant for the chosen management system. According to Soriano (et al., 2002), the aim of hiring a consultant is not only to draw up a plan but also to set up a relationship based on mutual collaboration so that the client learns how to resolve problems that may arise in the future when the consultant is no longer at hand. This especially refers to small and medium-sized organizations. By 2002, 95% of all small and medium-sized organizations used services of external consultants (Bennett and Robson, 2004). However, as it is pointed out in research of McLachlin (et al., 1999), the process of hiring a consultant isn't always successful for customers. The level of success when choosing a consultant, as well as his relationship with customers is also discussed by Gable (et al., 1996) who suggests a model for assessment of customer's success in choosing a consultant. Similar to this, Cebeci and Ruan (2007) suggested analytic hierarchy process as the most appropriate analytical tool when choosing a consultant who would satisfy customers' requirements in the best way, claiming that customers often don't appreciate differences in quality of consultants.

The fact is that information on references and personal characteristics of consultants are more and more available to public and that organizations preparing for implementation of some management system can use these information to choose a consultant. Except the description of personal characteristics and references of a consultant, information on the organization in which the consultant is employed (e.g. distance from customer, number of employees, possessing of ISO 9001 certificate and so on) are also available to organizations. Information rarely available to organizations are those about consultant's offer (e.g. price of service, terms of payment and so on). However, any research hasn't been conducted yet, so it is not known to which extent organizations search and use that kind of information, as well as how customers understand those information and trust them. Besides, there is a growing number of consultants for management systems that makes the choice more difficult for organizations.

In their research from 2000 (conducted on the territory of Australia) Kumar, Simon and Kimberley found out which indicators do management consultants find the key indicators for their personal success, and which can be related to strategic abilities. These are: quality of service, setting clear objectives, solving problems, integrity and honesty, client – consultant communication and credibility. After that, Simon and Kumar (et al., 2001) found out, through their research (conducted on the territory of Australia), what the customers' opinion on strategic abilities was that lead toward consultants' success. According to this research, five key abilities are: ability to listen to and comprehend the client, quality of service, client – consultant communication, integrity and honesty and technical knowledge. Using these research, Simon and Kumar also summarized the reasons why customers would hire a consultant. Some of the most important reasons are lack of knowledge and manpower, gaining independent and objective advices, getting additional funds and quick solution of disputed issues. Also, in their research conducted in 2004, Bennett and Smith pointed out the key criteria which affect the choice of a consultant. Those are high fee rate – price of consultant's day, duration – number of consultant days spent on project and total cost of service. They also pointed out, in the same research, that the choice of a consultant isn't related to the type of a consultant, working area or type of an organization. However, it is unknown how customers evaluate criteria for choosing a consultant which are mainly based on directions of the international standard ISO 10019:2005 for choosing a consultant and which bring together the criteria that refer to consultants themselves (through their personal characteristic and references) and criteria that refers to the organizations in which the consultant is employed (e.g. consultant's offer, size of an organization, distance from customer, level of equipment of the organization and so on). Therefore, the aim of this research is to assess how customers evaluated the criteria for choosing a consultant when they were choosing him for the first time. Additionally, this research also provides an insight into whether the importance of the same criteria changed after the process of the implementation of the observed management system. Such findings can be useful for organizations when choosing a consultant again (for example, if the observed organization inclined towards management system integration), as well as for consultants to improve quality of their services.

2. HYPOTHESYS

In this research we tested two hypothesis we find important, based on gained theoretical knowledge and experience in the area of consulting:

- H1. There is a group of criteria that are significantly more important than the rest of the criteria.
- H2. There is significantly difference in criteria ranks when choosing a consultant for the first time and after implementation of a management system.

3. RESEARCH SETUP

The research about customers' opinion on criteria for choosing a consultant was being conducted from april 2009 to december 2010. Questionnaire was delivered to the respondents personally or by e-mail.

Population and sample

The population of this research consists of all organizations from the territory of Serbia that were in the beginning of implementation of some management system (quality management system, food safety management system, environmental management system and/or occupational health and safety management system) and which, on that occasion, used services from external consultants. There isn't any official register of such organizations and there isn't an official register of certification bodies that work on the territory of Serbia. According to data from some certification bodies and public available data, we estimate that population of this research consists of about 300 organizations. However, this number should be considered as unreliable because many of certification bodies have a register of issued certificates but not register of certificated organizations so, considering that one organization can have several certificates (for different management systems), the number of issued certificates doesn't have to be equal to the number of certificated organizations. Also, there is no information on status of actual validity of the issued certificates in those registers. The majority of the population (99,7%) consists of small and medium-sized organizations (<http://www.capital.ba>, 12.08.2010.). We also noticed that, according to data from Economy register of Serbia, there are more service-oriented than manufacturing organizations. Most of these organizations are

from Belgrade and central Serbia and that is probably the consequence of unbalanced development of Belgrade and central Serbia compared to the rest of Serbia.

Accordingly, the sample chosen for this research consists of small and medium-sized organizations (which have up to 250 employees, according to http://ec.europa.eu/enterprise/policies/sme/facts-figures-analysis/smedefinition/index_en.htm). Most of them (28 of them) are service organizations from Belgrade and central Serbia (2/3 belongs to central Serbia, 1/3 belongs to the rest of Serbia). The sample is chosen randomly and the sample size is about 16%. Exactly, the questionnaire was delivered to 107 organizations, and we got correctly filled out questionnaires that were taken into consideration for analysis from 49 organizations that means the rate of responsiveness on the questionnaire was 45,8%. The rest of organizations weren't taken into consideration because they weren't ready for cooperation, they didn't fill out the questionnaire correctly or they didn't finish implementing observed management system. From each organization which responded to the questionnaire, we got the answers from director or chief manager (for quality, food safety, environmental or occupational health and safety).

The questionnaire

The questionnaire includes criteria for choosing a consultant which should be evaluated by an organization representative. The criteria were mainly derived from standard ISO 10019:2005: Guidelines for the selection of quality management system consultants. It lists what characteristics a consultant should possess but it doesn't point out how important are each of these characteristics. The respondents were asked to evaluate the importance of 25 criteria for choosing a consultant, listed in Table 1.

Table 4: Criteria for choosing a management system consultant

Group	Criteria	Source
Personal characteristics of a consultant	1. Fairness, honesty and sincerity	ISO 10019:2005; Simon and Kumar, 2001
	2. Communicativity and kindness	ISO 10019:2005; Simon and Kumar, 2001
	3. Discretion	ISO 10019:2005
	4. Capability of offering different and creative solutions	ISO 10019:2005; Simon and Kumar, 2001
	5. Determination and independence	ISO 10019:2005
	6. Dedication to the project	ISO 10019:2005
References of a consultant	7. Years of work experience in management systems through providing consulting services	ISO 10019:2005
	8. Years of work experience in management systems as a management representative	ISO 10019:2005
	9. Years of work experience in management systems through performing the function related to implementation of the observed management system	ISO 10019:2005
	10. Years of work experience in management systems as internal or external auditor of the observed management system	ISO 10019:2005
	11. Years of work experience in the area of the observed management system in the same area as customer's is	Work experience
	12. Possession of an additional education (attend courses and seminars, having published books and papers, having some rewards and recognitions and so on) from the area of observed management system or customer's area	ISO 10019:2005
Consultant's offer	13. Availability of service (waiting time from submitting a requirement for starting a project)	Work experience
	14. Lasting of service (offered deadlines for project completion)	ISO 10019:2005
	15. Share of days that a consultant will spend in direct work with employees within customer's organization compared to the overall time of project realization (in order to ensure that the consultant is familiar enough with	Work experience

Group	Criteria	Source
Data on consulting organization	products and processes of the organization)	
	16. The terms of service payment	Work experience
	17. The price of service	Work experience
	18. Distance of the consulting organization from customers	Work experience
	19. Number of employees in the consulting organization	Work experience
	20. Level of equipment of the consulting organization's rooms	Work experience
	21. Appearance of the consulting organization's rooms (if they are tidy and pleasant)	Work experience
	22. Availability of information on consulting organization and its employees (e.g. through the site, fairs and so on)	ISO 10019:2005
	23. Good reputation of the consulting organization	Work experience
	24. Recommendations (especially personal recommendations from business partners, customers, organizations that have been cooperating with the consulting organization and so on)	Work experience
	25. Information that consulting organization applies ISO 9001:2008 – Quality management system	Work experience

The respondents evaluated in total 25 criteria for choosing a consultant for management systems, which were grouped in 4 categories. The respondents evaluated the importance of the criteria on a scale ranking from 1=unimportant to 5=extremely important. The same respondents evaluated the same criteria twice. Firstly, the respondents evaluated the importance of the stated criteria before implementation of management system, while they, the second time, evaluated the importance of the same criteria after the implementation.

Except the given questions, there is one more, open question, in the questionnaire which gives a freedom to the respondents to add some of criteria which are maybe omitted in the questionnaire and they consider it should be among other questiones in the questionnaire. This question was also used to detect defects of the questionnaire through pilot data collection and analysis (conducted among 10 organizations that match the description of the sample of this research).

4. STATISTICAL ANALYSIS

We conducted two experiments:

1. One Sample t test for establishing the outranking criteria according to customer's preferences before and after implementation of management system.
2. Paired Samples t test for measuring whether there were changes in criteria importance, before and after management system implementation. In each of analysis, value of parameter p that is less than 0.05 point to statistically significant difference.

Identification of outranking criteria before and after implementation of management system

From data in Table 2 we can notice the difference in the customers' evaluating the criteria for choosing a consultant before and after implementation of management system. Before the implementation, the customers paid most attention to the following criteria: good reputation (Mean=4.469), consultant's dedication to the project (Mean=4.448), recommendations (Mean=4.408) and consultant's work experience as a consultant (Mean=4.286). This group of criteria is pointed out as the most important because the marks of these criteria didn't significantly differ from the highest value - good reputation (Mean=4.469). The customers also answered the question how they would evaluate the same criteria, if they had to choose a consultant for management systems again. In the same way, the group of criteria that the customers find would be the most important when choosing a consultant again is also pointed out. This group consists of the same criteria, but in different order: good reputation (Mean=4.632), consultant's dedication to the project (Mean=4.571), consultant's work experience as a consultant (Mean=4.530) and recommendations (Mean=4.469).

Table 2: The rank of criteria (One-Sample Statistics)

Before providing the consulting services			After providing the consulting services		
Criteria	Mean	Sig.	Criteria	Mean	Sig.
Good reputation	4.469	0.995	Good reputation	4.633	0.976
Dedication to the project	4.449	0.848	Dedication to the project	4.571	0.528
Recommendations	4.408	0.586	Work experience - consulting	4.531	0.311
Work experience - consulting	4.286	0.074	Recommendations	4.469	0.105
Fairness, honesty and sincerity	4.184	0.036	Fairness, honesty and sincerity	4.408	0.026
Price of service	4.184	0.004	Communicativity and kindness	4.347	0.004
Terms of service payment	4.122	0.003	Creativity	4.286	0.005
Communicativity and kindness	4.061	0.002	Availability of service	4.245	0.001
Lasting of service	4.061	0.005	Lasting of service	4.245	0.004
Availability of service	3.918	0.000	Work experience – auditor	4.204	0.000
Discretion	3.898	0.000	Price of service	4.163	0.000
Creativity	3.878	0.000	Discretion	4.102	0.000
Determination and independence	3.857	0.000	Terms of service payment	4.102	0.000
Work experience – function	3.796	0.000	Work experience – function	4.082	0.000
Possession of ISO 9001 certificate	3.776	0.002	Possession of ISO 9001 certificate	4.082	0.003
Work experience – auditor	3.694	0.000	Determination and independence	4.061	0.000
Share of days in the organization	3.694	0.000	Work experience in customer's area	4.000	0.000
Work experience in customer's area	3.592	0.000	Share of days in the organization	3.837	0.000
Availability of information	3.490	0.000	Work experience – manag. repres.	3.673	0.000
Work experience – manag. repres.	3.265	0.000	Availability of information	3.612	0.000
Additional knowledge	3.265	0.000	Additional knowledge	3.469	0.000
Appearance of organization's rooms	2.571	0.000	Appearance of organization's rooms	2.735	0.000
Number of employees	2.245	0.000	Number of employees	2.388	0.000
Level of equipment of org. rooms	2.245	0.000	Level of equipment of org. rooms	2.347	0.000
Distance from customers	2.061	0.000	Distance from customers	2.327	0.000

The group of the most important criteria is bold.

Difference between the importance of criteria before and after implementation of management system

We used the paired samples t test to check whether the ranking of criteria differ before and after management system implementation. From Table 3, we notice that this significance exists in the following pairs: For instance, in the first pair – Fairness, honesty and sincerity statistically significant increase of the mark was noticed from moment X (Mean=4,18; St. Deviation=0,928) to moment Y (Mean=4,41; St. Deviation=0,674), $t=-2,403$, $p=0,020$ (mutually). The average increase of value of the criteria observed in this Pair is -0,224, while 95% confidence interval extends from -0,412 to -0,37. The value of eta squared (0,11) shows that the influence of provided consulting service is medium. According to Cohen (et al., 1988), influence is considered to be small for each value of eta squared that is less than 0,06; influence is considered to be medium for each value of eta squared that is between 0,06 and 0,14; influence is considered to be high for each value of eta squared that is higher than 0,14).

Table 3: Difference between the importance of criteria before and after providing the consulting services

Pair	Criteria	Mean	Std. Deviat.	Paired Differences				
				Mean	95% Confidence Interval of the Difference		t	Sig. (2-tailed)
					Lower	Upper		
Pair 1	Fairness, honesty and sincerity - x	4.18	.928	-.224	-.412	-.037	-2.403	.020

	Recommendations - y	4.47	.680					
Pair 25	Possession of ISO 9001 certif. - x	3.78	1.476	-.306	-.595	-.018	-2.134	.038
	Possession of ISO 9001 certif. - y	4.08	1.239					

The criteria statistically different before and after implementation of management system are bold.

x- before implementation of management system; y- after implementation of management system

5. CONCLUSION

We considered, in this paper, the sample of 49 organizations which implemented some of management systems and, in that occasion, used the services of external consultants. The aim was to find out on what basis the organizations were choosing consultants for management systems, that is how did they evaluate the criteria for choosing a consultant (personal characteristics of a consultant, references of a consultant, the consultant's offer and data on consulting organization) in the moment of choosing a consultant for the first time, as well as was there a change in their value system of the same criteria after implementation of observed management system. The analysis showed that, after the implementation, when the customers gain a certain level of experience in working with consultants, they change their value system of criteria for choosing a consultant so there is significantly difference in evaluating criteria before and after implementation of management system when it comes to the following criteria: fairness, honesty and sincerity; communicativity and kindness; creativity; work experience in consulting; work experience as a management representative; through performing the function related to implementation of the observed management system; work experience as an auditor; work experience in customer's area; availability of service and possession of ISO 9001 certificate in terms of increasing the value of the considered criteria and good reputation in terms of decreasing the value of the considered criteria. We see that significantly difference didn't appear in each criteria which means that second hypothesis was partly confirmed. However, the group of the highest evaluated criteria, after implementation of management system remained the same as before the implementation. This group consists of the following criteria: consultant's dedication to the project (belongs to personal characteristics of consultant), work experience in consulting (belongs to references of consultant), recommendations and good reputation of the organization in which the consultant is employed (belongs to the information about the consulting organization). Existence of this group of criteria that are significantly more important than the rest of the criteria we can conclude that the first hypothesis is completely confirmed.

Unlike this, research conducted by Kumar, Simon and Kimberley (et al., 2000) and Simon and Kumar (et al., 2001), which are similar in the criteria being evaluated, point out 3 indicators that lead toward consultants' success, evaluated as the most important by both consultants and customers. Those are: Quality of service, Integrity and honesty and Client – consultant communication. Except those indicators, Setting clear objectives, Solving problems and Credibility are also evaluated as the most important only by costumers, while Technical knowledge and Ability to listen to and comprehend the client are also considered the most important but only by customers. These research was conducted on the theritory of Australia.

Research in this paper, conducted on the theritory of Serbia, was based on slightly different criteria, so the results do not match completely with the results from the previuos two research. Criteria for choosing a consultant being evaluated from the customers are mainly based on international standard ISO 10019:2005-Guidelines for the selection of quality management system consultants. Criteria form the standard were complemented with the criteria often used in practice (e.g. on tenders) which means that criteria in this research are both theoretically and practicaly grounded.

Indicators used by Kumar, Simon and Kimberley (et al., 2000) and Simon and Kumar (et al., 2001) refer to consultant's characteristics, while research in this paper also includes criteria refering to characteristics of the organization in which the consultant is employed as well as the characteristics of the service expressed through consultant's offer.

Criteria "Quality of service" which was evaluated as one of the most important in previously mentioned research was intentionally left out in this research because it is not clearly defined what is considered under the quality of service. The quality of service is too broad a term which can be evaluated through several criteria. There are another criteria used in those research that are, in this research divided into more criteria. When talking about consultant's characteristics, the most important, from the point of view of customers in Australia, are Technical knowledge, Integrity and honesty, Ability to listen to and comprehend the client and Client – consultant communication, while the key role, from the point of view of customers in Serbia, is Dedication to the project. Except these criteria, customers in Serbia found the most important Recommendations and Good reputation that are directly connected with the impression of previous work of the consultant. Reason for this may be found in the fact that the market in Serbia is relatively small and customers and their business partners, as well as other interested parties have good communication channels through which they exchange these and similar information.

This research is different comparing to the others because the evaluation was conducted twice. It is determined how customers evaluated criteria when they hire a consultant for the first time as well as how

they evaluated the same criteria after they gained some experience working with consultants. In addition to this, the group of the most important criteria is selected from the rest of criteria because there is statistically significant difference comparing with the others.

Abstract: Growing importance of so called “de facto” standardization can be seen in many areas because companies can not operate in isolation; matching problems have to be resolved and processes of formal standardization processes are time-consuming. Ad hoc de facto standardization is standardization without support of standards developing organizations (SDO). The main intention of this paper is to present example of “ad hoc de facto” standardization in the area of organizational sciences. This article presents development of non-public standard related to job classification in 21 communal and public-utility companies operating in Serbia based on the staff structure analysis, performance analysis, analysis of basic earnings and theoretical background.

Keywords: Ad hoc de facto standardization, Job classification, Public service companies, Restructuring

1 INTRODUCTION

When discussing about definitions of standardization and standards, in many cases, very narrow focus on this term is evident. According to ISO/IEC (1991) standardization is the activity of establishing, with regard to actual and potential problems provisions for common and repeated use, aimed at the achievement of the optimum degree of order in a given context. According to ISO/IEC (2004) and CEN (<http://www.cen.eu/boss/Pages/glossary.aspx#s>) standard is: “document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context”. However, not all standards are consensus-based or approved by a recognized body and standards may have a format other than document, e.g. software as in the case of Windows (Hesser et al., 2007, pp. 8).

In 1997. professor Henk de Vries introduced another definitions of standardization and standard which highly contribute to establishing theory of standardization. According professor Henk de Vries (1999) standardization is activity of establishing and recording a limited set of solutions to actual or potential **matching** problems, directed at benefits for the party or parties involved, balancing their needs and intending and expecting that these solutions will be repeatedly or continuously used, during a certain period, by a substantial number of the parties for whom they are meant. According professor Henk de Vries (1999) standard is an approved specification of a limited set of solutions to actual or potential **matching** problems, prepared for the benefits of the party or parties involved, balancing their needs, and intended and expected to be used repeatedly or continuously, during a certain period, by a substantial number of the parties for whom they are meant”. In these definitions **matching** problem is problem “of interrelated entities that do not harmonize with one another and solving it means determining one of more features of there entities in a way that they harmonize with one another, or of determining one or more features of an entity because of its relation(s) with one or more other entities” (de Vries, 1999).

2. HOW COMPANIES GET STANDARDS THEY NEED - DE FACTO STANDARDISATION

It has to be clear that term of standardization is not related to only institutional or formal standardization. Term of standardization can be used in area of internal or company-based standardization, cooperation-based or consortia-based standardization or national, regional or international standardization. Growing importance of so called “de facto” standardization can be seen in many areas because companies can not operate in isolation, matching problems have to be solved and process of formal standardization is time consuming. De facto standardization is standardization carried out by non-governmental parties other than formal standardization organization (de Vries, 1999). Many standards are developed by industrial consortia

or in cooperation with other parties involved. Reasons for using consortia based standards instead of usage formal standards (developed by organizations for standardization) might be (modified in accordance to Hesser et al., 2007, pp 18):

- **Speed.** Proposing new standard development to national or international organization for standardization is possible option but time and effort consuming. Consortia of companies with same and matching problems will have more interest to develop standards faster than SDOs.
- **Confidentiality.** In area of ICT, companies, that possess specific knowledge or developed technologies, may be interested in consortia-based standards to protect their specific intellectual assets, knowledge or technologies and to establish cooperation with others companies of interest. In other fields companies may recognize interest in solving matching problems, but may not be willing to allow interference in solving that problem with others out of consortia.
- **Intellectual property rights.** Formal standardization organizations (FSOs) allow the inclusion of patents in standards only when patent holder declares willing to negotiate licenses on reasonable terms. Companies that possess essential patents may prefer a consortium that allows high licenses fees.
- **Solving mutual or matching problems.** Many organizations out of consortia have not interest in solving particular problems. In many cases FSOs are not interested in development particular standards.

Knowing that companies have many options in area of standardization one question has to be answered: How companies get standards they need? If company needs standard and satisfactory standard does not exist, the new one has to be developed (figure 1). Company must decide whether to co-operate with other companies and interested parties or not. Next important issue is usage of standard development infrastructure of SDOs (Standardization development organizations). SDOs include formal standardization organizations (e.g. international, European or regional FSO); sectoral, professional or specialized standardization organization (SSO) and governmental or national standardization organization (GSO, NSO). Developing needed standards can be done without support of SDOs – that kind of standardization is called “ad hoc de facto standardization”. More about this and other ways of standardization (formal or de facto SDO standardization) can be found at work of de Vries (1999, 2010) and Hesser et al (2007).

3. EXAMPLE OF “AD HOC DE FACTO” STANDARDS DEVELOPMENT IN AREA OF ORGANIZATIONAL SCIENCES

3.1. Matching problem

This paper presents the ongoing experience in “ad hoc de facto” standard development in area of organizational sciences. During consultant work of the project team from the Faculty of Organizational Sciences, a matching problem related to the lack of standardized systematization of job positions in the 21 public and public-utility companies in Serbia (employing over 18000 employees) was observed. Observed companies were engaged in different industries and have had different classification of jobs, making comparison among them difficult. Consequently, employees performing similar jobs in different companies have different job titles, and specific positions are often treated as different jobs, although in essence are not. It was therefore necessary to introduce a new solution (model) that would have the smallest set of typical jobs and to associate these jobs with jobs existing in observed companies.

3.2. Need for standard

During the project of restructuring of public enterprises and public utilities consultants have proposed idea related to systematization of typical basic jobs in order to diminished different number of jobs in observed companies by several tens of times. The tasks of the project team, in development solution for “matching problem” included staff analysis, performance analysis, as well as salary analysis. The analysis were performed to describe current status within each company, but also to compare companies among themselves. However, it was necessary to modify representation of the existing structures in those companies.

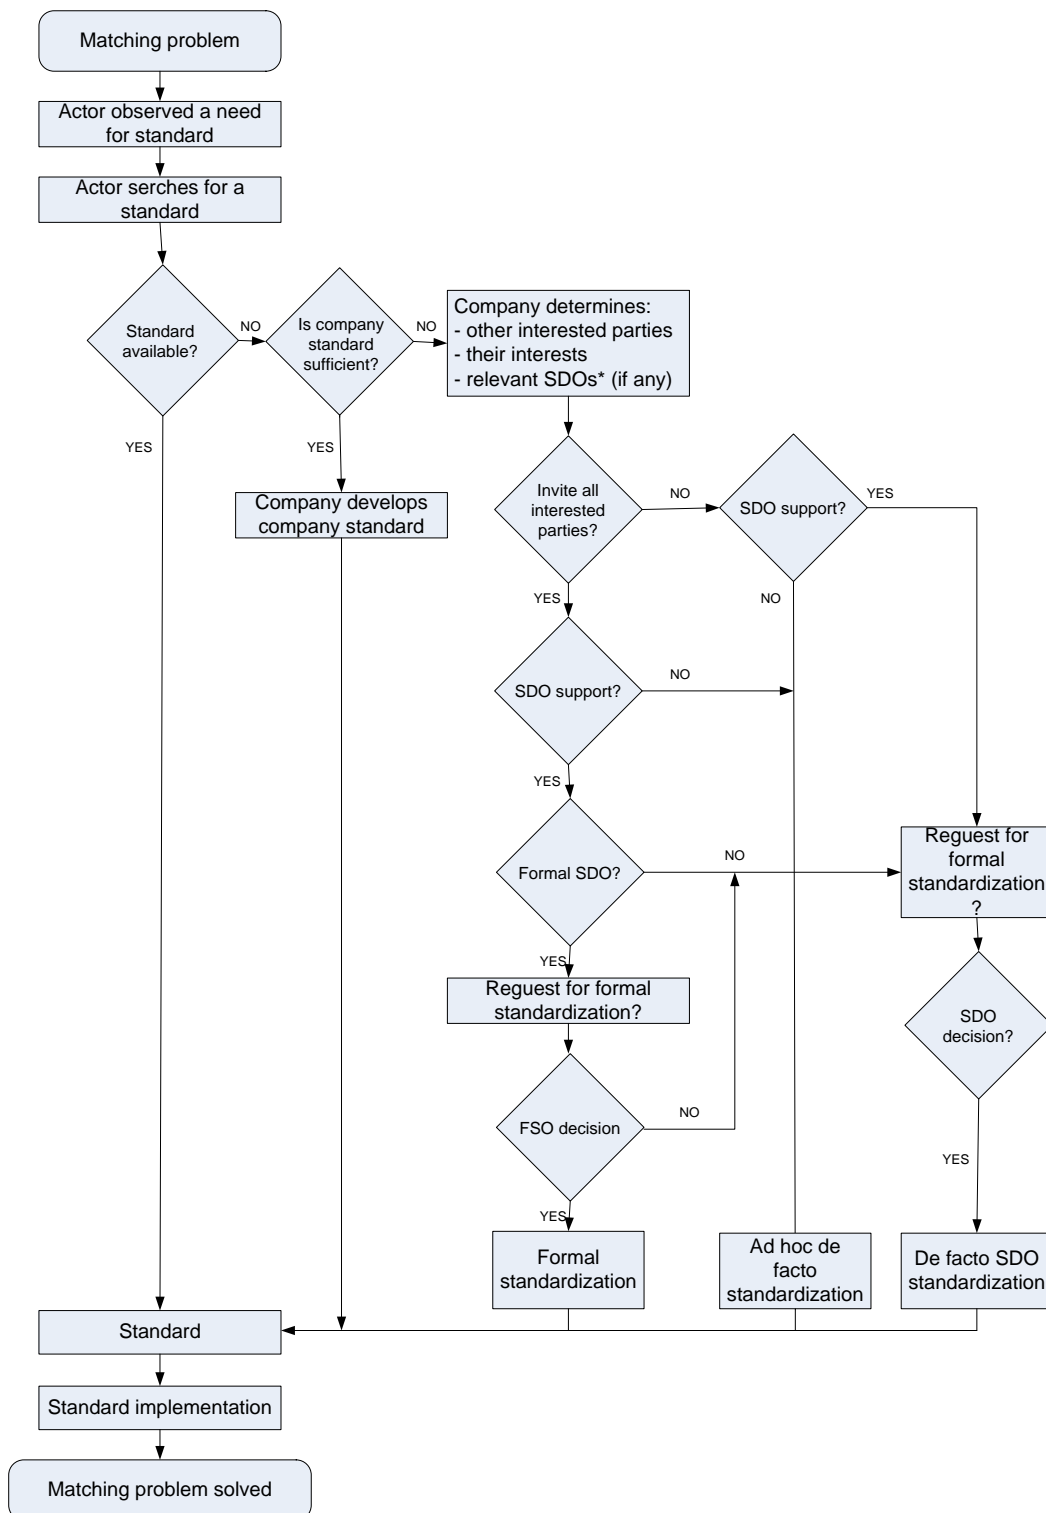

Figure 1. How company gets a standard it needs (de Vries, 1999, pp 16)

*SDO – Standards developing organizations include formal standardization organizations (FSO), sectoral or specialized standardization organization (SSO), governmental or national standardization organization (GSO, NSO)

3.3. Standard development

3.3.1. The staff structure analysis

The staff structure has been analyzed from the standpoint of its conformity with the requirements of efficient conduct of all business tasks. The analysis included also qualitative, in addition to quantitative characteristics of the organizational structure. The bases for the analysis of the observed group of companies were individual staff reports by companies. These partial analyses consist of analysis of the organizational structure and division of work in the company, analysis of span of management control, analysis of organization units by the criteria of core/non-core activities, analysis of the current job classification, the proposed systematization of jobs, analysis of qualification of employees, age structure, service and overall fluctuations. The analysis was made on the basis of the entire staff that was obtained from the personnel records of employees.

The staff structure analysis was based on:

- **The division of work:** Division of work helps to observe which model of organizational structure is characteristic of specific company, which are its organizational units, and what is the number of employees in each of them.
- **Analysis of the span of control:** The span of control shows the number of workers who are directly subordinate to a supervisor. The course of range of control is associated with the cost of management and efficiency of control of task execution. This analysis shows the total number of managers in the company, then the average span of control is by a supervisor, and the highest and lowest range by the organizational units.
- **Systematization of organizational units by the criteria of core/non-core activities:** In each company is necessary to find core units, which directly contribute to carrying out basic activities of enterprises, and non-core units, which provide indirect contribution. Depending on the company size this analysis was made at the level of sectors and/or offices.
- **The type and the number of employees in organizational units by the criteria of core/non core /support activities:** In each company were observed three groups of employees by this criterion. The first group consists of employees on core jobs, who directly contribute to the basic business activities. The second group consists of non-core employees, who contribute indirectly to the basic activities of the company. The third group consists of employing support staff, whose job is to provide support and assistance to other employees while performing their tasks. Results are shown in tables and graphs.
- **Analysis of the current job classification:** As stated, the analysis of existing jobs in the company proposed rationalization by the standardized jobs. In the existing classification was observed a large number of jobs that were valued differently, mostly because of the ability or commitment of employees, and with the departure of employees retained same way of evaluation. Therefore, a small number of standardized jobs is suggested and that still allow stimulation of employees over the variable part of salaries and related mechanisms. This analysis shows the total number of jobs in the existing classification, as well as the total number of standardized jobs in the company.
- **Systematization of typical jobs:** In accordance with the conclusions of analysis of the current job classification, a set of standardized jobs was proposed, through the enrichment of basic activities, with respect to technological limitations. The common services were conducted at the level of coordination of all public and public utility companies which were included in the project. For such defined positions, various categories that would depend on the level of education of an executor or any other parameter such as experience or previous results could be defined.
- **Analysis of qualification of employees:** Education of employees is analyzed according to the classification of the seven degrees of qualification. Staff MSc and PhD are classified for simplifying seventh degree in Serbian education system.
- **Analysis of the age structure of employees:** Age structure of employees is analyzed by indicators of the average, minimum and maximum age, in all organizational units. After that, there were made two classifications of personnel. The first classification divides the workers into groups by age single culture - pragmatism, existentialism, or conservatism. Age group up to 30 years (specific manifestation depends of the organizational culture) has the core value of pragmatism, seeks success and ambitions that motivate them, and is ready to work hard with the use of new technologies. The group aged 30-45 has tentatively culture existentialism, where the main motivators are quality of life, nonconformity, seeking autonomy, and loyalty of employees is directed primarily towards themselves and their own family. Age group over 45 years is characterized by conservatism, which, depending on the environment, can be manifested differently, but in our environment is often expressed through the rejection of change, desire for job security and resentment with new values that are accepted in the enterprise (Hofstede, 1990).The classification analyze workers by decades

of age, where the first covers the period up to 30 years, next to 40 and so to the last, which includes workers aged 60 and older. This analysis includes indicators of average age, then determines the difference in years between the youngest and oldest employee in the company, the average age by the organizational units that were previously defined, and the prevailing culture of the company.

- **Analysis of the overall experience of employees:** The analysis of total work experience of employees was completed by companies. Experience was analyzed by average, minimum and maximum values for all organizational units at the highest level, and in a later analysis four groups were formed: a group of up to 30 years of service, a group of 31-35 years of service, a group of 36-38 years of service and a group of over 38 years of service.
- **Analysis of the fluctuations:** Fluctuation analysis showed the total number of workers who had come and the total number of workers who had left the company in the observed period.

3.3.2. Performance analysis

Performance of the company includes its ability to achieve a certain result, under the given conditions of operation. Performance is, therefore, the ability to provide certain services or produce the products, based on what will be achieved by the income, with certain costs, by a number of people for some time.

The analysis led to the performance data of the period in which it was achieved with more or less efficiency, and identified the key causes of the achieved results. Performance management, in the context of the project, meant to determine the optimal relationship between specific characteristics of the organizational and staffing structure and the achieved results. This means that it is possible to determine in which direction some changes (rationalization) in the current organizational and staffing structure could be made, and this reduction should not affect the ability of the fulfillment of tasks. The achieved results by listed standardized jobs, which are measured on the basis of appropriate indicators, suggest that there are potential reserves for employees who perform these tasks.

Performance analysis was based on:

- **Analysis of performance by the value-creation-chain:** Performances of the organization are collectively shown in the value-creation-chain, which includes a clear distinction between the direct value creation activities and support activities. Selected structure allows the standardization of infrastructure activities and performance comparison of these activities in a variety of public sector enterprises, but also adoption of joint recommendations for all companies. Activities which create outputs represent the core business, and therefore the specificity of each company in the public sector, so the comparison is only partially possible at the group level, but is possible at the level of industry activity, even with companies that operate in the private sector. The analysis of the value chain in all public and public-utility companies shows the total number of employees in the observed public and public-utility companies, with total reserves in the observed group, the number of employees on support jobs and on jobs that carry the basic activity, as well as the largest reserves.
- **Performance analysis of the mass standardized jobs:** This analysis shows the twenty standardized jobs with the most employees, sorted by number of employees. Effects and reserves for standardized jobs with the largest number of employees are presented in tables. A negative value indicates that there is a lack of workers in a particular workplace, while positive value in this column indicates that there are reserves in the observed workplace.

3.3.3. Analysis of basic earnings

Analysis of basic earnings included basic earnings distribution within each enterprise and between enterprises. This analysis determined the relative relationship between different kinds of work being carried out in whole public service, as well as differences in wages for the same jobs in different companies, for which was used introduced standard model. As a result of this analysis, a summary of the current state and possibility to consider the need of making a unified payment system for public service at the level of the observed group were received.

3.3.4. Theoretical background

Assumptions for job classification are based on the theoretical basis of Henry Mintzberg and Michael Porter. For the purpose of creating a standardized model Porter value chain has been used as a well known in the

literature and in empirically proven model. According to that model, sharing of the overall organization's task is based on the different contributions of specific activities to competitive ability of the organization (Porter, 2001). This standardized jobs matching activities that are identified by modifying the Porter's value chain and Mintzberg's model (Čudanov et al, 2010), each part of value chain or organization block corresponds to one or more typical jobs. The functions are divided into 2 groups - support activities and primary activities - and then can be divided to the subgroups integrating a partial set of activities by functions (Dulanović & Jaško, 2009). Porter value chain is combined with Mintzberg's model, which divides organization into the 5 elements, namely the strategic apex, middle line, operating core, techno structure and support staff (Mintzberg, 1983). The presented inter-company standard of job classification is presented in (Jaško et al., 2010) and can be extended in each company for more specific jobs in the operational area if there is need for that. Connection of existing positions with standardized jobs was carried out on the basis of existing jobs systematizations and description of tasks on each specific workplace. Thus, for example, position of "Engineer GIS", "Specialist Analyst - Programmer", "Engineering Analyst - Programmer", "Engineering Information Technology", which have similar descriptions of the different companies in the typical model associated with the position of "IT Support Designer". In this way comparison among companies by the standardized jobs was enabled. Also, analyses described later in this paper were made enabled.

CONCLUSION

Growing importance of so called "de facto" standardization can be seen in many areas because companies can not operate in isolation, matching problems have to be resolved and processes of formal standardization processes are time-consuming. More and more standards are "de facto" standards - developed by parties other than formal standards developing organizations. However, many organizations are aware of matching problems, but are not informed or knowledgeable about usage of concept of "ad hoc de facto" standardization (Mijatovic, 2008, 2011). The main intention of this paper is to present example of "ad hoc de facto" standardization in area of organizational sciences. The aim of this paper was to show development of non-public standard related to job classification in 21 communal and public-utility companies operating in Serbia based on the staff structure analysis, performance analysis, analysis of basic earnings and theoretical background. This case is based on ongoing process of standards development and implementation. Results of this innovative practice in communal and public-utility companies operating in Serbia and standard effectiveness have to be explored in future research. In our future work we intend to examine potentially influential factors on adoption of "ad hoc de facto" standardization in management of communal and public-utility companies operating in Serbia.

Abstract:

Accumulated issues of societal security demand a complex and comprehensive approach to organization of society for their solution. The focus of security has been transferred from state to real society factors, which makes room for security science to investigate conditions and interactions of society's security and organizational context. The paper is focused on societal security approach from the point of view of risk existence and analysis for the existing and supposed dangers with the goal to organize society for preventive action, but also to be prepared for rapid and efficient response for protection of societal values. Specific highlight is put on standardized approach to risk management as the assumption of efficient identification of dangers and implementation of management process into society's organizational context.

Key words: challenge and threat, risk, societal security, management

1. INTRODUCTION

The last years of the 20th century brought new context and positions in international relations. The state as the basic form of society's organization lost its significance as the basic and the only security factor. Different conflicts in international relations pointed out the individual and the society in the whole as the inevitable security objects. The society became the object of security science interest from the aspect of factors which define it and solve more and more complex problems of societal security. In security studies there are two notions, *societal security* and *social security*, and between the two there is no clear distinction. Although those are synonymous, the development of societal security concepts is a consequence of the fact that traditional *national security* concept did not solve all the tensions which exist in society viewed as the most complex human collectivity. Thus, the society became a significant security object threatened by different phenomena and situations. All of these imply that there is a necessity of acquaintance and management of old-new threats, with the goal of prevention, but also response, in situations with threatening attributes.

2. NOTION AND SIGNIFICANCE OF SOCIETAL SECURITY

Eternal human pursue for secure life resulted with generation of different security approaches. One thing is certain; man has the ultimate need for living and creating in a secure environment. What was clear during the early beginnings of human society is that man was more vulnerable if he was alone. This fact caused the creation of different groups, formal and informal, which provided people with the achievement of different needs, and overall the need to be secured. Thus, the security became one of the priorities of development and progress of those organized 'groups'. The variety of needs and attributes which directed people towards organizing were a sufficient trigger for multiplying the problem, as well as for differentiating new organizing criteria. Namely, it was not significant if group just secures enough food or other life needs, but there was a question of origin, custom, affiliation, etc. This approach brought new and more complex groupings in social groups which now had a need for higher level of security achieved through the existence of its own territory and state. The existence of state understood the existence of different mechanisms which would secure the survival of the state itself with intention of progress, but also the society located at the territory of that state. For a long period of time, the state was pointed out as the exclusive object which should be secure. However, the sources of state instability were multiple on different bases, and the existing approaches to security did not solve problems. It became clear that challenges and threats to state security do not come only from the exterior, but from the relations within the state itself. The fact stated opened completely new approaches to security, namely the issue of state security segments related to the individual, social groups, and society in the whole.

In security arena the societal security showed up, which was not the same as the state security. With this fact, the state and social subjects became aware of opening of new security horizons. Besides the state and

supranational organizations, there is also a private sector which shows, with its capacities, knowledge, and capabilities, that it possesses the power of influence on security streams in society and state, and that it is significant security factor (Drennan, McConnell, 2008).

Changes in the environment, technical and technological development, and demographic expansion caused more complicated relations between peoples and nations, which increased their needs for even larger security of their own values. The efforts of society for building secure conditions for development and progress are becoming dependent from external and internal factors (Keković, Kešetović, 2008).

3. CHALLENGES AND THREATS TO SOCIETAL SECURITY

Contemporary society, set on the crossroads of global changes and internal needs and conflicts, is becoming very vulnerable on every change of the existing condition. There are different challenges in front of which the society can be found, from natural, through technical and technological, to social, economical, and military. The common characteristic of all challenges to security of society is the pursuit for a state different from the state of secure society (Aqirre, 2004). Regarding the fact that society or individual within society in most cases is not aware of the existence of challenges to his security, it is necessary to develop the awareness of all subjects of society about the existence of situations, events, and activities in which the security of society could be disturbed or questioned. Challenges, no matter where they come from, are potential elements which under certain circumstances can cause negative consequences to society's values. The configuration of challenges as phenomena, activities, or events, understands the existence of constructive elements that make the essence of every challenge and define the way of its action. The analysis of these elements and determination of the level of influence to society's values is the estimation of possibilities for certain challenge to be materialized through negative consequences to society's values. Every challenge which is determined to have great possibilities to result with negative consequences to society's values has a threat status. Causes of threats to society's values we can put into following groups:

1. Man-made threats,
2. Natural threats, and
3. Technical and technological threats.

Man-made Threats

In focus of majority of activities in one society, there is man. Regarding the imperfection on different bases, man in its engagement in work and production processes comes in situation that he acts conscientious or unconscious mistakes. Man-made mistakes could be observed on micro, middle, or macro levels.

On micro-level this kind of approach is focused on the role of individual. The biggest part of problem is directed to "how and why" people make mistakes.

Observation on middle-level leads towards the interest about organizational factors and processes which could have the role in causing the event with negative consequences. The key question is whether organized system can compensate human limitations and environment factors which facilitate the occurrence of negative events.

Through macro-level observation we can see the existence of possible causes which make negative events as more or less inevitable and unavoidable characteristics of modern society (Keković, Kešetović, 2008).

Natural Threats

The influence of natural forces on society's security is more and more explicit. Natural forces show their action through concept of natural disasters and other emergencies. The number of these disasters is constantly rising. Man is also contributing to the increase of number of natural disasters with his need to develop more secure society. Namely, intending to create more comfortable and secure living conditions, man is uncontrollably and unconsciously changing natural forces' streams. Consequences of natural forces' actions are seen in the loss of human lives, material destruction, and permanent changes of life functioning in environment.

Technical and Technological Threats

Technical and technological sources of threat mean the existence and development of technical and technological infrastructure as a subject of threatening of people's lives, their health, and environment. They include large chemical complexes, incidents and accidents in chemical plants, accidents in production warehouses and during transport of hazardous materials, nuclear power plants and other nuclear facilities, then stockpiling of radioactive waste, as well as other complexes that pollute the nature.

Fast development of information and communication technology, satellite communications and Internet had a negative influence on change of our perception of timely and spatial limitations. This technological development has consequences on both causes and characteristics of risk events. Technology became so complex that users often don't understand how it works, which is making finding and correcting the mistakes in functioning harder. Successful design of technological systems demands close connection of elements, which is increasing chances for the occurrence of cumulative effects of negative events (Keković, Kešetović, 2008).

4. RISK MANAGEMENT

In terms of existence of a vast number of challenges to society's security, the need for systematic dealing with their management arose. It means that the selection of the existing and future challenges which have potential to cumulate the negative effects is needed. Risk management is actually the tool which allows that. In order to be successful and sustainable, risk management has to be integrated into organizational processes of society and supported by social subjects. Risk management concept helps social organizations and society in general in efficient risk management through the application of standardized risk management process on different levels and within specific areas of society's activity. Such concept should provide that all information about risk that appeared within this process are properly processed and used in decision making on relevant level of society's organization.

Contemporary theorists are consent that organized and systematic risk management process in the area of societal security should have the following phases: context definition, risk assessment, risk treatment, monitoring and revision, and consultations and communication (ISO/DIS 31000:2008).

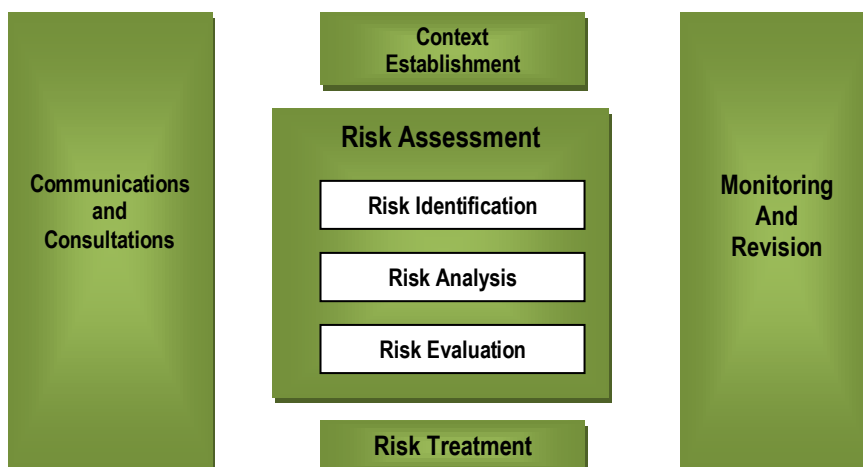

Figure 1: Risk Management Process

Source: ISO/DIS 31000:2008

Defining the Risk Management Context

The risk management process should be adjusted with culture, processes, and structure of organizing in one society. Through context definition the basic characteristics for risk management are determined for risk management, and also the scope and criteria for the rest of the process is set. The context can also include internal and external parameters relevant for social group. By defining the risk management context the goals, strategies, scope and parameters of society's activities or parts in which the risk management process is applied in should be established. Risk management should be done with full recognition of need for justification of sources used in risk management. Needed resources, responsibilities, and authorities should be specified according to real needs with respect to the existing threats, but also to those which could happen. For complete defining, the risk management context should be observed in relation to the internal and external factors.

The external context includes all the factors outside the subject which could influence to implementation of set goals. Understanding the external context is important for securing that external stake holders, their goals and interests are considered when risk criteria are developed. The external context is based on observation of the whole society, but with specific details from legal and regulatory conditions, understanding needs and

recognizing the stake holders and other risk aspects which are specific for the area of application of risk management process (Keković, Komazec, Glišić, 2009).

External context should consider the following:

- Cultural, political, legal, regulatory, financial, economical, and competitive environment, whether international or regional;
- Key initiators and trends which influence the society's goals;
- Perceptions and values of the exterior stake holders.

The internal context includes all the factors within the subject which could influence in a way in which the society is managing risks. Internal context should be determined because:

- a great risk for society or its parts means failure in achieving the strategic, project, and business goals with risk influencing on the ongoing organizational and political engagement, credibility, and society's values,
- goals and criteria of certain project or activity should be considered in light of society's goals as a whole, and
- Risk management is happening within projected society's goals.

Usable form of internal context depends on:

- abilities as resource of knowledge (capital, people, expertise, processes, systems, technologies),
- flow of information and decision making process,
- relation with internal stake holders,
- goals and strategies for achievement of planned goals,
- policies and processes,
- standards and referent models adopted by society, and
- structure (leadership, roles and responsibilities).

Risk Assessment

Risk assessment (Figure 1) represents comprehensive process of identification, analysis, and evaluation of risks. Risk assessment is of process character, and integrated within the organizational context of society (Keković, Savić, Komazec, Milošević, Jovanović, 2011).

Risk identification is recognition of risks relevant for projected society's goals. Society should identify risk sources, events or series of circumstances, as well as their potential consequences. The goal of identification is making of comprehensive risk list based on those events and circumstances which could help, prevent, decrease or slow down the implementation of goals. The comprehensive identification and risk registering is of essential importance, because the risk which was not identified in this phase is excluded from further analysis. Identification should include all risks no matter if under society's control or not.

In risk identification very important things are relevant and timely information. It is also related to appropriate first information about risk, if it is possible to get such information. Experts with appropriate knowledge should also be included in risk identification. After identification of what could happen, it is necessary to take into account the causes and scenarios showing what consequences could happen. All major causes should be considered.

Risk analysis is related to understanding of risk. It provides the input about the risk evaluation and decisions whether certain measures for risk mitigation or elimination should be undertaken, and which are the most suitable (the most acceptable) risk treatment strategies.

The risk analysis includes consideration of interdependence between risk cause and source, their positive and negative consequences, as well as the likelihood of occurrence of these consequences. Also, the factors that influence on the occurrence of consequences and likelihood of their occurrence could be identified. The risk analysis is focused on determination of consequences and likelihood of their occurrence, as well as on other risk characteristics. Special attention should be devoted to events or series of events that could have multiple consequences and could influence on large number of goals, specifically on those which are causing cumulative and synergetic effects and waterfall effects. Also, the consideration should include the existing risk control and its efficiency. Risk analysis is resulting with calculation of risk level.

$$RL = f(L, C) \quad (1)$$

RL-Risk Level, L-Likelihood, C-Consequence

Risk level is categorized into five degrees, e.g. categories: 1-insignificant, 2-minor, 3-moderate, 4-major, 5-catastrophic. Likelihood and consequences are also put into five degrees (Table 1).

Assurance with risk assessment and its sensitivity to preconditions and assumptions defined in risk management context should be considered in analysis and effectively transferred to decision makers and other stake holders if necessary.

In accordance with standard ISO 31010, in risk analysis there are various methods that can be applied for analysis of data identified during risk assessment process. Regarding the possibility of quality criteria definition for risk analysis, the matrix risk analysis method showed large applicability. The convenience is shown in precise criteria and risk elements relations definition, e.g. the quantification of primarily quality data. This possibility of defining the criteria from the view of risk management subject's needs is the true advantage. The criteria are defined by experts from given field with respect to standpoints of persons implementing the technological process.

Table 1: Risk Level Matrix

CONSEQUENCE		Insignifi cant	Minor	Moderat e	Major	Catastro phic
LIKELYHOOD		1	2	3	4	5
Rare	1	1	2	3	4	5
Unlikely	2	2	4	6	8	10
Moderate	3	3	6	9	12	15
Likely	4	4	8	12	16	20
Almost Certain	5	5	10	15	20	25

Risk evaluation includes the comparison of risks discovered during analysis process, and of criteria for risks determined within the consideration of the entire context. The final result of risk evaluation is determination of priorities of risk treatment (Table 1). Priorities are risk with level from 20 to 25. The goal of risk evaluation is help during decision making on basis of risk analysis results about what risks should be treated and what are risk treatment priorities. Society's goals and the scope of circumstances which can occur should also be the subject of circumstance analysis. In situations in which the choice should be made between options, it will depend on the social situation context. The decisions should consider the wider risk context and should include the consideration of risk tolerance defined by other social groups. Decisions should also take into account the legal limitations accepted by social structures.

Risk Treatment

Risk treatment is a choice of one or more options for accession to risk or application of those options. It can include cycle process of risk treatment evaluation, conclusion that residual risks are not able to be treated, creation of new risk treatment option and estimation of their effects until the achievement of appropriate degree of residual risk which can be reduced by society according to risk criteria.

Risk treatment options do not exclude one another, and they are no applicable in every circumstance, which depends of defined risk management context.

Risk treatment has to result with the construction of risk treatment plan. The goal of risk treatment plans is registry of ways in which the chosen options will be applicable, of resources, and timely and other limitations. Information which is entering into risk treatment plans can include:

- expected benefit,
- action and limitation measures,
- persons responsible for plan approval and persons responsible for plan application,
- suggested actions,
- monitoring and reporting demands,
- source demands, and
- time adjustment.

Monitoring and Revision

Monitoring and revision relate to:

- analysis and lessons learned from events, changes, and trends in society;
- detection of changes in exterior and interior contexts, including changes of the risk itself which could require a revision of risk and priorities treatment options; and
- checking if risk and treatment control measures are efficient both within plans and implementation.

The real improvement in implementation of risk treatment plans is showed by the achievement measure, which can be installed in management, measure and activities of internal and external reporting.

Monitoring or revision could include regular checks or controls of what is already present, which can be periodical or sudden. Both aspects should be planned and adjusted with defined goals (Kurtz and Browne 2004). It is not enough to count only on periodical reviews and controls. The results of monitoring and revision should be registered and sent internally and externally as reports when needed, and can also be used as input for revision of risk management concept. Responsibilities for monitoring and revision should be clearly defined.

Consultations and Communication

In every phase of risk management process the communication and consultation with interior and exterior stake holders should be undertaken. That is why in early phase the communication and consultation plan should be developed. This plan should identify problems connected to the risk itself, its consequences and measures which have to be taken when dealing with risk.

Efficient internal and external communication is necessary for securing that those responsible for implementation of risk management process, understand bases on which the decisions are made, as well as the reason why certain activities are necessary so that society's culture significant for risk management process would be improved.

Team approach to risk management has advantages in:

- risk analysis from aspect of different competence fields,
- development of communication plan,
- enabling appropriate changes in leadership during risk management process,
- securing that different views and thoughts are appropriately considered when assessing risk,
- taking care that interests of stake holders are understood and considered,
- helping during appropriate context definition,
- helping in appropriate risk identification, and
- securing improvements and support for risk action plan, from leadership's side.

5. RISK MANAGEMENT STANDARDIZATION

The variety of approaches and acting in finding solutions which are sustainable in terms of contemporary challenges, risks, and threats, is inevitably leading towards creation of security environment based on national capacities. One of basic characteristics of contemporary threats and crises is transnationality, the independence from national borders. Globalization trends, supported by modern technologies, Internet and lack of energy created the environment in which the society became vulnerable to threats made in distant parts of the world. It means that the need for creation of supranational security organizations has showed up. However, such organizations demand the adjustment of goals, methods and working language, as well as the approach to societal security (Landol, 2006).

International organization which enables the creation of such conditions and the adoption of international standards in the area of societal security is International Standardization Organization.

The basic idea of creation of international standards is based on participation of national standardization organizations, acceptance of global societal security principles, and implementation of agreed and adopted documents for national development strategies.

In forthcoming period, the survival of nations and social groups will depend on security and maintenance of society's critical functions, before the classic directing to the security of territories, and that means the ability for securing the functioning of government, economy, and civil society institutions, sustainability of critical infrastructure and democratic principles of state institutions' functioning which are under a great pressure in conditions of occurred crisis situations.

Society's response to risks and threats, with goal of decreasing their influences to the minimum and diminishing the social loss, has to be promoted and recognized as a social responsibility. When the incident occurs, society should understand that cooperation with other social groups and organizations in allocation of human and physical resources is necessary for continuity of its own operations because the resources demanded for emergency response and recovery could be deficient and dislocated.

6. CONCLUSION

The necessity of the existence and implementation of risk management related to security of contemporary society is connected with fast development and progress, primarily in technical and technological field. The price of higher living standard and easier life is paid through disturbed environment condition, ecological problems, increase of accidents, etc. The warning presence of mentioned dangers makes the subjects of society to increase the number of activities directed to their own security. Timely, realistic, and comprehensive analysis of present and future dangers gives the advantage to society structures in relation to

negative events. Regarding the globalization trends, influence to dangers, even on a local level, can demand the engagement of regional and world organizations, which demands a certain level of understanding with those organizations. Acceptance of standardization postulates in the area of societal security overrides the problems in communication and action, and facilitates the efficient direction of resources towards the goals set.

Abstract: Standardization has influenced improvements in many areas, from the quality of products and services to the quality of processes and systems. Moreover, it has contributed to the changes in the business philosophy that is not concerned solely with generating profits but also to having the responsibility for the influences that the economic entities have both on each other and on the other people, the environment and the society in general. By applying standards to a certain aspect of the management system (quality, the environment, occupational health and safety, etc.) economic entities accept the responsibility for their influences and bring not only profits, but also people into the focus of their attention. The paper discusses the identification of the management systems standards that have the greatest contribution to spreading the idea of humanism. The elements of humanism are reflected as effects in various segments and activities, which is discussed for each standard of the presented management systems, established on the international level. In this paper were used a general scientific method, and other general and special methods, such as: descriptive methods, methods of scientific observation, analysis, synthesis, concretization, generalization, and analogy. In accordance with the observed facts upon certain phases of research the results presented in this paper should challenge similar studies from all that are involved with standardization but also with any technological or scientific development.

Keywords: humanism, standards, effects, society, economy

1. INTRODUCTION

Experts in the area of standardization have been trying for many years to mathematically explain how the application of standards generates profits. What is in the world of economy called added value, in the area of standardization has yet another dimension. A very important, but so far neglected, value added to standardization is also humanism.

The improvements that come through saving time in the operating activities, better usage of the available funds, increasing customer satisfaction, reducing the costs of idle time, scrap, etc., are only the first level of positive effects of the application of standards. Essentially, the effects of standardisation can be viewed in three dimensions (figure. 1).

Figure. 1 : The spiral representing the effects of applying standards

Although most organizations find the main motives for applying certain standards to their management systems first and foremost in **Profits** that, among other things, come from good business and open markets and **Status** that ensures customer loyalty, but willingly or unwillingly as a side effect they achieve certain elements of **Humanism**.

2. BASIC ELEMENTS OF THE STANDARDS FOR MANAGEMENT SYSTEMS AND THEIR HUMANE ASPECTS

International Organisation for Standardization (ISO) has developed a great number of standards in all areas of human activity. As a rule, one of the consequences of applying the international technical standards is the globalization in the production area, resulting in a high level of universality of products so they can equally be used anywhere in the world. That is why the international standardization contributes both to the customers that can always have functional products at their disposal, and to the sellers that have markets for the products.

However, such technical standards are usually supported by the standards that define the quality management systems, environmental, occupational health and safety and other management systems (figure. 2). One of the common qualities that all the standards for management systems share is the existence of certain elements that directly or indirectly cause the appearance of some humane effects in their application, which tend to have the ability of being permanent. Which elements of standards have the explained qualities and how they generate the elements of humanity is explained in the rest of this paper.

Figure 2: The analogy of the connection between technical standards and management systems

2.1 Humane Aspect of Requirements Related to Management Responsibilities

One of the initial requirements of each standard related to the management systems is the requirement for organizational responsibilities and authorities. Numerous successful business systems show how important it is to adequately define the ways to satisfy such requirements. Since the central part in the humanism belongs to humans, clearly defined responsibilities contribute to their more devoted work, which results in certain satisfaction emerging from the acknowledgement and acceptance in their own working environment. Furthermore, by fulfilling this requirement of the standard a clear responsibility framework is defined for each individual and the possibility of conflict among the employees is avoided. This means that the employees cannot be in a dilemma about their responsibilities while making business decisions or about who to address in order to solve certain business problems, etc.

By further consideration a conclusion can be made that this requirement of the standard may even have a considerable influence on reducing the anomaly of the modern business era called mobbing. Mobbing is usually manifested in the atmosphere of non-defined responsibilities of the employees, which may produce negative consequences. Specialists in the field of psychology have made some assessments that mobbing can cause some serious psychological problems that can reduce working ability. Fulfilling this standard requirement can reduce the problem of mobbing to the minimal level, or can even eliminate it, since responsibility framework is strictly defined for each employee.

2.2 Humane Aspect of Requirements Related to Communication

The importance of communication, from the viewpoint of humanism, is reflected in the need of each human to be a part of the community, to contribute to a common goal and to prove their abilities. When such human needs have been fulfilled, an individual can achieve psychological stability and can freely develop in every possible sense. After all, such individuals direct their behaviour in a positive way, and continually work on improving their skills and knowledge.

The lack of good communication first causes the problems related to work efficiency. Such atmosphere further increases the number of conflicts that can lead to a growing number of unfulfilled work tasks on the side of the employee, which can cause some sanctions. Therefore, wrong communication can gradually cause chaotic atmosphere, inefficient business and general dissatisfaction of the employees.

Therefore, it is not a coincidence that each standard for a management system must contain the requirement for defining communication. It implies that the standard consciously demands communication on all levels of hierarchy as each organization represents a specific business system that functions through the constant exchange of information among the employees and all interested parties.

2.3 Humane Aspect of Requirements Related To Resource Management

The standards for resource management systems include people, infrastructure, working environment, etc.

2.3.1 Human Resources (competencies, awareness, training)

If we reconsider the fact that no business system can function without humans, we can easily come to the conclusion that human resources represent the most important resource for each organization. For a long time the human right to education and development has not been just a part of some manifest on human rights, but also a part of many laws applied on both national and other levels. Moreover, international standards indisputably demand all business systems that apply them to continually plan and realize the training and improvement for their employees. Although the first visible effect is the benefit of the employer because of the better company functioning, new ideas and working methods, the covert effect is of humane character because the central role belongs to an individual that develops his abilities, widens his knowledge, thus achieving both personal and professional satisfaction.

2.3.2 Infrastructure and Working Environment

It is well-known in specialist psychological circles that certain external influences, if continually exerted on people, can cause significant changes in their consciousness and behaviour. Even inadequate light conditions in the working environment, according to numerous researches, can cause less productivity, mild forms of depression, insomnia and other psycho-physical problems.

Unfortunately, even today we can witness that in many countries, as the result of poverty, there are serious abuses and inhumane working conditions. It is fully legitimate for every organization to be profit-oriented, but on the other hand there is an explicit requirement, in each management system standard, that demands meeting certain criteria related to the working environment and the infrastructure. From the humanism viewpoint, it could be interpreted as creating a suitable microclimate where each individual can efficiently and effectively conduct all his working activities. The consequence of all this is better functioning of the organization as a whole.

3. SYSTEMS (STANDARDS) THAT DIRECTLY CONTRIBUTE TO SPREADING THE IDEA OF HUMANISM

3.1 Standard ISO 14001 - „Environmental management“

The development of civilisation and technologies for exploitation of the natural resources has almost erased the line between making better life quality for people and endangering their environment. This is obviously a quite paradoxical situation, since without adequate environment it is not possible to have a quality life. Endangering the environment is continuously in progress through the exploitation of forests, water resources and the soil that endanger the survival of flora and fauna of the area in return. Moreover, the environment is endangered by industrial plants that release dangerous pollutants into water, air and soil thus endangering human health. Most countries formed so-called Black and Red books. Black book registers the irrevocably lost plant and animal species that, on the global level, are estimated to a few thousand species, while Red books register endemic species that have to be protected in order to survive. Since humans as individuals can survive only in a complete ecosystem it is necessary to make a great effort to sustain its equilibrium.

According to one of the divisions, the third generation of the human rights is the right to piece and clean environment. Carel Vasak that in the late 1970's established this division, considered these human rights as being most endangered because they did not have a legal and political confirmation of the time. If we bear in mind that the idea of the standard ISO 14001 was produced as early as 1972, it can be stated that this standard greatly contributed, above all to spreading the awareness of the environmental protection, and to managing business according to the principles of responsible behaviour towards the environment. (Three generations of human rights, http://en.wikipedia.org/wiki/Three_generations_of_human_rights)

If we compare the population increase, new technology development and the ever diminishing environmental space, it can be concluded that the role of the standard ISO 14001 is almost a missionary one. The application of environmental management system directly produces humane effects because the main objective is to provide the environment adequate for the survival of humans. Immediate effects are - a more rational exploitation of energy resources, reducing the risk of ecological incident occurrence, control management of all the aspects that influence the environment, as well as many other effects that in addition to humane, have various positive economic effects on the very organization.

Although the application of this standard cannot guarantee total absence of the environmental endangerment, each organization that applies it maximally reduces the negative ecological influences, or keeps under control the processes that can cause some serious consequences for the environment.

Such reduction of the negative influences on the environment provides people with time necessary to, along with the development of science in general, develop some new and better systems and technologies that will help people to use natural resources in a more responsible fashion and to keep the balance necessary for the survival of all the species including humans. Accordingly, the growing awareness of the environmental has created some new organizations that, through their activities, help the preservation of certain environmental segments. One of them is *Forest Stewardship Council* that has established an internationally accepted standard dealing with the lungs of our planet, the forests and how to manage them in a responsible way.

3.2 Standard OHSAS 18001/SA 8000- „Human safety – life“

Human beings start learning and developing early in their lives in order to be well-prepared for work throughout their lives. Work should provide them with adequate life quality but also with the possibility to develop professionally. However, we live in the world where people rarely find the job they were educated for and where the majority of population have jobs that, as a rule, destroy human dignity or even directly destroy the health and lives of people that do them.

However, the right of every human being is to work safely. According to the report on work injuries presented by The Ministry of Labour and Social Policy, the Republic of Serbia in 2009, a great number of work injury reports was recorded (Table. 1).

Table. 1. The recorded work injury reports in Serbia in 2009

(Serbian Government, Ministry of Labour and Social Policy, Annual work report 2009)

Rb	Injury type	The number of the recorded injuries
1.	Injuries at work	9.391
2.	Professional diseases	7
3.	Work-related diseases	3

The mentioned report analyzes the records dealing with the fatal, collective and severe injuries at work that happened at the very work premises under the close supervision or indirect control of the employer. Council for Safety and Health at Work performed the analysis of 876 work injuries (9 fatal injuries and 867 severe injuries at work) that occurred in 2009. It should be noticed that these are official, reported records and that, as in any other area of life, the unofficial records are far more disturbing.

According to the previous and considering the situation in other countries it can be concluded that the situation is similar. Problems exist everywhere in finding adequate solutions related to the safety at work, and coordinating organizational objectives for the greatest possible production and profits volume and the objectives concerning safety of the employees in such organizations.

Luckily, many subjects are being involved today in the battle for attaining the right for safety, including the organizations that establish standards. The requirements of such standards concern, above all, the

Figure 3: Work injury recorded in 2009 according to predominant working areas

(Serbian Government, Ministry of Labour and Social Policy, Annual work report 2009)

conditions and factors that influence or may influence the health and safety of the employees and all those present at the working environment.

Figure 4: Working conditions in a factory in India

OHSAS 18001 system has been designed to be compatible both with the generic system ISO 9001 and ISO 14001 and to help each organization that applies it to efficiently meet the requirements concerning occupational health and safety. The crucial areas defined by the standard are: a) making plans for danger identification, estimating and managing the risks; b) defining occupational health and safety management programmes; c) defining responsibilities; d) organizing training and raising the levels of awareness and competence; e) improving communication; f) emergency readiness and adequate response; g) measuring, monitoring and improving the performances of the system. (BS OHSAS 18001 Occupational Health and Safety/ Benefits, BSI) All this

requires the organization to responsibly and professionally demonstrates its readiness and commitment to apply the occupational health and safety measures, which demands certain investments. In order to further motivate the organizations to invest in application of the mentioned measures there is an identified range of the positive effects resulting from applying the occupational health and safety measures, including: a) reducing the number of incidents, b) reducing idle time costs and the similar costs, c) demonstrating accordance with the law, d) making the interested parties familiar with the fact that the organisation cares about occupational health and safety, e) showing the innovative and progressive thinking, f) easier approach to new customers and business partners, g) better health and risk management, both now and in the future; h) reduction of the costs related to non-compliance with the legal obligations concerning the occupational health and safety. In addition to all the motivational factors, there are also some legal frameworks in this area that oblige all the organizations to meet the requirements of such documents. Moreover, since there is a growing awareness among people of how important it is to treat the employees in a more humane way, organizations have started to create their image on the market in this sense, too.

Therefore, besides the system OHSAS 18001 other similar systems have been created like ISO 31000 dealing with risk management or SA 8000. The SA 8000 system has been created by the International association for Social Responsibility (SAI) and rests on the international human working rights and the improving work conditions. Unlike OHSAS 18001 system, where official records on the number of certified organizations is hard to find, there is an official record that the SA 8000 system comprised 2.478 certified organizations in 65 countries throughout the world, with more than 1.421.035 employees in year 2010 (Human Rights at Work, 2010 Annual Report, Social Accountability International).

Positive effects of this system application are recognised in the following: a) **improved reputation**: enables the organisation to show the basic values of the company and convinces the interested parties that it is serious in providing equitable and fair working conditions; b) **competitiveness**: in tender processes it becomes more and more important to provide evidence that the organizations are socially responsible. Certification provides evidence that working conditions are fair and that the organization is oriented in that direction; c) **independent acknowledgement**: increased credibility gained through independent audit by an organization approved by the Social Accountability Accreditation Service (SaaS) that is competent to provide detail and unbiased audit of the organisation; d) **transparency**: publicly available information about receiving SA8000 certificates; e) **involving all the interested parties**: all crucial participants, including the employees, union and employee representatives, companies, investors, nongovernmental organizations and the government are included in the SA8000 system (How can SA8000 benefit my organisation? <http://www.lrga.co.uk/standards-and-schemes/corporate-governance/sa8000.aspx>).

3.3 Other Standards with Humane Aspects

Organizations for standardization have established important standards that contribute to the achievement of humane effects in other areas, as well. Above all, these include the standards dealing with health issues, being a fundamental determinant of the survival and development of humanity, and consequently the society in general.

Unfortunately, globalisation in food production and marketing has accelerated spreading of the diseases caused by defective foods. World Health Organisation (WHO) has found out that millions of people die every year as a consequence of defective food consumption, 1.2 million of which die in the south-east of Asia and Africa alone. (Defective food as a serial killer, <http://www.stetoskop.info/Pokvarena-hrana-serijski-ubica-4528-s1-news.htm>) Therefore, the issue of food and its safety has become very important on the global level. The standards and systems whose objective is a full control of the production processes and the safety of finished products include the most frequently used **ISO 22000** i **HACCP** systems, are the standards that through their requirements keep safe both health and life of each individual.

Not all the cases of food poisoning are fatal, so we also have to take into account the factor of quick reaction and adequate diagnosis that doctors need in order to prescribe the most efficient therapy. In that case, human life can sometimes depend solely on the precise laboratory analyses. In order to prevent the possibility of error in laboratory analyses, **ISO 17025** standard for the quality management system in testing and/or calibration laboratories has been developed. Apart from the elements compatible to ISO 9001 standard an ISO 17025 standard system also contains the technical elements related to applying certain laboratory methods for testing, laboratory equipment and the qualifications of the testing staff.

Medicine is doubtlessly a science where an immense technological progress has occurred within a relatively short period of time. Besides the new diagnostic and treatment methods, a whole range of medical appliances invaluable for the treatment today, has been developed. Such a rapid development has resulted in the fact that certain diseases that used to be considered as fatal are now treated as routine surgical procedures with a simple postoperative recovery. The success of treatment heavily depends on the reliability of medical equipment. Therefore, medical equipment producers have a high responsibility to raise the level of reliability as much as possible, so they tend to use **ISO 13485** international standard that defines quality management system requirements for the medical equipment industry. The fact that many countries have decided to include this standard into their legal systems thereby fully regulating this segment of production show how important it is.

Technological progress has greatly contributed to the car industry that now produces a really impressive number of vehicles. Millions of passenger and heavy goods vehicles are used in traffic every day. Feeling the obligation to keep traffic participants safe in their car or lorry, International Organisation for Standardization has established **ISO 16949** standard that defines quality management system in car industry. Increased car reliability increases the safety of traffic participants in return, which results in protecting human lives and avoiding severe injuries.

ISO 26000 is a standard that directly concerns people. The concept of socially responsible business stems from the need of economic entities to coordinate generating profits with responsibility for people, the environment and society in general. A socially responsible business needs to establish: vision, leadership, a communication oriented community, efficiency and social responsibility demonstration, a system for measuring and analysis of its influence on people, profits and the environment and reporting. The basic items ISO 26000 deals with are: organisational management, human rights, work, the environment, responsible business, consumer issues and the involvement in work and development of the community. This standard practically supports the sustainable development related to the growth and changes that sustain and improve the environment, human resources and the society we depend on. The right that the current generation enjoys of exploiting the available resources and the environment cannot deny the same right to the future generations.

4. CONCLUSION

According to the facts given in this work, the initial hypothesis that the humanity is an integral part of each management system can be confirmed. Therefore, it can be concluded that the purpose of all the standards for management systems is not only the management of business but also the securing of all the main postulates of civilisation, which can be seriously shattered by the imperative of profits.

Humanism, as a way of thinking and action, is not only an obligation but a responsibility of us all. Unlike other activities, where humanism is practically a non-operating activity, management systems represent a business strategy that simultaneously sets the conditions for gaining both profits and humanism. The notion of humanism is finely interwoven into the most important elements of management systems in standardization. Clearly, the very nature of standards is voluntary, but having in mind the modern society awareness of the importance of humanism, certain legal frameworks have been set to stimulate the development in that sense.

Even the numerous opponents of the universality and standardization idea cannot ignore the fact that the effort to achieve more humane life and work conditions throughout the world is one of the main objectives of humanity, besides scientific and technological progress. Perhaps such approach and interpretation of the standardization mission can be a good argument for changing their opinion.

Owing to the limited space, this work does not discuss all the considerations related to humane aspects of the standards for management systems of organization, nor does it discuss all the standards where the mentioned aspects can be recognised. Nonetheless, the objective of this work is to encourage further research in the area that will have positive effects on the progress of society in general, particularly on the aspect of humanity.

Abstract: *This paper examines the implementation of the European Standard EN 13850:2011 for postal operators in Serbia, in terms of importance that it plays in raising the quality of postal services, given that its importance is even greater since the implementation of this standard is inevitable in the direction of further inclusion of our society into the European mainstream. At the same time, will be presented the UNEX system for measuring and improving quality of international postal services (UNipost EXternal monitoring system), introduced by the International Post Corporation (International Post Corporation - IPC), provided that the system is the basis for the implementation of EN 13850:2011. This paper will also discuss the indicators of postal service quality, and special attention will be paid to the transit time as a primary indicator that this standard implies.*

Key words: *quality, postal services, measurement, UNEX, transit time*

1. INTRODUCTION

As a precondition for further integration of Republic of Serbia into the European Union (EU), is set the alignment and adjustment of our legislation and standards with European. The European Commission emphasizes the need to have common rules for the development of community postal services and the improvement of Quality-of-Service (QoS). The Commission has identified requirements for postal QoS-Measurement systems that include:

- Independent end-to-end measurement capabilities;
- A focus on national and cross-border distribution service performance;
- A single, uniform and reliable system for monitoring distribution service performance within the Union.

European Commission has acknowledged that the different postal traditions and cultures in Europe would not allow for the establishment of one common unified European measurement system and that national systems should have sufficient freedom to reflect national needs and peculiarities. On the other hand, they should fulfill a defined set of minimum requirements to satisfy the information interests of the Commission, the regulatory authority, postal customers and postal operators themselves.

The objective of the measurement is to estimate the end-to-end transit time QoS given to the customer domestically in each European country and cross-border between the European countries.

The regulatory basis of EN 13850 is laid out in the Postal Directive 97/67/EC, as amended by Directive 2002/39/EC and Directive 2008/6/EC. Main guidance is given in Chapter 6 Quality of Service. Article 16 states: "Member States shall ensure that quality-of-service standards are set and published in relation to Universal Service in order to guarantee a postal service of good quality". Furthermore, EN 13850 is mandatory for measuring the performance levels of single piece priority or first class mail which falls under the universal service.

This European Standard specifies methods for measuring the end-to-end transit time of domestic and cross-border Single Piece Priority Mail (SPPM), collected, processed and delivered by postal service operators. It considers methods using representative end-to-end samples for all types of single piece priority mail services

³ This paper is derived from research within the project funded by the Ministry of Education and Science of the Republic of Serbia, under the name of "Reengineering the operator network of the universal postal service, with the organizational synergy of governmental and economic resources" (TR36040).

for addressed mail with defined transit-time service levels offered to the customer. This standard is applicable to the measurement of End-to-End⁴ priority mail services. (EN 13850 (2011))

The standardized QoS-measurement method provides a uniform way for measuring the end-to-end transit time of postal items. Using a standardized measurement method will assure that the measurement will be done in an objective and equal way for all operators in accordance with the requirements of the Directive 97/67/EC and its amendments.

EN 13850:2011 relates to the measurement of the SPPM services given to household and business customers that post mail at street letter boxes, over the counter at post offices or have pick-ups at their offices.

Benefits of implementing EN 13850 can be:

- Improving the quality of postal services,
- Improving the automation of postal processes
- Improving the management processes in the postal system,
- Improve communication, planning and administration.

Some of the advantages of EN 13850 are:

- Spotting and discovering weak links in the chain of mail transfer through the postal system,
- Getting a clear picture of the effectiveness of the postal system,
- Increase the reliability of transfer of postal items,
- Increase the speed of transfer of postal items.

2. UNEX MEASUREMENT SYSTEM AND POSTAL SERVICE QUALITY INDICATORS

International Post Corporation (IPC) has introduced UNEX (UNipost External monitoring system) in 1994, in order to measure and improve the quality of postal services in the international postal traffic, specially for verification the quality of postal services from end-to-end. The Post of Serbia joined the project of UNEX measurement system on 25/04/2011.

UNEX measurement system provides important data to be used as a basis for further actions to improve service levels. Within the European area, it is used for performance measurement of mail delivery. The objective of this measurement is to improve the quality of services, by pointing to areas where problems and congestion (bottlenecks of the international postal system) occur and reduce the time from admission to delivery of the postal item. This measurement is carried out continuously. The obtained statistics reflect real flows, trends and characteristics of the mail in international postal traffic. In accordance with EU directives in the field of postal services, key indicators for establishing international standards of quality are:

- The percentage of mail that was delivered to its final addressee within three days of posting (J +3) - speed indicator,
- The percentage of mail that was delivered to its final addressee within five days (J +5) - an indicator of reliability,
- Average number of days required for delivering the item.

These indicators relate to the delivery of international first class mail on European area. "J" is the date of receipt of item, while the parameters "+3" and "+5" express the required number of days before final delivery to the addressee during which time collection, sorting, national and international transport, and delivery take place. EU Postal Directive in 1997 set objectives for letter mail service on 85% or more of the items delivered to its final addressee within three days of posting (J+3, J for Jour (Day) + 3 days) and 97% or more of the items delivered to its final addressee within five days of posting (J+5, J for Jour (Day) + 5 days).

The chart below shows the trend over the years since 1997. Each bar represents the average proportion of international priority mail that was delivered within J+3. The number of countries included in the IPC UNEX system was 18 in 1997, 29 from 2005 to 2008, 34 from 2008 to 2010 and 35 in 2011. Last year the transit times in Europe had suffered from adverse conditions in both air and ground transport (i.e. the eruption of the Icelandic volcano Eyjafjallajökull in the first half year 2010 and the bad weather in December). In 2011 J+3,

⁴ Routing from the access point to the network up to the point of delivery to the addressee

the speed indicator, was up to 93.0%, recovering 1.3 percentage points out of the drop of 2 points in 2010 compared to 2009. (UNEX report, 2011)

The UNEX-18 category includes the 15 EU countries before the May 2004 enlargement, together with Iceland, Norway and Switzerland. In 2005 the UNEX monitoring was extended to 29 countries with the addition of Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Romania, Slovakia and Slovenia (called UNEX-29 above). Since 2008 UNEX has covered all 27 EU countries together with Iceland, No-

Chart 3: J+3 performance from 1997 to 2011

rway and Switzerland as well as Bosnia & Herzegovina (part), Croatia, the Former Yugoslav Republic of Macedonia and Turkey (UNEX-34). Lastly, Serbia was included as of April 2011 (UNEX-35).

The measurement is end-to-end, from posting in the origin country to delivery to the final addressee in the destination country, including the time for collection, sorting and transportation.

Chart 2 shows a comparison of aggregated 1994 and 2011 results, covering respectively 18 and 35 postal operators. For 2011 the average performance of the full group of 35 countries reached 93.0% of European cross-border first-class/priority letter mail delivered within three days of posting, J+3 (the speed indicator), and 98.1% within five days, J+5 (the service reliability indicator). Both indicators continue to exceed the objectives set in the EU Postal Directives of 85% in three days, and 97% in five days, and have gone back up compared to 2010, by 1.3 point in J+3 and by 0.5 in J+5. (UNEX report, 2011)

Chart 2: Comparison of results in cumulative performance in 1994 and 2011

In 2011 the average delivery time for the 35 countries was 2.2 days, an improvement of about half of a day since 1998, and of one day since 1994 when the UNEX measurement started, while extending the coverage at the same time. (UNEX report, 2011)

The design for UNEX Measurement System is overall in compliance with the current CEN standard EN13850 Postal services – Quality of service – Measurement of the transit time of end-to-end services for single piece priority and first class mail which specifies the methodology for monitoring of quality of service in Europe. Conformance to this standard is mandatory for the 27 posts in the European Union and those of Iceland, Norway and Switzerland.

After decades of successful application of bar code, emerged the need for advanced technology for tracking and identification of items through postal system that is not limited only to the identification of types of items. The answer is found in the RFID technology that is experiencing tremendous growth in recent years, although its fundamentals are present for several decades. (Peković, O., Tričković, I., Pajković, I., 2011) Each test letter in UNEX Measurement System contains a Radio Frequency Identification (RFID) device, so that as the test letter moves through the mail pipeline, the time of its arrival at specific points can be recorded automatically by radio receivers located in postal facilities. These radio receivers are linked to a global RFID Network run by the International Post Corporation. In a fully anonymous manner, they help to identify any delays which may occur along the postal process, from origin country to destination country.

Picture 1: Process of measuring from sender to receiver

The following table shows key performance indicators: the three indicators presented in this table are the speed indicator (J+3), the reliability indicator (J+5), and the average number of delivery days taken to deliver mail in the countries in the UNEX-in.

Table 5: Percentage of mail delivered in J+3 and J+5 and the average number of days required for delivery

¹Bosnia & Herzegovina (BA): the postal operator monitored in UNEX is "JP BiH Posta" d.o.o. Sarajevo. There are two other public postal operators in this country but in areas other than the one covered in UNEX.

²F.Y.R.O.M. stands for Former Yugoslav Republic of Macedonia.

³The Serbian Post, PE PTT communications "Srbija", joined the UNEX measurement and of April 2011.

Source: www.ipc.be

IPC publishes the UNEX end-to-end results for international European priority letter mail annually.

Method of calculation: based on the posting date for a five-day business week; that is to exclude Saturdays and Sundays, and to exclude national and regional postal holidays in the destination country. In 2011 the following countries had Saturday mail delivery: Bosnia & Herzegovina (partly), Bulgaria (partly), Denmark, France, F.Y.R.O.M., Germany, Lithuania, Malta, the Netherlands, Norway, Switzerland, Turkey and the United Kingdom. (UNEX report, 2011)

Statistical design: the UNEX measurement is carried out continuously over the year and covers both urban and rural areas in Europe. Yearly results are based on test items posted in that year. It mirrors the patterns and the characteristics of real international letter mail such as methods of posting (mailbox, post office, pick-up), methods of franking (stamp, meter, PP), weight (20g, 50g, 100g), size (C6, C5, C4), and addressing (machine typed, hand written). The statistical accuracy of 54 percent of the country-to-country results is lower or equal to 5%, within a 95% level of confidence, while 46 percent reach accuracy above 5%, mainly on small volume mail flows. (UNEX report, 2011)

The validity and independence of the statistics are guaranteed by the UNEX external measurement contractor, TNS Research International Ltd (London, United Kingdom). The UNEX quality management system at TNS Research International received the ISO 9001:2008 certification in May 2010.

3. TRANSIT TIME AS A QUALITY OF POSTAL SERVICE INDICATOR

The overall transit time QoS level is to be expressed as the percentage of mail distributed within J+n days end-to-end according to the Directive 97/67/EC and its amendments. It specifies a set of requirements for the design of a QoS measuring system for SPPM (Single Piece Priority Mail), involving the selection and distribution of test items sent and received by selected panellists. The sample design gives the specifications for the panellists and items to be representative of the chosen design basis. The design basis is the most appropriate structural information available to characterize all real mail distributed in the field of study.

Transit time calculation. The transit time of a postal item shall be measured in units of days and expressed as J+n days. The day of induction J is the date of the next collection after posting.

Continuity of measurement. The measurement system shall be continuous. Posting shall cover all months and weeks of the year and at least all collection days of the week in accordance with the definition of the measurement unit and the transit-time calculation rule. All periods of the year shall be included as well as Christmas, Easter and summer holiday periods.

Non-functioning of the postal operator and days of strikes or industrial disputes shall not be discounted. However, in case of "Force Majeure" events, deduction of corresponding periods may be considered. Any deduction shall be indicated in the reporting and be subject to audit.

Any intended deduction shall be reported to the regulatory authority without delay. Agreement with the regulatory authority on all planned deductions due to force majeure is required prior to the calculation of the annual report.

Calculation of the transit time. For the purpose of this European standard, transit times for domestic and cross-border mail shall be calculated according to the working week calculation rule. Published regional holidays may be subtracted in the calculation of transit time.

The calculation of the transit time takes into account test items posted before the last collection time of the day for the type of mail in the field of study. The last collection time is taken as stated on the postal letterbox, published at the post office or otherwise announced by the postal operator. Test items posted after that time shall be considered as posted on the next collection day.

If a test item is posted after the last collection time, then the day of induction J should be adjusted to the next working day for this type of mail.

Service performance indicators. The following indicators shall be used in the presentation of the transit-time service level result. Only valid test mail items shall be included in the calculations. All postal items delivered up to J+30 shall be considered in the calculations. Postal items not delivered by J+30 may be excluded, because they may be deemed as lost or are not detectable in the system any more within the reporting period.

- On-time performance: The percentage of postal items delivered within the defined service standard. The result shall be presented as the percentage of postal items arriving within the transit time J+n, where n represents the number of qualifying days for the service standard. All reports shall state the level of on-time performance accuracy achieved in the measurement period.
- Cumulative distribution of delivery days: The cumulative percentage of mail delivered within a given period from J+1 to J+10 shall be reported.

Methodology. The measurement shall be carried out by an independent performance-monitoring organisation. The test mail method shall consist of a process in which panellists act as senders and/or receivers. Senders induct test items into the postal operator's mail network and register date and time of posting; receivers register the date of delivery. Senders and receivers shall be spread over all the field of study based on the panel size and the corresponding minimum number of postal areas to be covered, in order to fulfil the specifications of minimum sample size, maximum panellist workload, stratification and geographical coverage. The sending and receiving process shall be organised in order to fulfil the specifications of the sample design. The test mail shall be manufactured in order to fulfil the specifications of the discriminant mail characteristics. A representative sample design may be realised either by a strict proportionality of the test mail flows with respect to the design basis, or by an over-representation or an under-representation of some strata. The latter requires corrective weighting, which allows restoring the proportionality. (EN 13850 (2011))

4. CONCLUSION

Republic of Serbia, which aspires to EU membership, is adapting to European laws and standards, and so the field of postal services is not an exception.

Current situation in our country, according to UNEX results of quality measurement in Post of Serbia, in international postal traffic is shown in Table 2, the results are for the period 25/04 – 30/11/2011 for J+3 and J+5.

Table 2: Achieved end-to-end transit time (Outbound and Inbound) for J+3 and J+5 by Post of Serbia

Serbian Post	J+3	J+5
Outbound	69.10%	86.20%
Inbound	53.20%	91.00%

Source: www.posta.rs

Taking into account that the EU postal Directive stipulated the obligation of receipt, transfer and delivery for 85% of international letters in J+3 and 97% of international letters in J+5, we can clearly see from Table 2 that achieved level of quality in Post of Serbia is below the required level which justifies the reason for implementation of EN 13850.

The reason for improving the quality of provided postal service of international mail, in addition to meeting customer demands for timely delivery and safety of letters, is that according to future system of calculating terminal dues, delivery postal operator will not be paid the full amount of the terminal costs for delivery if quality of delivery is below the prescribed quality standards.

All stated activities show the importance of the adoption of national standards and related documents based on European standards and related documents in the field of postal services.

Abstract: *This paper presents comparative review of two international standards issued by the International Organization for Standardization, ISO 14001:2004 i ISO 50001:2011. Both standards contain requirements with guidance for use and their implementation is explained through a PDCA model. The advantages and disadvantage of implementing both standards were pointed out. Online survey is conducted about presence and level of maintenance standards for environmental management system in companies in Serbia. Thirty companies participated in the survey, from all four sectors of the economy.*

Key words: *Environment, International Organization for Standardization, PDCA cycle, environmental management system, energy management system, survey, cost savings.*

1. INTRODUCTION

Since there is a human life on Earth, there is a link between nature and man. Together, they progressed and developed, and that balance has existed for centuries. Unfortunately, the time has come when the man "jumped" a few steps forward and because of that industry, science and technique has been developed and he totally forgot about the nature. To this day, nature did not forget that and it is warning us every day. Of course, the solution is not to go back in time when we didn't know what electric circuit is and when we knew much less about laptop and cars. What we can do is to emphasize that environment around us needs to be customized to the nature, and also that we need to restore balance that is lost a long time ago. As the years passed, people enjoyed in wealth that nature gave them and they weren't thinking about consequences. Industrial zones have been created and colossal factories were opened, but on the other side rivers were contaminated, trees were cut down and air was polluted. As the society modernized, nature was giving more intense signals that something is wrong. An increased number of earthquakes, eruptions, disrupted order of the seasons, extreme temperatures, tsunami and other catastrophes have led to the point where we need to sit down and ask ourselves, what have we done? Because of those worrying informations, International Organization for Standardization (ISO) decided that in addition to many standards adopt two more of great importance for society and nature, ISO 14001:2004 and ISO 50001:2011, which are seen as a possible solution for problems about environment and nature.

2. ISO 14001 : ENVIRONMENTAL MANAGEMENT SYSTEM

"People affect with their activities on environmental characteristics, and the effects of those characteristics negatively affect on physical and mental health."

Gary W. Evans

2.1. Environmental problems and standards as solutions

People concern for the protection of nature has always existed. It was reflected in secondary influence, spontaneity and unplanned activities. Starting from preindustrial period, environmental pollution was of minor importance than today, and major problems were related to human hygiene in urban areas. Beginning of the theoretical considerations about environment was related to the middle of the 18th century. As the degree of environmental pollution began to grow, the man started to plan the activities for protection of the environment and nature. Today we live in a World characterized by information technology, rapid and continuous development of society, but mentioned degree of environmental pollution is several times higher than in the preindustrial period, when it was at a sustainable level. Due to increased concern about environment, it was organized a United Nations Conference on Environment and Developmen on june 1992. in Rio de Janeiro which was the largest of all conference on this topic ever held. Near 10.000 official representatives from

about 150 countries including 116 national political leaders attended the Conference. This Declaration is one of the turning points in environmental protection. Declaration consists 27 principles (*Heleta Milenko, 2010*).

Constant grow of the degree of environmental pollution, which is reflected in several indicators, is the problem for decades for man. On global level, there are many organizations that are dealing with this problem. One of them is International Organization for Standardization. In the field of environmental protection, ISO issued a series of international standards for effective and efficient environmental management system. Standards can be applied in organizations of all kinds and sizes, can be adapted to different geographical, cultural and social terms and they provide elements for EMS (Environment Management System) that can be integrated with requirements of other management systems (ISO 9001, OHSAS 18001...). This series includes 15 standards, and because of their importance we present four of them:

- 1) ISO 14001:2004 – Environmental management systems - Requirements with guidance for use
- 2) ISO 14004:2004 – General guidelines on principles, systems and support techniques
- 3) ISO 14020:1996 – Environmental labels and declarations - General principles
- 4) ISO 14031:1996 – Environmental performance evaluation - Guidelines

Implementation of standards issued by International Organization for Standardization is voluntary. Implementation means establishing a system of organization according to the requirements specified by the standard. Requirements are designed to allow effective environmental management systems, and basic two elements of this requirements are documentation and training. Requirements for documentation define which documents organization must possess, implement and manage. Requirements for training are related to establishing and reviewing competence of employees who work in organization, concerning environmental management system.

2.2. PDCA model and ISO 14 001

Organizations who choose to implement management system according to standard ISO 14001, need to identify the environmental aspects which are arising from past, present and planned activities and base on their evaluation, need to determine the priority tasks of minimizing or eliminating the threat to the environment. As with many standards, organization must establish the environmental policy which contains general and specific objectives. Those objectives are implemented with the appropriate programs for their implementation and through the defined indicators organization monitor the way how they fulfill. Base on the environmental policy, organization makes environmental action plans. With planning, objectives are set, processes are established and necessary resources for the fulfillment of objectives are defined. As the system is established through the environmental policy and plans, it is very important to establish the mechanism of managing that system that consists corrective actions and checking. Management review refers to determination of the appropriateness and effectiveness, based on results of the review (*EN ISO 14001:2004*).

The activities of defining environmental policy and planning are the first phase of the PDCA⁵ cycle – **Plan**. Implementation and use are phase **Do**, checking, monitoring, measuring, analysis, defining corrective and preventive actions and internal audits are phase **Check**, and in the last phase **Act** are corrections, implementation of corrective and preventive actions and improvements. In the last phase all the elements initiate review of the environmental policy, and because of that PDCA model is circled and organization starts again from the beginning, from the first phase **Plan**. PDCA cycle is shown on figure 1. (*Filipovic & Djuric, 2010*).

⁵ PDCA – Plan, DO, Check, Act

Figure 1: PDCA model

3. ISO 50001 AND ENERGY AS A FACTOR OF INFLUENCE

"The most effective used energy is one that is never used"
Edwin Pinero

3.1. Energy management

Energy is involved in all areas of society. It is an important initiator of the business processes and the method of its consumption affects the environment in which we live. As an influential factor, the energy must be planned, distributed, directed and its spending must be controlled. Therefore, energy and its management could be considered in three main aspects: business, environmental and social aspect. Energy management, from the point of business, is activity that is a priority for many organizations because it is a significant segment of their business where it is possible to increase the efficiency of the entire system, and reduce costs. Environmentally speaking, we look at energy management through the reduction of emission of harmful gases that have adverse effects on the environment. As for the social aspect, energy management is a socially responsible activity, because in this way the organization demonstrates an awareness to society in which it operates, and wider, that energy must be managed because it causes adverse effects on the environment. The problem of energy management, is present at the global level for many years. As one possible solution of this problem, the International Organization for Standardization has set the model for effective power management through standard ISO 50 001, which was published in June 2011.

3.2. PDCA model and ISO 50 001

ISO 50001 is an international standard. Through its demands it influence the companies to use the PDCA model (Plan, Do, Check, Act) in the management of energy which they use as part of their activities. The main objective is to establish a system of companies, more precisely the processes within the system, which are required to continuously improve energy performance in terms of efficiency, usage and costs. Energy efficiency refers to measures that are implemented to reduce energy consumption, usage refers to the way energy is used and the costs are the amount of actual energy which is used in some of the processes. Standard follows the processes of PDCA model in order of continuous improvement of energy management systems, because this model has shown positive results in field of quality and the environment. In energy management it is started with defining the energy policy, energy planning that is based on previously adopted policies, through implementation and operation, to verify and management review (EN ISO 50001:2011).

Energy policy refers to overall intentions and direction of the organization in terms of energy it uses. The first step when editing management system according to ISO 50001 is to define the basic directions of the organization in terms of energy management. Energy policy should be a written statement by management that applies to all employees in the organization and that precisely defines the objectives to be achieved over time, and which refers to energy efficiency or energy management. The objectives, which are defined in the first step, are getting decomposed and parcelized of operations, through the tasks, to the activity. This second step is the planning of energy and despite of the breakdown of basic goals, it includes planning of resources that are necessary for achieving the objectives, then the methods and ways for monitoring the fulfillment of these goals and indicators and timeframes too. The third step is implementation of plans related to energy. These plans include the operations to be undertaken, the necessary resources for implementation and timescale to which certain activities should be completed. The review consists of monitoring, measuring and analyzing the results. Through the planned internal checks of system and in connection with the fulfillment of the requirements of ISO 50001, discrepancies are defined and corrective and preventive measures for their elimination are determined. These measures are listed in the report drawn by the team of auditors and the organization's top management approve their implementation. Through the corrections it is affected on discovered discrepancies based on reports of corrective and preventive measures. With corrective measures are eliminated the causes of conflict, and prevention is eliminating possible causes of conflict.

Based on the description of the model of system for energy management, it could be concluded that the activity of making energy policy and energy planning includes the first phase of the PDCA model – Plan ;

application and implementation phase includes the Do ; review , monitoring , measurement, analysis, defining corrective and preventive measures and internal checks are in the phase of Check, and the last phase of Act includes corrections, the application of corrective and preventive actions and improvements. In this last phase, improvements, corrections and other elements initiate a review of energy policy, with which is rounded the PDCA cycle and when it should start again from the planning stage (*Filipovic & Djuric, 2010*).

4. COMPARATIVE REVIEW

Considering possibility of implementation and the form of standards ISO 14001 and 50001 are very similar. They are applicable to all types of organizations, they are compatible with certain standards (ISO 9001, ISO 18001, ISO 22000), relating to the management systems. They may be subject of certification and they use a process approach for establishing and maintaining processes in the organization's management system. (*Heleta Milenko, 2010*).

The implementation of standards is not mandatory and there are many misconceptions that the standards ISO 14001 and ISO 50001, like all other standards, carry with them certain technical and other barriers. Certainly, the ISO 14000 series of standards not create barriers to trade, not impose new legal regulations and obligations or changing existing. Implementation of ISO14001 and certification as evidence of its application clearly shows that the organization cares about the environment which contributes to customer loyalty and business partners who can be confident in the organization contribute to sustainable development and the local community. This makes reputation of organization much better and market positioning easier. Communication with all stakeholders is improved and obtaining permits and authorizations is much simpler. The application of the standards ISO 50001 and ISO 14001, should not be necessarily based on certification. If an organization decides to regulate a system with this standard, it could expect cutting costs, which is achieved by saving the energy which is used in process. Regulation of the system does not have to initiate certification. Advantages and benefits of planning system by the standards of ISO 50001 and ISO 14001 are shown in Table 1.

Table 1 : Advantages and benefits of standards ISO 14 001 (*Heleta Milenko, 2010*) and ISO 50 001 (*EN ISO 50001:2011*)

ISO 14 001 : 2004	ISO 50 001 : 2011
Gaining the trust of stakeholders that the organization meets the requirements of the environmental policy	Cost savings and reduce greenhouse gas emissions
Gaining the trust of customers that there is a requirement of environmental protection	Increasing the awareness of employees regarding to rational use of energy
Maintaining good relations with the community	Greater insight and increased knowledge about the equipment and the overall energy impact
Increasing market share and reputation	Increased efficiency of production
Reducing the number of accidents	Improving maintenance procedures
Savings of primary materials and energy	Improving the image of the organization

Model of management system for protection of the environment is very similar in their activities to model of energy management system. As in Figure 2 is shown, the model of the ISO 14001 standard is based on the defining environmental policy, and model of the ISO 50001 standard on defining the energy policy and energy management policy. Other activities are based on these two policies, and the cycle is closing by reviewing, updating and re-defining the new policies.

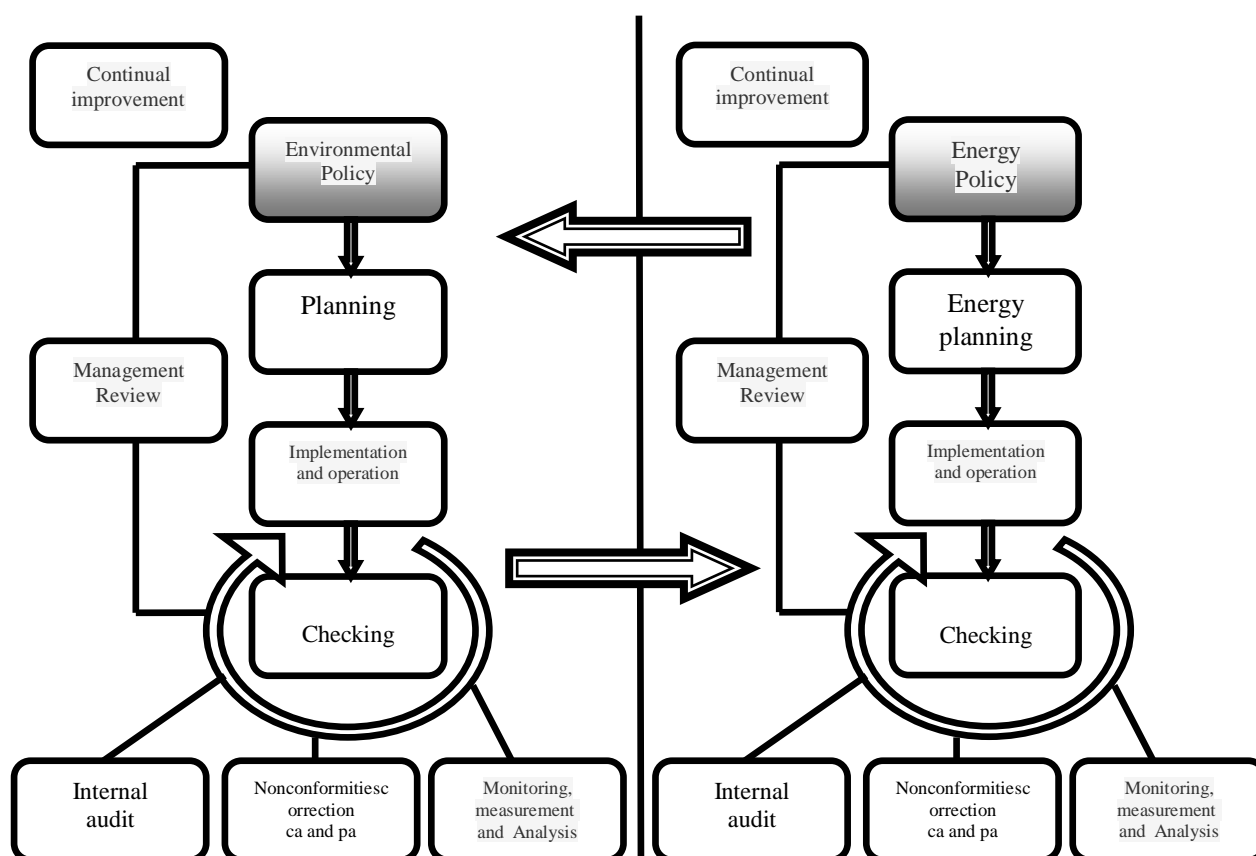

Figure 2. Comparison of models of management system of environmental protection and energy management systems (EN ISO 14001:2004 & EN ISO 50001:2011)

5. PRESENCE AND MAINTENANCE OF STANDARD ISO 14001 IN COMPANIES IN SERBIA – SURVEY

In order to determine the level of presence and maintenance of standard ISO 14001 in companies in Serbia, an online survey was conducted. Thirty companies who responded were the population for this survey. Depending on their main activities and economic sector, a classification is made and presented in Table 2.

Table 2 : Classification of companies in population by economic sectors

Sectors	Frequency	Percent
Primary sector - <i>Involves the retrieval and production of raw materials</i>	1	3.3
Secondary sector - <i>Involves the transformation of raw materials into goods</i>	14	46.7
Tertiary sector - <i>Involves the supplying of services to consumers and businesses.</i>	6	20.0
Quaternary sector - <i>health, culture, research, information, consultation, education, research, development, other knowledge-based services.</i>	9	30.0
Total	30	100

Questions were divided into two groups. The first group was related to standard ISO 14001, and the second group to standard ISO 50001.

From the population, 17 companies arranged their system according to standard ISO 14001, and 11 of them belong to secondary sector. The average time of maintenance ISO 14001 in their system is 2 years. The implementation has positive impact to their business, to a certain level, and 50 percent of those companies said that the implementation reduced their operating costs. Most of companies (88 percent) organize training for their employees approximately every 6 months. Also, from the population, number of companies who are informed about standard ISO 50001 is much lower than number of them who are not informed (9 companies who are, to 21 who aren't informed). Secondary sector is the one from where the most companies are. Only 2 of 9 are from different sector, one from tertiary and one from quaternary sector. All 9

companies who are informed, have implemented ISO 14001, and 8 of them think that implementation of ISO 50001 will reduce their operating costs. The results show that, 20 against 10 companies would accept an invitation to a seminar where the main topic would be introduction of ISO 14001 and ISO 50001 and their requirements. Also, the companies were asked to specify the type of energy that is used as a primary energy in their system. Results are shown in Table 3.

Table 3 : Type of energy that is used as a primary energy in companies in Serbia by economic sectors

Sectors	Water	Electric power	Oil	Natural gas	Other ⁶
Primary sector	0	0	1	0	0
Secondary sector	4	12	5	3	0
Tertiary sector	1	5	2	1	0
Quaternary sector	2	8	0	1	1
Total	7	25	8	5	1

Note: Most of companies specify several types of energy

From this survey, it is clearly that most of the companies, 83 percent of them, are using electric energy as a primary energy.

6. CONCLUSION

Implementation of environmental protection and energy management requires that funds, guidances and resources are available to organizations in order to provide them to effectively deal with these issues. However, resources and guidance can not be obtained from national institutions because in modern, global economy market crosses national boundaries and modes of regulation. International standards offer some solutions in this area. They are created by the same organization that will use them, they are adaptable to different types of organizations and their application is easy and outside of national frameworks.

In times of economic crisis, a necessary goal of planning system of management of an organization does not have to be a certification because it requires additional costs. The introduction of these standards can significantly reduce costs in certain fields, and this especially refers to the standard ISO 50001:2011, because it is focused on energy management. Companies need to understand the requirements of standard in order to provide significant savings.

Abstract: *In this paper we discussed about synergy of innovation and total quality management in reaching competitive advantage. We presented innovation and total quality management as very complex processes. Since good understanding of these processes is needed, we tried to discover the impact of quality on innovation, if it is an obstacle for innovation process or it helps innovation to be realised. We concluded that TQM dimensions, such as customer focus, training, empowerment and teamwork, rationality in the analysis of production processes and benchmarking can assist an organisation to be more innovative in its business activities. This paper should be an overview of importance and influence of TQM on innovation.*

Keywords: *innovation, TQM, competitive advantage, organisational climate, quality*

1. INTRODUCTION

Innovation but also quality can help company to increase competitiveness. Competitive advantage as innovation is defined as company's opportunity to achieve competitive advantage according to innovation and company's ability to manage successful innovations' projects. (Porter 1990) On the other hand, quality as competitive advantage is defined as need of businesses to recognize that providing a quality user experience is an essential, sustainable competitive advantage. It is user experience that forms the customer's impression of the company's offerings, it is user experience that differentiates the company from its competitors, and it is user experience that determines whether your customer will ever come back. (Jesse James Garrett 2002). Many authors view quality and innovation as two separate disciplines. Although this separation may be accurate in some respects, the two fields share quite a few philosophies and methodologies.

The entrepreneurial context of organizations today is characterized by growth of international competition, rapid technological evolution, and more demanding customers with changing and mature expectations, in short, a dynamic environment with unpredictable changes (Hashim et al., 2010). Firms have different strategies and courses of action that enable them to respond to such changes in the environment (Hitt et al., 2000). One of the main strategies is the creation of new products, services, or processes or the modification of existing ones (Brown and Eisenhardt, 1995; Dougherty, 1992). Innovation enables organizations to change as their environment changes. They have two alternatives: to innovate or to die (Storey, 2000; Hussain and Ilyas, 2011). Innovation can also improve organizations to make them more competitive, helping them to obtain competitive advantages in both global and international markets (Hitt et al., 1997; Tidd, 2001; Wang et al., 2008). Innovation increases competitiveness because it enables the organization to offer the market new and unique products/services and to make it difficult for others to learn about the resources needed, creating entry barriers and shaping the competitive game rules, thereby creating new values.

The implementation of a total quality management (TQM) system is another strategy that firms can use to respond to the demands of an increasingly turbulent and unpredictable environment (Khan et al., 2011). Quality is a crucial way to improve the firm's profits and ensure competitiveness. It generates improved products and services, decreases costs, increases firms' financial profitability, improves the image of products and services, and increases customer satisfaction. Quality is also a factor that motivates and integrates workers.

Question we discussed through this paper was if innovation and quality can be applied together to obtain competitive advantage in dynamic and changing environments. This paper is overview of innovations, total quality management and their connection. We firstly tried to understand both TQM as paradigm of management and complexity of innovation and then tried to find relation between them.

2. INNOVATION

Innovation can take several forms: in products, production processes or management systems. Innovation in products is related with R&D and consumers needs. Innovation with processes relates to changes in machinery and other elements not directly related with employees and have the aim of increasing productivity (i.e. increasing quality and reducing costs). Innovation in management systems has the aim of adapting these systems to new environmental conditions and improving the way in which people are managed and work is organised. This form of innovation can become necessary by changes in the process, such as automation and the application of mistake proofing devices as typically described by Shingo (1986).

Companies tackle innovation in two basic ways: by copying or developing their own innovations. The first strategy can be useful in situations in which companies enjoy competitive advantages, such as low wages, easy access to raw materials, protected markets, etc. However, in order to obtain competitive advantage, the second strategy is a better approach. This argument is valid not only for innovation in products and processes but also for innovation in management.

Creating and sustaining an orientation to innovation is necessary to foster innovation (O'Reilly, 1989; Russell, 1990; Russell and Russell, 1992; Craig, 1995; Schneider et al., 1994; Judge et al., 1997; Filipczak, 1997; Hurley and Hult, 1998; Martins and Terblanche, 2003; Wan et al., 2003). It is not enough to talk about innovation and believe in it. One must take it seriously and ensure that it happens by developing an orientation to innovation in which management's values become employees' practices (Hofstede, 1994). From a theoretical point of view, we identify various arguments to explain the connection between innovation and orientation to innovation. The first focuses on the way individuals are socialized in the organization. The socialization process involves how individuals learn what behaviors are acceptable and how activities should be performed. Individuals' sense of shared norms in the organization helps them to identify whether innovative behavior is part of the organization's way of acting.

The second argument is that organizations disseminate orientation to innovation by establishing forms of behavior and activities reflected in structures, politics, practices, procedures, etc. For example, if the organization provides resources for the support of new ideas (Teslut et al., 1997), individuals will perceive that the organization values innovation and will act accordingly in the workplace by innovating.

The third and last argument is that successful innovation requires solving series of problems related to the ambiguity and uncertainty involved in implementing innovation (for example, low motivation to initiate and to support innovation among the organization's members). Having a set of norms for innovation (clear expression of the organization's values and behaviors regarding innovation) can, however, generate the motivation and commitment necessary for sustaining successful innovation. Because such norms guide the organization's members toward the right behavior, they constitute an effective way of implementing innovation (Zaltman et al., 1973).

Results from various research studies show that the perception that the organization values innovation affects innovation positively. Organizations should therefore develop and sustain a climate of support to achieve greater innovation capacity. Based on the literature review, we will establish four essential strategic and structural factors to determine the factors that influence orientation to innovation: cohesion, recognition, decentralization, and formalization. Cohesion and recognition are related to the organization's members and are crucial to stimulating innovation. The structural factors, decentralization and formalization, have received the most attention in the literature, as they are considered to be the main determiners of innovation.

It attempts to verify how a work context characterized by cohesion, recognition, some degree of formalization, and decentralization can create orientation to innovation and thus foster innovation accompanied by greater innovation capacity (Germain and Spear, 1999; Hartmann and Patrichison, 1996; Shani and Rogberg, 1994). The implementation of TQM also influences the different variables, encouraging greater orientation to innovation (Prajogo and Sohal, 2006, 2003;).

3. TOTAL QUALITY MANAGEMENT

TQM is a paradigm for management, it propagates some defined values, behavior and methods of work (Gallear, Ghobadian, 2004). So, if we would treat TQM as program for changing organizational culture, then one of the reasons of the failure of TQM implementation would be wrong understanding of this program, which impacts only a partial implementation of TQM (Yong, Wilkinson, 1999). It is worth mentioning that the sections of organizational culture intersect with TQM areas, including ways of work and systems of values. Because of that we can assert, that organizational culture is changing because of TQM implementation. Can TQM generally be in practice implemented? Researches show, that TQM is very rarely "all inclusive". Implementing TQM, attention is paid to the cultural workers' changes. Wilkinson (1992) separates three traditional TQM view alternatives. First view is oriented to "light" quality characteristics (personnel authorization, personal learning and etc.) and it obligates to define the style of management by delegating responsibility, to increase the independence of personnel. Second view is oriented to "hard" factors of production (system measurement, work control, usage of statistical procedures). The third view includes the elements from the first and second and is oriented to the need of scientific methods, understanding of workers as part of the team. To every cultural workers group one of these views could be applied, but only the usage of all three views will make it possible to successfully implement TQM in an organization.

Assertion can be made, that by orienting to organizations culture factor, TQM can be implemented in two ways – cultural changes or less resistant way (Kekale et. al, 2004). It is necessary to pay attention to the fact that implementation of TQM in organizations should begin from the very top of management levels (Oztas, Ozbay, Yeginhobali, 2004). Mentioned cultural factor is an internal condition of the organization, which decides the success of TQM implementation, but there are many external factors too, which are conditional – leadership, economic survival, global competition (Warwood, Roberts, 2004).

Will TQM remain essential to future companies? It is important to understand that today's business surroundings are very unstable. To remain competitive under these conditions, companies should become more flexible, transform into a suitable form. One of possible transformation forms – modular corporations. Attention should be paid to the fact that "light" TQM factors have a strong impact on organizations' activity. It is proven, that these "light" factors transform quality control system to TQM (Rahman, 2004).

We must confess that with the change of the surrounding conditions the view point to quality should also change. The connection between TQM principles and the implementation of innovations should be found in space of economic knowledge. TQM should help companies to solve innovation problems (Elshennawy, 2004).

4. RELATION BEETWEN TOTAL QUALITY MANAGEMENT AND INNOVATION

If an organization wants to implement some kind of innovations by already used quality management methods, then quality management would help to achieve the goal. But if the organization has only the knowledge about quality management methods, then the implementation of quality management method would be treated as the first innovation.

When the concept of TQM first appeared it was considered as an innovation in management thinking, but this does not necessarily mean that it is a necessary facilitator of innovation.

Companies applying TQM can more easily assimilate innovations imported from other situations due to the willingness of its employees to accept new ideas which are promoted by the TQM approach. They can also develop their own innovations by building on the work of both continuous and breakthrough improvements. The approach of TQM to process flow management is ruled by rationality. SPC and other quality management tools and techniques have as their aim decision making using real data and to facilitate the rational analysis of the problems (Deming, 1986). This is against the non-innovative way of thinking that frequently appears in companies in which things are done the way they have always being done. Therefore, a company that works and operates according to a TQM philosophy will be more willing to accept and adapt to any management innovation.

The impact of implementation of TQM on customer satisfaction in costs, improvement in profitability, and productivity has been analyzed extensively in the literature. However, the repercussions of TQM for orientation to innovation have hardly been analyzed. Our review of the literature (McAdam, 2001; Prajogo and Sohal, 2001, 2003; Zairi, 1994, 1999) shows that some research considers TQM a necessary strategy to create a climate of support for innovation. TQM helps to identify which processes must be renewed or replaced by new, more efficient ways of doing work in the organization. Thus, quality supports the creation of

a climate of innovation. Among TQM principles and practices that help to create a climate of support for innovation, we emphasize the the following: (1) continuous improvement, which makes employees more willing to accept new ideas; (2) orientation to the customer, which introduces changes in organizations in order to satisfy customers' needs, stimulating innovation; (3) training programs, which develop employees' basic knowledge and abilities so that they are better prepared to understand and accept new systems to perform their tasks; (4) empowerment and teamwork, which help employees to generate ideas for improvement, encouraging innovation; and finally, (5) benchmarking, a thoroughly innovative practice whose goal is to discover whether other organizations do things better, to copy these methods, adapt them, and achieve the levels of efficiency of organizations that develop best practices (Alam et al., 2010). For authors such as McAdam (2001) and Detert et al. (2000), the principle of orientation to the customer and continuous improvement of TQM involve identification of customers' needs as a foundation for generating ideas for innovation and the constant search for ways to improve the organization. Both actions are necessary to construct a climate of support for innovation. Likewise, Zairi (1994; 1999) argues that TQM provides the impetus and commitment required to establish a continuous climate of innovation. Quality stimulates creativity and the generation of new ideas among employees.

5. CHANGING TQM TO FACILATE INNOVATION

Grossi (1990) states that innovation requires changes in the operating system and therefore must be driven top-down. However, many of the changes generated by a TQM policy are provided by all members of the company, from shop floor to administrative departments, in particular when a policy deployment is employed. Without a deployment using the Catch, Reflect, Improve, Scrutinise and Pass (CRISP) cycle as outlined by Lee and Dale (1998), these sources of innovations could be biased by the specific interests of the people who work in each department and function and this could hinder achievement of company vision and its vital few objectives.

Long term relationships with suppliers in a partnership approach dictate that if changes are made then these need to be implemented with the involvement of the supplier and without a change in source of supply, certainly in the short term. It could be considered that this TQM dimension could be an obstacle to changes in supplier management, since breakthrough changes could imply the need to change the supplier.

Quality management tools and techniques can be treated as "traditional" improvement instruments which have been around for some considerable time. This can imply that they are used as they have always been. In the future some of these tools and instruments may become obsolete or will need changes in how they are applied. For example, increased levels of automation may change the way in which quality-related data is collected and this may have an influence on how SPC is applied (i.e. automated devices can collect the data and intelligent and expert systems can aid the decision making).

Companies should not look at TQM as a static set of recommendations that are going to be valid for ever; just as TQM is about challenging the status quo, this also applies to the TQM dimensions. Top management have to lead this way of thinking.

6. CONCLUSION

The advantages and disadvantages of TQM to develop and facilitate innovations have been discussed in this paper. It is argued that TQM does not hinder business innovation. In fact, some of the TQM dimensions, such as customer focus, training, empowerment and teamwork, rationality in the analysis of production processes and benchmarking can assist an organisation to be more innovative in its business activities. However, for this to happen the TQM concept has to be well understood by management, in particular, the senior management team. Continuous improvement does not mean that the changes made are the sole responsibility of employees, management needs to be fully involved in facilitating process improvements and providing the requisite leadership. It should also not be forgotten that TQM is also subject to change and has to adapt to new conditions of work, competition and environmental situations, all driven by innovation.

Abstract: *Assessment is the essence and the starting point of a planning process. Especially important is assessment which relies on the strategic level of decision-making. This document emphasizes the importance of the assessment making process for the defence and security strategic management decision-making, as well a permanent need for their updates with the appearance of new factors and trends of development. Analyses of some previous assessments¹ have been taken into consideration, from the standpoint of checking characteristic conclusions given within them. Taking into consideration global events which have already happened in the period covered by this assessment, partial analysis has been done, in other words - checking of given conclusions. That points to the uncertainty of future events in long-term assessments. This especially needs to be kept in mind in strategic management decision-making in defence and security.*

Keywords: *defense, security, decision-making, strategic crisis management, assessment, global future, uncertainty²*

1. INTRODUCTION

Decision-making is the component of daily activities which decision-makers do individually or within the team. Taking a decision precedes preparation which covers defining of problem and collection of relevant information. The every decision withdraws determined responsibility for decision-maker because it influences on the future states of system and brings necessary effects or consequences.

In dependence on which level of management are made, decisions can be: strategic, operational and tactical. The strategic decisions are made on highest levels of legislative and executive power, and are related on the improvement of strategic position in the future. The operational decisions are made on lower levels, and are related to development and realization of strategic decisions.

As the level of decision-making is higher, the importance and consequences of decisions are bigger. Because of the lack of information, on the strategic level of management unstructured decisions are much more represented, in other words decision-making realizes in conditions of a risk.

In the defense and security area strategic level is the level on which legislative and executive power establishes national security aims and makes decisions about the development of resources for their achieving.

Defining of national strategic objectives and suitable strategy requires, previously, to conduct detail research and analyses of global surrounding in which the state is, all changes which will happen in surrounding and influences which changes provoke in the state. Also, it is necessary to execute research and analysis of state potential, as bases for necessary adaptation to difficultly predictable and changeable surrounding through the defining and realization of specific strategies.

¹ „Global Trends 2015: A Dialogue About the Future With Nongovernment Experts, National Intelligence Council, CIA, December 2000“ and „The DCDC Global Strategic Trends Programme 2007-2036“ which represents „an independent view of the future“ produced by the Development, Concepts and Doctrine Centre (DCDC), within the UK's Ministry of Defence (MOD) and it is „a source document for the development of UK Defence Policy.“

² In the paper is reported a part of results of research on the project: „Effective sources of new technologies and defense concentration through social changes and strategic orientations of Serbia in 21st century (III47029 MNT RS) which is financed by Serbian Ministry of education and science.

External analysis of state surroundings and internal analysis of potentials and resources presents the framework of strategic analysis as sub process of the strategic management, which gives bases for the defining of strategic alternatives. This means that the strategic analysis, in general, covers two basic parts: analysis of factors of global and regional surroundings and internal factors. Those analyses should result as much as objective prediction of trends.

The strategic management should be turned to future. Therefore is necessary to predict, with the profound certainty, future states and future events, in order to be able to define aims which we want to achieve and define strategies with whose realization future aims could be reached.

Because of decrease of uncertainty in the security area, anticipation of future is very significant part of strategic management. Anticipation of future is very significant element in the strategic management in defence and security. Element of future presents a major characteristic of strategic management and key difference in relation to the operational management.

From all this we can clearly claim that good prediction is necessary for the implementation of national strategy and for the achieving of wanted results in the future.

Good prediction in defense and security implies making of the universal and relevant assessment, which will analyze factors and trends which influence on future events and enable to identify security challenges, risks and threats.

2. DECISION-MAKING IN THE STRATEGIC MANAGEMENT IN DEFENSE AND SECURITY

Deciding is a component of all basic functions of management and carries off on process in which manager, individual or collective body, on the situation assessment basis, predicts development of states, manifestations and events, by choosing between a several alternatives brings the decision about further directions of action of whole organization or her particular organizational units and members. Decision is the final result of decision-making process.³

In strategic management in defense and security, decision-makers has huge responsibility, because from their correct decision depends further development of events and dimensions of their consequences. Consequences at this level are significant because decisions influence on the basic values and interests of state, and the price of good and bad choices is high, in social, political, economic and human sense.

Complex analyses of security policy and development of future scenarios is the starting point for decision-making in opposing to security challenges in defence and security area. Identification and analysis of threats includes the assessment of a number of risks and analysis of different variants of scenarios.

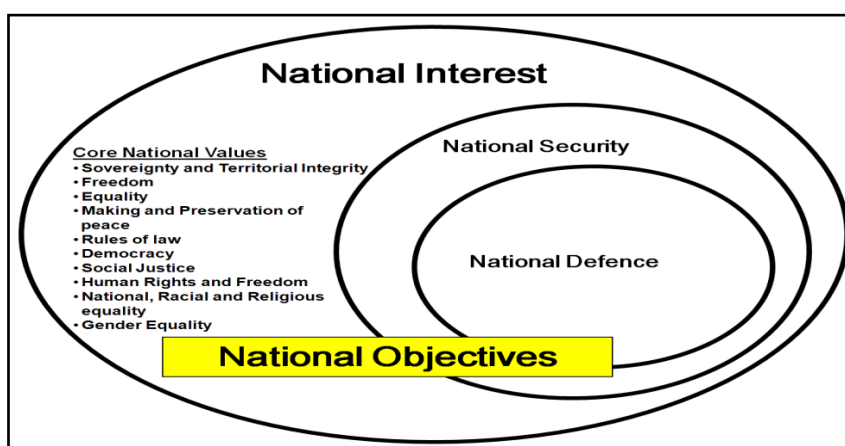

Figure 1: At the strategic level, the MOD/GS should look at contributing to the outer rings⁴ in order to formulate the policies for the inner ring

³ James Reason, Human Error, Cambridge University Press, Cambridge, 1990.

⁴ Source: National Security Strategy of Serbia

Process of forming risk assessment is exceptionally significant because it enables state bodies, in other words participants in deciding in the defence and security strategic management, common understanding of risks that the society faces.

For the analysis of complex phenomena in security, which are characterized by unpredictability, transnationality and asymmetry, it is suitable to apply the general morphological analysis which serves to identify and explore all groups of possible relationships contained in a given complex of security problems.

Morphological analysis begins by identifying and defining the parameters (or dimensions) of the complex of issues that need to be explored, and assigning the range of relevant "values" or conditions of each parameter. By crossing the parameters of n-dimensional matrix morphological box is constructed. Three-dimensional matrix is a morphological field that contains all the formally probable relationships. Each cell of the n-dimensional box contains a specific "value" or condition of each parameter. The study of all configurations on the field determines which of them are possible, viable, practical...

Analysis of socio-political problems is conducted through a specific number of scopes of conditions and quantified variables. Groups of non-quantified conditions are synthesized in adequately defined relations that represent "areas for solutions".

Three-dimensional matrix would include threats, functional tasks and technological needs, and can be supplemented by other parameters. The answer to the risks may include technical, human, operational and management elements.

In addition to morphological analysis in analyzing the security environment the other types of analysis are also being applied, notably the SWOT analysis.

Analysis and evaluation of the security environment is the basis for identifying potential scenarios for threats to the security.

The scenario is a description of a way in the future (developmental scenario) or a description of a future situation (situational scenario). The content of scenario can include: resources, technology, command and management or environment, but primary issue are conditions of conducting operations in the future.⁵

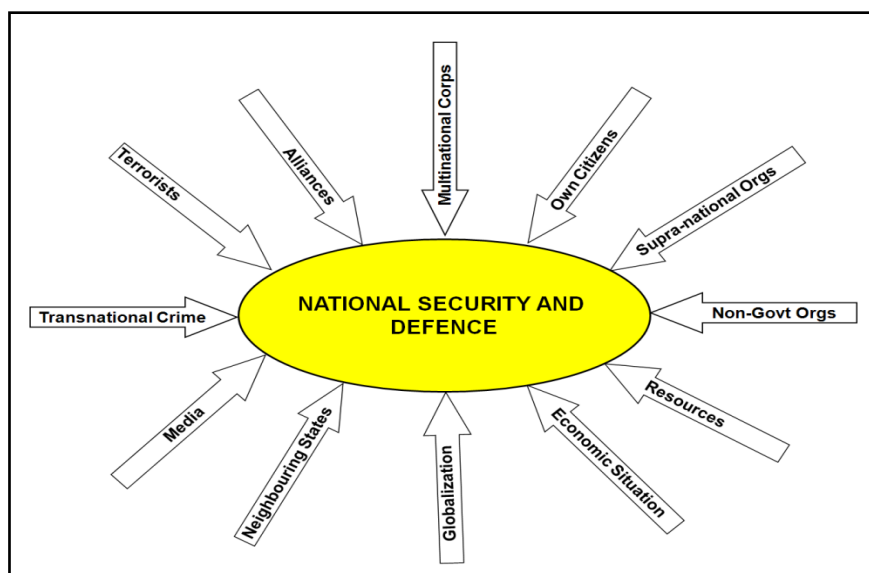

Figure 2: External factors of national security and defence

The process of scenario development involves several steps in the process of assembly, development and assessment.

⁵ Planning and Development Department (J-5) GS of SAF (2009), The Staff Study „The Planning of Development of Serbian Armed Forces Based on Capabilities - draft , Belgrade.

The process of assembly consists of identifying the purpose or the central issue for the scenario. Development is a systematic process of identifying key scenario routers with the appropriate values and the corresponding dependencies and variations between them. Phase of assessment includes a review of scenario and verification whether it satisfies some necessary conditions (review of the usefulness, completeness of required information and checking of internal consistency).

The goal is to keep the number of scenarios as small as possible. The scenarios are based on the respect of the current situation, the observation of trends and expectations of future development of the events. As time passes, the global characteristics are changing (political relations, technology, environment, demographics, social values, military structures, etc...), including the scenarios. Scenarios are developed over time.

At the strategic level scenario focuses on the political challenges in relation to national interests. Closely connected with this is a strategic-military level of scenario, which translates the political challenges in the military strategic challenges.

Formulation of scenarios requires identification of the driving factors within the raised issues for whose identification could be used various techniques, e.g. structured brainstorming technique (exchange of ideas).

Morphological analysis which is used prior to writing of scenario provides consistency in change of scenario dimensions.

The scenario should meet the criteria of credibility and relevance. Events in the scenario must make sense and be credible. Credibility cannot, however be confused with probability. Likelihood itself is not a criterion; on the contrary, the scenarios often address issues that have a low probability. Credibility, however, means that the scenario must seem "possible".

Relevance, in terms of scenarios, means the utility for its individual purpose. In terms of scenario for military purposes, it should include questions that could explain the development of conflict or other situations where military force may be used. For this purpose, the script must contain enough relevant information and be useful for analyst or planner.

Linking the assessment to decision making is allowed by the analysis of different scenarios, which should indicate the nature of future events.⁶

3. RELEVANCE OF LONG-TERM ASSESSMENT IN THE SECURITY AREA

Identification of driving factors inside the question which considers some scenario, presents the basis for making of relevant and credible scenario. Correct identification, well assessed importance and influence of certain factors and their trend in future, essentially influence on content of the scenario.

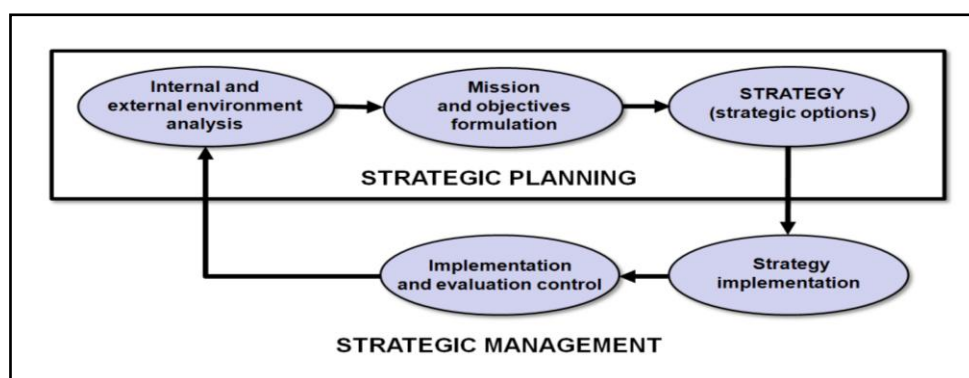

Figure 3: Strategy, strategic planning and strategic management

Considering that the decision-making process in defense and security strategic management is based on scenarios, the importance of assessment relevance in this process is clear.

⁶ Planning and Development Department (J-5) GS of SAF (2009), The Staff Study „The Planning of Development of Serbian Armed Forces Based on Capabilities - draft , Belgrade.

As illustration of relevance of long-term assessment in defense and security area is taken Study (assessment) „Global Trends 2015: A Dialogue about the Future with Nongovernment Experts”, issued on December 2000. This assessment consists of conclusions about that key initiating factors are identified; how conclusions given in previous assessment, „Global trends 2010“, have been changed; how previously identified initiating factors have been expanded and more directly tie up with trends which now are being forecast for the next 15 years; how events and trends in key states and regions influenced to considerably revise some of earlier predictions.

Protagonists of assessment making⁷ have been working on the identification of the main initiating factors and trends which will form the world up to 2015, and on that basis Report (assessment) have been composed whose conclusions we examine.

In this assesment as the key initiating factors are identified⁸:

- Demographics.
- Natural resources and environment.
- Science and technology.
- The global economy and globalization.
- National and international governance.
- Future conflict between and inside states and nations
- The role of the big powers.

According to assesment „no single driver or trend will dominate the global future in 2015, each driver will have varying impacts in different regions and countries and the drivers are not necessarily mutually reinforcing; in some cases, they will work at cross-purposes“.

Key drivers and trends will intersect to create an integrated picture of the world of 2015, about which we can make projections with varying degrees of confidence and identify some troubling uncertainties of strategic importance.

Assesment provides a flexible framework to discuss and debate the future. Judgments about demographic and natural resource trends are based primarily on informed extrapolation of existing trends. In contrast, many judgments about science and technology, economic growth, globalization, governance, and the nature of conflict represent a distillation of views of experts inside and outside the Government. About projections about natural phenomena, we can have fairly high confidence; the latter are more speculative because they are contingent upon the decisions that societies and governments will make.“

The drivers emphasized in this assesment are valid for this examination process. The Report suggests that some of the trends will persist; others will be less enduring and may change course over the time frame we consider. Essence of assesment is identification of driving factors, determination which ones matter most, to highlight key uncertainties, and to integrate analysis of these trends into a national security context, from what results identification of issues for more rigorous analysis and quantification.

In the Report is given overview on conclusions delivered in the previous assessment Global Trends 2010, published in 1997 in order to realize how given assessments are changed. Over four years, the judgments have been tested. Various audiences were energetic in challenging, modifying or confirming judgments given in assesment. The lively debate that ensued has expanded treatment of given drivers, altered some projections made in 1997, and matured autor's thinking overall.

This is some characteristic parts of Report: „Global Trends 2015 amplifies several drivers identified previously, and links them more closely to the trends we now project over the next 15 years. Some of the key changes include:

- Globalization has emerged as a more powerful driver. GT 2015 sees international economic dynamics -including developments in the World Trade Organization - and the spread of information technology has much greater influence than portrayed in GT 2010.

⁷ National Intelligence Council (NIC) with a range of nongovernmental institutions and experts.

⁸ Source: Report „Global Trends 2015: A Dialogue About the Future With Nongovernment Experts“.

- GT 2015 includes a more careful examination of the likely role of science and technology as a driver of global developments. In addition to the growing significance of information technology, biotechnology and other technologies have much more weight in the present assessment.
- GT 2015 provides a more complete discussion of natural resources including food, water, energy, and the environment. It discusses, for example, the over three billion individuals who will be living in water-stressed regions from North China to Africa and the implications for conflict. The linkage between energy availability, price, and distribution is more thoroughly explored.
- In the regional sections, GT 2015 makes projections about the impact of the spread of information, the growing power of China, and the declining power of Russia.

Figure 4: GDP of emerging powers showing dramatic projected growth for India and China⁹

Events and trends in key states and regions over the last four years have led us to revise some projections substantially in GT 2015.

- GT 2010 did not foresee the global financial crisis of 1997-98; GT 2015 takes account of obstacles to economic development in East Asia, though the overall projections remain fairly optimistic.
- As described in GT 2010, there is still substantial uncertainty regarding whether China can cope with internal political and economic trends. GT 2015 highlights even greater uncertainty over the direction of Beijing's regional policies“.

Research of interplay these driving factors and trends indicates some important uncertainty which will be explained only just during the proceeding of event and when leaders bring political decision which today cannot foresee. We quote transnational and regional problems for which the future is, according to our analysis of trends, too difficult to foresee with the confidence or the preciseness.

- Science and Technology
- Asymmetric warfare
- The Global Economy
 - Chinese economy in the constant growth
 - The US economy suffers a sustained downturn
 - Europe and Japan fail to manage their demographic challenges
 - Emerging market countries fail to reform their financial institutions
- Global energy supplies suffer a major disruption
- Regions and states
 - The Near East
 - China
 - Russia
 - Japan

– India

This very significant issues of national security which request continuous analysis and interim audits policy in next years.

Shown assessment can serve as the example which illustrates the large dynamics of changes, present in long-term assessments. In order to long-term assessment be useful for the analyst or the planner, especially in defense and security management and to produce credible and relevant scenario, parameters which characterize specific appearance, have to be based on relevant information.

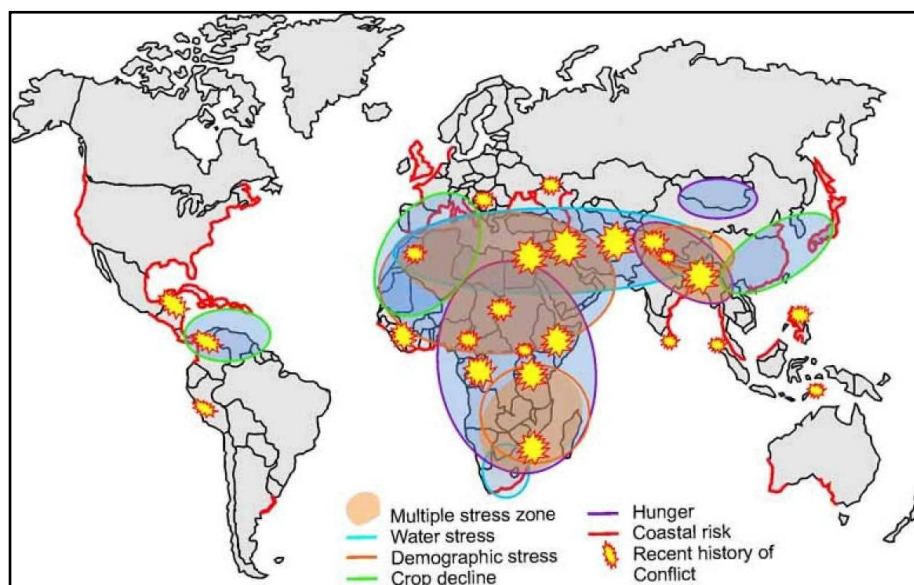

Figure 5:

Stress Zones: Instability is likely to be greatest in areas of Multiple Environmental Stress¹⁰

Consideration of shapes and intensity of influences of single parameters to long-term assessment, their correlations in the concrete situation for the concrete state and concrete moment, presents the great challenge for decision-makers.

5. CONCLUSION

An essential prerequisite for making objective decisions is relevant assessment and reliable prediction. Given the importance of decisions at the strategic level and the consequences of wrong made decisions, the conclusion that is the quality assessment of all factors that affect global and domestic environment and the proper consideration of their impact on national interests, is the question to whom should be paid great attention.

In making of assessments, whose summary is given in this paper, besides making carriers, participated and non-governmental institutions and many experts from academies and the private sector.

The benefit of working on the strategic future is not to predict the future, which is unpredictable, or to enable organizations to control it. It is about trying out options, so that they are more capable if it happens.

National security issues are important and require continuous analysis and periodic review of assessments and decisions based on them.

Abstract: *Competitive advantage of strategic partnerships is derived from learning and acquisition of new knowledge. Through the process of efficient use of knowledge, strategic partnerships put innovations into practice. Knowledge is the basic resource that influences efficient utilization of other partnership's resources. Resources themselves do not bring competitive advantage. Ability to use these resources in a way that is superior to the one seen on the part of the competition brings competitive advantage. Faced with the pressure coming from the competition, growing numbers of strategic partnerships create special systems and procedures with the aim of collecting, memorizing, disseminating and using knowledge. The primary aim of our research is to emphasize the importance of learning and knowledge in the process of creating innovativeness and reaching competitive advantage. Namely, successful strategic partnerships stand for innovative partnerships that continuously create new knowledge and apply it at different levels. Focusing on the research hypotheses, the paper will rely on the qualitative methodology of research. It is the authors' attempt to draw relevant conclusions through the comparison and generalization of the stated theoretical standpoints and best business practices. One of the conclusions is that success of a partnership to a large extent depends on the effective transfer of knowledge between partners, which leads to the creation of innovations. We hope that the findings of our work will be useful to both theoreticians and practitioners in the field of strategic management.*

Key words: *strategic partnerships, innovativeness, learning, transfer of knowledge, competitive advantage*

1. INTRODUCTION

The primary resource and the main source of competitive advantage in the 21st century is knowledge. Seeing the process of learning as the only way in which they could survive in turbulent environment, growing number of modern companies turn into learning organizations. Companies establish strategic partnerships with the aim of expanding knowledge bases and accessing specific types of knowledge. Namely, strategic partnerships that are able to learn continuously and apply new knowledge in the process of creation of superior products and services win the advantage on the market. Encouraging of organizational learning and acquisition of knowledge significantly affects innovativeness of companies. Innovativeness of strategic partnerships determines their competitiveness on the market. Being innovative under modern business conditions is an imperative for survival, growth and development of companies and their strategic partnerships. Innovation refers to the process of utilization of new knowledge with the aim of changing organizational processes or with the purpose of creating new products and services that the market requires. The scope and result of innovative activities of strategic partnerships stand for the indicators of their total business success.

The paper starts with the hypothesis that learning and knowledge stand for the primary driving forces of innovations under contemporary business conditions. Realization of the learning process results in the creation of new knowledge that is considered a key input of innovative processes. Namely, strategic partnerships create their own internal environment that motivates partners to learn and create knowledge. Knowledge acquired in that way spurs the process of innovativeness and enables strategic partnerships to obtain and maintain competitive advantage.

* The paper is a result of research within the framework of Project No.179081, named: "Researching contemporary tendencies of strategic management using specialized management disciplines in function of competitiveness of Serbian economy", which is supported by the Ministry of Education and Science of the Republic of Serbia

Starting research hypothesis resulted in additional hypotheses. Namely, if focus of the research is taken into consideration, it can be stated that innovations stand for the basic requirement for achieving competitiveness of strategic partnerships. There is correlative interdependence between innovativeness and competitiveness. Innovations are, as we notice, the basic vehicle for achieving competitive advantage. At the same time, competition forces strategic partnerships to be innovative.

Last but not least, it can be stated that the transfer of knowledge within strategic partnerships stimulates the development of innovations. Access to new knowledge in strategic partnerships is achieved through interaction among partners and their exchange of knowledge. Transfer of knowledge increases the value of knowledge and stimulates activities that satisfy both sides, which results in the creation of strong knowledge base. Creation of a strong knowledge base results in the creation of conditions for the realization of the process of innovating.

2. IMPORTANCE OF INNOVATIONS FOR THE COMPETITIVENESS OF STRATEGIC PARTNERSHIPS

By entering strategic partnerships, companies gain access to resources, new technologies, knowledge and new markets. Moreover, they obtain economies of scale and economies of scope and they join forces with the purpose of innovating. Therefore, strategic partnerships are the favourable environment for learning, exchange of knowledge, innovating and realization of efficient strategies that provide competitive advantage within the global economy. Success of strategic partnerships on the international market increasingly depends on their innovativeness. Investment in innovations is regarded as similar to “arms race” (Betz, 2001, p. 81). Competition forces strategic partnerships to innovate. Due to the fact that no one wants to stay behind their rivals, no alliance dares to stay behind the competition when spending on innovations in the long run is taken into consideration. Namely, alliances, i.e. strategic partnerships constantly tend to increase investments in innovations with the purpose of surviving within the competitive game.

The purpose of existence of strategic partnerships is to obtain access to resources and transform these resources into innovative products and services by adding value. There is strong correlation between product innovations and market behaviour. New products add up to the process of winning and maintaining the market share, as well as to the process of increasing profitability. In case of mature and acknowledged products, increase in competitive sales stems not only from the ability of a company to offer products at lower prices, but also from various non-price factors, such as: design, quality and adaptability to customers' demands. Product lifecycle significantly decreased. For example, lifecycle of home appliances or computers is measured in months, and even the development of complex products, such as cars, takes less than three years. This trend obliges strategic partnerships to use innovations with the purpose of replacing products with their updated versions. Besides, lead time imposes additional pressure on all partnerships to take part in the market game. Namely, not only should they produce new products, but they should also do that faster than it is the case with their competition. Experiences of a great number of strategic partnerships prove that strong source of competitive advantage is achieved by creating innovation that no one else can create or by doing things better than others. For example, at the end of the 20th century, the Japanese had big advantage in some sectors of automotive industry, ship construction and consumer electronics. This advantage was based on their superior abilities in innovations and production. Significant source of competitive advantage is also reflected in the ability of a company to offer better services to customers – faster, at lower prices and of higher quality (Davenport, Leibold & Voelpel, 2006).

The idea of the significance of innovations has become widely accepted. It has become part of the culture of some countries to such an extent that it has turned into a cliché. The speed at which innovations are developed nowadays implies that the creation of one innovation usually gives birth to the idea (and the need) related to another innovation. New idea often points to other ideas, especially in situations when one invention requires another one with the purpose of becoming functional and more efficient. Innovation, as a way of achieving competitive advantage, in its broadest sense includes new technology, new way of performing tasks, new product design, new production process, new market approach and new way of training of human resources. Innovations can appear in various forms. Therefore, they are reflected in each introduction of novelty to the structure and functioning of partnership that contributes to the increase of economic efficiency and effectiveness of business. Also, one of the characteristics of the competition that is based on innovations is that it can appear from all sides. Namely, competition is not only reflected in well-known competitors whose business and moves are generally known. The competition can include unknown competitors from completely different business areas as well. Due to this fact, strategic partnerships have to be on the alert constantly and able to predict their competitors' moves.

Within global competitive environment, majority of strategic partnerships are faced with one choice – “innovate or disappear” (Lasserre, 2003). This choice is accepted by strategic partnerships, which believe in success and actively strive towards innovations in spite of the fact that innovations can be uncertain and highly risky. Strategic partnerships are ambivalent about innovations. Partners are, on the one hand, aware that innovations are necessary for the survival and growth of the alliance. On the other hand, they fear the risk and uncertainty that innovations bring with themselves. To put it simply, there is a fear of failure that might result from a single wrong step. Therefore, strategic partners accept innovations, but there is also resistance to innovative changes.

Process of learning is of extreme significance for the realization of innovation process. Existence of strategic partnerships in turbulent environment is, in fact, conditioned by constant learning and acquisition of new knowledge. By acquiring new knowledge, knowledge-based innovations are created. These innovations have the longest lead time and they are usually focused on the improvement of the strategic position of a partnership. Knowledge-based innovations involve configuration of different types of knowledge. Creation and transfer of knowledge in strategic partnerships bring invaluable benefit to all the partners within the network.

3. LEARNING AND KNOWLEDGE AS THE FACTORS OF INNOVATIVENESS OF STRATEGIC PARTNERSHIPS

Under modern business conditions, the only lasting source of competitive advantage of strategic partnerships is found in their ability to learn. Realization of the process of learning enables strategic partnerships to adapt to turbulent changes coming from the environment. In their attempts to create added value, alliances have to learn faster than their rivals in the environment and offer new knowledge in a more efficient and effective way. Research performed by Stanford University confirmed that the total human knowledge acquired up to 1900 doubled by 1950 and that it is still being doubled every 5-8 years (Lasserre, 2003).

There are numerous reasons for which learning is in the centre of attention of academic community and managers as well. Firstly, concept of “learning organization” has gained popularity among big companies that entered strategic partnerships at the moment when they tried to develop structures and systems that are generally much more adaptable to changes within the environment. Secondly, changes within the environment increase uncertainty of business and force companies to learn and do things in a different way. Thirdly, learning has a strong analytic value (Pasher & Ronen, 2011). Learning is an extremely dynamic process that enables strategic partnerships to face the threats and opportunities from the environment by increasing bases of knowledge. Learning in partnership aims at increasing business effectiveness and achieving competitive advantage. However, learning is not an easy process. It is often frustrating for involved partners. Nevertheless, it stands for the necessity for at least two reasons (Pasher & Ronen, 2011):

1. Because of devaluation of existent knowledge, and
2. Because the knowledge can be lost in case of lack of repetition and failure to memorize it.

There are two kinds of learning: learning through repetition and learning directed at finding contradictions (Bacera, & Gonzales, 2004). Learning through repetition is performed within a well-known framework and can be divided into adaptive learning and “single-loop learning”. Learning directed at finding contradictions results in examining and changing of basic assumptions and established contexts. It can be marked as generative learning or “double-loop learning”. Generative learning is of special significance for the process of reaching innovativeness of strategic partnerships. In case the environment is turbulent and marked by discontinuous changes, partners within the alliance might decide to use the concept of “double-loop learning”. Those changes influence the alliance's constant and generative learning and transformation. Contemporary strategic partnerships and strategic partnerships of the future are the ones that will apply generative learning. Adaptive form of learning can be applied by those strategic partnerships that do business within stable environment. Some of the advantages of learning within the partnership are reflected in the fact that partners are able to learn from one another.

Learning process results in knowledge. Acquisition of knowledge is a process that should be accompanied by motivation. With the help of knowledge, as the basic resource in contemporary business environment, partnerships are able to make other resources, such as labour, capital and natural resources, more productive. Productivity, which stands for the result of knowledge, must be constantly improved. Great

number of theoreticians have studied and described individual knowledge. The development of modern business pointed to the importance of collective (organizational) knowledge. Knowledge that is used, expanded and upgraded in partnerships stands for the form of collective knowledge and can be classified into two categories:

- Compatible knowledge
- Complementary knowledge (Bergeron, 2003).

Compatible knowledge refers to the process of expansion of knowledge that the employees already have. Complementary knowledge refers to knowledge that does not belong to the employees' domain. If knowledge is observed from the standpoint of cognitive dimension, it can be: explicit (that can be easily expressed) and implicit (that is difficult to express since it is usually tied to a specific context). According to some research, 42% of total knowledge belongs to the category of implicit knowledge (Bergeron, 2003).

Human knowledge is a dynamic category whose constant improvement is based on the development of science and technology, which consequently results in fast expiration of existent knowledge. Because of that, permanent learning concept's practical market application is increasing, and it has become one of the dominant strategic goals of management. Although human knowledge and expertise are difficult for quantifying, they stand for the source of creation of value for buyers and owners. Data, on the basis of which 50% of GDP in developed economies is based on knowledge, i.e. intellectual property and human expertise, points to the central role that knowledge has within modern economy (Lasserre, 2003). Knowledge-based economy relies on constant learning and acquisition of new knowledge. This is further supported by the facts about the recent trend of constant erosion and amortization of knowledge that expires up to 50% over the period of three to five years (Iyer, 2002). Therefore, learning and knowledge are significant factors of innovativeness as the source of competitive advantage of strategic partnerships.

It is characteristic of strategic partnerships that they present learning as based on the experience of others (partners in the alliance). Namely, success of strategic partnership depends on partners' mutual trust as well as on the degree to which they are ready to learn from one another. Nowadays, successful partnership is synonymous with partnership that learns, collects all accessible knowledge, experience and intellectual resources with the purpose of achieving good performances and values for their shareholders. Tidd, Bessant & Pavitt (2005) point out that "innovation in the knowledge economy is not merely the process of creating new products. Since partnerships either innovate or disappear, innovation is, in its essence, an element of production and other business processes" (p. 67). Strategic partnerships enable more efficient utilization of knowledge, which is reflected in realization of innovations, while at the same time reducing the time necessary for their implementation.

Learning in strategic partnerships can be traced through five dimensions: through environment, tasks, processes, skills and goals relative to the phases in the development of strategic partnerships (Table 1). Environment includes both internal and external environment – market, competition, culture, government, organizational culture, human resources, etc. In this context, the tasks refer to common tasks on which the establishment of a partnership depends. Processes stand for the roads towards realization of a task, which leads towards realization of defined goals (Iyer, 2002).

Table 1: Learning through phases of development of strategic partnership from the standpoint of five dimensions (adapted Iyer, 2002, p. 4)

<i>Dimensions of learning</i>	<i>Spotting and selection of partners</i>	<i>Research and meeting of partners</i>	<i>Expansion</i>	<i>Establishment of partnership</i>
Environment	External contents (cultural and national elements)	External and internal contents, corporate culture of partners and managerial practice	External contents with the purpose of utilization of new chances	External contents with the purpose of using new opportunities
Tasks	No or few tasks	Identification of common tasks	Creation of common tasks	Re-examination of common tasks, creation of new ones

Processes	No or few processes	Research and identification of common processes	Creation of common processes	Re-examination of processes
Skills	Explicit knowledge on prospective skills of partners	Initiation of the process of transfer of implicit knowledge for later phases of the development of the alliance	Transfer of knowledge and skills	Development of new knowledge and skills for common benefit
Goals	Strategic plans and initial goals of prospective partners	Partners' goals, searching for common and compatible goals	Establishment of goals of the alliance	Constant evaluation and re-examination of the goals of the alliance with the purpose of long-term competitive advantage

With the purpose of efficient realization of learning in the alliance, existence and accessibility of knowledge are necessary. Sole existence of knowledge does not guarantee efficient learning. The best results in the process of learning in strategic partnerships are achieved if:

1. Formal and informal ties among partners are strong, and if
2. Organizational culture of partners is compatible (Iyer, 2002).

Basic problems that appear in the process of learning in partnerships are the problems of integration of partial knowledge as well as methods of generation and memorizing of knowledge of individuals who belong to different organizations. The problem is reflected in systematization and memorizing, i.e. storing of knowledge. Concepts with the help of which these problems could be solved are: concept of knowledge maps, concept of management based on skills and concept of transactional memory (Lasserre, 2003). Concept of *knowledge maps* uses diagrams to present group and individual knowledge. The aim is to collect related information in the form of texts, stories, graphical displays, models and numbers and display them graphically. Knowledge maps have to be accessible to all at all organizational levels and they have to be displayed in appropriate form so that they could be useful. *Management based on skills* focuses on skills, competences and description of profiles for all positions and workplaces. This concept is focused on the creation of a clear distinction between skills that are necessary for a certain work position and the skills that an employee possesses. This concept is applicable only with respect to task-oriented and non-multidisciplinary jobs. *Concept of transactional memory* is based on the explanation of knowledge exchange, coding systems, storing and utilization of information of employees who are in constant contact. This concept is based on two components: members' individual memories and transaction process that constructs and uses individual memories with the purpose of making them accessible to all individuals. Transaction process starts when all group members start to acquire knowledge that belongs to other member's expertise. Concept of transaction memory can be descriptively displayed by division of directories in computer networks and it involves three key processes: updating of directories (when people learn what belongs to the domain of other people's knowledge), allocation of information (when new information are sent to the person whose domain they belong to) and renewal of information (when missing information are found in knowledge from similar domains).

Strategic partnerships constantly invest in knowledge and education of their employees, offering them numerous programs for acquisition and improvement of various knowledge and skills. Realizing the significance of knowledge and permanent learning for efficient business, leading international companies started the process of establishing their own schools and even universities as special centres for learning, training and development of their existent as well as prospective employees (for example, Motorola). Trend of investment in knowledge is increasing. The most successful companies invest from 3 to 5% of their revenue from previous year in different forms of learning and education of their employees (Betz, 2001). Knowledge, seen through the prism of expansion of total perceived information, possibilities, skills and abilities that enable individual decision-making, is no longer an obligation and "privilege" of management. It is becoming an obligation and a necessity regarding all employees within one business system.

Employees will have to adjust to “deep knowledge” and specialization in their field of expertise, which is going to replace “general knowledge”, where people know a little from everything but still not enough. Permanent education and training of employees with the purpose of becoming professionals occupy a special place in that system.

4. TRANSFER OF KNOWLEDGE IN STRATEGIC PARTNERSHIPS AND CREATION OF INNOVATIONS

Acquisition and exchange of knowledge and innovations are important motives for entering strategic partnerships in which partners exchange, directly or indirectly, various forms of knowledge. Fusion of innovations is another motive for the establishment of strategic partnerships. One of the partners may bring special knowledge on business process that is crucial for achieving competitive advantage and that is harmonized with existent technological resources of other partners. Acquisition of knowledge in business fields that are not close to primary business activity of a company that entered the partnership can also stand for the motive for entering the partnership. Strategic partnerships see their business logic in the support to the process of transferring and management of knowledge among partners. The aim is to connect compatible partners that will be able to create new knowledge and exchange existent knowledge with the purpose of creating innovations. Partnerships provide partners with the possibility of acquisition, development, exchange and improvement of knowledge, which results in further growth and development of partners' companies. Intangible assets are necessary for the creation of new knowledge and result in innovations.

The concept of transfer of knowledge is often used in generic sense and it stands for any kind of intentional or unintentional exchange among individuals, teams, groups or organizations. In the process of knowledge transfer there has to exist clearly defined source, recipient and goal. Knowledge is built in organizational structures, processes, procedures and routines, which is why it is difficult to transfer it and separate it from the whole (Jennex, 2008). Certainly, the ability to transfer knowledge stands for the primary source of competitive advantage of strategic alliances.

Contrary to other resources in alliance, knowledge cannot be used up. What is more, it can be expanded. Besides, transfer of knowledge cannot be regulated by contracts. Transfer of knowledge is facilitated by intense communication and social interaction among partners. Transfer of knowledge can be described as communication among employees from one company and employees from another company within the alliance regarding specific problems (Inkpen, 2008). The problem might occur among employees who are not ready to adopt new knowledge, which hinders the process of transfer. Motivation factor is very significant for the successful transfer. Employees should be stimulated to cooperate, communicate and exchange knowledge. Partners' justified fear that the process of transfer of information and knowledge might strengthen the position and competitive advantage of one of the partners creates the necessity of the creation of environment characterized by mutual trust. Moreover, partners' constant interactions are expected to build mutual trust over time, which strengthens partners' relations and facilitates the process of knowledge transfer. Partners' mutual trust is crucial for the process of knowledge transfer.

Partners cooperate with the purpose of acquiring different knowledge that they cannot create themselves. Partnerships that use different forms of knowledge on the basis of which they realize innovative activities promote the so-called innovative behaviour. However, knowledge exchange is a complex process. It involves personal contact, experience and direct interaction so that knowledge could be shared. Problems and difficulties in the process of knowledge transfer among strategic partners occur due to (Lasserre, 2003):

- Differences in business processes, which might result in difficulties in coordination
- Differences in understanding of important terms, which might result in wrong interpretation within processes of communication or knowledge exchange;
- Different organizational cultures;
- Lack of centralized knowledge in each separate organization from which employees come.

Partnership's final goal is to contribute to the increase of innovations and improve performances at the level of entire partnership. Primary task in the process of stimulating innovations is to secure transparency of the process of innovating. It is achieved with the help of tools of interpersonal communication directed at creation of information (knowledge) as well as at their further spreading. Equally important task is to secure credibility

of innovative processes. It is achieved by inclusion of all partners in the process of selection and determination of priorities regarding innovation projects. Transfer of knowledge can be achieved through different mechanisms, such as: moving of employees, training, communication and personal relations, observation and adoption of examples of good practice, transfer of products and services, obtaining of patents, scientific and technical publications, presentations as well as interactions with suppliers and customers. Regardless of the methods that are used in the process of knowledge transfer, knowledge has to be adapted and modified so that it could be successfully applied (Stefanović, 2010). By transferring and utilization of knowledge, its value increases and the network of those who possess valuable knowledge is expanded, which creates new possibilities for utilization and expansion of knowledge.

With the aim of facilitating the transfer of knowledge among partners as well as making the way of expression of knowledge easier, specific strategies were developed. When used in practice, these strategies are combined. These are: strategy of socialization, strategy of externalization, strategy of combination and strategy of internalization (Bacera, 2004).

1. *Strategy of socialization.* Socialization stands for the transfer of implicit knowledge from one subject to another. It is undertaken with the purpose of acquiring knowledge that is related to realization of employees' routine operations. In practice, this way of knowledge transfer refers to the imitation of work procedures, work processes and behaviour in the process of realization of tasks. Transfer of implicit knowledge implies that subject that adopts knowledge should always be in physical contact with the subject who emits implicit knowledge. There is the possibility of transfer of this kind of knowledge through telecommunication channels. However, in that case, there might appear problems of misunderstanding and harm as a result of misunderstanding.
2. *Strategy of externalization.* Externalization stands for the process of transfer of implicit knowledge into explicit knowledge. It refers to codification of implicit knowledge to some permanent medium with standardized physical shape. By applying this strategy, partners' acquired knowledge is protected from the loss of accumulated implicit knowledge acquired in the previous period and saved from oblivion. This strategy saves the time period that would be used for repeating past practices in the future. Moreover, costs that are necessary for reaching the level of explicit knowledge needed for realization of some operation or task are reduced.
3. *Strategy of combination.* Strategy of combination refers to transfer of explicit knowledge into explicit knowledge. This means that existent knowledge is upgraded. Knowledge written on some medium can be the subject of interest. In combination with a new idea it results in the creation of new knowledge that can be further upgraded or that can be transferred to implicit knowledge.
4. *Strategy of internalization.* Internalization refers to transfer of explicit into implicit knowledge. It refers to practical application of knowledge. Theoretically developed assumptions of problems are verified through practical testing.

5. CONCLUSION

Changes related to customers' demand, technology, new product introduction and the like oblige strategic partnerships to learn and acquire knowledge constantly. Strategic partnerships offer the possibility of acquisition and development of knowledge through cooperation of involved partners. In that way, strategic partnerships become the source of innovative ventures.

The paper pointed to the fact that learning and knowledge stand for the basic driving force of innovations under modern business conditions. It can be seen that numerous pieces of evidence unequivocally point to the fact that the survival of strategic partnerships is conditioned by learning and acquisition of new knowledge. Partnerships that want to be successful and make progress on the market have to be innovative. Expansion of innovativeness and, consequently, achieving of competitive advantage result from the realization of the processes of learning and acquisition of knowledge. It can be stated that generative learning is of special significance for achieving innovativeness of strategic partnerships.

In order to be efficient, innovation process has to be focused on its end goal, which is reflected in introduction of new products and new processes that create competitive advantage. Innovation process is complex and requires dedication of all involved partners. Management of innovations frequently represents a challenge because it involves high degree of uncertainty, which is why it is necessary to make a selection of innovations and decide about the scope and type of innovations that will be realized. Success of this venture requires identification of the domain and scope of innovations, management of innovation process and

cooperation with partners within innovation process and the like. It can be concluded that innovations stand for the basis of survival and the basic tool for achieving competitive advantage of strategic partnerships.

Level of progress of strategic alliances is in close connection with the quality and quantity of knowledge gained, as well as with the ability to exchange knowledge among its members. Adaptation to trends, new technologies, market demands and demands set by the competition also implies acquisition of new knowledge. Within that process, employees who are open to changes and ready to accept new knowledge and experiences are of crucial importance. The process of creation of knowledge involves education of all employees, as well as distribution of knowledge among employees, teams, development groups or partners. Within this process, existent knowledge is expanded through intense communication and new ideas are created. It can be concluded that the success of partnerships depends on the effective transfer of knowledge among partners and creation of innovations.

Abstract: *Survive and success of organization at competitive environment of contemporary world is required the contentious and suitable selection and implementation of applications that is because of change, revolution, speed, lack of insurance is from most factor and feature. These important issues are realized from design and determination of goal, strategy, programming and implementation of strategy and control and evaluation of application. Most of organizations at implementation of strategies and management of application are not successful. Research shows that this issue is not only by the incomplete define of strategy but also because of lack of suitable applied evaluate system and perfect framework for integrity and compatibility at these works. At this research time preference at 5 years strategies of Iran SADERAT bank at the framework of balanced scored cards measure for the determination of highest preference aspect. Also, prerequisite of each of strategy specify for the successful implementation of strategies. At least, Weight of four – sided model of balanced scored card has determined based on importance, at this case, indexes which have more importance at the balanced scored card of Iran SADERAT bank for success of bank have specified.*

Key words: *balanced scorecard, strategy, human resources, information technology, process, market, customer*

1. INTRODUCTION

Important change and revolution at the human's life has found various dimensions, And every day has added in its speed. Patterns of balanced scored card is strategies which can be helpful and conducive at the survey and evaluate of organizations. but this model can be representative of extent of distortion of goal and is not related to the distort from goal (changes of organizational environment and features of every organizations are different from other organizations).

However every organization is familiar with automobile in this case. automobile is required the adoption of suitable strategies from the driver for reaching to goals and passing the routes of travel. at this case, most of indexes that survey at the organizations, have not directional and meaningful relationship than strategies, but, these index are representative of warrant for management of organizations until adopt new strategy and suitable applied program for organizations.

From above matters, we understand that time at the strategic thinking and strategic programming play important role. However, existence of tools can emphasize the time and importance of indexes and strategies are necessary. Survey of possible design of active tools and factors for evaluate of applications of organization's programming is one of the points that pay attention to it.

Also, at this research, try with addition of importance of (weight), preference (time) at the BSC aspect can find the cause of distortion by identifying the distortions which can help the managers and decision makers of organizations for the finding suitable routs at the short times for the changes or correction of applied strategies and tactics.

Other important points is that sometimes we face with strategic programming by using of balanced scored card with lack of balances of applications which point out us two subjects: first: adoption of wrong goal and strategies. Second: wrong implementation of strategies or misunderstanding of their correct preferences which each of them could alone or at combination with fundamental factors to be balanced aspect of BSC. This research tries to find answers to the questions.

2. LITERATURE REVIEW

Balanced scored card (BSC), is one of the suitable and applied present tactics at performing strategies and perfect applied evaluation which describe the viewpoint and mission of organizations at the cause

and effect relationship at four financial, customer, internal process, growth and learning (human resource, unrecognized capital of organizations and informational systems) and lead to understanding of missions, applied viewpoints and ideas for whole internal and external beneficiary.

Goodstein, Nolan, and Pfeiffer has expressed at the 1992: strategic management is process from which it members of every organizations visualize the future and establish the necessary process and measures for reaching to it. (MOBAYENIDEHCORDI, 1386, page 22). In the other word, strategic management is set of designed theories and frameworks for helping to working managers, at the programming thinking and strategic measures and is related to the long term success at working of organizations. Even are tools which can through it program for future. (MOBAYENIDEHCORDI, 1386, page 22)

Strategic management is kind of decision making process which can relate the internal environment of organizations with opportunity, threats of external part of organizations which value of each of factors to be specified at the realizations of this goal s. (MIRSEPASI, 1373).

For strategic programming, there are various models at the management knowledge. Which one of the most applied of them is balanced scored card models.

Kaplan and Norton make familiar the activity of manager of organizations as a practice of airport pilot: as the airport pilot is required the petroleum, speed, air pressure, temperature degree and map of rout for the safe flight, management require the various information at the different aspect of itself and other financial criteria lonely cannot provide the adequate information about key action of organizations. Based on these factors, introduced the techniques of balanced evaluate.

Viewpoint and strategy is connected with aspect of balanced scored card. Financial, customer, process, growth and learning aspects in which balanced scored cards has introduced based on it, are related to each other as complementary and integrated process and are representative of common, motivate, inductive, and controversy image of about available situation of organizations in which should be measured from four-fold aspect of balanced scored card.

This research survey the various dimension of Iran SADERAT bank by the 5 years case study by Iran SADERAT bank in which its model has designed based on balanced scored card. The model of balanced scored card has 5 aspects which are Financial aspect, Customer and market aspect, internal process aspect, Human resource aspect and Informational technology aspect.

3. RESEARCH QUESTION

- 1) What is time preferences for implementation the strategies of IRAN SADERAT bank at the 5 years program?
- 2) How is prerequisite of implementation the strategies of Iran SADERAT bank at the 5 years program?
- 3) Do the axes and dimensions SADERAT bank at the 5 years program have same importance?
- 4) What are axes and indexes of balanced scored cards?

4. RESEARCH METHODOLOGY

Present research is applied based on the goal of research method in which scientific application is considered and based on the ways and methods of accessing the related data are measured – descriptive. Statistic community is included the employed experts at the SADERAT bank. At this research expertness is related to the people who have the master of art and even 5 years job experience at the banking.

4.1. TIME PREFERENCE AT THE IMPLEMENTATION OF SADERAT BANK

Iran SADERAT bank has strategies for reaching to its goals. These strategies have designed based on the balanced scored card models. Important issues are the time preference in which should be considered. While ignorance to these issue lead to strategies could not reach the organization to its goals. At this case, questioner which is related to the dimension of balanced scored cards of SADERA bank is given to the experts. Outcome of time preference which are related to the customer and market strategies are presented at the below:

Table 1: Time preference of SADERAT bank

Weight average	Key index of success	Strategies	Aspect	Row
5.40	Suitable Rate of deposit	Attraction of cheap resource	Market and customer	1
5.40	per cent of expiry charge	Reduce the delayed charge		2
5.40	Capitation of branch income	Improvement of branch of network	Market and customer	3
7	per cent of loyalty of customers	Focus on customer	Market and customer	4
5.20	Role of market from banking deposit	Strategies of market improvement	Market and customer	5
5.60	Ratio of coverage of personal banking	Improvement of personal banking	Market and customer	6
5.60	Ratio of coverage of firm banking	Improvement of firm banking	Market and customer	7
5.40	Ratio of coverage of personal banking	Improvement of personal banking	Market and customer	8
6.20	Ratio of coverage of international banking	Improvement of international banking	Market and customer	9
7.00	Rate of outcome of facilities and investment	Focus for outcome of facilities and investment	Market and customer	10
7.00	per cent of electrical distribution	Improvement of electrical banking	Information technology	11
8.40	Ratio of coverage of electrical card	Improvement of electrical network	Information technology	12
5.80	Ratio of integrity of process and systems	Reengineering process and systems	Internal process	13
5.80	per cent of cost of research and	Innovative management	Internal process	14
5.60	per cent of quality and quantities human	Balance of quality and quantities human resource	Human resource	15
6.60	per cent of satisfaction of staffs	Insurance of working level of staffs	Human resource	16
5.00	per cent of organizational learning	Identification as a learned organizations	Human resource	17
6.00	Applied outcome of staffs	Applied and moral Elevation	Human resource	18
6.40	Market and customer		Financial	19
7.80	Information technology		Financial	20
5.20	Internal process		Financial	21
5.60	Human resource		Financial	22

As seen in the above table, average of time preferences at every strategy and even result are representative of preference of experts has specified at every low, average, high .

4.2. PREREQUISITE AT THE TIME PREFERENCE STRATEGY OF SADERAT BANK

Every of strategies has prerequisite to be implemented. At this case , there are strategies in which are dependent to other strategies and when implementation of prerequisite don't start , there aren't strategy for realizations of them . So prerequisite of strategies are important for implementation of them. In which organization should pay attention to them for better realization of goals.

At table 2: prerequisite of each strategies of SADERAT bank has presented. With attention to the below table , can understand which of strategies of SADERAT bank are precedent on other strategies of balanced scored card .

Table2: Prerequisite strategies of SADERAT bank

prerequisite	strategy	row	Aspect
14,9,8,7,4,4,3,5,4	Attraction of cheap resource	1	Market and customer
13,10,10,3,4,7,	Reduce the delayed charge	2	Market and customer
11,9,8,7	Improvement of branch of network	3	Market and customer
12	Focus on customer	4	Market and customer
13,8,5,5,4	Strategies of market improvement	5	Market and customer
13,7,5,5,4	Improvement of personal banking	6	Market and customer
12,1,5,4	Improvement of firm banking	7	Market and customer
14,1,1,2	Improvement of personal banking	8	Market and customer
13,3,12,12	Improvement of international banking	9	Market and customer
18,4	Focus for outcome of facilities and investment	10	Market and customer
15,14,14,7,14	Improvement of electrical banking	11	Information technology
16,11	Improvement of electrical network	12	Information technology
14,2,1,18	Reengineering process and systems	13	Internal process
21,15,5,15	Innovative management	14	Internal process
13,9,15	Balance of quality and quantities human resource	15	Human resource
21,15,5,15	Insurance of working level of staffs	16	Human resource
13,9,15	Identification as a learned organizations	17	Human resource
17,16,12,10	Applied and moral Elevation	18	Human resource
12,4,5	Market and customer	19	Financial
15,11,12	Information technology	20	Financial
13,124,22,20,14	Internal process	21	Financial
16,5,15	Human resource	22	Financial

4.3. RESEARCH ABOUT DIFFERENCE OF IMPORTANCE OF AXES OF BALANCED SCORED CARD MODEL

For determine of difference of importance of axes of balanced scored card model of SADERAT bank has used the FRIDMAN test.

Theory 1- axes of balanced scored card model of SADERAT bank have not same importance.

Theory H0: axes of balanced scored card model of SADERAT bank have same importance.

Theory H1: axes of balanced scored card model of SADERAT have not same importance.

Table 3 show the average of expert degree about the axes.

Table3: Table of ideas of experts toward axes

	Mean bank
Financial aspect	B1 3.81
Customer and market	B2 2.69
Information technology	B3 3.25
Human resource	B4 2.47

With attention to above table, observed that ideas of experts toward axes are different. Even presented for survey of meaningful difference between various group of experts and meaningful difference of test are provided at the table 4.

Table 4: Result of FIRMAN test about axes of balanced scored card

N	16
Chi-Square	11.327
Df	4
Asymp.Sig	.023

As you see at the above table, meaningful level 0.023 has received. And is representative of meaningful difference between different groups and theory H0 reject and theory H1 confirm. As result axes of balanced scored card of SADERAT bank have not same importance.

At this case, for determination the difference at the index of every model at balanced scored card of SADERAT bank, related theory has tested by FRIDMAN test. And in all of the theories, theory H0 reject and theory H1 confirm. At result, can say that index of each axes have not same importance.

4.4. IMPORTANCE OF INDEX AND AXES OF DIMENSION OF BALANCED SCORED CARD MODEL:

In order to determine of main index and aspect of balanced scored card model of SADERAT bank has used the proximal techniques of social curve. Because of decision matrix is not available. So couple comparison has used by experts. So gathering of questioner of couple comparison has used the geometry average for determine of elements of decision matrix.(decision matrix which resulted from geometry average bring continuously.)

For determination of rate of compatibility and weighting of criteria has used from selected expert software. And weight of aspect and index of balanced scored card model has expressed. Table 5 is representative importance of different aspect of BSC from viewpoint of SADERAT bank experts. Rate of compatibility of matrix has received by the Expert Choice software at the 0.09. Therefore recent matrix has compatibility.

Table 5: Couple comparison matrix about axes of balanced scored card

Comparison matrix	Financial	Market and customer	Internal process	Information technology	Human resource	Weight
aspects						
Financial	1	2/88	3/00	1/93	2/21	0/383
Market and customer		1	2/85	3/34	3/03	0/271
Internal process			1	2/26	3/59	0/143
Information technology				1	2/23	0/084
Human resource					1	0/119

Received Decision matrix, is related to financial index of balanced scored card model which presented at table 6. Rate of compatibility for this Matrix by using selection expert software is received at the 0.09. Therefore present matrix has necessary compatibility.

Table 6: Couple comparison matrix about financial index

FINANCIAL	A	B	C	D	E	F	G	H	I	Weight
A Outcome of rights of stock occupier	1	5.60	4.59	3.14	4.04	2.74	3.67	4.00	4.54	0.318
B Whole income		1	2.70	2.73	1.99	2.53	3.49	4.04	4.63	0.167
C Outcome of property			1	4.68	3.67	3.63	3.71	2.41	5.32	0.100
D Capitation of personnel income				1	2.35	1.99	1.50	1.68	1.81	0.084
E Margin of perfect profit					1	4.04	4.79	4.63	4.08	0.115
F Lever proportion						1	4.44	4.04	3.17	0.083
G Proportion if profitable property and whole property							1	4.44	3.75	0.066
H Proportion of visual deposit and saving to whole deposit								1	2.62	0.038
I Rate of suitable deposit									1	0.028

Decisions matrix is related to index of market and customer of balanced scored card at the table 7. Rate of compatibility for the matrix by using the selected expert software has received at 0.1. So present matrix has necessary compatibility.

Table 7: Couple comparison matrix about customer and market

Market and customer	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	
A Rate of role of market	1	3.4 1	3.0 0	4.3 1	2.0 5	1.9 4	2.9 1	4.2 1	2.5 4	2.5 9	2.5 9	2.9 7	3.2 7	2.0 3	2.4 1	.15 0
B Capitalization of branch income		1	2.4 6	3.5 2	1.9 9	1.8 1	2.9 1	4.3 5	4.0 8	3.3 4	3.5 6	3.0 0	3.9 1	1.9 3	3.2 3	.12 9

5. CONCLUSION

Result of research of time preferences at the 5 years perfect strategies of SADERAT bank shown that between strategies of market and customer at SADERAT bank , strategies of focus on customer and focus on outcome of facility and investment have highest level of time preferences . at the information technology , information technology , strategies of improvement electronic network has highest level of time preferences.at the internal process ,of reengineering strategies of process and systems , and innovative management have same time preferences. At the human resource, strategies of insurance of working level of staffs have highest level of time preferences.financial aspect of is studied from another aspect that is according to balanced scored card model of SADERAT bank for realizing the financial goal of other aspect in which as fundamental strategies has surveyed. Based on this case, from view point of experts of SADERAT bank, information technology hashighest levelof time preferences.

With attention to related research and analysis can express the time preferences as below table. As seen at the above table, strategy of improvement of electrical network has highest time preferences between other strategies.

Table 11: Time preferences of whole strategies of SADERAT bank

STRATEGIES OF TIME PREFERENCES	12- IMPROVEMENT OF PERSONAL BANKING
1-IMPROVEMENT OF ELECTRICAL NETWORK	13- IMPROVEMENT OF FIRM BANKING
2- INFORMATION TECHNOLOGY	14-BALANCE OF QUALITY AND QUANTITATIVE HUMAN RESOURCE
3- FOCUS ON CUSTOMER	15- HUMAN RESOURCE
4-FOCUS ON OUTCOME OF FACILITY AND INVESTMENT	16- ATTRACTION OF CHEAP RESOURCE
5- IMPROVEMENT OF ELECTRICAL BANKING	17- REDUCTION OF DELAYED CHARGE
6- INSURANCE OF WORKING LEVEL OF STAFFS.	18- IMPROVEMENT OF BRANCHES OF NETWORK
7-CUSTOMER AND MARKET	19- - IMPROVEMENT OF PERSONAL BANKING
8- IMPROVEMENT OF INTERNATIONAL BANKING	20- STRATEGIES OF IMPROVEMENT OF MARKET
9- APPLIED AND MORAL ELEVATION	21- INTERNAL PROCESS
10- REENGINEERING OF PROCESS AND SYSTEM	22- IDENTIFICATION AS A LEARNER ORGANIZATION
11- INNOVATIVE MANAGEMENT	

Recent result of determination of prerequisite is seen at the table 2. From important issue should pay attention to it is that with determination of prerequisite of strategies is not shown higher time preference. and this prerequisite are time- dependent .means that if organization to be successful at one time preferences , may change the prerequisite or become prerequisite of another strategy . Even relational prerequisite are not related to the time preferences with implementation of strategies but also their relation is cause and effect.

Determination of degree of importance of five index of balanced scored card that is representative of implementation of strategy of SADERAT bank that show the time preferences of something insure the continuation of program . in which are attention to the indexes from AHP couple comparison matrix that have most degree of importance.

At this case, based on the result of degree of importance of index , fundamental index of each of balanced score card model are following:

- ✓ Most important index of balanced score card model = financial aspect
- ✓ Most important index of financial aspect = outcome of right of stock occupier
- ✓ Most important index of customer and market = rate of proportion of market.
- ✓ Most important index of internal process= per cent of cost of research and improvement.
- ✓ Most important index of information technology = per cent of electrical distribution.
- ✓ Most important index of human resource= per cent of balance of quality and qualitative human resource.

Abstract: *The main goal of this paper is to underline the importance of the manager's preparation for negotiations. Though negotiation can easily be considered as one of the oldest human activities which we also use today it on a daily basis, both in private and business interaction, its research in academic circles started relatively late. First research in this field appeared in the late 1960s. From then on, negotiations are in the focus of theoretical experts in different fields, who examine various aspects, such as social, behavior, communication, ethic, law, cultural and economic aspects of negotiations.*

Keywords: *globalization, interculturality, management, negotiations*

1. INTRODUCTION

There is no doubt that numerous negotiation abilities and skills are required as well as adapting to other cultures is strongly connected to human relations, especially on the international level. It is necessary for a negotiator to adapt his/her behavior to cultures of the people he/she is doing business with.

Adapting to other cultures means introducing the negotiator to the facts that may be of great importance. If the negotiator knows that he/she will be doing business with the people who belong to a different culture, he/she needs to gain knowledge about history, customs and habits of that culture.

In international negotiation we need to be aware of various elements of the culture of each country, as well as what we need to do in order to adapt to that culture, avoiding behavior which is based on false understanding or prejudices. The main reason for those false understandings of other cultures, so called "ethnocentrism", is a belief of one social group that its ways of behavior are the best possible. The transition towards market economies in countries which are closed, protectionist, and centralized economies, influences that the model collision is not formed around ideological issues, but around culture. The benefits from knowing other cultures are: maintaining relationships easier and communication with foreign clients, easier understanding of the attitudes of people that we negotiate with, assistance in understanding of the people who belong to different cultures, avoiding mistakes which might put negotiations in danger, gaining of certain identity on a personal or entrepreneurial level, motivation of the employees to work in branches in foreign countries.

2. CULTURE AND NEGOTIATION

In real life situations, it is astonishing how people of different countries can act differently. According to that fact it is not possible to do business in a foreign country in the absolutely same way as we do it in our home country. It is generally known that the perception of business is different from country to country and that there are great cultural differences which need to be overcome in order for the business to be done properly. There are many ways to find out about other cultures, for example via various literatures, or through conversations, while nowadays the main source of information about other cultures is the internet. In many companies there are different ways of training for intercultural interactions. This training encompasses introduction of facts as history and religion, social and political environment, business practices, economy, tourism, etc. Religion is very important in daily life of all Islamic countries, especially in the Middle East. In certain cultures, it is very offensive to look women in the eyes, and in some other cultures, even a hand shake is not an acceptable way of greeting.

When a negotiator gets introduced to a different culture, his/her work does not stop there, because he/she needs to get prepared to accept the differences that he/she comes across, and to be able to adapt his/her

behavior if visiting a foreign country. Therefore, he/she needs to respect the norms, to adapt to differences, but also to keep his/her own identity.

Negotiation with a foreign culture creates a better working environment and a more relaxing working atmosphere, which helps in achieving better results and reaching the business goals. It will leave a positive impression on a person you do business with if you have put an effort in finding out about the culture of his/her people and the facts that might be useful. This is one of the ways of building a style of a business negotiator, since one of the characteristics a negotiator needs to possess is the ability to adapt to other cultures. On the other hand, the negotiator needs to be motivated in order to prepare for the meeting with the members of other cultures, and to know that it will be useful for him/her, it will make it easier for him/her and the foreign partners, and that he/she will leave a good impression and gain respect from the other negotiating party.

One of the first authors who analyzed the effects of culture on international businesses was R.T. Hall. He started from the term “context”, which is a set of information which is collected during a meeting and which is closely related with the circumstances under which that meeting is held. Based on the context in which the negotiations are held, we can differentiate two cultures:

1. Cultures of “low context”. These are the cultures which use clear and specific verbal and nonverbal forms, with complete grammatical terms and with no subjective judgments. Speaker mostly speaks about what they want to say. The members of these cultures value clear, direct and precise information – the less there are dual meanings and uncertainties, the better. This type of communication is typical for the Western, Anglo-Saxon countries, like the United States of America, Great Britain and Germany.
2. Cultures of “high context”. In this group of cultures information is unclear: behavior and circumstances are more important than verbal expression itself. A greater part of information is expressed through the behavior of the speaker, than through the verbal messages he/she sends. This type of communication is focused on people and their feelings and it is typical for the cultures, such as ours, Arabic, Latin and Japanese.

The world is not divided into cultural blocks which can be clearly defined or which coincide with the country borders. Most international negotiators are more focused on geographic regions than on specific countries, especially if those countries are small. It is common to say: “I will do business in Latin America or in Eastern Europe.” In most cases the styles of negotiation are grouped in six large geographic regions: Europe, North America, Latin America, Arabic countries, Asia and Africa. Comparison of cultural models of negotiation styles is seen through five aspects:

1. Use of time (punctuality in the meetings; orientation towards past, present and/or future; the pace of negotiations...),
2. Personal/professional relations,
3. Rules of communication (how to transmit messages, is it a question of verbal communication only or is a nonverbal communication present as well)
4. Consession and agreements (the moment in which the most important concessions are made is analyzed, also the ways in which agreements are made),
5. Decision making.

In this paper the European, Asian and Arabic model of negotiation will be examined.

3. COMPARING CULTURAL MODELS IN THE PROCESS OF NEGOTIATIONS

There are numerous examples of differences in doing business while taking the influence of culture into consideration and the following review will further illustrate this diversity in examples of several countries and how their local cultures affects the business or decision-making process.

Europe

The use of time has a strictly defined meaning to northern and central Europeans. Meetings begin and end when agreed. Topics are pre-planned. When the meeting is going as pre-planned, the satisfaction is greater and the involved parties are considered more professional. In the Mediterranean part of Europe the concept of time is more flexible and meetings are not planned in such detail. The main topics are more important than the time constraints. When negotiating with people from Eastern Europe, they most often refuse to talk about long-term goals. The time span of business negotiations is mainly present, or within the next year or two.

Personal/professional relations. In Europe the quality of life is valued, consisting of family life, leisure and rest, which all comprise a person's personal life. Personal relationships are kept outside the business environment. European management does their work according to the rules of the company and do not involve their own personal issues and opinions in doing business. The business relationship between the negotiators is very important. Features such as social status, education at prestigious business schools or some knowledge of sports (especially golf) is valued.

The rules of communication. Communication style is very different from one European country to another. The British are usually indirect and cautious and use their sense of humor well. The French have a more direct style, sometimes even with loud conversations, having intellectual discussions. Germans are serious, they try to maintain a distance from all involved parties. Communication is much livelier in Mediterranean Europe, often using non-verbal communication. There are big differences between the Eastern Europeans, ranging from the indirect and shy behavior of Czechs, to the direct and emotional behavior of Russians and Poles. Generally communication in Europe is formal.

Concessions and agreements. The starting positions in the negotiations are defined depending on the power of the negotiating parties. European negotiators feel comfortable in situations of conflict. It is common to criticize the arguments of the opposing party. Concessions are made bit by bit, throughout the negotiation process. If by the end of the talks, positions have not been synchronized, the more powerful party will impose a one-sided agreement and will not make any other agreements of the great importance for further progress.

Decision-making. In Europe, decision-making is generally based on hierarchy, although the structure of enterprises is very different from country to country. In Germany the decision making process is slower because the control of the company is held by councils made up of shareholders, employees and management. In the Netherlands the company managers have greater negotiating powers which make the process quicker. In Mediterranean Europe, it is common that a company is controlled by a small number of people. Decision-making in Eastern Europe is usually a long and incomprehensible process for foreign negotiators. It is necessary to always confirm the arrangements with each level of management in enterprises.

The use of time. In developed areas of Asia executives work in M time, which means that each job is done separately. Accuracy is highly appreciated. Orientation is generally long term, so there is a great interest to know the company and the people at workplace. With reference to this the negotiations are long-term. A foreign negotiator must be patient and not to impose negotiations regarding prices and delivery conditions. In high-level negotiations much time is devoted to social activities (meals, shows, etc.), but this does not mean it will make closing the deal easier. As soon as there is a business relationship between two local companies a job being done with foreign partners will be transferred to the domestic ones.

Personal/professional relations. Achieving adequate business and professional relationships in Asia is a basic requirement for doing business. The dependence that exists between government, public companies and large companies creates a network of relationships that is difficult to get into. In Asian societies professional relationships are more important than personal ones. Introductions and making contacts are made at the official level.

The rules of communication. For citizens of Asia courtesy is the general rule of conduct, especially towards those who are not part of their group, which includes foreign negotiators. Verbal messages do not have the same meaning as in the West. In China, a "yes" does not mean agreement, but only a desire to appeal to the opposite side, in order to resume negotiations. In Japan, the term "think about it" certainly means that the proposal was not accepted. Language is controlled and indirect, a low tone of voice is used, and discussions with looking directly at the counterparts in the eyes are avoided because it can be considered aggressive.

Concessions and agreements. It is believed that negotiations make up entity more than concrete agreements. The main topics are discussed throughout the process, bearing in mind that this is usually done by large firms which wish to obtain all possible information before making a decision. Since decisions are made by consensus, it is easy to assume that the negotiation process will be long and that the agreements are made primarily at the end. Contracts signed do not have the same value as in the West. In China, a contract means the beginning of relationships that will be constantly examined and re-negotiated, rather than the highlight of the negotiation process. For the Japanese, a contract means the bare minimum of agreement that can be expanded or changed if circumstances change.

Decision-making. In large Asian companies the structure is very hierarchical, with multiple levels of decision making. Lower-level managers need to report to their supervisors and prove their ability to achieve a good agreement. Agreements are realized quickly.

The use of time. Arab culture is oriented on the past, traditions and customs are honored, as opposed to the changes and progress. During a month, all kinds of jobs are suspended, so that people dedicate their time to prayer. For Muslims time is in God's hands. Past, present and future are according to God's will. This is why there is great uncertainty in fulfilling short-term agreements. Accuracy is not a highly valued quality. Foreign negotiators must be very patient and flexible in their use of time. Any display of impatience is badly interpreted and may prevent a foreign negotiator from achieving goals and creating a network of contacts in the country.

Personal/professional relations. Arab negotiators have a value system in which personal relationships are put ahead of professional ones. For them, the most important personal relationships are family "blood ties". Making contacts within a certain enterprise through a family member of the company owners can be crucial for a good outcome of the negotiation. For Arabs, the financial gain is a consequence of establishing good and solid trade relations with foreign partners. Arabs show great hospitality at business meetings. They offer coffee, tea, soft drinks and food, which the negotiator should accept. Also, exchange of gifts is customary.

The rules of communication. The Arab culture is very formal in introduction. The meeting begins with rather complicated greetings, during which people are introduced according to titles, business cards are exchanged and inquiries made about the trip, hotel, impressions of the country, and so on. In a culture of "high context" such as this, non-verbal communication is very important. Gestures are semi-dramatic, so to speak, the language is exaggerated, as are the meaning and tone, and looking directly in the eyes is essential. People sit very close to each other and a sign of good manners is to touch the person with whom you are talking. Personal questions should be avoided in talks as well as discussions about politics and religion. The tone of voice demonstrates the social position and family influence of the person speaking.

Concessions and Agreements. Bargaining is a common way to reach an agreement in Arabic countries. Negotiators who know how to bargain are very respectable, if they are polite and do not offend anyone in the process. It is hard to evaluate verbal agreements. A verbal "yes" is very uncertain. The contracts are more of a starting point of a relationship that needs to grow stronger in the future, rather than the final step or the outcome of successful negotiations. Goals, deadlines, prices, etc., are discussed in detail based on further circumstances.

Decision Making. The structure of power in Arabic enterprises is very hierarchical. The decisions are made by the general manager of the company. Therefore, the foreign negotiators will sooner or later have a conversation with the head of the company or organisation. It should be kept in mind that the highly ranked executives do not possess the knowledge of specific fields or technical profile. They make decisions based on strategic and personal details, rather than proposals and agreements suggested. The bosses are like fathers to their employees, they look after them, in return for loyalty and trust.

Based on all of the above, we can come to the conclusion that the differences in business cultures are evident and that respect is necessary during the business negotiation process. Cultural globalization is an encounter of different cultures and customs. The flow of goods, capital and people across the borders brings also a flow of habits, customs and cultures. This process often initiates different reactions among different people. Some consider the effect of a new culture as a positive development that enriches the existing culture, while others see it as a threat to the national values and rules.

4. CONCLUSION

Though negotiation is exceptionally old social and business activity, as old as trade, throughout history it didn't receive too much space in research and expertise. Learning about negotiations as an interdisciplinary phenomenon started only in the sixties of last century. Throughout that relatively short span of time, theoretical experts have underlined different aspects of this way of social and business communication. However, in spite of different stages and change in environment that demanded different approaches in negotiating, many experts agree that negotiating is made up out of certain number of phases.

For each and every of this phases, it's possible to extract and certain elements that can lead to successful outcomes. Negotiation skills are thus not be looked at as a God given talent, because it is by itself quite worthless. Successful negotiating lays in knowing verified theory and negotiation experience. Negotiating should be looked at as one of the key business processes that add value to the company, but for both the buyers and other business partners. Such approach towards negotiating is still in a very early phase at Serbian companies. A large number of managers at high positions are members of negotiating teams, and they consider communication skills as a key asset when recruiting new team members. A large number of negotiators can use a clear and comprehensive language when negotiating. It is important that confronting parties understand each other's stand points, goals, desires, and distance to which they may be willing to go when compromising. This understanding comes out of the communication and the solid standing grounds. This position must be communicated in clear and understandable language, with no hidden meanings. Non verbal communication helps in clearing out possible misunderstandings and doubts. It is also important to read non verbal signs of both sides for successful negotiations, as it sometimes may speak more than words. All of this only confirms the staring hypothesis that communication enhances chances for successful negotiations.

There are no successful negotiations without sometimes long and thoroughly preparations. These preparations include identification of subjects and structure of negotiations. Inexperienced negotiators often think that cusses of negotiations is in the ability to persuade someone, being quick on the answer, intelligently change the way of the conversation, being eloquent, etc.

Even though all the above qualities can certainly help the negotiations process, the true key lays in preparations before the interactive process between the sides, especially in the light of understanding cultural differences.

STRATEGIC MANAGEMENT AND HUMAN RESOURCES

Srđan Babić¹, Tatjana Cvetkovski² Violeta Cvetkovska Ocokoljić³

¹IDEA d.o.o., Belgrade, srdjan.babic@idea.rs

³Graduate School of Culture and Media, vcvetkovska-ocokoljic@megatrend.edu.rs

Summary: Modern business environment puts the organization to new challenges that must be included in the strategic management of the organization. The main changes are related to the process of globalization and all what it brings. By defining its strategy, the organization tries to achieve its long-term goals taking into account characteristics of the external environment, relying on its own strengths and taking into account its own weaknesses. The key resources of today's organizations are human resources. *In order for an organization to be successful, human resource management must be closely linked to business strategy.* Human resources can be a primary source of competitiveness *as well as* a key weakness of an organization. Under the present conditions, organizations that operate globally *usually* move their capital because of these resources, because they are in some parts of the world cheaper or *they have* a better quality than in others. In the future, to get quality and talented employees will be increasingly difficult. Many suggest that a battle for talent among organizations is yet to come. However, what appears as a question is how many organizations are aware of the importance of human resources and *how* many of them are thinking about it as a strategic resource *today and* in the future. Conducted studies show that many organizations still do not have necessary talent for their business strategy implementation *and that the talent gap is one of the top three risks in achieving business strategy.* In order to confirm the importance of this relationship, the paper will rely on a part of the research conducted by Manpower Inc. during 2010.

Key words: *strategic management, globalization, human resources, competition*

1. INTRODUCTION

In each organization human resources should be managed in a way that is congruent with organizational strategy. The major objective of the human resources management should be to integrate decisions about people with decisions about the results an organization is trying to obtain or with the strategic objectives of the organization.

For company is crucial to identify skills necessary in the future and then rapidly develop a critical mass of employees with those skills. In order to survive in a competitive market, companies will need to ensure timely development of new skills of employees, or to attract qualified workers (Cvetkovski, Cvetkovska Ocokoljić, Babić, 2010).

In the new economy, everything becomes global. Employees move and work is moving too. Organizations set up operations near new markets and sources of supply. Unemployment is persistently high in developed and even in many developing countries, yet organizations worldwide report difficulty filling key positions. Simultaneously, employers are seeking ever more specific skill sets and combinations of skills that will help drive the organization forward. Propelling the movement of talent around the world are widespread demographic changes—in particular the big gap in population growth between developed and developing countries. So how should employers respond to the forces of talent mobility? Many see it as an opportunity to cut labor costs and elevate their skills mix. Others see it as a threat to their hold on their best talent. Of course, employers have only limited control over the factors that determine where workers work, and why (www.manpower.com).

The pressure to find the right skills in the right place at the right time will increase in the future. This will happened because working age of populations will decline, emerging markets will farther rise, and the nature of work will change. Therefore, it is considered that the greatest treasure of an organization would be its employees, their knowledge, abilities and skills and the process of forecasting and talent mobility planning will become an integral component of the business planning process.

2. STRATEGIC MANAGEMENT AND NEW ENVIRONMENT

Derived from the ancient Greek word *strategos*, the word „strategy“ originally referred to the „art of the general“. Strategy has very strong military roots, the word itself dating back to around 500 BC with the work of Sun Tzu, a Chinese military strategist. The application of the principles of military strategy to business competition, known as strategic management is a more recent phenomenon, developed since the 1960s (Peng, 2009).

Some authors say that the strategy is the company's game plan. In the broadest sense, the strategy is the term used to describe someone's long-term plan and activities aimed at achieving a certain goal. A good strategy takes into account all relevant internal and external elements of the business.

Figure 1 presents the basic elements of mission and strategy, formal structure and human resource management as interrelated systems that are embedded in the turbulent environment. Today, firms should include human resource management as an integral tool in defining and implementing their strategy.

Figure 1: Strategic management and environmental pressures (Fombrun, Tichy, Devanna, 1984)

Internet and information technology have changed the nature of the business and competition, because the information can be easily exchanged, there is electronic commerce, it is possible to conduct meetings, although participants of the meeting are not in the same place etc. Power of buyers has increased. They influence the reduction of prices, demand higher quality or better service and they are turning competitors against each other.

Knowledge and continuous learning are critical elements of success today. New economy led by those who effectively manage knowledge - who create, discover and combine the knowledge in order to create new products and services faster than competitors. Because of that companies require special skills of employees. Also, the state borders are not a problem for companies looking for the best employees so here we can talk about the global labour market. All this increases the mobility of employees.

Various aspects or segments of the environment that should be analyzed are: demographic, socio-cultural, political-legal, technological and economic segment, but globalization is present in all of these segments and it is considered as a basic characteristic of today's business environment.

Being strategic, means have clear organization's objectives, being aware of the organization's resources and responsive to a dynamic environment.

3. CONNECTION BETWEEN STRATEGIC MANAGEMENT AND HUMAN RESOURCE MANAGEMENT

The basic goal of human resource management (HRM) is to have the right man, on the right place, at the right time. To have something like that, it is necessary to conduct activities such are: human resource

planning, recruiting, selecting, socialization and orientation, training and development, performance appraisal, compensation and benefits, career development etc.

The importance of the effective management of people as a source of competitive advantage, encouraged people to talk about strategic role of human resource management in today's business organizations. All organisations on the global market compete in order to be more successful, and their success depends to a large extent of their capabilities to attract, develop and keep the key employees.

Human resource planning is considered as an integral part of strategic business planning process. Actually, between human resource planning and strategic business planning exists a strong link. Providing the necessary number of people with appropriate skills and qualities enable achieving the strategic goals of the organization (Jovanović Božinov, Kulić, Cvetkovski, 2008).

In the HR planning it is important to mention the internal and external labour offer.

- ❖ Internal offer includes all employees in one organization. Internal labour offer is constantly changing because new people come into the organization, and the other are leaving for various reasons.
- ❖ External labour offer is related to the labour market from which the employer normally recruits professionals for positions in the organization.

Today, in order to highlight the strategic importance of human resource in practice is in use the term strategic human resource management. The main objective of strategic HRM is to link HR practices with business strategy. But in practice is also in use the term International HRM, linked to the globalization of business and focused on issues associated with the cross-national transfer of people.

4. WHY ORGANIZATIONS NEED GLOBAL APPROACH TO HUMAN RESOURCES?

People are the main resource of any organization. A dynamic workforce, made up of skilled and educated individuals fully involved in their work, will certainly facilitate the organization's ability to achieve and sustain high performance and achieve its goals (Cvetkovski, Langović Miličević, Cvetkovska Ocokoljić, 2011).

World population is constantly growing, but its growth has been slowing down since 1970. This decline refers to the world as a whole, but the decline in growth rate among the more developed countries is larger than it is among the less developed countries.

Source: U.S. Census Bureau, International Data Base, June 2010 Update.

Figure 2: World population (1950-2050)
(<http://gsociology.icaap.org/report/demsum.html>)

The population structure is also significantly changed. Up to 2050 more people over 60 than children less than 15 years will live on the earth. In Europe this is already the case. According to Eurostat in 2010 in the EU-27 there were 15.6% people under the age of 15 years and 17.4% older than 65 years (http://epp.eurostat.ec.europa.eu/statistics_explained/index.php/population_structure_and_ageing)

Africa has the youngest age distribution today, with 41 per cent of the population under the age of 15 and just about 5 per cent of the population aged 60 years or over. In contrast, in Europe the number of older persons has already surpassed the number of children. In 1950 almost 12% of the world's population lived in the present EU states. In 2050, according to Eurostat, it will be just 4%.

The median age of 37.3 years in more developed regions in 2000 is well above the median age of 24.1 years in less developed regions, but both more developed and less developed regions can expect these median ages to rise. In the 50-year projections, the median age for Europe rises ten years, from 37.7 to 47.7 years. The median age for Africa rises almost as much, from 18.3 to 27.5 years. The other major areas are all intermediate between these extremes

(<http://www.un.org/esa/population/publications/longrange2/WorldPop2300final.pdf>)

Emerging economies are becoming increasingly common in the international arena. In terms of human resources, initially they are competing mainly with cheap labour, but today the situation has changed. Their work force is becoming better and better and now slowly attracts investors with quality as well. It is also related to the fact that the number of potential students is growing, especially in countries like China and India. These are changes that strategic management must take into account.

5. BUSINESS AND HR STRATEGY IN PRACTICE

It is interesting that relationship between business and HR strategy was investigated in *Workforce Strategy Survey* conducted by Manpower Inc. during 2010. Survey included 37,866 employers (human resource executives and senior managers from small, medium and large public and private organizations) across 36 countries (Workforce Strategy Survey, Manpower Inc., September 2010).

When asked if they had the talent necessary to execute their business strategy, 84% of employers affirm that they do, but employers were focused on present. However, 10% of employers said they didn't have the talent they needed, and 6% wasn't sure if their talent could execute their business strategy or not.

Figure 3: Research results about necessary talents and business strategy
(Workforce Strategy Survey, Manpower Inc., September 2010)

Of those employers who know that their talent isn't adequate for their business strategy, 46% said that this talent gap is one of the top three risks to their business strategy. Another 6% was unsure, while 48% said that they didn't believe that talent gap is a primary risk to achieving their objectives.

They also made a regional breakdown and results are as follow. Employers in the Americas are the most satisfied with their talent, with 92% reporting that they have the talent they need to execute their business strategy, while only 84% of employers in the Europe, Middle East, and Africa region (EMEA) and 76% in the Asia Pacific region feel they have the talent necessary. One striking regional difference is that of the employers who state that they don't have the talent necessary to execute their business strategy, 61% of employers in the Americas see it as one of the top three risks to the strategy, while only 46% of employers in Asia Pacific and 37% of employers in EMEA consider it as a primary risk.

Figure 4: Research results: regional breakdown about necessary talents and business strategy (Workforce Strategy Survey, Manpower Inc., September 2010)

It is interesting that among other issues, employers were asked if their organization had a workforce strategy that aligned with their business strategy, and while 77% of respondents report that they do, 9% are unsure of their workforce strategy and 14% report they lack an aligned workforce strategy.

Figure 5: Research results: HR strategy, environment and business strategy (Workforce Strategy Survey, Manpower Inc., September 2010)

Of the 77% of employers that have aligned workforce and business strategies, only 64% believe their workforce strategy is fully agile enough to address the changing needs of the economic environment, 29% believe that their workforce strategy is partially able to meet changing needs, while 4% say it is not, and 3% are uncertain of its agility.

Of the 14% of employers who say they don't have a workforce strategy aligned with their business strategy, 53% said they were doing nothing to create one and 5% weren't sure what they were doing about it. Other said that they were thinking about it (20%), revising their current strategy (10%), outsourcing the work (5%), or taking another approach (7%).

In second part of the research, the 14,385 employees surveyed in Canada, France, Germany, Italy, Japan, the United Kingdom and the United States were asked if they have a clear understanding of their companies' business strategies and how their roles support them, and 79% report that they do clearly understand both the strategy and their role. In contrast, 5% said they either don't understand the strategy or their role, 5% said they do understand the strategy, but not their role, while an additional 11% are unsure.

While the majority of those surveyed say they understand both the company business strategy and their role in it, there's a discrepancy between the level of understanding of those in India, where 91% indicate they understand both the strategy and their role, and those in Japan, where only 56% understand both the strategy and their role.

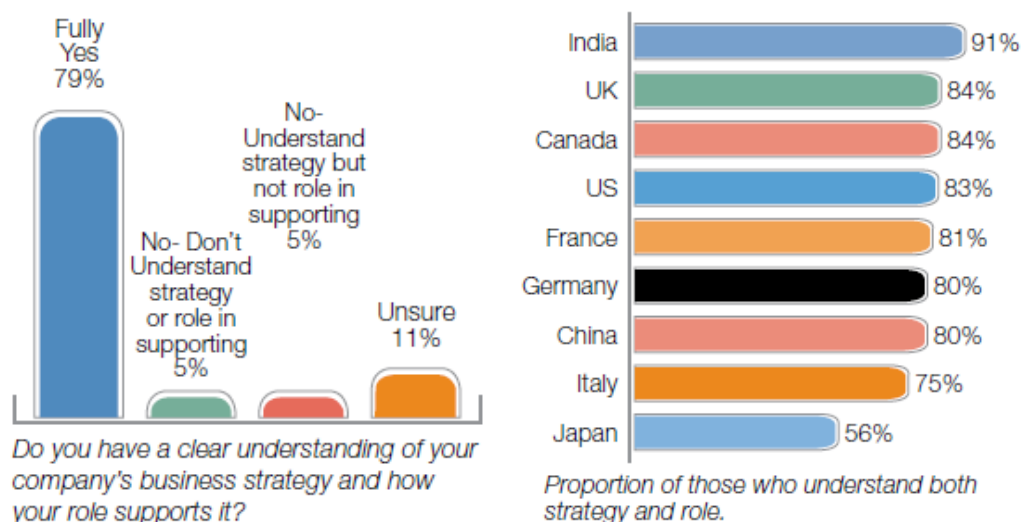

Figure 6: Research results about understanding company's business strategy and employee role (Workforce Strategy Survey, Manpower Inc., September 2010)

6. CONCLUSION

The strategy of each organization has to be closely associated with planning and recruitment of human resources. Jobs cannot be realized without people, and quality and cheap workforce is what every organization is looking for.

Employers need to transform their strategies in the face of growing global competition. They must respond quickly to a rapidly changing marketplace. In the World there is a growing disconnection between where labour is needed and where it is available. Globalization provides access to large potential markets and provides access to raw materials and labour, well-trained managers and other experts.

Today, organizations in order to fulfil their strategy must develop more flexible and talented workforce. The workforce ensures the implementation of the strategy but it could be also a factor that limits the organization's strategy.

Organizations may say their workforce strategy is aligned to their business strategy, but Manpower finds that most of them are thinking only about the here and now and are not positioned to build the workforce they need to achieve the company's business strategy in the future. HR strategy has to be aligned to business strategy and agile enough to address the changing needs of the economic environment. Employees must understand their company's business strategy and how their role supports it. Organizations must be focused on the professional development of their workforce. Talent shortages will worsen during the time and replacements for those exiting the workforce will become more difficult to find.

The HR planning will have to be an integral and key component of the business planning process in the future.

Abstract: *One big challenge for all organizations in strategic management today is that they must be global and must direct their human resources towards global business if they want to reach any stage of development, to gain and maintain a competitive advantage in the coming years. The global environment has not changed the way business is made, but it has created the need for organizations to manage human resources in a global context, and implement information technology that can help this way of doing business. Regardless of economic conditions, organizations large and small, public and private have come to realize that the strategic management of business systems needs to take into account a factor of intercultural relations both in human resources management and in the implementation of information technologies.*

Keywords: *strategic management, globalization, business systems, intercultural relations, human resources, information technology*

1. INTRODUCTION

With increasing levels of multiculturalism strategic management of business systems should be considered in light of cultural factors that affect their usefulness. Many scientists in their research include complete findings of intercultural dimension in business in the last two decades. With a growing national diversity in today's business environment culture is still an important factor. The results of research which will be shown in this paper imply that there is still a scientific difference in the measure of values with cultural background which is crucial sign for international cooperation the inflexible management on human resource will not succeed. So, research has proven the existence of different values between different cultures and being aware is major significance for international cooperation. Different needs and expectations of employees in different countries require HR managers to implement a policy that is flexible enough to respond to local requirements and to meet personal expectations at higher level. On the other hand the development of information technologies is faced with numerous challenges, such as cultural diversity and intercultural management. Cultural diversity is strongly connected to the global development due to team members having different national, organizational and professional cultures (each and every business task requires project team and project approach). The very diversity can have a positive impact on the promotion of creativity but it can be also obstacle in communication and knowledge sharing. Even though different cultures cause different ways of business communications, using of new technologies in daily business and private life leads to universal pattern of behavior. This evolutionary process allows individuals in different locations, different cultures, expectations and goals to be part of a virtual team. So, this paper research will point out a link between cultural heritage of a country, on its modern business culture on the development of information technology, human resources management and therefore on the strategic development of business systems.

2. STRATEGIC MANAGEMENT OF BUSINESS SYSTEMS AND TALENT MANAGEMENT

In a global economy, if the development of business systems is to be ensured must invest in human resource. The vision of global leaders is to attract, develop and retain talent. In the terms of global talent management new trends must be seen such as demographic changes, aging workforce and increasing global mobility. Only by investing in talent, they will be in a position to succeed in a highly competitive market. In addition, organizational culture and leadership development has a significant impact on the keeping of talents. Considering all these factors, access to global talent management enables the development of business systems. The responsibility for managing talent management is shared across the organization - from CEO to first line managers - to identify and develop the optimal strategy of engagement of employees, loyalty and retention. In addition, the Department of Human Resources must develop an

integrated and proactive strategic approach to relation to talent management. Another problem faced by the companies is how to keep talented employees. Awards and prizes also help and it is necessary to create an atmosphere of togetherness, teamwork and conditions for their further development and improvement. It is very critical to attract and retain talent. In addition, companies with good reputation have an advantage in attracting talent. Another effective strategy for hiring talent is directing the specific source of talent. For example, at IBM, employs 42% of people with disabilities have the key skills in marketing, IT architecture and software engineering (*IBM Corporation, 2005*). Strategies can be developed in accordance with the objectives of the company, following careful evaluation of current and future needs of organizations in the human resource management, and thus making conditions for further development. At the same time, organizations need to plan the development of talented leadership. It is important to 1) determine whether a program of talented staff development allows an organization to be competitive, 2) to assess whether employees see leadership programs as legitimate. For example, should they be considered seriously? Do these initiatives really affect business decisions? Therefore, the need for talent creates a movement between countries. The United States rely on foreign talent, especially in certain industrial areas. At American universities, for example, there are not enough graduates in science and engineering. By 2012, 28% of the nation's scientists and engineers will reach retirement age. These changes already reflected in 2000, so that today 22% of positions in the world of science and engineering are occupied by foreign experts, as opposed to 14% in 1990. By contrast, countries such as China and India have a wealth of talent in science, engineering and technology. Every year, China produces 350,000 engineers and India 120,000, compared with 63,000 in the United States. (*Langović Milicević, Cvetkovski, 2010*)

A recent study of global companies, for example, has stated that companies are concerned with the development of future leaders and skills to manage the global business environment. Key findings show that the most important factor in the global talent management (GTM) is the level of participation of the Director General, the board of directors and leaders of global talent management. On average, for example, managers spend 16% of their time speaking publicly about the GTM, mentoring and participating in elections of talent. Board of directors in 46% of companies participating in the assessment of key employees and 39% meet with selected talented workforce during the year. (*Langović Miličević, Langović, Pažun B., 2010.*)

The study of global talent management has shown that 43% of the companies see the retention of key talent as an issue that will have the greatest impact for the further development of business systems. Furthermore, 72% of organizations are concerned with the negative impact on the final result due to inadequate skills of workers. The study emphasizes that a lack of talent or developing and retaining of the talented labor force is a threat to many global companies. For example, 33% of companies state to be 11% of their workforce to retire within the next two or three years. However, only 50% of organizations have defined a list of necessary skills for the future. (*Dell D., & Hickey J., 2002*)

Executives from six countries in 15 different were interviewed for the study purpose 2004, emphasizing that the assessment of high- performance employees should be the future of the companies. The research indicates that significant improvement of employees, performance influence further development of business systems. (*Lawler, III. E. E. 2005, Summer*)

The most effective process for identifying talents is open and honest discussion. Yet, all companies do not have the same approach due to cultural differences. 80% of U.S. companies have this approach, compared with 55% of European companies (*Corporate Leadership Council, 2003*). The global talent management emphasis encouragement of diversity in the development of talented manpower. The emphasis is on the business outside the home country and learning about cultural differences in the talented workforce development.

Looking to the future of companies, various kinds of labor relations, employment and non-standard models of relations among employees will be increasingly used, but all companies need to think about the global talent management if they want to maintain the excellence at the global level. Companies that have already raised the issue of talented workforce will be well positioned for the long-term growth.

3. TALENT MANAGEMENT AND THE SITUATION IN EUROPE

The Boston Consulting Group (BCG) and the European Association for Personnel Management (EAPM) conducted a survey of 1350 managers from 27 of the European Union countries. (*Langović Miličević, Langović, Brankica Pažun, 2010*) The conclusion reached by that European companies will faced with lack of

manpower, especially talented workforce. This problem is already acute in Germany, Austria and Switzerland. Business environment is era of intellectual property and - industries based on knowledge, in society of aging, and top managers need to understand that human resources are a major source of competitive advantage. The research highlighted the importance of human resources. Only 30 percent of respondents said that they begun to tackle the first few challenges in human resource management. The report highlights specific steps that should be taken in this regard. There is a problem of the lack of talent, both in Europe and new markets abroad, so that companies must take steps now if they want to continue their further development. Companies must have a global approach, i.e. they have to ensure the recruitment of people from around the world in order to fully benefit from the resources of talented workforce and ensure continual development. Companies should also strive to meet needs of different ethnic groups and nationalities.

The workforce in Western Europe is characterized by loss of skills and knowledge as well as loss of productivity. It is necessary that companies become learning organizations. Corporations must prepare their employees to deal with complex and accelerated pace of global economy. Simply investment in training programs will not automatically improve productivity. Instead, managers must clearly define and measure the return on investment. In order to attract and retain highly talented individuals from around the world who will be required to have the ability to perform in new markets, corporate governance and cultural change, companies will need to offer flexible work arrangements. Respondents in Italy admit that they are going through rapid modernization, rising immigration, and that they are under conditions of increased global competition. Therefore, change management and cultural transformation, are problem they face. Corporate responsibility management in Russia emerged as a major priority, largely because local authorities are putting pressure on companies to make up for deficits in local budgets and Russian companies. The reason for this is fact that companies want to show the world that they can be good corporate citizens. Executives in Spain are primarily concerned with the lack of talented workforce because they want to transform their companies in learning organizations. They face a large influx of immigrants, and employees will have to be able to manage in different cultural settings. Executives in United Kingdom in human resource management face the problem of adjusting to the global environment. Their executives set two issues as priorities on the national agenda: the global talent management and leadership development.

4. THE CULTURAL IMPACT OF INFORMATION TECHNOLOGY IN BUSINESS SYSTEM

The culture of business has been in focus in the last two decades. Culture is still an important dimension with a growing national diversity in today's business. Culture is important for many aspects of business life, especially in terms of design, development and management information systems, protocols and infrastructure. The design and management choices in information systems are the result of individual values, and these values are the product of socio-cultural background. The designer values are the product of professional designers, social and organizational context which includes education and experience of the individual. According to that, their choice of design is strongly influenced by socio-cultural environment. The impact of cultural factors on IT results has not been explored enough by researchers of information systems despite the universally acknowledged importance. When people deal with information technologies in information systems, human cultural values must be taken into consideration. Many cross-cultural researchers, including Hofstede, were criticized for not providing clear guidelines. Geert Hofstede's research has had a profound influence on academics and practitioners. Hofstede's model has a critical role in the implementation of many business systems, including: entrepreneurial behavior, conflicts, dynamics and effectiveness of the working group, innovation, leadership styles, management control systems and many other cross-cultural issues. It is necessary for the researchers to overcome many factors that are not common in typical research tasks. (*Jones M., Alony I., 2007*)

- Definition problems
- The methodological simplicity
- Equivalence - four different dimensions: functional, conceptual equivalence of measurement instruments

As a result of Hofstede multinational studies, four dimensions of cross cultural diversity that influence the development of information systems can be distinguished (*Patel L., Patel S., 2009*)

- power distance - distance can impact information systems and it has been studied by many researchers. Power distance also has a run-in web page design and user interface. For example, the website of the university in Malaysia highlights the symbols of power, while the website of the University in the Netherlands

focuses on the students and shows how they have the ability to be trained (there is a possibility of a virtual tour of the Faculty through the camera).

Using information technology for interpersonal communication can be interrupted in various ways which is, caused by cultural differences. As the e-mail communication is considered the least intrusive, the use of information technology can promote communication between employees at different hierarchical ladder / positions in the companies.

The negative social effects of using e-mails, despite the individual efforts of individuals, training and other types of training and looms, can lessen the importance of this communication "tools". Also, communication through information technology could be considered as too "remote", which might be less popular.

- individualism / collectivism - This scale measures whether people prefer to work in groups or alone. It indicates the degree of social / communication integration. The U.S. has the lowest value on this scale, i.e., they prefer individual results. These individual aspects or results arise from the cultural values as it is expected from people to be independent at an early age. On the other hand, for people in Guatemala it is the most important to work in groups and their performance is attributed to cooperative achievement. Life in Guatemala would probably be based on close family ties, with strong community support.

Promoting cooperation is one of the main goals of information systems. Tools such as the internet and forums, *shared drives and Group Support Systems*, are some of the tools that support collaboration. They provide new ways for knowledge sharing, reuse and expansion of cooperation. These tools support group discussion, decision making and assist in networking. Within the framework of Hofstede cultural (*Jones M., Alony I., 2007*), it is possible that individual culture is resistant to the collaborative efforts of support, while collectivist cultures will adopt it more easily. It is possible that the development of such common information systems is more pronounced in individualistic societies, whereas collectivist societies do not require additional support.

- masculinity / femininity - This scale does not apply to the dominant sex. It depicts the degree to which male features such as power, assertiveness, performance and success are more preferred over female characteristics, such as personal relationships, quality of life, services and welfare. Japan ranks as the lowest on the scale of Hofstede (*Jones M., Alony I., 2007*) and shows that they are very paternally oriented. On the other extreme of Hofstede research are Sweden and Norway. People in these two countries are likely to show more empathy for your colleagues.

Interpretation of "fatherly" approach to IT management can be interpreted as a controlled, centralized approach. With regard to standards, architecture, settings and processes, centralization involves top-down approach. Developers who work in the "masculinity" are more oriented to target and process, and developers who work in the "femininity" are more oriented to long-term relationships. Some researchers suggest training as a solution to the developers with distinct "effeminate" characteristics, to be closer to developers with outstanding features "masculinity." It has been proven that good relations between people promote trust exchange of knowledge, contributing to better organizational performance. It therefore seems that an employee with a marked trait "feminine" contributes significantly to the organization.

- avoidance of uncertainty - cultural dimension of uncertainty avoidance is the degree to which people feel threatened due to lack of structure or uncertainty of events. It refers to the way that people in future will act according to a situation, and have a complete control over events or beyond their control. People with low uncertainty avoidance will require a structure with clear rules and guidelines. Hofstede (*Jones M., Alony I., 2007*) found that Greece has the lowest degree of uncertainty avoidance. Since the people in Greece would be willing to make decisions and they will require a very structured work routine. Swedes, on the other hand, can do well without structure and they have a high tolerance for ambiguity. The researchers found that uncertainty avoidance plays a major role in small technology companies form alliances. Small companies are faced with two types of uncertainty: relational uncertainty, which is derived from the risk of partnership and technological uncertainty, which is derived from the risks of new technology on its own. The researchers found that companies and medium level of uncertainty is likely to access the technological alliances, to avoid uncertainty. It has been proven that avoiding uncertainty has an impact on the planning and implementation of ERP systems. In a comparative study of American and Chinese implementation of ERP systems, it is noticed that there is more planning and attention to detail in Chinese companies. Much emphasis is placed on the accuracy of the new ERP system with Chinese companies. In a study of technology acceptance

model across cultures, it was found that uncertainty avoidance is different in different cultures when they have to adopt new information technologies.

Dependence on information systems brings another dimension of uncertainty and risk. Possible threats include thieves, loss, misuse, destruction, and denial of service. Consequences can include inaccessibility, legal liability and financial losses. They can be detrimental to the survival of the organization. All these risks can be reduced / mitigated, but the cost is associated with this reduction. It is expected that companies with low risk tolerance invest more in mitigation of these processes. Further research on how different cultures influence these threats can provide additional information.

5. CONCLUSION

The result of studies made by the Institute of Prognoz AG suggests that Germany will already have the shortage of three million people in the labor market in 2015 (*Langović Miličević, Langović, Pažun B., 2010*). The study states that in five years, German companies will lack a million people with higher education. In addition, there will be the shortage of 1.3 million craftsmen and people with secondary education and even 550, 000 people without professional qualifications. The conclusion of the authors of the study is that the lack of labor force will be evident "at all levels, from unskilled workers to university graduates." There will be even the shortage of lawyers for whom it has been stated for years that there have been too many on the labor market. Unmet needs for skilled labor force will increase even to five million people by 2030. This will, for the German welfare, mean the loss of 3800 billion euros, according to a study (*Randall S. Jackson Sch., 2010*). Trade associations have already asked to make a bigger effort in solving this problem. They require the opening of more all-day schools, better offers for additional training of employees as well as measures that would ensure their fewer young people, especially students, leave schools without diploma. However, economists believe that all these measures are not sufficient to overcome the threatening lack of millions of labor force and not to mention the lack of talented workforce.

In fact, world companies already faced a major threat to the global shortage of talent in the late 1990s. Finding talent, retention and management has become a key challenge for the development of business systems in the global environment. Talent management is a strategically important issue for companies that and to ensure their further development. Among the factors that shape the specific challenges and responses of some companies there are: which include: (a) globalization, (b) demographic changes, (v) the demand for workers with the necessary competencies and motivation, and (d) the supply of the necessary competencies and motivation.

Conceived broadly, the global talent management (GTM) refers to the systematic use of certain policies and practices of human resource management. This includes various aspects related to the location and relocation management, planning and forecasting, training and development, and evaluation of employees in accordance with the development problems of workers and regulatory requirements.

In terms of globalization, new jobs open up which require higher levels of competence, broadly defined as "basic and advanced skills, knowledge and skills," or "right" know-how. In addition to the increased need for basic skills and advanced skills, there is a number jobs that involve "knowledge work" and that therefore there is an increased demand for so-called "knowledge workers". They include managers, leaders, technicians, researchers, accountants, computer scientists, consultant, medical and pharmaceutical professionals. In multinational companies, talented workers often work together in teams that cross cultural and geographic boundaries: "In the 21st century, knowledge creation, integration and coordination are considered a base of successful operations of multinational companies."

Today organizations face much greater challenges in finding workers with the competencies they need to perform various tasks, regardless of location in the world. In fact, workers at all levels are more important than ever for the development of multinational companies that hope to be competitive both, globally and locally. As a result, they have to be attractive.

However, companies that develop the competencies necessary for global success have good reasons to invest significant resources in talent management., but the success of this venture is still elusive. Based on response of more than 1,300 managers around the world, one the most important obstacle were identified. That main problem for further development of business systems is when managers do not want to recognize the differences in performances among employees due to cultural differences.

What is also imposed new conditions of globalization is the development of business software that constantly pushes the limits that are placed by companies or countries. Available to the media become more sophisticated. Advanced technology costs less. Trends in software development go more towards the "virtual nature". This evolutionary process allows individuals and even teams from different locations and from different cultures with different expectations and goals, so managers must be aware of how cultural differences among its members can influence the activity in various stages of the cycle.

Demanding needs of the IT development industry, leading the metamorphosis from traditional forms of development applications to modern virtual nature. Lack of skills, the fact that the development process costs, extended development time as the special requirements of the local market. These extended development time and cultural diversity are some of the obstacles that multinational companies are trying to overcome engaging virtual teams. However, there are barriers which arise in the implementation and maintenance of virtual teams, the most common barriers were related to the characteristics of team members. The main common factor that influences the effectiveness of virtual teams are different national cultures of their members. Individuals from different cultural areas may have different beliefs, values, competencies and understanding of priorities. There are different models of national culture, so that practitioners are trying to understand the cultural differences between teams that collaborate together or within a team.

IT professionals have different views on the importance of cultural differences. Culture is a sensitive topic for discussion because it has to do with archetypes. The most effective way to deal with cultural differences is to use any of the archetype as a starting point and that is constantly supplemented with new information. It should be emphasized that all the time dominated by individual differences in cultural differences. There are several types of cultures that exist and are responsible for patterns of behavior of team members.

Each individual is a member of multi culture: one or more national / ethnic cultures, one or more of professional culture, functional culture, corporate culture and team culture. But today, thanks to numerous studies and referring to Constantine (*Constantine L. 1995*) IT professionals belong computer culture, which is stronger than any other culture. For example, a Russian programmer is more like an American programmer, the developer, than Russia's marketing manager. This argument provides the opportunity for endless debate about whether the cultural differences emerged to the surface in virtual IT teams despite strong professional IT culture.

So, these changes in the global environment shaping the strategic management of business systems. On the other hand because of all the pronounced changes in the environment, business systems thanks to changes in human resources and information technology, trying to find new organizational forms, new structural solutions, the flexibility and necessary adaptive. The new business system has a significant implications for the practice of human resource management and that is causing major changes. The new business systems emphasis global talent management, manage with their resources and with their approach to the development and use of information technology. So, for the strategic management of business systems is important to involve the impact of national cultural differences and investigate the cultural impact on the each business activities..

Abstract: *The aim of this paper is to indicate the importance of strategic investment in health system development. The new paradigm stresses that investing in health system is investing in health and well-being. Further, it introduces the view of investing in health as a determinant of economic growth. Although there is vast evidence from different studies in support of the fact that increase of investment in health systems results in better health and more effective economic growth (in terms of GDP), there are still differences in the levels of efficiency of health systems. This paper suggests that beside the importance of investing, Serbia must strategically invest in health system development. This means optimal allocation of limited resources, prioritising, goal-oriented investment and pressure on efficiency. After the introduction of a new paradigm and theoretical framework of the impact of health on economy, a comparative analysis was made of health systems in Serbia and several other countries. This empirical analysis shows investment gaps in our health system. The main limitation in building a case of investing in health system is a lack of performance measurement and consequently a lack of relevant data. Finally, the paper suggests introduction of strategic purchasing as a tool for strategic investment in health system development. Goal-oriented contracting between purchasers and providers is expected to bring gains both to health and to the efficient use of resources.*

Keywords: *strategic management, strategic purchasing, investment, health sector, health performance*

1. INTRODUCTION

Investing in health, in addition to being a worthy goal in itself, produces enormous benefits, both on individual and country level. This view brings paradigm shift according to which health is not merely seen as an end in itself, but in addition it can be considered a means that brings further benefits, especially to the economy (CMH, 2001). In this sense the investing in health system is investing in economic growth based on productivity gains from healthier workers.

Investing in health, in addition to being a worthy goal in itself, produces enormous benefits, both on individual and country level. This view brings paradigm shift according to which health is not merely seen as an end in itself, but in addition it can be considered a means that brings further benefits, especially to the economy (CMH, 2001). In this sense the investing in health system is investing in economic growth based on productivity gains from healthier workers.

However in Serbia it seems that this paradigm is far away from our perception of health and investing in health system development. Serbian health policy-makers have been under enormous pressure for two past decades over concerns about financial sustainability and cost-containment instead of concerns brought by new paradigm. Although financial sustainability and cost-containment are common concern both rich and poor countries, because resources available to any society are finite, emerging evidence is recasting health systems not as a drain on those resources but as an opportunity to invest in the health of the population and doing so in economic growth (Figueras et al., 2008). The acceptance of new paradigm in Serbia could bring fundamental reassessment of the role of health system in society.

In addition to traditional concerns on health status, its influence on health expenditure or high economic costs of health inequalities, new paradigm signify impact of health system development on economic productivity. This is something what policy-makers in Serbia often forget during the policy making process. Serbia has set target to establish knowledge driven economy where human capital is crucial for reaching the goal and it is determined by both education and health level.

The impact of health on economic productivity was recognized and confirmed back in 2001 by the Commission on Macroeconomics and Health, which found that in both high- and middle-income countries, poor health dragged down economic growth. People in poor health are less likely to work and, when in work,

are less productive. They are less likely to invest in their own education or to save for retirement, and so to support the wider economy. Evidence from numbered studies indicates that economic position of countries today is in great deal associated with population health status, which is determined by investment in health system development.

But consideration of investment in health system development must include learned lesson that there is an important distinction to be drawn between the capacity to make an impact and actually making it. If Serbian health system is to secure the investment needed to realize his potential, it must be seen to be efficient and effective, and it is here where strategic management is crucial. Whereas policy-makers in the past often reformed without critically evaluating their efforts, they now need to introduce strategic management system and doing so define expectations, track resources and demonstrate outcomes and outputs. Strategic management as a framework for performance management makes possible a structured assessment of how health systems are doing and what can be done better.

Naturally as a part of Europe we are first looking up on countries of the European Region and their practice in health system development. The Europe has experienced waves of health system reforms with no country exempt. Reforms have reflected wider societal debates, the search for efficiencies and, in many cases, wholesale political and social change. They have also consistently sought to enhance the performance of one or more health system functions: reform of health service delivery, resource generation, financing reforms, stewardship reforms etc.

Although all this reforms are important for health system development the purchasing reforms would be maybe the first step needed for our health system development. It addresses the issue of how to allocate pooled resources in order to lever the changes that policy-makers want. Purchasing reforms often involve more explicit market elements that allow fund holders to specify volume, timelines and quality of care. These include strategic purchasing, the introduction of a purchaser-provider split, contracting, case-based or performance-related payments, and sometimes more explicit market elements such as provider competition or selective contracting. These mechanisms give purchasers leverage over priorities but have associated risks, not least that providers will focus only on the specific targets to the detriment of other areas. The success of purchasing reforms and management of potential adverse affects depends heavily on information to assess what is being purchased and on performance measurement.

2. THE IMPACT OF HEALTH ON THE ECONOMIC GROWTH

The impact of health on economic growth is nowadays more obvious than ever before. Maybe it started with neo-classical economic theory but the pressure on creating knowledge based economy where the human capital is with no doubts most important success factor definitely bring out the health as investment goal.

Referring to the neo-classical economic theory economic growth depends on an increase in the labour supply and an improvement in the productivity of labour and capital. It treats productivity improvements as an exogenous factor meaning that productivity is assumed to be independent of capital investment. Therefore labour supply and improvement in productivity of labour are simple dependent on health status of workforce.

Second the health status of workforce in knowledge based economy, what Serbia stated as one of the most important goals to achieve, seems to be even more critical determinant of economic growth. Economic growth is seen as an endogenous process that could be driven in particular by investments in human capital, especially skilled labour through education but also health. Thus it is simply to track that raise of individual's productivity depends on investment in health.

Literature review on this subject finds evidentiary support in numbered studies. For this paper it was interesting Suhrcke's et al. (2005) study "The contribution of health to the economy in the European Union" suggesting that health could contribute to economic outcomes (at both the individual and the country level) mainly through four channels: higher productivity, higher labour supply, higher skills as a result of greater education and training, and more savings available for investment in physical and intellectual capital. Although this suggestion refers to high-income countries it is also suitable for middle-income countries where Serbia belongs to.

It seems reasonable to assume that health of individuals is condition for higher production per hour worked, enhanced physical and mental activity and greater flexibility and adaptability to change. All these gains could

increase directly or indirectly productivity. Therefore, with better population health in Serbia it can be expected higher labour productivity, maybe even more than in developed countries.

The second suggestion is that with healthier individuals the labour supply is higher. Labour supply is measured by sick days which individuals spent not working, but also have impact on wages, preferences and life horizon. Suhrcke et al. (2005) explains these intermediate factors as follows:

- If wages are linked to productivity and healthier workers are more productive, health improvements are expected to increase wages and thus the incentives to increase labour supply (substitution effect)
- Being healthy might allow higher lifetime earnings and therefore an earlier withdrawal from the labour force (income effect)
- As health improves, working becomes less cumbersome, and therefore the individual might be ready to take up more work in exchange of leisure time
- Health improvement reduces the needs for consumption (e.g. of health treatments or medicines) and therefore reduces the relative preference for work, leading to a reduction of working time and an increase in leisure time
- Finally, if good health changes neither preferences nor wages, but raises life expectancy, the individual's needs for lifetime consumption would increase, leading to a higher labour supply

Beside the discussed labour productivity and labour supply in knowledge based economy higher productivity is obviously determined by individual's education level (higher skills as a result of greater education and training). Nevertheless, again one of the dependent variables that determine the success in education is individual's health status. Children with poor health tend due school absenteeism to have poor results in education process and often early drop-out. Also due to lower life expectancy, individuals would have less motivation to invest in education and training. Therefore, the circle has the following form: starts with poor health that lead to less education, less education lead in knowledge based economy to lower productivity which lead to lower earnings, lower earnings lead to lower savings what results in lower propensity to invest in physical or intellectual capital. In sum, there are a number of channels that may causally link health and economic outcomes on the individual and on population level. Serbia must work on improving population health in order to increase productivity and achieve economic growth in knowledge based economy.

3. COMPARATIVE PERFORMANCE ANALYSIS OF SELECTED HEALTH SYSTEMS

Previous chapter contained the theoretical consideration about health impact on economic growth and this chapter will supplement it with evidentiary support. Evidentiary support is consisted from results of data analysis with data gathered from World Health Organization – European Regional Office database called European Health for All Database (HFA-DB). HFA-DB provides a selection of core health statistics covering basic demographics, health status, health determinants and risk factors, and health-care resources, utilization and expenditure in the 53 Member States in the WHO European Region. The data are compiled from various sources, including a network of country experts, WHO/Europe's technical programmes and partner organizations, such as agencies of the United Nations system, the statistical office of the European Union (EUROSTAT) and the Organisation for Economic Cooperation and Development (WHO, 2012).

Selected parameters for analysis were: 40 countries from European region, year 2009 as a last year with needed data and indicators GDP per capita and life expectancy at birth. In this analysis GDP per capita was used as a measure for economic growth and life expectancy at birth as a health indicator (adequacy of this indicator as a measure of health status of population is discussed elsewhere). Analysis for selected parameters showed that health status of population is determinant of economic growth confirming the theoretical considerations. It showed that healthier nations have higher economic growth (Figure 1). This means that better individual's health is precondition for higher productivity, higher labour supply and higher skills (educational level) and more savings for further investing in health as a physical capital or intellectual capital.

Figure 1:Life expectancy at birth and GDP per capita (2009), source: WHO, 2012

The analysis revealed that there are three groups of countries:

- The first group with life expectancy at birth less than 72 years and less than nine thousand GDP per capita: Belarus, Kazakhstan, Kyrgyzstan, Republic of Moldova, Russian Federation, Ukraine
- The second group with life expectancy at birth between 72 and 78 years and less than 20 thousand GDP per capita: Bulgaria, Croatia, Czech Republic, Estonia, Georgia, Hungary, Latvia, Lithuania, Poland, Romania, Serbia, Slovakia, Turkey
- The third group with greater than 78 years of life expectancy at birth and greater than 20 thousand GDP per capita: Austria, Belgium, Denmark, Finland, France, Germany, Greece, Iceland, Ireland, Israel, Italy, Luxembourg, Malta, Netherlands, Norway, Portugal, Slovenia, Spain, Sweden, Switzerland and United Kingdom

It could be easily said that these results were expected: the most developed countries with highest economic growth have healthiest population. However the second question was: does most developed countries have the healthiest populations due to higher ability to invest in health or healthier population brings higher economic growth due to higher productivity, labour supply etc.

In order to answer to that question we analyzed same two indicators just for third group of countries but for period of 40 years, from 1970-2009. Analysis showed high correlation between life expectancy at birth (Figure 2) and GDP per capita (Figure 3). The correlation for selected indicators and countries from third group was: Austria (0.956), Belgium (0.947), Finland (0.929), France (0.965), Ireland (0.956), Italy (0.960), Netherlands (0.961), Spain (0.923), Sweden (0.943), United Kingdom (0.967). Even more important is to notice that correlation for this group of countries was significantly higher than for all three groups together where correlation was only 0,76, point out that there is some efficiency gap in health care systems.

Figure 2: Life expectancy at birth, in years (1970-2009)

Figure 3: GDP per capita (1970-2009)

On the other hand, research “Health Care Systems: Efficiency and Institution” conducted by OECD Economics Department (2010) showed that there is also significant correlation between life expectancy and health care spending. Joumard et. al (2010) used two methods for identifying the health gains associated with health care spending: Panel data regressions and Data Envelopment Analysis (DEA). They identified with panel data regressions that a gain in life expectancy at birth of slightly more than one year for both females and males over the period 1991-2003 could be in particular attributed to the increase in health care spending per capita which amounted to more than 50% in real terms over the same period. The results also suggested that health care spending is the single most important factor explaining differences in health status across countries, though other factors also play important roles. However, results of panel data regressions shed light on performance in transforming health care resources into health status across countries assuming that unexplained differences in health status indicators across countries reflect efficiency differences in the use of inputs. Research showed that DEA and panel regression results were remarkably consistent in suggesting that potential efficiency gains in the health care sector might be large enough to raise life expectancy at birth by more than two years on average across the OECD (holding all inputs constant) while a 10% increase in health care spending per capita would increase life expectancy by only three to four months (Joumard et. al, 2010).

Finally, high positive correlation between life expectancy at birth and GDP per capita are undoubted, meaning that healthier population is more productive and brings faster economic growth. Also there are results suggested that health care spending is the single most important factor explaining differences in health status across countries but potential efficiency gains in the health care sector might have even larger

influence. To achieve higher economic growth Serbia must have healthier population, what only can be achieved through investing in health system development but with great respect for efficiency gains through strategic investment.

4. STRATEGIC INVESTMENT IN HEALTH SYSTEM DEVELOPMENT

In Serbia the serious lack of data is, as could be expected, a prime cause of the relative weakness of research on the effects of health on the economy. This lack of evidence may have been holding back an adequate policy response. Following the evidence presented in this paper, policy-makers who are interested in improving economic outcomes would have a strong case for considering investment in health as one of their options by which to meet their economic objectives.

The paper suggested that if Serbia wants to have higher economic growth must improve health status going from second group to third group with life expectancy at birth greater than 78 years. To achieve this goal it must be considered health care resources and the most important health problems, see following (WHO, 2012):

- Number of physicians: for Serbia is 284.2 per 100,000 population; average number of physicians in selected group of countries is 348.1 per 100,000 population
- Number of General Practitioners (GP): for Serbia is 71.32 per 100,000 population; average number of GPs in selected group of countries is 84.54 per 100,000 population (minimum in Slovenia with 49.8 GPs per 100,000 and maximum in France with 165.78 per 100,000)
- Average length of stay in hospitals (performance indicator): for Serbia is 9.4 days; in selected group of countries is 7.74 days
- SDR¹¹ all causes, 0-64¹², per 100,000: for Serbia is 322.05; average for selected group of countries is 167.1
- SDR, diseases of circulatory system, 0-64 per 100,000: for Serbia is 96.13; average for selected group of countries is 30.57
- SDR, ischaemic heart disease, 0-64 per 100,000: for Serbia is 34.29; average for selected group of countries is 15.03
- SDR, cerebrovascular diseases, 0-64 per 100,000: for Serbia is 25.01; average for selected group of countries is 5.82
- SDR, malignant neoplasms, 0-64, per 100,000: for Serbia is 107.43; average for selected group of countries is 62.38
- SDR, malignant neoplasm female breast, 0-64 per 100,000: for Serbia is 18.79; average for selected group of countries is 12.87
- SDR, cancer of the cervix, 0-64, per 100,000: for Serbia is 7.19; average for selected group of countries is 1.63
- SDR, trachea/bronchus/lung cancer, 0-64 per 100,000: for Serbia is 31.32; average for selected group of countries is 14.31
- SDR, diabetes, 0-64 per 100,000: for Serbia is 6.29; average for selected group of countries is 2.61

Listed indicators showed that we have significantly smaller number of physicians than average number of physicians in selected group of countries and the same problem is with general practitioners which should be gate keepers. The problem is even bigger if we consider the gap in health status depicted with indicators in the second part of the list (Figure 4). Normally the consequence is that average stay in hospitals is longer than in selected group of countries. The problem could be efficacy but also low use of GP's as gate keepers and utilization of preventive medicine.

¹¹ SDR is the age-standardized death rate calculated using the direct method, i.e. represents what the crude rate would have been if the population had the same age distribution as the standard European population.

¹² Standardised death rates are calculated for the age group 0-64 - premature death

Figure 4: SDR for selected causes, 0-64, per 100000

For dealing with challenges of health system in order to meet goals imposed by sustainable development necessity in Serbia strategic purchasing should be the first step. Serbian health system has lack of investment but may be even more have problematic efficiency gap, both resulting in low health system performance. Accordingly strategic purchasing has been identified as a key component for the improvement of health systems performance. It's potency to improve performance lies in possibility to bring together a range of separate functions with the potential to improve efficiency, effectiveness and responsiveness, but also make a major contribution to the achievement of public health goals. Recognizing the potential of this approach, the World Health Report 2000 put forward strategic purchasing as a major option for improving performance of health systems. It argues that where a purchaser model exists, countries should move from passive purchasing – whereby a predetermined budget is followed or bills are simply reimbursed retrospectively what is case with Serbian health system– to strategic forms of purchasing in which proactive decisions are made about which health care services should be purchased, how and from whom (Figures et. al, 2005).

The purchasing-based models keep third-party payers organizationally separate from health service providers. Figures et. al (2005) the rationale for this purchaser-provider split summarize in terms of five main objectives:

- First, service may be improved by linking plans and priorities to resource allocation, for instance, shifting resources to more cost-effective interventions and across care boundaries (such as from inpatient to outpatient care). Purchasing can thus be regarded as an alternative way to take some measures that have traditionally pursued via planning.
- Second, population health needs and consumer expectations may be met by building them into purchasing decisions.
- Third, providers' performance can be improved by giving purchasers levers such as financial incentives or monitoring tools, which can be used to increase provider efficiency.
- Fourth, the separation of functions within publicly operated health systems can reduce administrative rigidities generated by hierarchically structures command-and-control models. Management can be decentralized and decisions making devolved by allowing providers to focus on efficiently producing the services determined by the purchaser.
- Finally, the separation of functions can be used to introduce competition or contestability among public as well as private providers and thereby use market mechanisms to increase efficiency.

To move from passive purchasing to strategic form of purchasing Serbian health system should start from changing contracts between purchaser and providers. The new types of contracts should be used to reflect the purchaser's health objectives and the health needs of the population, and to define what services are to

be provided and under which terms. Considering advantages and disadvantages of different types of contracts for making a difference in Serbian health care system it should be started with market-entry contracts. Market-entry contracts describe the obligations to be fulfilled in order to take part in the health care network, they are accreditation or licences for providers and doctors, they are long-term and prerequisite. Once when the health care network is set, the purchaser can do the selective contracting combining market-entry and process contracting to a select group of providers. Through this process selected group of providers is organized as supply structure and adapted to health needs and policy objectives. This adaption should be made with two types of process contracts: combination of performance contracts to provide strategic framework and service contracts, in particular cost-and-volume contracts (viewed as a combination of sophisticated block contracts and a cost-per-case contract) to provide risk sharing between purchasers and providers. It is important to notice that purchasing model blur the line between the public and private providers and doing so introduces necessary competition for efficiency gains. In addition, it introduce consumer choice and exit as a classical mechanisms for influencing an organization's behavior in a market system etc.

The most important benefit of introducing strategic purchasing through new contracting process is creating contracting process as an integral part of health policy implementation. Contracts between purchaser and providers should be incorporated into the broad planning process, and contracting cycle should be linked to the planning cycle. In this way planning process begins with assessment of the population health needs and the establishment of a set of health priorities. In Serbian case that would be non-communicable diseases partly showed in Figure 4: diseases of circulatory system, malignant neoplasm and diabetes. These three priorities would form the basis for developing purchasing strategy and would be followed by the establishment of a set of requirements and targets to be achieved through contracting. Next step would be identifying, selecting and contracting providers (public or private). Contracting process should be done through negotiations about elements: type of contract, output definition and size, time, subcontracts by speciality or client group, payment arrangements in term of incentives and sanctions, risk-sharing, specification of services and quality, monitoring etc. The last step should be managing contracts with central part of monitoring implementations of contracts by purchaser. The result of this process should be included in planning and contracting process punishing bad performers. In this way the investment in Serbian's health system development could be implemented through new health care system network consisted of both public and private providers that have market-entry contracts guaranteeing the quality of service and through contracts with reliable providers that are enough efficient, effective and responsible to meet both performance targets set by purchaser and consumers expectations. Instead of building of new facilities through strategic purchasing Serbian health system could just employ already existing capacities in private sector. The main benefit of health system development should be health and efficiency gains.

4. CONCLUSION

The main purpose of this paper has been to review theoretical considerations and empirical evidence on the economic impact of health. Our point was to make a powerful economic case for investing in health and consider bringing paradigm shift in Serbia. This paradigm shift could rise to potentially important policy implications: if health were to become recognised as an investment that brings an economic return, then this would be expected to strengthen the position of health and health policy-makers and might make other economic policy-makers seek to consider health as one, of several, options by which to achieve their primarily economic objectives. In sum, we find that there is much evidence documenting the positive contribution that health made to the economy in most developed European countries and assume that the same positive results could be expected in Serbia with acceptance of new paradigm.

Paper is consisted of three parts, first describes the impact of health on economic growth, second gives evidentiary support for previous theoretical consideration and in last part it suggests introduction of strategic purchasing in Serbia health care system. Strategic purchasing is seen as a first step for developing more efficient, effective and responsive health care system that could bring both health and efficiency gains is an end goal. Also this investment option is the one that with less brings more. There is a vast of evidence that healthier population brings higher economic growth in particular in knowledge based economies. Remains to be seen when Serbian policy makers will accept health as investment goal and determinant of economic growth.

PROBLEM SOLVING TEAMS IN STRATEGIC GOVERNANCE

Abstract: *Strategic governance is based on adequate organizational processes, but very often problems appear which require immediate attention. Organizations on a strategic level are lethargic and slow in responding to problems. Hence, in this paper, our goal is to explain the importance of establishing problem solving teams which rely on theoretical knowledge and practical experience. It is clear that in complex organizational systems problems appear more frequently than in smaller organizations and it is much harder to find solutions to them. Our article explains steps in the problem solution process as a part of strategic governance, as well as how ad hoc-established problem solving teams might yield faster solutions and improve the overall decision making process. A decision making process is a complex task that requires adjustments by the organization to produce an adequate solution. When problems arise, the creation of ad hoc teams is one of the most helpful tools in strategic governance.*

Keywords: *strategic governance, problem solving team, strategic analysis, conflict, solution*

1. INTRODUCTION

The terms 'governance' and 'good governance' have become increasingly common in the development literature. As a concept, 'governance' has two key aspects: It (1) describes the process of governmental decision-making and (2) the manner by which decisions are put into practice (or, in some cases not put into practice). Theoretically, whatever the precise nature of the political system within which they function, public institutions have three functions: (1) conduct public affairs (2) manage public resources, and (3) guarantee the realization of a range of human rights. 'Good governance' succeeds in delivering these objectives in a manner and context that is (mostly) free of abuse and corruption and with due regard for the rule of law. Note, however, that 'good governance' is an ideal – difficult to achieve and to implement in its totality. There are two key dimensions to its implementation. On the one hand, good governance should be a primary internal goal of (preferably, democratically elected) governments. In addition, virtually all developing countries are dependent on various external actors for developmental inputs and, increasingly, such actors demand proof of the implementation of 'good governance' factors in order to begin or to continue to disburse developmental assistance (Haynes 2005). Strategic governance in goals oriented decision making process requests, among other, adequate analysis of external and internal environment. One of the most important internal factors is accountability. Governmental institutions must be accountable to the public and to their institutional stakeholders. In general, organizations and institutions are accountable to those who will be affected by decisions or actions. Accountability is a key way to ensure that this power is used appropriately and in accordance with the public interest. Strategic governance is term which has been derived from governance.

2. WHY STRATEGIC GOVERNANCE?

Strategic governance is the process and practice of establishing and delivering an organization's strategy. In this regard it is necessary to manage a number of aspects of the organization that are of strategic significance. In particular aspects such as:

- Recognition of core competencies
- Understanding environmental changes
- Identification of threats and opportunities
- Balancing stakeholder expectations
- Evolving an appropriate culture
- Embracing the impact of technology and innovation
- Understanding the motivations of staff and customers
- Being able to understand the significance of elements within the value chain

- Recognising the impact of critical success factors (Neal, 2006)

The McKinsey 7 S model is helpful in explaining this point as it highlights the key dimensions, or levels, that need to be addressed:

- Strategies (H)
- Structures (H)
- Systems (H)
- Staff (S)
- Skills (S)
- Styles (S)
- (S)Shared Values (S)

The key point here is that three of the areas are defined as hard (H) and, as such, they are levels over which senior management has full control and where change can be made relatively quickly. Consequently, it is unsurprising that management address these areas first and, often misguidedly, think that the other levels, defined as soft (S), will take care of themselves. Obviously, organizational problems appear in the strategic governance and to solve these issues in hard (H) areas is important to manage organization appropriately.

3. WHY PROBLEM SOLVING TEAMS?

Having improved the quality of governance can often be viewed as a frustrating activity, and many problems have rising. It means that we have to face with inefficient governance and questionable accountability. Consequences might be inefficient organization development, inefficient decision making and many other impacts. Problem appears always when we have different interests, outside and inside of dedicated organization and when answer or solution is requested. In this case we can define problem as a gap between an actual and desired situation. Problems have typical characteristics that can be summarized as follows:

- lack of clarity of situation,
- multiple goals,
- complexity and
- Time consideration.

The resolution of problems requires a direct action on each of these characteristics that are encountered. (Dietrich Dörner 1996, Joachim Funke 2005). Establishment of problem solving team has the main role in problem management. For that purpose it is important to establish problem solving teams. In the decision making process, solving problems are parts of efficient governance, but very often problems are not under control. This kind of team requests flexible structure and excellent communication skills among each member of the team. It is necessary to build an adequate process of participative decision creation. (Adizes 2008) Team should be consisting of experts who can establish structure and decision making in which trust and respect are in favour. Sometimes, under pressure from decision makers team leaders should accept inadequate and useless persons as members, mostly because of illiteracy or because of lack of trust or respect. The most important is to try to avoid this kind of influence and reject inadequate members. Problem solving team has to have independence and expert based opinion and solutions. Problem solving team should have characteristics of cooperative work, common interests and trust and to have internal conflict which must be constructive. To avoid destructive conflict and have constructive outputs, symbiosis of the team is of extreme importance. Respect among team members is highly likely to turn conflict to right way and to make it constructive from which we can learn from differences among teams and produce better decisions. Trust among team members is important to check is "win/win" combination desirable in the future. In that case conflict is constructive instead destructive, from opinion conflict to constructive dialog and the best possible solution as final result of the original conflict. (Adizes 2008). Consultations among problem solving team members are on a regular basis, team leader cannot work by him, he/she should have consultations on a regular basis with all team. Adizes pointed out that perfection of the strategic management is developing through team work where dominant characteristics are cooperation, communication, trust and respect, which is perfectly applicable to strategic governance as well.

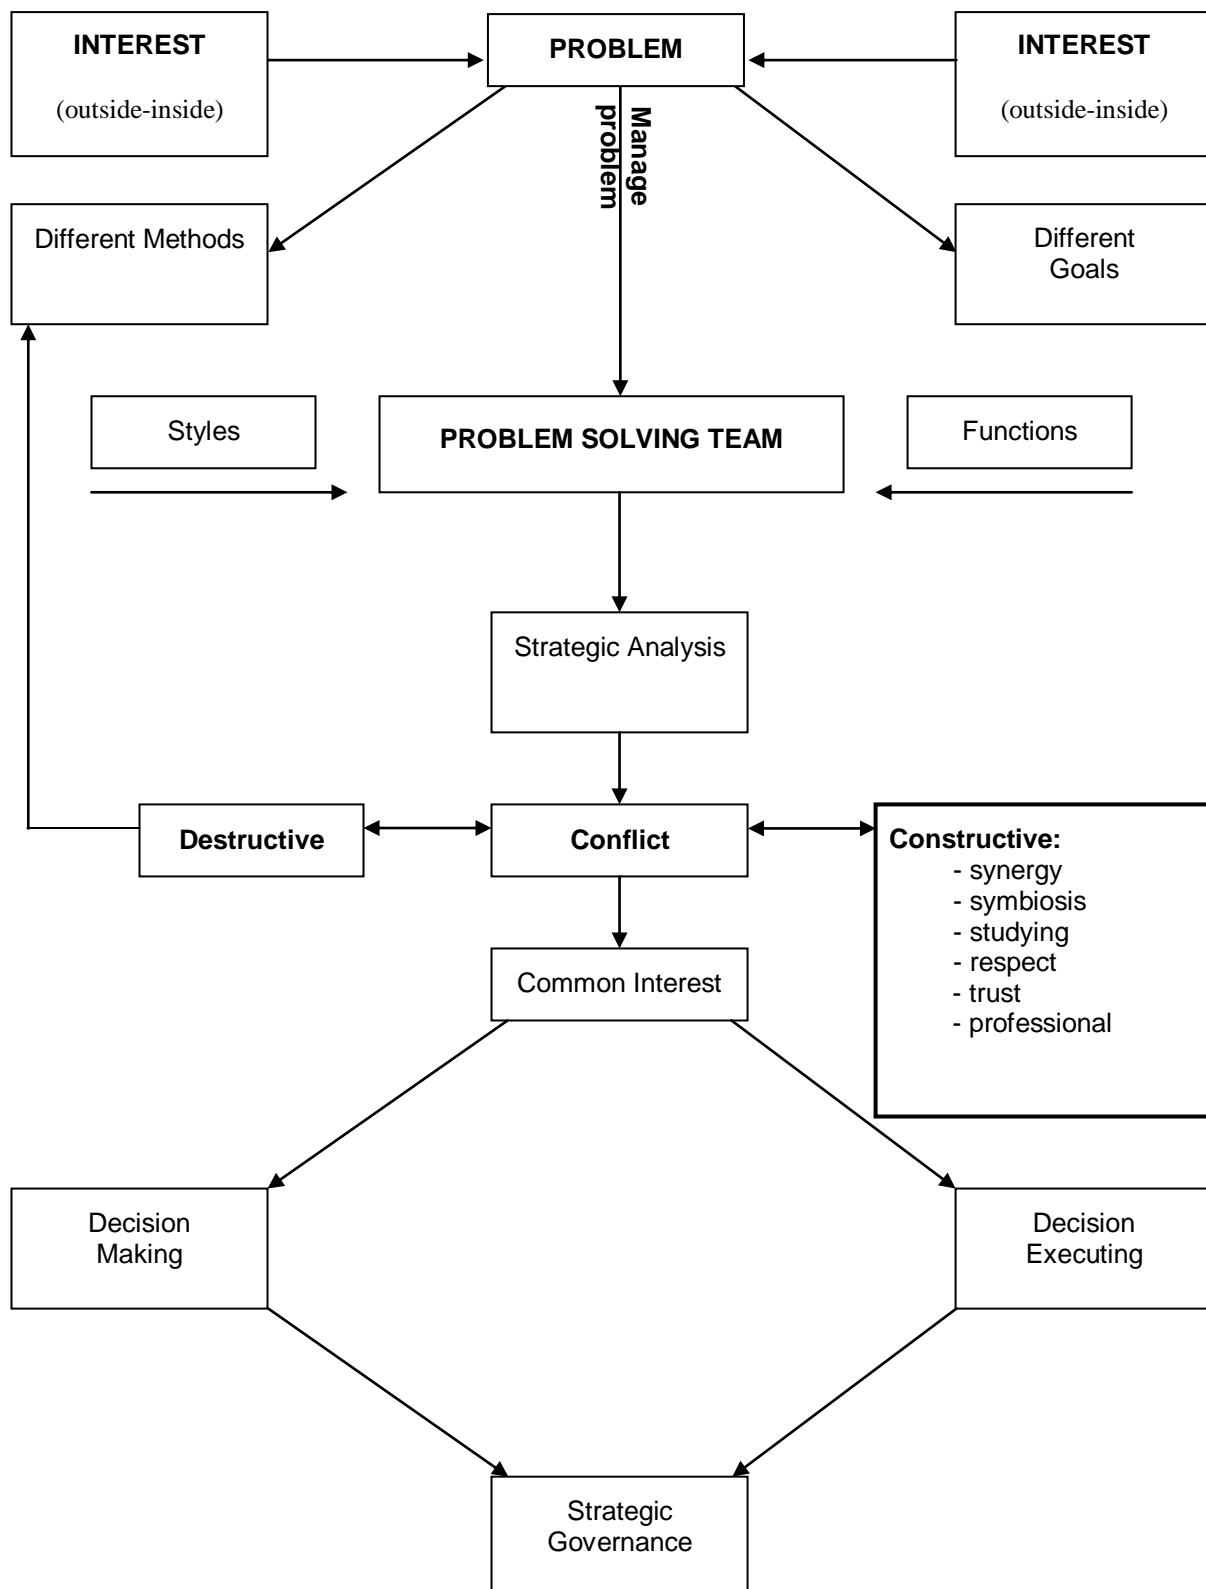

4. PROBLEM-SOLVING TECHNIQUES

Mayer explaining techniques which are usually called problem solving strategies.

- Abstraction: solving the problem in a model of the system before applying it to the real system
- Analogy: using a solution that solved an analogous problem
- Brainstorming: (especially among groups of people) suggesting a large number of solutions or ideas and combining and developing them until an optimum is found
- Divide and conquer: breaking down a large, complex problem into smaller, solvable problems
- Hypothesis testing: assuming a possible explanation to the problem and trying to prove (or, in some contexts, disprove) the assumption
- Lateral thinking: approaching solutions indirectly and creatively
- Means-ends analysis: choosing an action at each step to move closer to the goal
- Method of focal objects: synthesizing seemingly non-matching characteristics of different objects into something new
- Morphological analysis: assessing the output and interactions of an entire system
- Reduction: transforming the problem into another problem for which solutions exist
- Research: employing existing ideas or adapting existing solutions to similar problems
- Root cause analysis: eliminating the cause of the problem
- Trial-and-error: testing possible solutions until the right one is found
- Proof: try to prove that the problem cannot be solved. The point where the proof fails will be the starting point for solving it

5. PROBLEM SOLVING STEPS:

1. **Verification, defining** – in process of defining it is necessary to ask very painful questions, in order to clarify problem. Team leader have to determine how deep to go into problem to find core of the problem.
2. **Evaluation criteria establishment** - once the problem has been identified, evaluation criteria should be established which might be: efficiency, effectiveness, vulnerability and how identified criteria might affect the problem. For decision making strategic level is important to find the best possible criteria which might affect the problem.
3. **Alternative policies identification** - list of possible alternatives can be very long and is huge obstacle to find out the best.
4. **Solution evaluation** - possible solution evaluation performance
5. **Solution presentation** - the best possible presentation of the solution
6. **Applied policy monitoring** - to exclude danger of taking wrong way in decision making every step must be monitored and analyzed.

Graphic 1: Problem solving team

6. STRATEGIC ANALYSIS

Mintzberg (1994) said that we can see very often misperception defining strategic analysis as a part of strategic thinking, on the contrary analysis are crucial part of strategic planning, while strategic thinking are based on synthesis. In every problem solving situation, strategic analysis are developing as a part of strategic planning process. Strategic analysis is the process of taking known information about situations and

entities of strategic importance, characterizing the known, and, with appropriate statements of probability, the future actions in those situations and by those entities. Obviously, a set of problem-solving talents are essential for analysts. Since the other side may be hiding their intention, the analyst must be tolerant of ambiguity, of false leads, and of partial information far more fragmentary than faces the experimental scientist. According to Heuer (1999), in an experiment in which analyst behavior was studied, the process is one of incremental refinement: "...with test subjects in the experiment demonstrating that initial exposure to blurred stimuli interferes with accurate perception even after more and better information becomes available...the experiment suggests that an analyst who starts observing a potential problem situation at an early and unclear stage is at a disadvantage as compared with others, such as policymakers, whose first exposure may come at a later stage when more and better information is available.

Experienced analysts recommend seeing oneself as a specialist on a team, with 5-10 key players. Learn something about each of them, both in terms of how they express themselves, and how you can reinforce their strengths and support their weaknesses. The analyst must constantly ask himself, "what do they want/need to know? How do they prefer to have it presented? Are they still trying to select the best course of action, or have they committed and now need to know the obstacles and vulnerabilities on their chosen path?"(Ikke, 2005)

Other team member may know how to handle the likely challenges. The analyst's contribution is in recognizing the unlikely or providing connections that are not obvious. Consumers must get information in a timely manner, not after they commit to a decision they might not have made having rougher information available sooner.

Sometimes, when the producer is struggling with how to meet the needs of both internal and external customers, the solution is to create two different types of products, one for each type of customer. An internal product might contain detail of sources, collection methods, and analytic techniques, while an external product is more like journalism. Remember that journalists always address:

1. Who?
2. What?
3. When?
4. Where?
5. Why?

Krizan (1999) points out regardless of its form or setting, an effective collation method will have the following attributes:

1. Be impersonal. It should not depend on the memory of one analyst; another person knowledgeable in the subject should be able to carry out the operation.
2. Do not become the "master" of the analyst or an end in itself.
3. Be free of bias in integrating the information.
4. Be receptive to new data without extensive alteration of the collating criterion.

An analysis is not a nicely arranged scrapbook of raw data. It should have a summary of the key characteristics of the problem, followed by the key variables and choices. Increasingly deep analysis can explain the internal dynamics of the matter being studied, and eventually to prediction, known as estimation.

The purpose of strategic analysis is to reveal to a specific decision maker the underlying significance of selected target information. Analysts should begin with confirmed facts, apply expert knowledge to produce credible but less certain findings, and even forecast when the forecast is appropriately qualified. Analysts should not, however, engage in fortunetelling that has no basis in fact.

7. CONFLICT

Conflict might be defined as an incompatibility of ideas among team members. Team leader has to identify and manage with conflict in a sensitive, fair and efficient way. As we mentioned before, role of problem solving team leader is not to eliminate conflict, than use it in a constructive way. In this particular problem, is

said that conflict of ideas is even desirable on an early stage of formulating problem solving proposals. Constructive conflict in solving problems has several positive effects such as:

- Strengthen different views,
- Positive ideas are rising,
- Ideas development,
- Bring out the best from all team members

Destructive conflict in problem solving brings us again to the beginning of process and established team failed. In that case there are two solutions, disband established team or to start again in same team but with different inputs.

Common interest is when conflict is constructive and ideas are developed from where deriving decision making and what is harder decision executing.

8. CONCLUSION

Strategic governance is always sensitive. Considering findings, advantages of problem solving teams in the strategic governance are:

- Faster and easier identifying scope and importance of the problem (conflict) to be solved;
- The possibility of taking into account the different functions and styles of leadership in solving the problem (conflict);
- More people with different skills and abilities to participate in making strategic decisions;
- Rapid development of high quality strategic analysis with less mistakes and oversights;
- Creating the conditions for finding ways to different interests (channel) into a common interest (partial elimination of the problem);
- Creating conditions for new decisions to be largely consistent with previous decisions made;
- Creating conditions for teamwork and responsibility, synergetic adoption and implementation of strategic decisions;
- Increase confidence of decision makers in the decisions proposed by problem solving team;
- Ability to predict future.

STRATEGIC FRAMEWORK FOR EUROPEAN DEFENCE RESEARCH, TECHNOLOGY AND INDUSTRY

Nebojsa Nikolic¹, Momcilo Milinovic² Radomir Jankovic³

¹Strategic Research Institute, Belgrade, nidzan@ptt.rs

²Faculty of Mechanical Engineering, University of Belgrade

³School of Computing, Union University, Belgrade

Abstract: *This paper presents a strategic framework for European Defence Research, Technology and Industry. Integrative processes in the European Union imply appropriate integration in the field of defence research and technology development, as well as the industrial production of military equipment and other products and services needed in the defence branch. The integration of defence industries of the Member States and their transformation towards a coherent European Defence Technological and Industrial Base seems to be a logical step in a wider process of the building and development of the European Union. Likewise, integration is defined as a goal in strategic documents related to the European Security and Defence issue. However, reaching a state of a united and consistent European Defence Research Technology and Industrial Base will not be an easy and fast task. There are many challenges: a problem of redundant (not only duplicate) resources; problems of access to national defence markets; a problem of remaining competitive on the world market; a question of priorities in technological development, etc. The main advantage for small states, in this context, lies in the opportunity to promote their resources, adopt higher standards, access the huge European and potentially other markets, and to connect with larger players and their best practices.*

Keywords: *strategy, defence, industry, European, integration*

1. INTRODUCTION

European Security and Defence Policy (ESDP), latter transformed to the Common Security and Defense Policy, (CSDP), is starting point for all aspects of security and defense considerations at the European level. The policy recognizes main security challenges and threats, and defines general directions and visions how to respond. Threat analysis is important because it influence process of defining and tailoring forces capabilities. Kind and scope of needed capabilities defines, further, kind, quality and quantity of defense equipment.

European Security Strategy assess that large-scale aggression (classic war threat) against any Member State is improbable, while some other threats are much more actual, and those are taken as key threats to the European security:

- Terrorism;
- Proliferation of weapons of mass destruction;
- Regional conflicts;
- State failure; and
- Organized crime.

European security strategy defines three strategic objectives: Addressing the Threats; Building Security in European Neighborhood; and An International Order Based on Effective Multilateralism. To achieve these objectives, the strategy suggests few guiding principles for all stakeholders: to be more Active; to be more Capable; to be more Coherent; and to be Cooperative (to work with partners).

European Defense Agency (EDA) was founded in July 2004, by the Council of Ministers, in order to support the Member States and the Council in their intent to support European Security and Defense Policy. There are four main function of EDA:

- Development of European defense capabilities;
- Promotion of cooperation in armaments production;
- Sustaining and development of defense technological and industrial base and defense equipment market;

- Advancing research and technology.

Strong European Defense Technological and Industrial Base (EDTIB) which “operate” on the competitive European Defense Equipment Market (EDEM) have fundamental importance for successful European Security and Defense Policy. Up to now, EDTIB is rather a collection of national Defense Technological and Industrial Bases, then one consistent, non-redundant and united technological and industrial base. The similar problem exists for the case of defense equipment market. Because of that fragmentation and redundancies of capacities and market, cooperation is imperatively important and deserves to be pointed out.

There are four strategic documents for development of the four EDA functions:

- Capability Development Plan;
- European Armaments Cooperation Strategy;
- European Defense Technological and Industrial Base Strategy; and
- European Defense Research & Technology Strategy.

Capability Development Plan (CDP). CDP defines future military needs and priorities of ESDP. CDP is not a supranational plan, instead it is a common vision of Member States regarding future defense capabilities as answer to the perceived security threats in the future.

European Armaments Cooperation (EAC) strategy, mainly promote European armaments cooperation and its enlargement with a goal of supporting capabilities for Common Security and Defense Policy. The Cooperation is one of the leading challenges due to specifics of the European Defense Industrial Base.

European Defense Technological and Industrial Base (EDTIB) strategy offers vision of future European defense industrial scene as one based on three principles: Capability driven; Competent; and Competitive. In the future, EDTIB should be more integrated and interdependent, with more specialization and less redundancy (or duplication), and with more care on place and role of small and medium companies in defense business.

European Defense Research & Technology Strategy (EDRT strategy), has a goal to obtain more effective R&T for supporting military capabilities. EDRT strategy defines the set of key technologies of the highest priorities as a lighthouse for investment decisions and research efforts.

2. KEYSTONES FOR EDTIB

EDTIB keystones are identified by PEST (Political, Economic, Societal, Technological) analysis. However, first factor (Political) is divided on two entities, due to its specifics for European Union and its Member States. EDTIB exist, operates and develops in a specific European environment defined by next keystones:

- **EU policies;**
- **National policies of individual Member States;**
- **Economic environment;**
- **Societal environment;**
- **Technological environment.**

EU policies related to defence and security, industry and technology, research, and market. This factor contains policy papers and directives related to the next: Coordinated European policy on security and defence; Future operations and priority threats; Consolidation of demands; Intra-EU trade of defence equipment; EU-USA trade of defence equipment; European coordination of Research and Development.

National policies of individual Member States, presents theirs traditional relations and attitude to the national defence and technology industrial base. This keystone consists of next factors: National defence budgets; Bottom-up cooperation between Member States (on bilateral and multilateral basis); The role of NATO; Offset policy; Integration between defence policy and security policy; Integration of general industrial policy and defence industrial policy; Public-private partnership (traditionally, defence related issues in European countries was managed by the state); Ownership of defence industry (differs from state to state).

Economic environment, is very complex containing various factors: availability of resources (human-skilled labour, capital, knowledge, infrastructure, physical resources); demand conditions (level of demands for products and services in domestic and outside market; level of development and availability of other industries closely related to defence industry and level of cooperation and integration, as well as issues of globalisation, barriers for market entry and exit, competitions and rivalries among industry and market players).

Societal environment makes indirect influence mainly. It could be explicit in the sense of public opinion on support for military missions and activities, development of defence forces and level of defence spending (military budget in general, and acquisition of new equipment particularly). Intra- governmental relationship, in a sense of trade-off among various ministries competing for budget shares, is important and relevant indicator of the level of readiness of the society to invest more or less in defence branch instead of more or less investing in a healthcare, education, welfare, environment, etc. Other societal factors with possible influence on EDTIB are: demographic issues (aging population, declining population, intrastate migration and global migration); regional development; healthcare pressure; lack of natural resources; public attitude towards military operations and additional security measures (like those against terrorist threat).

Technological environment. Development of EDTIB could be influenced by wider technological aspect in many ways: New technologies on the free market ("civilian"; "supply" side) can initiate its involvement into defence branch (Examples: new energy technology, next generation software, complex system modelling, advanced computer technology, intelligent electronics and mechatronics, molecular biotechnology, advanced material technology); Military demands are changeable from time to time (mission changes, nature of warfare changes, threat changes, battle environment changes, interoperability issues, force protection, battle awareness, etc) and that lead to new development ("demand" side); Dual use of defence and civilian technologies brings mutual benefits; Growing cost of high-tech products and services brings the same high cost if applied or used in defence equipment; New trends in innovations involve novelties in defence equipping and services (e-learning, networking, cyber space threats).

3. STRUCTURING PRIORITIES

Evidently, there are many influential factors for EDTIB. Some of them has little power or very indirect influence, others could be very important. Also, results could be different for different European countries.

An example of structuring priorities associated to the set of influential factors for EDTIB (Bekkers et al. 2009) shows that a factor entitled as:

- "A coordinated European security and defence policy",

has the highest importance for development of EDTIB. This result is based on a questionnaire answered by a group of 14 experts from the branch (but with different backgrounds: politics, industry, army personnel, defence researchers and consultants). It is not strange that questions of coordination and coherency are frequently pointed out even at the highest political levels of EU (Ashton, 2012). Next to this most important factor, are:

- National defence budgets;
- Nature of priority threats and future operations;
- Dual use technologies and innovations;
- Coordination and consolidation of demands (towards EDTIB);
- Trade agreements of defence goods (particularly on relation EU-USA);
- Defence industry ownership;
- Increasing cost of modern defence equipment;
- Barriers in defence market;
- Competition level in defence industry;
- Level of industry specialisation and mergers,
- Market strategies;
- Globalisation of the industrial structure; etc.

Many of those influential factors are mutually related and interfered to each others. In example, a number of the largest companies on defence market are global players in the sense that they are international (located in more than one country; present at many national defence markets; private owned and relatively independent of any national government). Also, many of those companies are not exclusively dedicated to defence equipment production, but they diverse theirs production portfolio in other ("civilian") directions. Good example of concrete analysis with regard to some of the mentioned factors (Globalisation issues, above all) is presented by Franck et al. (2011).

In the same questionnaire Bekkers et al. (2009), find out that some factors eared much lower relevance for EDTIB, and those are: Demographic factors (global migration, ageing population); Budgetary pressure caused by increasing health budget demand; Future EU enlargement; Availability of skilled industry labour; Role of NATO in defence; etc.

4. GENERAL TRENDS IN DEFENCE INOVATIONS

Defense research and technology used to hold a leader position for decades after World War Two, and serve as a basis for progress in other –non military domains. That situation started to change few decades ago and today we have reversed situation. Adopting and exploiting advanced technologies produced by "civilian R&T", for the defense equipment needs, became a common place today. This way of technological advancing of defense equipment is cheaper, quicker and more effective, but also it is more demanding in the sense of better flexibility, initiative and invention.

Defense research actors (both: individuals and organizations) have to be well and on time informed, networked, creative, and active in order to be able to successfully find, recognize and implement appropriate civilian technological product in a correspond defense equipment or a need (under development or modernization). Researchers and research organization must have high level of competency and innovation talent to successfully perform this task. However, scope and dynamics of appearing of new technological assets is such that a single organization usually hasn't capacity to use all potential benefits from that abundance of advanced technologies. Because of that, networking of defense research organizations and individuals, become imperatively important. But, there are still some defense areas which do not have their civilian counterparts (like explosive ordnance).

Some general trends in defence innovations include:

- Soldier modernisation (different modules for protection and sustainment on the battlefield);
- Advancing armoured fighting vehicles;
- Developing high-performance aircraft;
- Creating high-performance special-purpose ships;
- Development of unmanned platforms and robotics;
- Further development of precision weapons;
- Development of Beyond Visual Range weapons;
- Improving decision support tools and the use of it;
- Improving information gathering, selection and sharing;
- Improving situational awareness in real time;
- Advancing communication links;
- Enabling networks capabilities;
- Enhancing capabilities for computer network operations;
- Advancing Information operations;
- Advancing Intelligent logistics;
- Improving Life cycle management for various technical items;
- Munition (explosive ordnance) management;
- Nuclear, Biological and Chemical defence;
- Non-lethal and less lethal weapons development;
- Direct energy weapons development.

5. CONCLUSION

Strategic framework for the European Defence Research, Technology and Industry, consists of a set of policies and strategic documents. European Defence Agency is main organization at European level charged to “unify”, currently dissipated and doubled, defence resources of the Member States. Integrative processes in European Union assume appropriate integration in the field of defence research, technology development and industry production of military equipment and other products and services needed in defence branch. Integration of defence industries of the Member States and their transformation towards coherent European Defence Technological and Industrial Base, seems to be logical step in the wider process of building and developing European Union.

However, achieving the state of united and consistent European Defence Research Technology and Industrial Base will not be easy and fast. As it was in the other fields, this “unification” of defence resources and market will be long-term process with hard multilateral negotiations and influence of the Member States. There are many challenges: problem of redundant (not only duplicate) resources; problems of access to national defence markets; problem of staying concurrent on the worlds market; question of priorities in technological development, etc.

Main advantage for small states, in this context, is opportunity to advance its resources, adopt higher standards, access huge European and potentially other markets, and to connect with larger players and their best practices.

ACKNOWLEDGEMENT

This work is supported in part by the Ministry of Science and Technological Development of the Republic of Serbia under Project No. III-47029, (Project title: “Cost Effective Selection of New Technologies and Concepts of Defense Through Social Reforms and Strategic Orientations of Serbia on 21st Century”).

STRATEGIC CONTROL WITH A SPECIAL REVIEW OF THE BALANCED SCORECARD (BSC)

Melisa Softić¹, Dževad Mujović², Amela Ahmatović³

Summary: *Process control means comparison of the realised with the planned in order to reveal deviations and take corrective steps. Mechanisms of control need to be defined in a way that does not cause a decrease of business effectiveness, and also needs to be represented in a manner that makes it able to avoid ineffectiveness, confusion and chaos. Traditional strategic control means measuring the effect at the end of a process and for that reason it is impossible to do necessary corrections of the process. Strategic control means analysing realised results which are compared with the designated standards, which show effectiveness and efficiency of certain actions. Strategy control was not done well because the results measuring was done only with the instruments and methods which can be quantitatively expressed. To that goal, an ideal concept of a balance sheet is that in which mechanisms of control and management are developed according to the basis of the business strategy and vision. The Influence of these changes resulted in the development of a balance sheet from a system for measuring performances to a strategic management control system, which helps the strategy realization.*

Key words: control, traditional control, modern approach, balanced scorecard, measuring performances, planning, management.

1. INTRODUCTION

"Planning without control is senseless, control without planning is impossible". (Jürgen Wild, 1981)

Process of control means comparing the achieved with the planned with the purpose to reveal deviations and taking correctional actions. Control is necessary in all phases of certain actions. Mechanisms of controlling need to be defined in that way that they don't influence on the reduction of effectiveness in work, but also needs to be present in that matter in which it could avoid ineffectiveness, confusion and chaos.

Strategy is a method how to fulfill the purpose. Taking into consideration that companies do work in competitive conditions, strategy is the only way to make a connection between company and environment. She gives the answers to questions where the company is now and where it wants to be and defines way which help get to the wished state. In the process of implementing strategy, it's necessary at the same time, to control, the process with the goal to as soon as possible to determine and remove deviations. Therefore, purpose of control is to make available to company to review their goals. When strategy is created, confirmed, balanced, transferred and when participation is achieved, next step is "controlling" the strategy. This step of control includes measuring, review and recovery of the strategy.¹³

Most important elements of every process or system of control are:

1. In advance set goals, plans, politics, standards, norms, rules of decisions and criteria.
2. Methods of measuring current activities, if it's possible quantitative.
3. Methods of comparing current activities with designated criteria.
4. Correction of current activities, with the goal of reaching wanted results.¹⁴

First element of this system has the purpose to give answer to question what purpose are those and results which are planned to be achieved in the future. Criteria around this element, which are given in advance, need to be quantitatively expressed.

Second element means measuring results of current activities. Results of measuring are necessary to be expressed in the same measurement units in which are given criteria or standards from the first element. In the scope of this element, precision is necessary.

Third criterion means comparing the measured results with the set criteria and determine deviations, also show ways to remove deviations. Also it's necessary to define allowed deviations, so attention is focused on unwanted deviations.

Fourth element is dedicated to correction of unwanted deviations. Decision can be that, that it is not necessary to do any corrections, if all activities are progressing according to the planned.

2. TRADITIONAL VS MODERN STRATEGIC CONTROL

2.1. Traditional strategic control

Traditional control implies following steps:

- Highest management formulates strategies and determines goals.
- Implementation of strategies
- Measuring the effect according to designated group of goals.

Traditional approach, system of control was based according to the principle of feedback, which starts from measuring the effect to formulating the strategy. This process characterizes longer time backlogs, which are mostly connected to the cycle of yearly business of a company. With this way of control, real effect is compared to before planned goal. This system of control is convenient with the conditions of a stable environment, when goals can be simple and safely measured.

Picture 1: Traditional approach to strategic control
(Branislav Djordjevic & Danijela Janjic-Vasiljevic, 2010)

Traditional strategic control means measuring the effect at the end of a process and for that reason it's impossible to finish necessary corrections of the process. If for example, realization of strategy takes for years, it's meaningless to do strategic control at the end of the process.¹⁵ We conclude that traditional strategic control is inefficient and worst case, irresponsible to the economical subject.

2.2. Disadvantages of traditional strategic control

The end of 70s and beginning of 80s of the 20th century is the time that characterizes dynamic and complex work process, which have again, highly enhanced influence on process of strategic control. Problem and disadvantages of traditional way of strategic control have interested theoreticians about which in the coming period, a lot of studies and critiques will appear. Direct reason was consequences of oil shocks from 1973 and 1979 - 1980, which revealed all disadvantages of the late and inadequate reaction on the field of strategic control.

First to write on this subject was Lorange¹⁶, who by strategic control understood control of the ability to gain and comprehend new knowledge, also the control of ability of transformation of economical subject.

He made a difference between 2 approaches of control on the strategic level:

- "strategic momentum control" which is suitable with the continuing development of environment and which focuses on planned parameters, so called "planned-realized-state".
- "strategic leap control", which is suitable with the discontinuing development and goals whose focus is on turbulent environment.

2.3. Modern strategic control

Modern approach to strategic control means adaptation, prediction of internal and external changes. Between the process of formulating strategy, implementation and control there is a huge level of interdependence. This approach means two types of strategic control: control of information and control of behavior. First type of control gives answer to the question does the organization do the right things? And other type of control answers on the question does the organization do things in the right way during the implementation of strategy?

¹⁵ Georg Schreyögg/ Horst Steinmann, Strategische Kontrolle, Wiesbaden (1985), str. 391.

¹⁶ Lorangeve Methode, Franz Xaver Bea, Jürgen Haas, Strategisches Management, Stuttgart (2005), str. 233.

Picture 2: Modern approach to strategic control¹⁷

Control of information means the whole environment, internal and external and makes possible constant update and review of predictions and assumptions of organization which have founded the firm strategy. In that way disadvantages are removed of traditional approach of strategic control - time backlogs are shortened, changes in the environment are revealed sooner, abilities of the organization to react fast and flexible are improved.

Control of behavior means implementation, or to correctly do things, which applies the availability of levers: culture, reward and restriction. Companies have to develop balance between culture, reward and stimulation, restrictions and coercion, with the goal of adequate reaction to changes and adaptation to new requests of the market.

Modern systems of control, to be successful, needs to have next characteristics:

1. Attention must be focused on changeable information, which top managers think are strategically important.
2. Information must be so important that managers on all levels give them meaning and attention
3. Generated data and information must be interpreted in the best way and they must be subject on meetings
4. System has to be a catalyst for uninterrupted debate about information, assumptions and action plans.

Into modern strategic systems of control, strategic uncertainties are included, which can come from changes in technology, state laws, competition, the taste of the buyers...

Strategic control is directly connected with other phases of management, especially with planning, because with control reached goals are analyzed which are compared with designated standards, which shows effectiveness and efficiency of some actions. However next to registered deviations of reached to planned, in this phase correction of deviations is performed.¹⁸

The whole meaning of control of management is to improve performance on both, the individual and organizational level. Control is the basis for needs of training, motivation to get standards and development of the individual.

2.4. Concept of strategic control of Schreyogg and Steinmann

Georg Schreyogg and Horst Steinmann developed in 1985, according to the latest models of strategic control, their concept of strategic control. This concept is based on consequent following and control of strategy during her implementation. This was a big step instead of that time present models of strategic control.

As a reaction on noticeable disadvantages of that times models, Schreyogg and Steinmann have divided strategic control on 3 different parts of control¹⁹:

- strategic control of planning
- strategic control of implementation
- strategic monitoring

Core of strategic control is strategic monitoring, although the first two steps are important the same. While strategic control of planning deals with assumptions, which are determined in the beginning of process,

¹⁷ Prof. Dr. Branislav Djordjevic, Emeritus, Dr. Danijela Janjic-Vasiljevic, OBEZBEĐIVANJE INFORMATIVNE KONTROLE: EFIKASNO REAGOVANJE NA PROMENE OKRUŽENJA, Međunarodna naučna konferencija, Kruševac, 2010

¹⁸ Mihaela GHICAJANU, STRATEGIC PLANNING AND CONTROL IN MANAGEMENT BY OBJECTIVES, (2008), str. 4

¹⁹ Georg Schreyögg/ Horst Steinmann, Strategische Kontrolle, Wiesbaden (1985), str. 401

during that time strategic control of implementation deals with gathering information, which appear during the process of implementation, so in time, danger can be noticed for the process of implementation.

These three steps of strategic control make a whole of strategic system control. According to the concept of Schreyögg and Steinmann strategic control is a continuing process, which starts already with the planning and follows the whole process of implementation.

3. INFLUENCE OF ENVIRONMENT ON STRATEGIC CONTROL

For strategic control is important to clearly define relevant environment. Also it's necessary to determine which factors have the most influence on the process of strategy control. Having into consideration the fact that business environment is dynamical and changeable; it's very hard to find balance between environment and control. According to system theory of Luman²⁰, it's necessary to artificially reduce the complexity of factors of environment, on an acceptable level for strategic control.²¹

However, the more complex the environment, the bigger possibility is that factors, which are fundamentally important for strategic control of designated economical subject, are left out. With that, during the design of environment in which the process of control will be done, it's necessary to include all important elements of environment, on which influence needs to be counted on.

Factors which influence on the process of strategic control can be divided this way:²²

- Macroeconomic
- Technological
- Social-cultural
- Law-politic
- Ecological

Next to global factors of environment, it's important to mention the factor of competitive environment.

In macroeconomic factors we include elements like gross domestic product, monetary system, inflating movements, foreign currency course, buying ability of inhabitants, etc.

Technological factors importantly influence on the dynamic of change in environment through the process of technological progress and innovation.

Social-cultural factors include system of value in society, demographic trends, social milieu of society and also general trends of movement in a society.

Law-political factors are working on the law system (workers' rights, laws about protecting the intellectual property, laws about responsibilities of developer and the bidder etc.) also with the immediate political environment. Ecological factors include the availability of natural resources, ecological responsibilities, necessity to recycle etc.

Common denominator of global factors of environment is that they influence economical subjects. Meanwhile, economical subjects can't control global factors, which mean that the influence of global factors is one-way.

Factors of global environment start from the so called strategic triangle. Also the concept of strategic groups needs to be mentioned.²³ Welge and Al-Lahm were doing analysis, on which factors of environment, companies especially pay attention and they came to the results that companies regularly analyze consumer behavior and market of competitors. Reason for that is to get an authentic image of expectations from the perspective of a consumer. According to that analysis least attention is paid to the social-cultural factors by the companies.

4. BALANCED SCORECARD AS A RESPONSE TO PROBLEMS IN STRATEGY CONTROL

In the period before, strategy control wasn't done well for the reason that measuring of results was done with the instruments and methods which can be quantitatively expressed. However, financial results show only before business was done and there are no information about economical subject, how it did its work and how it will be doing it in the future. Robert Kaplan and David Norton in 1992 revolutionized the research of metric with their implementation of a "balanced scorecard".²⁴ Method of balanced scorecard is a deductive system in which according to strategy and vision, business is developing mechanisms of control and management.²⁵

²⁰ Luhmann Niklas, Zweckbegriff und Systemrationalität, Frankfurt (1973), str. 322.

²¹ Horst Steinmann/ Georg Schreyögg, Management, Wiesbaden (2000), str. 129.

²⁴ Peter S. DeLisi, Strategy Execution: An Oxymoron or a Powerful Formula for Corporate Success?, str. 11

²⁵ Friedtag, Herwig R./Schmidt, Walter: Balanced Scorecard – Mehr als ein Kennzahlensystem, Freiburg (2002) S.199

Picture 3: Possible perspectives of balanced scorecard concept

Source: Friedag, Herwig R. /Schmidt, Walter: Balanced Scorecard – More than one performance measurement system, Freiburg (2002), page.199

It still includes financial markers but next to them it includes a dimension of pleasure of the consumer, dimension of efficiency of finished internal processes and dimension of innovation, learning and development of the workers.

Kaplan and Norton tried to method of balanced scorecard and strategy. From one side, they managed to set a direct connection between all strategic goals according to some dimensions, and on the other side, they found cause-consequent rate between the measurements.

Influence of these changes made the balanced scorecard to develop from system of performance measurement to strategic management control system which helps realization of strategy and transport strategy to programs, actions and initiative. Her role is to help and lead the process of control.²⁶

According to the measurement of results, Kaplan and Norton say the following:

1. Measuring has to be balanced and to include more than financial measurement

²⁶ Ljiljana Bonić, Bojan Krstić, Komplementarnost upravljanja zasnovanog na vrednosti i balansne karte performansi u funkciji stratejske kontrole, Ekonomski fakultet Niš, (2010), str. 594

2. Measuring should merge the operational and strategic measuring
3. Measuring has to be objective, to start from strategic goals and to be focused on main challenges, but also main characteristics of the product and service
4. Measuring has to be in balance with the phase of the life cycle of the product and service
5. Individual measuring has to be agreed with the total measurement on the level of the company.

5. CONCLUSION

Effects of this concept are mirrored in the fact that companies supply available access of analysis of different alternatives and develop analytical evaluation of the alternatives.

Balanced scorecard provides:

- Achievement long year goals
- Focus on maximizing the value
- Supplies functional behavior of the manager, because of the new way of measuring the effect.
- Provides focus on determinates which influence on growth of value in the future
- Also provides identification of activities which do not contribute to value growth.

One of the main disadvantages of balanced scorecard is the uncertainty which measures need to be implemented, so the previously set goals can be optimal fulfilled. Also, companies are used to use a huge number of measurements, which in the long run, can make the implementation even harder. The rule is that the maximum number of measurements is not to cross the number of 25.

Advantage of balanced scorecard is his systematic and logical construction, and that's why it's easy to be implemented and use in all parts of a company. In last case, balanced scorecard is an instrument for comprehensive and integral implementation of goals of a company.

OUTSOURCING AS A BUSINESS STRATEGY

Jelena Vasković¹, Nemanja Čović²

¹FON, Master Studies, jecavaskovic@gmail.com

²TF Bor, Master Studies, ncovic82@gmail.com

Abstract: *Outsourcing is a strategic decision that a company can make in the case of possible opportunities involving the transfer of part of its activities to a partner specialized for that job. That could improve the whole business process and reduce expenses. This kind of decision brings a lot of benefits to the company, which are firstly reflected in savings, but also in a possibility of hiring specialists who will do the job in a professional and timely manner. Additionally, with this kind of business strategy the company can focus all its resources on its main activity, unconcerned about the work delegated to its outsourcing partner.*

Although benefits of this kind of business decision-making are great, there are some disadvantages, which are primarily reflected in the distancing of the company from its clients in cases when the outsourced activity involves communication with customers. With the passage of time, the company becomes increasingly dependent on its outsourcing partners and that could be considered as a lack of its business strategy. If the company hires workers from other states, that could be a serious problem for the country, since that means fewer opportunities for local specialists.

Key words: *outsourcing, globalization, off shoring, strategic decision, business improvement, profit*

1. INTRODUCTION

Outsourcing represents the process of transferring ownership under existing business function of one organisation to another, specialized for that job. Two companies can make an arrangement which includes providing services with agreed payment. This way of conducting business is making cooperation between two companies easier in their spheres of influence or core businesses. In that way they can facilitate business, improve skills and decrease the lack of expertise in the areas they want to outsource. Outsourcing arrangement can also include transfer of the workers involved.

Modern economy era is characterized by this kind of business. This term has appeared in America in the end of last century and represents transferring an existing business function to other organisation, instead of traditional internal managing of that business.

Outsourcing is sometimes wrongly interpreted and mixed with terms out-tasking and off shoring, which are not its synonyms. Out tasking means transferring one segment of the business process to another organization where management control is not transferred (key characteristics of outsourcing). Off shoring is the sub variant of outsourcing and it represents business process outsourcing from one country to another. The most frequently transmitted operational processes are manufacturing and accounting (Munch, 2009).

2. ADVANTAGES OF OUTSOURCING

As the time passed by organization has been realising advantages of doing business with outsourcing and benefits which are coming with it. There are many motives which cause introduction of outsourcing. The main reason is cost reduction. This could give new opportunities to the business to invest money in upgrades and core activities going forward.

There are many other benefits which have appeared by introduction of outsourcing, beside savings:

- Focusing on the main business activity – workers, infrastructure and other resources are concentrating on the development
- Knowledge – hiring the company specialized in particular areas with high-knowledge of the personnel responsible for the execution of the assignment.
- Management capacity - improved method of capacity management, services and technologies where the risk of providing excess capacity is on a supplier.

- Introduce easier changes - with introducing of outsourcing, organizations can make changes which independently would not be able to cope.
- Risk management - companies that do business with outsourcing partners, share with them the responsibilities and risks.
- Scalability – preparedness of temporary or permanent increase or decrease in production.
- Speed in introduction of new services
- Access to new technologies that the company would not be able to afford without the help of outsourcing partners.

3. DISADVANTAGES

Although advantages of outsourcing business strategy are positive, there are some drawbacks. One of the biggest disadvantage is the lack of direct communication between the company and its clients. This can prevent a company to build successful relationship with customers, which can lead to dissatisfaction on both sides. Another important deficiency is reflected in the company's ability to control all aspects of its business, which makes it dependent on its outsourcing partners. If some business partners unexpectedly decide to terminate cooperation that could significantly interfere with the normal functions of the company or the implementation of the project which part is outsourced.

4. ONLINE OUTSOURCING

This way of doing business gives the opportunity to hire a third party to perform certain business tasks over the Internet. With introduction of online outsourcing, company can achieve significant savings and therefore becomes more competitive on the market. On the other hand, critics of outsourcing believe that this method takes away the possibility of hiring local experts from the particular area of expertise.

Companies often use this strategy of doing business for specific business purposes. The most common examples of outsourcing are human resources, accounting, bookkeeping, different types of analysis etc. Instead of paying full-time employees, the companies would preferable hire a third party which performs the necessary tasks for them. Outsourcing is very important in scenarios where companies have need for more staff to perform casual assignments. Organization needs fewer resources to hire a specialized company which would perform a task than to hire new staff or train the existing one.

Online outsourcing allows the company to reduce costs so it would not have to pay more employees than it is necessary. Home shoring is a process in which the company hired workers from the country in where is located and who would work from their homes and carry out certain business processes. Such employees may do the tasks such as taking over the customer service calls, editing, etc.

Online outsourcing also has its disadvantages which are mainly reflected in decreased opportunity for potential employee in a country where the company is located. Many firms hire workers from other countries, because they are willing to do the same job for less salary, where the company generates significant cost of savings. For example, in America, very often companies hire workers from India who are able to perform the same tasks for less pay, than local workers (Benoit, 2008), (Straub, 2008)

5. DIFFERENCE BETWEEN OUTSOURCING AND OFFSHORING

It often appears that the terms outsourcing and offshoring are mixed, although they do not relate to the same. Outsourcing refers to hiring a third party, which carries out the tasks that are traditionally performed by someone from the organization. On the other hand, offshoring means relocation of the whole company or one of its part to another country.

Outsourcing is used to reduce expenses, get experts and achieve other benefits. This way company can hire workers from the country where it is or from the other one.

Off shoring is considered as subform of outsourcing. Company may decide to relocate some or all of its activities to another country, when considered profitable. If during this process work still performed by employees in the company is ongoing, then the concepts of outsourcing and offshoring is not related to the same. However, if it is decided to hire a third party, to do the job, then both term can be used for that company (Siffat,2010).

Another difference between those two practices is location. On one hand, outsourcing does not particularly require involvement of the third party from abroad. Therefore it is within the borders of one country just as profitable as when it is international. On the other hand, off shoring is always done outside the home country.

Many assume that those business opportunities are limited to activities of the IT industry, but this strategy can be applied to almost every form of business (Soffit 2011).

6. TYPES OF OUTSOURCING

There are many types of outsourcing, but some can be extracted as the most common:

BPO (Business Process Outsourcing) involves transfer of business to the provider of these services. Usually those are jobs that do not require a high level of technical knowledge. The term is often linked to production, such as Coca-cola, which uses outsourcing for large segments of the supply chain management. BPO processes are divided into two groups:

- back office outsourcing - includes internal business processes such as human resources, finance, accounting, etc.
- front office outsourcing - consists of user-oriented services such as call centre services.

ITO (Information Technology Outsourcing) is outsourcing of activities related to work with computers and Internet, such as programming. ITO is most commonly introduced due to lack of resources and reduce costs.

KPO (Knowledge Process Outsourcing) is outsourcing of business activities that require a high level of expertise in certain areas. KPO involves processes which usually seeks advanced information search, analytical and technical skills and in some situations, making decisions. The whole concept of KPO is based on the information. The areas most commonly used are e-marketing, animation and design, data analysis, writing and content development, etc.

HRO (Human Resources Outsourcing) - This term refers to the scenario when company has decided to delegate all or part of a process that is related to human resources to third party, specialized in the area of operations. HRO is commonly used by small and medium enterprises and is particularly useful for newly formed companies. They can decide to outsource entire HR department or its section. Large companies can sometimes decide to switch certain part of the HR activities to a third party. Health care and pension plans are examples of processes that large companies outsource, because specialized partner is able to give significantly better responses to questions and requests of employees. Some of the most common HR processes (which are outsourced) are: recruitment, training and development of employees, payrolls, etc (Soparnot, 2011)

7. THE PROCESS OF INTRODUCTION OUTSOURCING IN BUSINESS

Any innovation that is introduced into business processes of an organization must pass pre-determined stages. The same principal applies for outsourcing and if the company would like to introduce it in its daily business, outsourcing would go through several stages. Since introduction of outsourcing is strategic decisions, it is logical that first stage is characterized by the question whether this mode of operation fits into company philosophy and what role would it have in its activities. Next stages are evaluation and selection. More precisely it has to be estimated if outsourcing project is appropriate. Company has to determine possible locations for its application and choose potential executors. In order to be protected both sides have to ensure that contract will define the current working relationship between company and its outsourcing provider.

8. OUTSOURCING IN THE WORLD

This type of business which has been established in America during the 90's, took part in business so much, that in 2004 was already a popular topic of political leadership and public. It led to debate on the impact of outsourcing on the local workforce and economy. Presidential candidate in 2004 John Kerry, criticized the companies which outsource abroad, avoiding paying taxes. According to polls 71% of citizens believe that outsourcing is extremely bad for domestic economy, while 62% of citizens believe the government should

take certain measures in the form of tax increase, for companies which outsource abroad. The American workforce felt dissatisfied because companies are enabled to hire cheaper labour, while their rights are reduced. The conclusion of many people is that many outsourcing-off shoring contributes to threaten the position of the middle class in society (Hira, 2005).

In European Union law signed between member states in 1977, supplemented in 1998 and consolidated in 2001, guarantees all the rights for employee if he/she loses his/her job because company has decided to outsource. In general, employees whose job(s) are outsourced can benefit from the protection offered by the directive. Searching for the opportunity to reduce costs many Western companies transferred part of their jobs to Eastern European countries. Unlike America, where outsourcing and off shoring are represented in all sectors, several consulting studies have shown that in Europe this type of business is generally being exploited by the banking sector and other financial service firms such as insurance companies. Outsourcing in Europe has produced good results and the application of this kind of business strategy is constantly increasing.

Outsourcing business model has expanded horizons and possibilities of many companies. In a constant desire and needs for cost reduction, many companies have transferred their jobs beside Eastern Europe to Asia. Companies which are doing business in IT, computer technology and software development, thanks to this kind of business, have found their interest in countries like China and India. Today we can confidently state that India is the leading country in software development. India has become an attractive country where many companies (which are not primarily devoted to software development) want to outsource in various fields such as processing and collection data, telephone directories and more. If this country continues with product and whole system development, combining software and applications, this uprising will provide long-term significance of the Indian subcontinent, making it a major global provider of software and putting it, in the competitive position with traditional software countries in the U.S. and Europe. Research shows that China, Malaysia and Philippines are also becoming desirable locations for outsourcing. In the near future, it is expected, that activities in this aspect of business, will expand along the entire Indian Ocean, including market in South Africa, Malaysia, Australia and Singapore. However, the main market will be India, with its potential of more than one million new jobs in the field of outsourcing-off shoring of financial services (Werner, 2001), (Frischmuth, 2005).

9. CONCLUSION

The fact is that many organizations, because of the rapid development of the market, increase competition, technological progress and continuous need for reducing costs, have made a business model such as outsourcing. This mode of operation has enabled the migration of knowledge, expertise, information and techniques, from highly developed countries to less developed and undeveloped countries around the world, contributing to increase globalization. This has created the global division of labour and led to new operational models and business structures. Financial institutions have been forced to reevaluate their position and the way they do business.

Outsourcing from year to year becomes more popular and acceptable business model from financial institutions, which are among the first that have started with outsourcing. Many other organizations in the field of IT-I, automotive and other companies from various spheres of business are also using outsourcing. Organizations have realized the advantages of this business model and implement it. It is obvious that in a lesser or greater extent this business model has shown growth and success and therefore achieving goals and purpose of company existence, profit.

IMPROVING BUSINESS THROUGH RISK MANAGEMENT

Dejan Tošev

Training command, Army of Serbia, Belgrade, dejantosev77@gmail.com

Abstract: Individuals, organizations and the whole society are at risk more than ever, owing to the technical and technological progress, economic development and social progress. The risk can be reduced through the process of defining a strategy for preventative action and increasing safety measures. In the process, risk management is coordinated with the long-term needs of the individual, organization or society and using different methods and analyses, solves the problem of the gap between the current situation and the achievement of an ideal or desired state with minimum risk, respecting the defined strategies for responding to risks. Applying GAP analysis defines the list of risk priorities and proposes a strategy plan for responding to risks, which is necessary to comply with the existing state in line with the desired lossless.

Key words: risk, risk management, organization, procurement, GAP analysis

1. INTRODUCTION

Modern organizations are characterized by a large number of risk events. Drawing on the literature, this paper defines the concept of risk and exposes a possible concept of risk management, which in the operational work could be part of decision-making process in order to improve business. Thus, risk management can reduce the harm of occurrence of adverse events that may provide an assessment as probable.

Actions of the organization are planned at present, and all potential decisions in their implementation may be "playing", but the concrete realization comes in the future, in which the results are also expected. The future is by definition unknown and uncertain, so the implementation of actions and expected result are uncertain.

Improving business through risk management generally means that the risk is recognized in all stages, so as to the decision-making process would take measures to mitigate risks and achieve the desired objectives. Therefore, risk management involves improving operations, to ensure increased probability of achieving desired goals, and decrease the possibility of adverse events and adverse outcomes.

In many cases the perception of risk is based on experience, monitoring and predicting industry trends. Many theorists have justify this approach and define it as a success. In the area of the sphere of economic decision for some strategic investments may not be based only on prediction, but should have a defined size and to be constantly evaluated in order to be successful at any time. The risk is always current, changing, dynamic and can be viewed as a processing activity.

2. DEFINITION OF RISK

Risk can be most generally identified as a situation in which there is a possibility of occurrence of an adverse event. Under adverse event in the economy is considered a loss or an unexpected cost. From the theoretical point of view, risk is considered to be uncertainty regarding the outcome of an event, in a situation where there are two or more features (Marović Boris & Avdalović Veselin, 2006).

Traditionally, risk management was limited to pure risks, which included: property, personal liability and risks.

Modern theories of risk management belong to a more recent date. They developed in the last twenty years, when the organizations began to expand the scope of risk management, such as taking into account all the risks they face. Organizations acquired the ability to identify risk, measure it, understand the potential consequences and take appropriate measures for its avoidance or mitigation of its consequences. Of course, all this success directly depends on the availability of authoritative information (Šolak Zdravko, 2003).

The essential task of modern risk management comes down to management changes, in contrast to traditional management, which is tasked to regulate and control, or to maintain the system in steady state. If we take into account that changes in the present time very common, dynamic, comprehensive, and with an uncertain outcome is necessarily imposes an increased need to manage these uncertainties that carry certain risks.

Changes in the environment or to obtain new information (financial, manufacturing or control) can influence the initial risk assessment. The requirement for a successful risk assessment is producing timely and accurate information.

However, despite the availability of authoritative information hardly anyone can successfully predict future trends and activities. For these reasons, risk management, is one of the most creative jobs of contemporary organization.

In the literature one finds several definitions of risk. Kerzner defines risk as the probability that a project (task) suffered a failure and the consequences of that failure. According to one conception, Kerzner defines risk as a function of probability of occurrence of risk events and consequences that result from implementation of the risk event. The total risk is increased if the risk increases the likelihood of events or consequences caused by these events.

According to the second concept, Kerzner defines risk as a function of risk event and risk management strategies. In this case, good risk management means to identify the risk event and ensure adequate management strategies to avoid or minimize the consequences that would result from implementation of the identified risk event.

Crouhy M, Galai D. and Mark R, (2006) go so far in the glorification of risk management that they identify it with the conduct of war, "what is war for generals, that is risk management for managers" (p. 4).

3. CONCEPT OF RISK MANAGEMENT

Risk management involves a set of methods and techniques used to reduce the possibility of realization of unwanted adverse events and consequences and thus increase the likelihood of achieving the intended results. The concept of risk management is based on the basic assumption that it was planned, far-sighted, structured, informative and always applicable technique (Samed Karović & Nenad Komazec, 2010). The key to successful risk management is a good strategy, planning and early implementation of measures.

Although each risk management strategy depends on the nature of the organization, risk management must include: risk planning, risk assessment and measures to mitigate risk.

Each management process begins with planning, which can be defined as the process of setting future goals, assumptions about the environment in which to implement the objectives defined, the choice of the direction of action, means and ways to achieve goals. Planning involves internal and external analysis, ie analysis of the environment and the ability of the organization in a variable environment, in order to obtain relevant information.

The information in the process of risk management is essential. Changes in the environment or to obtain new information may significantly affect the change in the original risk assessment.

In addition to risk planning, it is necessary to measure risk and assess the frequency and size of risk exposure. Risk is determined by measuring the importance of a risk for an organization. Adequate risk assessment requires the application of expert knowledge for understanding the information and use of qualitative and quantitative methods.

The risk of a quantitative method, based on the estimated probability of an event and the assumed amount of loss or damage. The problem is the lack of data and uncertainty about the probability of an event. The most widely used approach to risk analysis is a qualitative method. No need for data on the likelihood, but is used to estimate the possibility of loss (damages) or do not respect the absolute values of the parameters, but qualitatively taken their impact on risk.

Taking action to mitigate risk selection process is the best strategy from the existing plan strategies to manage risk.

Risks multiply and complicate the development of technology and increase the overall social standards. This means that we must live with the risk, and that is why it is necessary to find methods for their management. One such method is the GAP analysis.

4. GAP ANALYSIS APPLICATION

If we carefully analyze the risk management process, analysis of internal and external factors shall be based on comparison of risk assessment and define a plan of strategies for responding to risks. GAP analysis can provide a practical solution to these problems, and to the gap between the current situation, the possibilities of the organization and the ideal or desired state, ie permeates through the entire process of risk management.

In essence, GAP analysis sets and gives the answers to two questions:

- What is the situation now?
- What would we like it to be?

GAP analysis is carried out through four steps (Figure 1):

- identification and recording of risk (status quo),
- analysis and risk assessment (identification problem),
- defining recommendations (required),
- a proposing plan strategies for responding to risks (solutions).

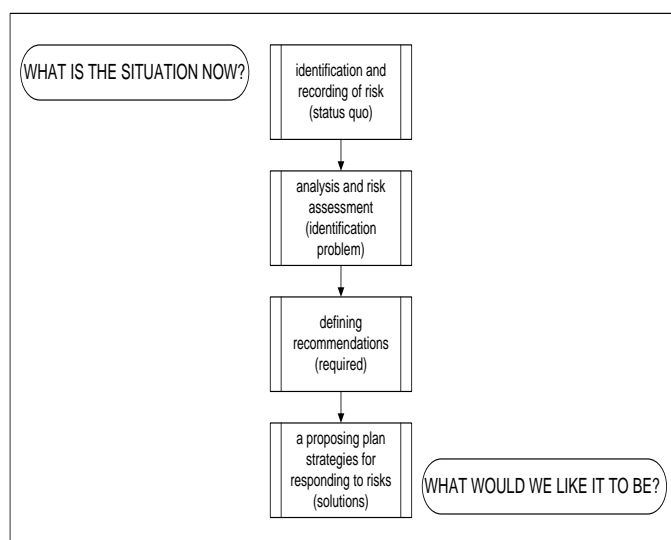

Figure 1: Realization of GAP analysis (adjusted <http://www.webteh.hr/usluge/pci-dss-implementacija/gap-analiza>)

Risk identification is the first step in the overall process of risk management. Risk identification is the process of identification and classification of risk events that in the future may have a negative impact on the goal that is implemented and can lead to losses. It covers the process of determining, recording, classification, and ranking hazards that can realize the negative impact. Since the continuous risk management process that takes place continuously throughout the year, this means that the identification of risk, not only the determination of risk at the beginning but also throughout the whole year of business organization. The risk is usually classified by cause of apparition, and sometimes by the consequences. The ranking is usually done by the possibilities of risk management, and by the solution (risk weight). Efficient implementation of the planned objectives can be achieved if all the risks are not known in advance. Therefore, the identification of risks is very important step in the process of risk management.

For proper management and risk identification, it is important that the organization fully understands the nature of the risk and its relationship and impact of internal and external risks. Problems can arise as a manifestation of non-compliance of internal and external factors (Philippe Carrel, 2009).

After the identification of risk events next step in the process of risk management is its analysis. In this step it is detailed analyzed and evaluated the likelihood of a risk analysis of interdependent risks, defines the space and time where the risks can be expected to determine the size and impact of risks to achieving goals. The implementation process involves analysis to take into account all the risks identified in the identification stage. The usual practice is that risks that are considered high risk are analyzed in detail. However, risk analysis should be very cautious. Although much importance is given to high-risk analysis, the risks of low-risk must not be overlooked, which set or combination can make a big impact on the process of realization of the goals.

As a wayout of risk analysis in the third step are defined recommendations.

Based on the recommendations, and according to the capabilities of the organization, the possible solutions, are proposed a plan of strategy made for responding to the risks, and measures and actions that should be taken so as to the current state corresponds to the desired state without consequence.

GAP analysis is one of the most important steps in planning stages and risk comparisons, and begins with phase of analysis of internal and external factors. GAP analysis is the result of a strategy plan for responding to risks that must be respected and implemented to the current state at any time agreed with the desired state.

An example application of GAP analysis in the planning of risk in a real organization (just a function of procurement) can be seen in Figure 2:

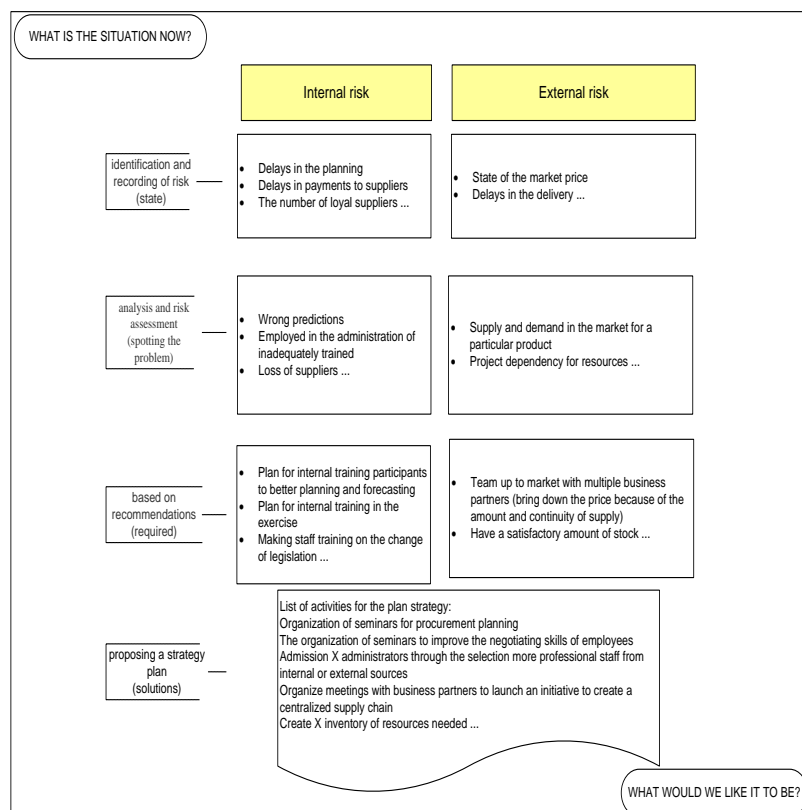

Figure 2: Example of GAP analysis in the procurement process

The planning results (of any function in the organization) is a plan with specific measures, activities, deadlines and carriers. from the above examples can be seen that the resulting gap analysis based on recommendations from the plan a strategy for responding to risks, where necessary observed is the plan to

be agreed with the status quo desired. The practical importance of the gap analysis is reflected in the definition of recommendations and its reformulation in the specific plan as the basis for the work.

5. CONCLUSION

The very organization of the risk assessment must be good. Poor attitude to risk management can lead to a miscarriage of the desired state, that is, significant losses in the organization.

Although the risks can not be entirely predicted, most of them can be still predicted with good management and treatment, and uncertainty that accompanies the risks can be largely transformed into a certainty. Through risk management it is necessary to identify important risk factors and develop a proper risk management plan, to be reduced to a minimum the likelihood of a risk event and its bad influence.

The main objective of this study is a scientific description of the application of GAP analysis of risk management, taking into account the real possibilities for the realization of research, pointing to the importance of risk in modern organizations.

Examining the possibilities of GAP analysis of risk management has established its practical applicability. In the present example the use of GAP analysis is described and observed the content and manner of its application.

The importance of research is reflected in the practical application of GAP analysis in all phases of risk management, particularly in defining the list of risk by the priorities according to which a plan for strategies for responding to risks is developed.

Abstract: *This paper is aimed at highlighting the importance, significance as well as the role social entrepreneurship has in making a contribution to the achievement of the concept of sustainable development and achieving the main millennium goals. The activities of social entrepreneurship oriented towards the achievement of the concept of sustainable development include a new approach demanding the implementation of the principle of social responsibility. The incapability of states, governments and big companies to solve the society's social problems treads a path for innovative social entrepreneurs to offer services that satisfy people's basic needs, especially those of marginalized groups, as well as those of generations to come. Social entrepreneurship activities open new possibilities for big companies, too, to more actively become involved in achieving the concept of sustainable development. The establishment of new social values based on knowledge, creativity and social responsibility contributes to the encouragement and development of social entrepreneurship having a significant influence on a balanced social, economic and cultural development.*

Key words: *social entrepreneurship, sustainable development, social responsibility, social enterprises, change*

1. INTRODUCTION

The moment contemporary society exists at is characterized by social, political, economic and ecological problems. On the other hand, it is necessary that a balance between economic and social development as well as a natural environment humans need to live in should be achieved. Also, it is needed that decisions at the global level be reached on social-economic issues, comprising: global warming, atmosphere pollution, poverty eradication, technological innovations and economic development.

The role of social entrepreneurship, as a form of social economy, is, first of all reflected in the improvement of the quality of living¹ as well as in achieving the concept of sustainable development, while, simultaneously, social problems are transformed into managerial ones, solved in an innovative and entrepreneurial way. Social entrepreneurs engage themselves in reviving hope that problems will be solved and spreading optimism in the field of achieving sustainable development. Differently from big organizations, they do not attempt to modify the world's good practice but are focused on what is possible to achieve at the local level.

The United Nations' Millennium Declaration with its eight main millennium goals², adopted at the New York Millennium Summit in 2000, bound states, both rich and poor, to do their best to reduce poverty, promote sex equality, achieve the peace, democracy and sustainability of natural environment. As early as in 2002, it was clear that these goals would not be achieved in many countries.³ In September 2010, at the UN General Session, the status of the implementation of the millennium development goals was revised and it was concluded that the main factor influencing the non-fulfilment of the obligations was a lack of funds to finance the millennium development goals⁴.

⁴Innovative financing for the MDG's: A precondition for success; New York, 20-22 Sept. 2010, taken from http://www.un.org/esa/ffd/events/21Sept2010_SideEvent_InnFinForMDGs.pdf

Social development is a complex process impossible to program or manage by a linear intervention. Given the fact that there is no unique formula or reference point ensuring a balance between nowadays' consumption and saving for the future, sustainable development remains a process we incessantly learn about, a process in need of innovative solutions and models for the creation of sustainability.

2. THE INFLUENCE OF SOCIAL ENTREPRENEURSHIP ON SOCIAL TRANSFORMATION

The Report of the World Commission on Environment and Development from 1987, entitled "Our Common Future", indicates that the policy of economic growth and global crises (energy, development and environmental crises) are a danger to humans and the planet Earth, with no possibility of its regeneration⁵. Fifteen years later, at the World Summit on Sustainable Development held in Johannesburg in 2002, there were statements that the global environment is increasingly suffering⁶. It has become obvious that climate changes are more rapid and natural disasters more frequent and more devastating, while air and water pollution have reached alarming dimensions. However, market globalization provides new dimensions of these problems, reflected on developing countries which are becoming more sensitive and vulnerable and are having a more difficult time in solving such problems, because its costs are unevenly distributed. On the other hand, it has become clear that neither developed organizations nor multinational companies are capable of offering necessary innovative solutions to the achievement of sustainable development at the global level. One of the main reasons for this is the fact that the solving of problems influencing the achievement of the concept of sustainable development requires that we solve a series of interrelated problems which, as such, cannot be eliminated by direct intervention because there is no clear picture of the chain of causes⁷. Also, aid for the poor by means of food, drug or educational service and medical care direct donations, does not ensure the change of the system that has caused the emergence of poverty. An especially sensitive social group – the extremely poor⁸ – has a high natural increase growth rate, which brings about a quicker increase in the number of the extremely poor in comparison with the development of efforts for poverty suppression. The projected population growth until the year 2045, as presented by the World Bank, shows that 1.5 billion out of 2.2 billion new-born population will be born in the lowest-income area whereas 0.026 billion will be born in the highest-income area⁹.

To achieve the concept of sustainable development and solve the stated problems, a new approach is needed, the one that, first of all, includes the implementation of the social responsibility principles, which represents the basis for the development of social entrepreneurship changing human lives as well as the system creating and maintaining obstacles to achieving sustainable development; it is also an increase in all people's awareness of a high degree of responsibility in all spheres of life and work, even in the one concerning the simple population reproduction. In that view, it is necessary that social marketing concepts should also be applied through organized activities carried out by organizations taking care of the welfare state in order to elevate the awareness of marginalized groups to a higher level that would also involve the concept of social responsibility related to uncontrolled reproduction, which is extraordinarily important from the aspect of overall sustainability.

Social entrepreneurship as a possibility of and an opportunity to overcome numerous social problems is increasingly becoming a legitimate model of implementing social changes, encouraging the recognition and solving of problems existing in society. Social entrepreneurs have a double role to play and make a double contribution to society: firstly, they contribute to specific changes through their business, and secondly, they stimulate other individuals and organizations to engage themselves in shared finding solution to problems of contemporary society. Change is undoubtedly a term one cannot avoid when contemplating over contemporary business and living conditions. Only change creating a new and sustainable balance and contributing to finding a solution to the root, i.e. cause of a problem, not its consequences, is real and credible change. This fact has been recognized by social entrepreneurs who are becoming initiators of the remodelling of different social fields (health-care, living environment,

⁸ The World Bank defines extreme poverty as living with less than 1US\$ per day

⁹ United Nations, (2004), Department of Economic and Social Affairs, Population Division, World population to 2300, New York, taken from <http://www.un.org>

education, social protection, entrepreneurship development) in that they take advantages where others fail to in order to upgrade systems, design new, effective and sustainable solutions and create new approaches to social values.

If sustainable development is observed as “development satisfying needs of the present in a way that the possibility of future generations to satisfy their own needs is not threatened”, according to the definition contained in the Brundtland Report, then two concepts which sustainable development consists of are possible to observe¹⁰:

- a) the concept of needs (special and basic needs of the poor, which have the most important significance) and
- b) the concept of limitations (economic development conditioned by the current degree of the development of technology and the protection of living environment).

Social entrepreneurship activities for achieving the concept of sustainable development can be conducted in three fields:¹¹ 1) by satisfying humans’ basic needs, 2) by developing a society in which norms, rules and behaviour are determined as preconditions for taking part in social and economic development, and 3) by translating assumed needs of future generations into current actions.

The satisfying of humans’ basic needs is the absolute priority of social activities necessary for achieving sustainable development. There are numerous examples of the social entrepreneurship of profit and non-profit organizations making their own contributions to achieving the Millennium Goals. The biggest non-profit organization in the world that influences the lives of millions of people, dealing with sustainable development issues, BRAC¹², addresses the problems of the reduction of poverty, disease, illiteracy and social injustice. Founded in Bangladesh 40 years ago, this organization has directed its activities towards the education of people and communities to realize their potentials by means of economic and social programs and also towards the segment of the transformation of the process of change in personal lives and, simultaneously, in the overall community. Thanks to social entrepreneurship, i.e. different social enterprises (handicrafts shops, printing houses, dairies), and being the biggest non-profit organization in the world, BRAC generates 80 per cent of the budget, i.e. 485 million dollars today. The success in the field of social entrepreneurship and in achieving sustainable development has encouraged the World Bank to grant loans to BRAC and other non-profit organizations dedicated to the same task – the strengthening of the economic power of Bangladesh. On the basis of the so-far successes of social entrepreneurship and economic indicators, the World Bank forecasts that Bangladesh could join countries of the middle revenue rank by the year 2016¹³.

The other crucial aspect of development is the creation of a society where norms, rules and behaviour are determined as preconditions for taking part in social and economic development. Social enterprises should engage themselves in order to establish and enhance discipline, interpersonal support, individual responsibility as well as responsibility towards the community. It is necessary that new forms and models of behaviour be developed, as well as that the view of life and an individual’s prospects be changed through different educational programs. The research BRAC initiated with an aim to enhance the quality of education, the teaching process and the educational system in a school in Bangladesh asked a question intended for children between 10 and 12 years of age concerning what they would like to do once they have grown up. The results accounted for answers completely contrary to the expected ones. So, the respondents did not want to be rickshaw drivers nor housewives, either; they wanted to be doctors, professors or managers¹⁴. Such ambitions and expectations of the new generation give rise to the society’s responsibility to create conditions for their achievement as well. The lack of a market, as well as opportunities, the non-existence of an efficient input market as well as infrastructures limit people in their use of their own knowledge and their productivity, too. Organizations thinking in an entrepreneurial way and having developed their social sensitivity, such as BRAC or SEKEM, have been trying to make a connection between poor rural areas with the existing urban zones’ markets or the international market.

¹⁴Seelos, C., Mair, J., (2005), Sustainable development: How social entrepreneurs make it happen, IESE Business School, University of Navarra, taken from www.iese.edu

Egypt's social-entrepreneurial organization SEKEM¹⁵ was founded in the year 1977 on the area of 70 ha of desert soil; however, today, it is a pioneer in organic agriculture in Egypt, placing its products in both local and international markets. Part of SEKEM's profit is used as a financial support to different non-economic activities concerning the achievement of sustainable development.

The third aspect necessary for sustainable development is the translation of assumed needs of future generation into current actions. Today, it is impossible for us to know the exact nature of future needs; however, it is certain that future generations will need to make their own choices on their own. The concept of sustainable development imposes the imperative of behaviour which makes it possible for generations to come to make their choice, not shrinking that possibility. The research related to this theme called "British Public Opinion on the Needs of 'Future Generations' was carried out by the Intergeneration Foundation and Foundation for Democracy and Sustainable Development in November 2011¹⁶. To one question: what it is the most important to leave to future generations, 46% of the respondents answered – a healthy planet, 16% – the technology and skills for the survival of mankind, 16% – safety and security, 9% – a developed economy, 8% – a developed society, and 4% – non-polluted nature. Apart from these questions, today's society should certainly take into consideration some other factors significantly influencing the lives of those to come, no matter if they make their survival easier or endanger it. When assumed expectations of new generations are in question, professor Tough of Toronto University highlights that strategies and actions are needed in the following fields¹⁷: peace and security (the elimination of nuclear and biological weapons, the application of non-armed methods, the strengthening of the spirit of tolerance and community); living environment (intensive activities to achieve the concept of sustainable development when agriculture, forestry, fisheries, feral animals, water and energy are concerned); catastrophes (identifying all potential catastrophes that can endanger or destroy human civilization, such as: epidemics, biological experiments beyond control, cosmic phenomena and taking all necessary measures to avoid catastrophes); knowledge (the implementation of steps ensuring that culture, knowledge, literature, music and arts and other heritage are saved for generations to come); children (child poverty reduction, famine, child negligence and abuse, and bringing up children with good mental and physical health, self-confidence and learning and thinking skills) and learning (enabling permanent lifelong learning, which should contribute to each individual to live and be responsible for one own self, the community and the planet, as well as for generations to come).

Due to an increasing concern of ever-worsening conditions of our living environment, a fact has been recognized that new generations' living conditions directly depend on our responsibility towards our natural environment today. Some countries, such as Bolivia or Norway,¹⁸ have more seriously approached the obligation of the promotion of interests of future generations by today's generations by implementing those obligations in the state Constitution. Non-profit organizations are also very active in achieving the concept of sustainable development when living environment is concerned. One of the biggest and most respectable world organizations for the protection of nature, the WWF¹⁹, supported by even five million people, is active in more than one hundred countries on the five continents. The Greenpeace²⁰ global organization exists, as they say themselves, because the fragile planet Earth deserves a solution, change and action, and their campaigns are waged because of climate changes, the devastation of rainforests, the violation of the ocean's ecosystem, genetic engineering, pollution and nuclear weapons. Social entrepreneurship of small organizations also significantly contributes to sustainable development and the preservation of living environment. To reduce the waste's damaging effect, especially the one of plastic, social entrepreneurs produce bio composite degradable materials, and in Malaysia and Indonesia (where 80% of the world palm oil production is realized), food transportation packaging is produced from palm-oil post-extraction residues²¹.

²¹ Pandey, A., Mukherjee, G., Kumar, S., (2009), Creation of economic and social value by social entrepreneurship for sustainable development, International Journal of Human and Social Sciences

All the mentioned activities of social entrepreneurship contribute to the achievement of sustainable development because they, first of all, influence the fulfilment of the basic needs of today's and future generations, changing the view of life and an individual's prospects, creating a society supportive of those changes.

3. THE CONCEPT AND POSITION OF SOCIAL ENTERPRISES IN EUROPE

In Europe, the concept of social entrepreneurship appeared for the first time in 1990, after the establishment of the cooperative movement in Italy. The journal called *Impresa Sociale (Social Enterprise)* began to discuss issues related to social entrepreneurship as a response to unsatisfied social needs. "Social Cooperatives" established by the Italian parliament in the year 1991 used to be the first legal form of organizations of similar social enterprises. Simultaneously, in other European countries, there were also similar initiatives; in the year 1996, the EMES²² network was formed, covering the then 15 European Union member countries, whose aim was to study the emergence of social enterprises in Europe. According to EMES, the concept of social enterprises is based on two series of indicators – economic and social. In order to account for the economic and entrepreneurial dimensions, it is necessary that an enterprise satisfy the following four criteria²³:

- a constant production and/or service providing activity;
- autonomy from the state and private sectors;
- an enterprise consciously takes an economic risk to achieve own incomes;
- an enterprise employs a certain, though minimal sometimes, number of paid workers, although volunteers most frequently take part in working activities in a social enterprise;

According to the same source, and with an aim to point out the social dimension, an enterprise should fulfil the following five criteria:

- to carry out business activities to achieve social performance and benefit for the society or a certain marginalized group;
- to be formed and act as the result of an organized and solidity campaign of the citizens;
- to make management and decision-making inside the enterprise be independent of the equity share and be based on the "one member-one vote" principle;
- to have users participate in the managing structure of a social enterprise;
- to have the profit limited distribution practice.

In both Europe and the USA, the basic mission of social entrepreneurship and social enterprises is to contribute to the community or create a "social value", not to distribute a profit. The American approach to social entrepreneurship includes entrepreneurs – individuals motivated to solve social problems, whereas in Europe, the organizational approach to social entrepreneurship is more present²⁴.

At the European Union level, social enterprises make almost 10% of all enterprises (around 2 million social enterprises) and employ 6% of all employees in the EU, whereas the number of users of services provided by social enterprises is more than 100 million²⁵. Apart from the social function it performs, social entrepreneurship significantly contributes to Europe's economic development through the development of social economy. Within the European Union's countries, the International Centre for Research and Information on Public, Social and Cooperative Economies (CIRIEC) carried out research with the following goals: to assess the level of the recognition of social economy in three important spheres: public administration, the world of academics and scientists as well as the social economy sector itself in each country and identify and assess other similar concepts²⁶. The results account for the fact that three groups of countries are recognized:

²⁶ Chaves R., Monzón Campos J. L., (2010), Social Economy in the EU, Social Policy Review, Year 17, No. 1, pp. 113-138, Zagreb.

- countries with the highest level of accepting the concept of social economy – including France, Italy, Portugal, Spain, Belgium, Ireland and Sweden. In France, as well as in Spain, social economy is legally acknowledged, too;
- countries with a middle (relative) level of accepting the concept of social economy – including Cyprus, Denmark, Finland, Greece, Luxembourg, Latvia, Malta, Poland and Great Britain. In these countries, the concept of social economy coexists together with other concepts such as the non-profit sector, the volunteering sector and the social enterprises sector. In Great Britain, the low level of recognizing the concept of social economy is in contrast with the government's policy of supporting social enterprises. In Poland, it is quite a new concept, however more and more accepted, and the structural performance of the European Union has contributed to that the most;
- countries with small recognition or no recognition at all of the concept of social economy – including Austria, the Check Republic, Estonia, Germany, Hungary, Lithuania, Holland and Slovenia. The social economy concept is little known of or is still in the cradle, whereas similar concepts such as the non-profit sector, the volunteering sector and the non-government organizations sector enjoy a very high level of relative recognition.

On the basis of the European Union's data, it is possible to notice that there is a permanent increase in the number and organizational forms within social economy. In the last two decades, these organizational forms have been contributing to not only employment but also to finding a solution to numerous social problems because we must bear in mind the fact that the health-care and social protection provided on the basis of social economy covers 120 million users²⁷.

Table 1: Service and Production Types in Social Enterprises

<i>Social enterprises' activities</i>	<i>Types of social enterprise</i>	<i>Number of organizations %</i>
Social services	29	19
Recycling	28	18

Education	5	3
Trade	3	2
Services	3	2
Agriculture	1	1
Total	155	100

Source: European Movement in Serbia, (2008), Social Enterprises and the Role of Alternative Economy in European Integrations Processes, p. 31

As it can be seen from the table, the most present field of the activity of social enterprises is the one of organizing social services substituting public programs, especially when the disabled-related programs are in question. Reasons lie in the impossibility of the public sector to offer sufficiently acceptable and adapted social protection solutions which would cover different target groups. As a solution to these shortcomings, social enterprises offer socially responsible programs for one part of the population, where special efforts, empathy, enthusiasm, a new and more efficient system for the integration of individuals and social groups in society as a whole are needed.

The studies focused on the development of this field say that, apart from social services, social entrepreneurship activities are oriented towards numerous local problems such as: recycling,

²⁷ European Movement in Serbia, (2008), Social Enterprises and the Role of Alternative Economy in European Integrations Processes, p. 31

transportation organization, tourism, local handicrafts or free time organizing, social housing and the protection of living environment²⁸.

Social entrepreneurship does not make its contribution only via innovative individuals; its power lies, and increasingly does so, in the strategic partnership and cooperation with the economy, government, universities and, of course, entrepreneurs on an interpersonal basis. In connection with that, the European Commission simplified the procedures for commencing business activities of social enterprises, i.e. it facilitated their access to the capital market, so, in future, they will not predominantly be dependent of the state budgets' funds. With an aim to promote a concrete social market economy, which is essential for the Europe 2020 Strategy, the European Commission started the Initiative for Social Business²⁹. This should stimulate the creation and growth of social enterprises given the fact that social enterprises have been prioritized in financing within the framework of the EU regional policy. In the time period 2014-2020, the European Union plans to help the repayment of the debt and social enterprises' new investments with about 90 million Euros, which should contribute to the growth of the number of jobs in social economy.

4. THE DEVELOPMENT OF SOCIAL ENTREPRENEURSHIP IN SERBIA

The condition of social entrepreneurship in Serbia is assessed as an unused possibility for Serbia to reduce poverty, unemployment and the social exclusion of marginalized groups, and to enable a more balanced regional development. In Serbia, there is still no adequate legal and decree-level regulation for the successful functioning of social enterprises; at the same time, there is no sufficient degree of knowledge of this sector's potential, either³⁰. The Act on Professional Rehabilitation and Employment of the Disabled³¹ introduces the term "social enterprise" in our legislation for the first time, while the new Act on Social Protection³², adopted in the year 2011, was reached with an aim to stimulate social inclusion, also enabling disabled people's organizations to become authorized providers of certain services inside their local communities. In Serbia, there are about 15,000 social enterprises including non-government organization, associations and cooperatives, too.³³ The review of organizations in Serbia, on the basis of the definition of social enterprises according to the EMES network's research conducted in the year 2008, shows that there are 1150 organizations in Serbia with social enterprise characteristics, namely³⁴:

- citizens associations,
- cooperatives,
- professional enterprises for the employment of the disabled,
- dependent spin-off enterprises established by citizens associations (most frequently in a form of limited liability companies and joint-stock companies),
- business incubators, and
- agencies for the development of small and medium enterprises.

The mapping results point out the fact that the total number of part- and full-time employed workers in social enterprises is about 12,000, which is no more than just 0.5% of the total number of the employed in Serbia. On the other hand, it is estimated that there are between 700,000 and 800,000 persons with disability, 160,000 of whom are capable of labour³⁵.

Although social entrepreneurship is an addition to the market economy, it is only about to develop in Serbia, and currently exists in the form of individual initiatives by which unemployment and social exclusion issues are solved in individual cases. The secondary research results account for the fact that the majority of social enterprises penetrates the market with no special privileges whatsoever, compared to the European Union countries where they are enabled that. Social enterprises in Serbia are strongly

oriented towards agriculture, retail activities and job-finding intermediation. The majority of these enterprises sell their products and/or services to citizens and profit enterprises. Also, the majority of social enterprises in the market operate individually, without entering partnerships.

“The Network for the Development of Innovative Social Entrepreneurship”³⁶ project (ISEDE NET) was being implemented in the time period from March 2009 to September 2011 and was supported by the EU. It had been designed with an aim to help the development of the social economy and social entrepreneurship in the region of South-east Europe and encourage a more competitive job-finding and social cohesion market in Europe. Among other things, it was aimed at determining possible drivers of social entrepreneurship oriented towards the job-finding and inclusion of threatened population categories in the society and the achievement of socially responsible activities. The Network members are provided with:

- free business support services in the fields of business doing, marketing, finance, the development of human resources and legal aid;
- a facilitated communication amongst registered social enterprises enabling the exchange of information, learning about new business, cooperation development and exchange of goods and services;
- better visibility of certain social enterprises.

There are three most important general conclusions that can be derived from the breakdown of the condition of social entrepreneurship in Serbia at this moment, namely³⁷:

1. In Serbia, there is an obvious and urgent need for a closer and better definition of the framework for the development of social entrepreneurship. (This conclusion is grounded on the fact that a large number of marginalized persons are in need of support as well as those facts that a certain number of social enterprises already exist and do business in Serbia.)

2. In Serbia, there is a good basis for the development of social entrepreneurship. (Numerous attempts are recognized in trying to actively contribute to social inclusion and sustainable development via different legal frameworks and ways of financing. Positive experiences from the European environment encourage the development of the awareness of the strengthening of social cohesion, whereas the theme of social entrepreneurship is making its steps within the framework of national institutions and legal regulations.)

3. In Serbia, there are numerous obstacles to the affirmation and development of social entrepreneurship. (The establishment and financing of social enterprises has not been institutionalized yet because, unfortunately, there is no sufficient understanding of the significance of this sector and its role in the planning of the national budget and activities has not been gained an insight into. On the other hand, social enterprises have no sufficient knowledge and entrepreneurial skills to respond to problems and unsatisfied needs of the society.)

It is important to add the fact that it was in Rio de Janeiro in 1992 that the problem of inclusion of developing countries³⁸ was recognized as economic and technical. Also, it was concluded as necessary to provide an international financial and technical support to countries whenever convenient involving the private sector in implementing national policies and programs for sustainable development. Accordingly, in 2007 Serbia adopted a national strategy for sustainable development³⁹ based on the globally accepted principles identified in the Declaration of Sustainable Development in Johannesburg, the UN Millennium Development Goals and the EU Sustainable Development Strategy. The vision of sustainable development sees Serbia in 2017 as an institutionally and economically developed country with adequate infrastructure, compatible with EU standards, with a knowledge-based economy, efficient use of natural and man-made resources, greater efficiency and productivity, well-educated people, with a preserved

environment, historical and cultural heritage, the state where there is partnership of public, private and civil sectors, providing equal opportunities for all citizens.

5. CONCLUSION

The sphere of the influence social entrepreneurship has on social and economic development is significant. The majority of researches point to excessive population, excessive consumption and excessive pollution, and they highlight the necessity of sustainable development accompanied by a rational use of resources, the protection of living environment, waste recycling and poverty reduction, the controlled population reproduction. In such circumstances assumptions for the creation and development of social enterprises are developed, too, and they are: the connectedness with the local community and offering welfare by solving concrete social problems, stimulating local development and supporting local institutions and markets to achieve general social benefits of the local community. The idea and practice of social entrepreneurship are not new in the business world, but the concept of social entrepreneurship is being diversified in organizations, industry and geographical areas, and recently it has been paid greater attention to within the framework of the public and private sectors as well. Given the fact that neither big companies nor states' governments have succeeded in doing much to achieve the concept of sustainable development and reach the millennium goals, there is still a chance and hope that innovative and enterprising individuals and groups will be using a new and more efficient approach to, locally first, then globally as well, manage to satisfy the need to actively contribute to social inclusion and sustainable development.

Abstract: Selecting meaningful and effective tools for measuring environmental performance is becoming increasingly important due to the increasing costs of environmental operations; market, regulatory and public pressures; voluntary initiatives, such as the International Chamber of Commerce Business Principles for Sustainable Development; and international standards, such as the International Organization for Standardization (ISO) 14001. Many metrics are already in use. These include lagging indicators, which measure outputs such as pounds of pollutants emitted or discharged; leading indicators, which are in-process measures of performance; and environmental condition indicators, which measure the direct effect of an activity on the environment. Each type of indicator has its own strengths and weaknesses, and different audiences; most organizations use a mixture of them. Organizations that measure, manage and communicate their environmental performance are inherently well placed. They understand how to improve their processes, reduce their costs, comply with regulatory requirements and stakeholder expectations and take advantage of new market opportunities. This paper considers some of the ways in which organizations are now developing new "win-win-win" strategies in this area with the aim to simultaneously benefit the organization, its customers, and the environment.

Keywords: *sustainable development, sustainable organization, environmental performance indicators, measuring environmental performance indicators*

1. INTRODUCTION: SUSTAINABLE DEVELOPMENT AND SUSTAINABLE CONSUMPTION AND PRODUCTION

Concurrent to the publication of Our Common Future, the 1987 report of the World Commission on Environment and Development, and the UN Conference on Environment and Development (UNCED) held in Rio de Janeiro in June 1992, the concept of sustainable development - involving the integration of environmental thinking into every aspect of social, political, and economic activity - has become central to the environmental debate. Therefore, societies and businesses need to make a drastic shift to a sustainable socio-economic system with fewer environmental impacts. There is an increasing recognition that good environmental performance makes good business and organization sense.

As a result of population growth and economic development, humans have exerted a considerable impact on the Earth and have become seriously incompatible with natural resources, environment and economy. At the same time, as outcomes, environmental problems appear as one of the greatest problems of the 21st century. The rapid technological advancements and industrialization have resulted in an increased level of negligence and insensitive behaviour, leading to the destruction of environmental balance (Cetin & Nisanci, 2010).

Population growth demands a new concept of development – one that is sustainable and that takes into account the satisfaction of the needs and desires of every citizen of the Earth, of the pluralism of societies, but also the balance and harmony between humanity and the environment. The implication of this ecological situation is obvious: to be sustainable, human beings must live within nature's carrying capacity; and they must measure where they are now and how far they can go (United Nations, 1972).

Sustainable development is a global development management philosophy that aims to conserve the integrity of the Earth's ecosystems while supporting economic growth and social welfare, and therefore, is linked to ongoing economic growth and development (Petrović et al., 2011). It was developed by the Brundtland Commission during the World Commission on Environment and Development in 1987 (WCED,

1987). Sustainable development has been defined in many ways, but the most frequently quoted definition is from *Our Common Future*, also known as the Brundtland Report:

Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts: the concept of needs, in particular the essential needs of the world's poor, to which overriding priority should be given; and the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs.

The use of this definition has led many to see sustainable development as having a major focus on intergenerational equity. Although the brief definition does not explicitly mention the environment or development, the subsequent paragraphs, while rarely quoted, are clear. On development, the report states that human needs are basic and essential; that economic growth, but also equity to share resources with the poor is required to sustain them; and that equity is encouraged by effective citizen participation. On the environment, the text is also clear: The concept of sustainable development does imply limits - but absolute limits but limitations imposed by the present state of technology and social organization on environmental resources and by the ability of the biosphere to absorb the effects of human activities.

It is undisputed that all definitions of sustainable development require that we see the world as a system - a system that connects space; and a system that connects time. The concept of sustainable development is rooted in this sort of systems thinking. It helps us understand ourselves and our world. The problems we face are complex and serious - and we can't address them in the same way we created them.

Further on, one of priorities for immediate actions in strategies of sustainable development every company is sustainable consumption and production. This strategy sets out how this is being taken forward, through measures to promote:

- better products and services, which reduce the environmental impacts from the use of energy, resources, or hazardous substances;
- cleaner, more efficient production processes, which strengthen competitiveness; and shifts in consumption towards goods and services with lower impacts.

World goods and services production growth of 6.000 billion dollars in year 1950 to 43.000 billion in 2000 caused devastation of environment to the extent that we couldn't even imagine 50 years ago. If the world economy continues with 3% growth a year, production of goods and services will quadruple in 50 years accumulating in total sum of 172.000 billion of dollars (Emil, 1994).

In last 20 years new global awareness that demands switching to sustainable production is increasing. Instead of emphasizing quantity and a mass production now emphasize is given to quality. Additional value is not knowledge based anymore but resource based. Innovation is not reflecting in finding new ways of increasing existing capacities for exploiting the nature anymore but in finding alternative materials which can be used in production process. That's how different kinds of waste usage, that was just piling before and further more polluting the environment, came about.

Sustainable consumption issue was raised for the first time as one of the key issues of sustainability at UN Conference on Environment and Development in Rio in 1992. Two decades since, different experts from this area agree that progress in tracking consumer habits and thinking the ways of changing them is too slow. Sustainable consumption emphasizes that quality of consumption must increase, both of today's generation and the future ones. This concept demands optimization of consumption subject, in order to sustain in time utilization and quality of resources, hence environment as well (Emil, 1994).

2. ENVIRONMENTAL IMPACTS

Although, several papers already discussed companies' environmental impacts, the precise meanings of this construct often remains unclear and badly-defined (GLRI, 2005). Possible reason for this ambiguity is that perceptions of environmental impact "differ depending on one's view of the environment and the components of the environment that one values" (Riha et al., 1996). Further, environmental impact is

defined as the degree to which an organization's business processes, activities and operations positively or negatively affect the natural environment. The environmental impact is the consequence of the organization's actions in relation to the quality and cleanliness of air, water and soil and, more generally, to the short-term and long-term health of Planet Earth's global ecosystem.

A major initiative of sustainable businesses is to eliminate or decrease the impact made on the environment by harmful chemicals, materials, and waste generated by processes to manufacture products and services (Becker, 2008).

The impact of such human activities in terms of the amount of greenhouse gases produced can be measured in units of carbon dioxide and is referred to as the carbon footprint. The carbon footprint concept branched off from ecological footprint analysis, which examines the ecological capacity required to support the consumption of products (Hawken et al., 1999).

3. MANAGING AND REPORTING ENVIRONMENTAL PERFORMANCE

Responsible businesses are at the heart of society. Companies that understand their links with the communities they operate in, and their impact on the environment, are most likely to prosper in the long-term. At the same time, interest from stakeholders in firms' environmental performance is at an all-time high. There is an increasing recognition that good environmental performance makes good business sense. Environmental risks and uncertainties impact to some extent on all companies, and affect investment decisions, consumer behaviour and Government policy. Further on, management of energy, natural resources or waste will affect current performance; failure to plan for a future in which environmental factors are likely to be increasingly significant may risk the long-term future of a business.

Companies that measure, manage and communicate their environmental performance are inherently well placed. They understand how to improve their processes, reduce their costs, comply with regulatory requirements and stakeholder expectations and take advantage of new market opportunities.

There is an increasing demand for company reporting that is sharper and more focused on the key impacts on the business and on the environment. It takes needed reporting of environmental performance, which will benefit in two ways:

- It will provide management information to help exploit the cost savings that, good environmental performance usually brings; and,
- It gives the chance to set out what is significant in firm's environmental performance.

Environmental performance indicators provide information on how to understand and assess the environmental performance. Businesses would implement meaningful activities on environmental conservation if they could select appropriate environmental performance indicators. Environmental performance indicators would facilitate environmental communication with stakeholders if they were included in environmental reporting.

ISO (The International Organization for Standardization) issues a guideline of the environmental performance evaluation process as ISO 14031 (Environmental Performance Evaluation – Guidelines: Specifies the purposes of environmental performance evaluation, preparation of an evaluation plan, data collection, review of results – this was regulated as JIS Q 14031 on October 20, 2000). Although the guideline defines the concept and procedure of selection of environmental performance indicators, it does not cover development of actual indicators.

In the meantime, environmental performance indicators are being developed by overseas research organizations including WBCSD (World Business Council for Sustainable Development) and GRI (Global Reporting Initiative).

Managing and reporting on environmental performance can lead to significant business benefits as well as benefits for the environment:

- *Cost savings and productivity gains.* Businesses can save costs and increase efficiency through reducing and managing resource use. Typical areas where cost savings are identified include the use of raw materials and supplies, reductions in waste, water and energy use and

transport, travel, and packaging. By reducing environmental impacts, such as waste to landfill, businesses can significantly reduce any associated taxes or levies, or avoid the cost of compliance altogether. Responsible management of risks and liabilities can lead to reduced insurance costs.

- *Improved sales.* Businesses can benefit from improved reputation amongst their customers (and potential customers) by reporting on relevant environmental issues in a clear and transparent way. Good reporting improves customer confidence. Informing customers of efforts to improve organisation's environmental performance can lead to increased confidence in products and services.
- *Preferred supplier status.* Large organisations are increasingly requiring suppliers and contractors to submit environmental performance information to satisfy the expectations of their own shareholders. Reporting on environmental information can make a more attractive supplier than competitors.
- *Increased attractiveness to the investment community.* Investors, financial analysts and brokers are now asking questions about the sustainability of business operations. Reporting on environmental matters provides a good indication of what measures an organisation is taking to reduce risks and develop opportunities.
- *Product and service innovation.* Measuring and managing environmental impacts drives and supports innovation in product and service development, helping to secure new markets and customers or safeguard existing ones.
- *Employee recruitment.* Clear reporting of an organisation's efforts to manage its environmental performance helps to attract high-calibre employees as good environmental reputation and performance can be an important factor in an employee's choice of employer.
- *Licence to operate.* Managing environmental impacts and minimising the organisation's impact on the environment can reduce the exposure to fines. It can improve relations with regulators and help ensure the company maintains its licence to operate by providing assurances about compliance with environmental legislation and conformity with other relevant laws and regulations.

4. MEASURING ENVIRONMENTAL PERFORMANCE INDICATORS

Since the United Nations Conference on Environment and Development in 1992, sustainability has become a widely shared goal. Although information can provide an improved basis for decision-making and gauging progress, accountability is possible only if goals and measures of progress are explicit. Appropriately formulated indicators can provide such measures, enhancing the diagnosis of the situation and making progress or stalemate obvious to all.

Environmental performance indicators provide businesses with a tool for measurement. They are quantifiable metrics that reflect the environmental performance of a business in the context of achieving its wider goals and objectives. Also they help businesses to implement strategies by linking various levels of an organisation (business units, departments and individuals) with clearly defined targets and benchmarks.

Metrics can measure the business value of environmental programs or progress as well as the environmental performance of business operations. This can be particularly effective in demonstrating the value of environmental efforts to management. It can also provide data with which business units can design more efficient processes, decreasing material usage and environmental impacts while at the same time increasing yield and profitability.

The last several years have seen the development of several trends in environmental metrics. Some of these trends are:

- the globalization of metrics,
- increasing emphasis on sustainability in its environmental context (the efficient use of resources) and efforts to develop sustainability metrics,
- increasing use of environmental management systems as benchmarks of environmental performance,

- and emphasis on the integration of environmental performance with business performance with the goal of reducing costs and material losses, and improving yield, market share, and profitability.

Environmental indicators are essential tools for tracking environmental progress, supporting policy evaluation and informing the public. Since the early 1990s, such indicators have gained in importance in many countries and in international foray (European Commission, 2003).

Usually, three categories of environmental indicators are defined for evaluating and reporting the environmental performance of an organisation (European Commission, 2003):

- Operational Performance Indicators (OPIs):
 - Input indicators:
 - Materials,
 - Energy,
 - Services supporting the organisation's operation,
 - Products supporting the organisation's operation.
 - Physical facilities and equipment indicators:
 - Design,
 - Installation,
 - Operation,
 - Maintenance,
 - Land use,
 - Transport.
 - Output indicators:
 - Products provided by the organisation,
 - Services provided by the organisation,
 - Wastes,
 - Emissions.
- Management Performance Indicators (MPIs):
 - System indicators:
 - Implementation of policies, and programs,
 - Conformance,
 - Financial performance,
 - Employee involvement.
 - Functional area indicators:
 - Administration and planning,
 - Purchasing and investments,
 - Health and safety,
 - Community relations.
- Environmental Condition Indicators (ECIs):
 - Environmental media indicators:
 - Air,
 - Water,
 - Land.
 - Bio and anthroposphere indicators:
 - Flora,
 - Fauna,
 - Humans,
 - Aesthetics, heritage and culture.

Operational performance indicators (OPIs) concentrate on the aspects associated with an organisation's operations including activities, products or services and can cover such topics as emissions, product and raw material recycling, fuel consumption of vehicle fleet, or energy usage.

Management Performance Indicators (MPIs) concentrate on the efforts of management to provide the infrastructure for environmental management to succeed and can, among others, cover environmental programmes, objectives and targets, training, incentive schemes, audit frequency, site inspections, administration and community relations.

Environmental Condition Indicators (ECIs) give information on the quality of the environment surrounding the organisation or the local, regional or global state of the environment. Examples include the water quality of a nearby lake, the regional air quality, concentrations of greenhouse gases or the concentration of certain pollutants in the soil. While they may be quite wide-ranging they can be used to focus the attention of the organisation on the management of the environmental aspects associated with significant environmental impacts.

5. CHOOSING ENVIRONMENTAL INDICATORS

As noted, many environmental indicators are needed to fully describe the environmental impacts of a pest management product or method. To use the example of pesticide toxicity, there is no single species or group of biota that is most sensitive to all pesticides and thus useful as a surrogate for all others in toxicity testing. This truism applies to other environmental perturbations as well -- we cannot rely on a single indicator species or abiotic effect to tell all we need to know about impacts of any management decision. Scientists are therefore faced with the need to test and evaluate impacts on various groups of biota, and then integrate the results in order to create a composite assessment of environmental impacts of a pest control method or other management strategy. One can grasp the conceptual challenge this poses by thinking about how one would go about weighting and summing an evaluation of impacts on human beings in relation to impacts on other biota, especially if the impacts were dissimilar in magnitude and type.

Another challenge to creating a composite assessment of environmental impacts of organizational strategies is finding a meaningful common currency to describe different types of impacts. In answering many questions about environmental impacts, monetary values do not adequately describe non-market costs -- such as the loss of an individual life, loss of biodiversity, impacts on 'non- game' species, disruption of an ecosystem, future costs of current soil erosion, or loss of non- replaceable resources. Ongoing research in several disciplines (and inter-disciplines) is aimed at devising means of valuing environmental and other non-market goods; much of this work falls under the rubric of 'resource ecological economics' (Daly et al., 1994)

Another challenge of creating composite assessments of environmental impacts is due to the reality that there is no one set of social or environmental indicators that are most appropriate to use in assessing impacts of agriculture. Different circumstances and objectives prioritize different indicators and interpretations. One may answer the question of how to integrate; weight and value impacts in the context of one assessment scenario, but these issues will re-emerge when the question of environmental impacts is asked on a different scale or with different objectives. For example, the types of data required to create a decision model for a farmer to use in the field in choosing a 'least impact' but efficacious pest control method, may not be the same as the data required for a national policy model assessing other area practices. The design of an assessment system must, therefore, be appropriate to the objectives of the audience served.

6. QUESTION OF BIAS TOWARDS FUTURE

There are several ways in which we can be biased against considering future, as compared to present impacts. The issues that tend to concern us most are those that occur in our immediate space and time frame. This implies that current activities which lead to environmental impacts at more distance places and times tend to receive less attention. For example, majority of impact tests emphasizes their short-term lethality rather than their chronic and cumulative impacts. Or we may be more interested in the short-term reduction in damage that occurs than in the long-term impact on populations caused by the same issue. Long-term and cumulative impacts are more difficult to comprehend and quantify than short-term impacts and there are less data generally available. As a result, less weight tends to be given to these impacts in environmental assessments.

A second manner in which we can be biased against the future as compared to the present is by not considering impacts associated with future events (Garetz, 1993). Future impacts of future events can be more uncertain than assessing impacts of current events, but this does not mean that such impacts are less important. For example, the Superfund Program and Hazardous Waste Program were established primarily on the basis of future rather than current risks.

Another problem for current assessments is that as environmental systems change or become better understood in the future, the impact of EPI may be assessed differently. This implies that assessors must be aware of new information and problems, and be prepared to modify or change their assessment methods to account for changes in our knowledge base.

7. CONCLUSION: TOWARDS SUSTAINABLE ORGANIZATION

Since the United Nations Conference on Environment and Development in 1992, sustainability has become a widely shared goal. Although information can provide an improved basis for decision-making and gauging progress, accountability is possible only if goals and measures of progress are explicit. Appropriately formulated indicators can provide such measures, enhancing the diagnosis of the situation and making progress or stalemate obvious to all.

Environmental performance indicators provide businesses with a tool for measurement. They are quantifiable metrics that reflect the environmental performance of a business in the context of achieving its wider goals and objectives. Also they help businesses to implement strategies by linking various levels of an organisation (business units, departments and individuals) with clearly defined targets and benchmarks.

The impact of environmental matters on organization performance is increasing and will continue to do so. For example, poor management of energy, natural resources or waste can affect current performance; failure to plan for a future in which environmental factors are likely to be significant may risk the long-term value and future of a business. Therefore, governments expects that businesses will need to use environmental performance indicators to adequately capture the link between environmental and financial performance (Petrović & Slović, 2011).

The green and sustainability trend has manifested in pressure from consumers, shareholders, employees, partners and governments (regulations) put upon companies to embrace more sustainable and green practices. Many companies resorted to [greenwashing](#) instead of actually creating green innovations by marketing their product in a way that suggests green practices.

However, there are many companies that have taken the sustainability trend seriously and are doing so profitably (Tueth, 2010).

Organizations that give back to the community, whether through employees volunteering their time or through charitable donations are often considered to be socially sustainable. Organizations also can encourage education in their communities by training their employees and offering internships to younger members of the community. Practices such as these increase the education level and quality of life in the community (Becker, 2008).

In order for a organization to be truly sustainable, it must sustain not only the necessary environmental resources, but also its social resources, including employees, customers (the community), and its reputation.

POSSIBILITIES OF IMPLEMENTING ENVIRONMENTAL MANAGEMENT AND AUDIT SCHEME IN SERBIA

Jelena Kostić

University of Belgrade, Faculty of Organizational Sciences, jelena.d.kostic@gmail.com

Abstract: *In this paper we analyze EU examples of successful EMAS implementation into two branches of economy. We chose auto-industry and education, due to their importance for the Serbian economy. The EU Environmental-Management and Audit Scheme (EMAS) is a management tool for companies and other organizations which is used to evaluate, report and improve their environmental performance. Audi Hungaria Motor Kft. is a company which is very similar to "Fiat automobiles Serbia", one of the most important manufacturers in Serbia. It was used as an example in this paper, and analyzed in several different areas of their businesses: ecology, social awareness, environmental awareness, etc. The other part of this paper is oriented towards education, which is constantly growing. The University of Macedonia that has already implemented EMAS can show the possibility of incorporating EMAS into the Serbian educational system, analyzed on the example of the University of Niš. Costs, benefits and trammels are analyzed in both of the examples.*

Keywords: Ecology, EMAS, Serbia, Industry, Environment

1. INTRODUCTION

The EU Environmental-Management and Audit Scheme (EMAS) is a management tool for companies and other organizations to evaluate report and improve their environmental performance [1]. Environmental management is not, as the phrase suggests, the management of the environment as such, but rather the management of the interaction and impact of human societies on the environment. The scheme is globally applicable and open to all types of private and public organizations. The scheme has been available for participation of companies since 1995 and was originally restricted to companies in industrial sectors. Since 2001 EMAS has been open to all economic sectors including public and private services. (Morrow, D. et al. 2002.). Environmental management aims to ensure that ecosystem services are protected and maintained for equitable use by future human generations. (Milieu Ltd. and Risk et al. 2009).

Serbia is very open and fertile ground for investments. Already many companies have grown and expended their businesses into profitable parts of hardworking Serbian regions. One of the most interesting divisions for growth is the car industry. In Serbia there is an already functioning auto industry. With low labor costs and huge possibilities for expansion, it is the perfect choice for investments. By implementing EMAS investors would benefit from the reduced costs that operating within EMAS rules provides. (Web site ec.europa.eu 15.04.2012). Other very important field that is in constant growth in Serbia is education. As a public field, education has many possibilities for more efficient functioning that will be provided by implementing EMAS. In Serbia education is free for students, which means that the Government has high costs when it comes to education every year. Investing in more efficient functioning, which EMAS concludes, provides that "education machine" runs more economically and that environmental awareness rises in minds of student and workers as well. (Web site ec.europa.eu 29.04.2012)

2. COMPANIES IN EU THAT USE EMAS AND THEIR SERBIAN COUNTERPARTS

Audi Hungaria Motor Kft. is one of AUDI-s outsourced companies. It produces engines for every Audi model and assembles the whole car for models Audi TT, A3 cabriolet and others as well as some models for Volkswagen, Seat and Skoda. This operation, stationed in Hungarian city Győr, employs 5845 worker. (Web site www.audi.hu 21.04.2012)

On the other hand, "Fiat automobiles Serbia" is one of Fiat outsourced factories which they run as partners with Republic of Serbia. It's the biggest production complex of this type in South-Eastern Europe. Factory is equipped with the latest technology which provides for 5000 workers and engineers excellent conditions to work in. (Web site www.fiatsrbija.rs 25.04.2012.)

These two companies have similarities in many aspects such as number of employees and production technology. Analysis of effects which implementation of EMAS in Audi Hungaria Motor Kft. can show what benefits could be expected if “Fiat automobiles Serbia” would implement EMAS as Audi Group in Hungaria already did.

In the other example the University of Macedonia Economic and Social Sciences, located in Thessaloniki, Greece, is analyzed. It is a twenty year old institution, housed in a group of buildings with a total area of approximately 40,000 square meters, consisting of amphitheatres, teaching and seminar rooms, offices and the areas of the administration sections. University of Macedonia employs around 863 people including professors and staff, and more than 15,000 students attend lectures. It has 8 departments and offers both bachelor and master degree.

The University of Niš is a state-governed educational and research institution. At present, the University comprises 13 departments, all of which offer bachelor, master and PhD degrees. It employs 1560 people including professors and staff, and over 28,000 students at all of levels of studies. The University of Niš is almost twice as big as University of Macedonia, if compared by the number of employees, students and departments.

The analysis of benefits which were caused by implementation of EMAS in University of Macedonia, could indicate the effects it would have on business of University of Niš as they are proportionally similar.

3. HOW THE EMAS WAS IMPLEMENTED

The proper implementation of the EMAS Regulation is monitored and controlled by European Commission, which is also **in charge of its development. Besides the regulatory role, the Commission also** promotes the scheme at the EU level. Key actors in the verification and registration process ensure the public credibility and reliability of the scheme. Furthermore, key actors ensure that the applicability of the scheme is enhanced. After an organization has conducted an environmental review, set up an environmental policy and program and carried out an internal audit, an environmental verifier ensures that an organization seeking registration is in compliance with the requirements of the EMAS Regulation (verification). Environmental verifiers also verify the reliability, credibility and correctness of the data and information in the (updated) environmental statement and other environmental information provided by organizations (validation). The final step in the EMAS implementation process is to apply for EMAS registration. (*Web site ec.europa.eu_27.04.2012.*)

Automotive industry

Audi Hungaria Motor Kft. implemented EMAS into overall corporation behavioral in 2005. This decision was guided by the desire to substantiate its responsibility of communicating the company's values to society with the implementation of concrete measures, and by the wish to actively and positively contribute to the environmental as well as social and cultural processes of the city of Győr. Moreover, over the years it has become clear to the company that environmental protection is not only an ecological, but also an economic question. The view that expenditures for environmental protection are not profitable is long obsolete. At appropriate points, efficient interferences can be created and improvements of the environment may lead to economic advantages. The implementation of EMAS confirms the enterprise's interest is not only in the environment but also in the sustainable development of the city where the company is located. Since the introduction of EMAS, indeed, the enterprise has managed to implement a large number of plans:

- It decided to organize the transport of materials and engines between Győr and Ingolstadt, the mother company in Bavaria, by rail instead of by road for ecological reasons.
- An examination of the environmental management system as well as of the environmental policy regarding its fitness and appropriateness takes place regularly, with updates - if necessary.
- The workers, according to their functions, are constantly informed on issues related to environmental protection, in order to promote their sense of responsibility towards the environment.
- Implementation (in 2005) of the BUWAL method for a better analysis of environmental aspects and effects.
- In 2007 Audi Hungaria Kft. was nominated in the category “large organizations” at the EMAS Awards ceremony 2007 in Lisbon - the most prestigious award in environmental management granted to top companies and local authorities since 2005.

Management of the company emphasize that they hadn't encounter almost any particular difficulties implementing the EMAS. This ease has been possible only because of the huge effort and great commitment both of the management and the staff of AUDI Hungaria. Furthermore, during the whole process leading to the acquisition of EMAS certification, Audi Hungaria was supported and accompanied by 10 years experience of the mother company Audi AG, which had already implemented EMAS in November 1995.

Education

In order to enhance its contribution to society, the University of Macedonia embarked on the pursuit of environmental excellence by implementing a fully blown environmental management system in 2004. The University of Macedonia is the first university (and the first organization in the wider public sector) to implement an environmental management system, in Greece. The University has chosen to apply EMAS because it considered it the best instrument to not only continuously improve its environmental performance, but also to promote transparency and an open dialogue with the public. Furthermore, it could join the very active group of EMAS-registered universities in Europe and exchange ideas and best practices with them. The international collaborations lead to participation in the Virtual Campus for a Sustainable Europe project while the University is currently in the process of applying for a Regional Center of Expertise (RCE). (*Web site www.uom.gr 19.04.2012*).

The main results of the 4-year implementation of EMAS include:

- identification of the most important environmental impacts of the University's operation, and taking the appropriate actions for the optimal use of natural resources, including conservation of water and energy and the subsequent economic benefits
- improvement of hygiene and safety and the ensuing reduction of labour accidents
- reduction in the use of materials and more appropriate waste management and recycling of materials (paper, electric and electronic devices, batteries, etc) with the subsequent economic and environmental benefits
- offer more and attractive choices to students by increasing the number of courses with environmental content in the University's curriculum
- improve, qualitatively and quantitatively the University's research activity by extending it to the area of environmental protection and offering additional choices for international collaboration

They have indentified the main difficulties in implementing EMAS as:

- to overcome the red tape obstacles inherent to the Greek public sector
- to convince faculty and staff members to actively participate in the activities of the environmental management system
- to ensure the constant and substantial support of the University's authorities
- to secure the necessary financial resources

4. ACHIEVED BENEFITS

Implementing EMAS into organization implies certain costs such as fixed costs. Some of fixed costs are validation/verification fees, registration fees, integrating EMAS logo into corporate design. There are some external costs that implementing EMAS poses almost as essential, such as consultancy expertise to support implementation and reporting. Some new internal costs also appear, like the costs of personnel and technical resources needed for implementing, as well as for administering and reporting. EMAS helps companies optimize their production processes, reduce environmental impacts and use resources more efficiently. Benefits from EMAS companies can be clearly seen in enhanced environmental and financial performance, enhanced credibility, transparency and reputation, enhanced employee empowerment and motivation. (*Web site ec.europa.eu 27.04.2012*.) Every year the "EMAS Awards" honors the relentless efforts on environmental protection of EMAS registered organizations. The European Commission hands out these important environmental awards since 2005. An EMAS Award is the most prestigious award in environmental management and is handed out to top performing companies and public authorities in six categories. In this paper we estimate the effects implementation of EMAS could have on business of

Serbian companies in auto industry and education, by analyzing companies in EU with the same characteristics, which have already implemented it.

Automotive industry

After implementing EMAS Audi Hungaria Motor Kft. experienced radical changes in regard to environmental relations, ecology awareness of the employees, society's observation of the company. In real numbers the result for the company was:

- The recycling ratio reached a quota of 97%.
- In spite of increase in production of 140.75% the company has been able to reduce the use of energy by 0.25%, by implementing energy saving measures.
- Air pollution decreased by 0.29% due to further implementations of innovative, pollution free technologies - such as cold tests and treatments with minimum quantity lubrication. (*Web site ec.europa.eu 15.04.2012*).

Education

The University of Macedonia also environmentally improved its business as they achieved to:

- Reduce the consumption of paper per faculty and staff member from over 60kg in 2004 to 20kg in 2008
- Increase gradually the recycling of paper (from zero in 2004) to above 70% in 2008 of the total purchased quantity
- Recycle almost 85% of all photocopy and printer toners purchased
- Recycle 563 electronic devices in 2008, mainly computers and printers
- Minimize the rate of increase in energy consumption despite a continuous increase in the intensity of use of the University premises and an increase in the number of faculty staff and students, through a series of energy-saving measures in the refrigerating, heating and lighting system. (*Web site www.uom.gr 19.04.2012*).

5. POSSIBILITIES OF EMAS IMPLEMENTATION IN SERBIA

Automotive industry

"Fiat automobiles Serbia" is a very suitable candidate for implementing EMAS, since Fiat is already an ecologically awakened company. To reduce emission they have developed and use eco-friendly systems such as Start&Stop and eco:Drive. In the past year the company managed to reduce engine emissions for 30 percent, by using efficient, low pollution engine types like Multi Jet, Multi Air and Twin Air, which was acknowledged as the engine of the year in 2011. (*Web site www.fiatsrbija.rs 25.04.2012*). Due to its high resemblance with the Audi Hungaria Motor Kft., with the same number of employees, same field of work and manufacturing field, it could easily follow the same path in implementing EMAS. Fiat could gain the same benefits as Audi, such as reaching a very high quota of recycling ratio (>95%), reducing the use of energy by implementing energy saving measures, decreasing air pollution ... Workers would be more ecologically aware, the whole company would gain benefits such as reductions in energy and resources expenditures, additional cost reductions, improved employee morale, better internal communication and modernization of management. All of which leads to higher profit in a sustainable system.

Education

Since universities are autonomous from the state, they can implement new management policies more efficiently than other institutions in public sector, which makes them ideal candidates for implementation of modern business policies. In our example the University of Niš could be refreshed by implementing EMAS in a similar way that the University of Macedonia was. New environmental system could help with overcoming the red tape obstacles inherent to the Serbian public sector, convincing faculty and staff members to actively participate in the activities of the environmental management system, ensuring the

constant and substantial support of the University's authorities, securing the necessary financial resources. It would minimize the rate of increase in energy consumption through a series of energy-saving measures in the refrigerating, heating and lighting system, saving millions of RSD on yearly bases.

For example if the University of Niš could reach the goal of recycling 85% of all photocopy and printer toners, like the University of Macedonia did, it would greatly relax their budget. As they use about 7 million RSD yearly on new toners, and the price of recycling is almost three times lower, they would stand to save nearly 3.8 million RSD, every year.

6. CONCLUSION

As the examples show, proper implementation of a good program for environmental management leads to both direct benefits, such as decreasing expenses by recycling and indirect benefits, and indirect benefits, like enhancing companies reputation and public image, which all leads to more successful business. Since Serbia is somewhat behind other European countries in environmental legislation and management it has a great potential for development in this area. Furthermore it can benefit greatly from their experiences. By observing and analyzing examples of successful EU companies, with similar counter parts in Serbia it is possible to make projections of expected benefits, as well as to anticipate possible problems, and drawbacks.

Implementing EMAS in Serbian industry and administration, by following lessons learned from EU companies, can significantly increase the efficiency and sustainability of the economy.

TECHNOLOGICAL PROGRESS IN THE FUNCTION OF SUSTAINABLE DEVELOPMENT

Marija Petrović-Ranđelović¹, Tatjana Stevanović²

¹University of Nis, Faculty of Economics Nis, marija.petrovic@eknfak.ni.ac.rs

²University of Nis, Faculty of Economics Nis, tatjana.master@gmail.com

Abstract: *One of the key issues that has long occupied the attention of economists in discussions led regarding the possibilities for achieving sustainable development refers to the potential effectiveness of technological development to minimize or neutralize the negative effects of economic growth on the environment. Since technology is the main agent of change in the sphere of production and consumption, the aim of this paper is to highlight the role and importance of the development of technological solutions in a manner conducive to achieving sustainable development goals. With increasing global awareness of the need for solving the problems in the field of sustainable development and the importance of taking a strategic approach in providing responses to the challenges of sustainable development, the immediate reaction of multinational companies was reflected in the identification of new business strategies and policies and creating technologies that support the objectives of sustainable development. Many companies have become aware of the possibility of realising direct business benefits from the introduction of new, sustainable technologies in the business, based on minimizing the use of resources and energy, more efficiently meeting the needs of consumers and minimizing the negative environmental impact. Based on the analysis of the experiences of some leading companies in the implementation of technological innovations, this paper should also contribute to a clearer understanding of the importance of introducing new technologies for achieving more efficient business from the point of sustainable development. In accordance with the subject matter and research goals, the following methods will be used during the research: method of induction, method of deduction, method of analysis, method of synthesis and method of generalization. The application of specific methodology of scientific research in this paper is motivated by the need to contribute to a clear understanding of the problem which is the subject of the research in order to achieve the main goal of the research.*

Keywords: *sustainable development, technological development, sustainable technologies, technological innovations*

1. INTRODUCTION

After setting up the basic premise of sustainable development in the Report of the World Commission on Environment and Development (WCED) in 1987, this concept experienced broad political popularization, while the proper selection of methods, measures and instruments for its materialization becomes a real challenge for the governments of all countries, as well as business sector on a global level. To its widely popularization contributed the apprehension on unsustainability of traditional models of economic growth in the long run, since it ignores the effects of achieving greater economic growth on the environment. However, it would be wrong to conclude that this concept sets limits to economic growth. Changing the nature of economic growth, not its limitation lies in the basis of the concept of sustainable development. Thereby, World Commission on Environment and Development (1990) pointed out that “rather than growth or no-growth, as the debate about environment and development has sometimes been cast, the central issue is what kind of growth. The challenge of sustainable development is to find new products, processes, and technologies which are environmentally friendly while they deliver the things we want”. The concept of sustainable development, in fact, indicates on the need for introduction of modifications in the way on which the human activities exercised of in order to ensure their sustainability in the future and prevent irreplaceable environmental damage that would otherwise limit the capacity of Earth to support such activities.

“Before the Brundtland Commission, “development progress” was associated with industrialization, and measured solely by economic activity and increases in wealth. Environmental protection was perceived by many as an obstacle to development. However, Our Common Future recognized “environment or development” as a false dichotomy“(Martino & Zommers, 2007, p. 10). The concept of sustainable development, namely, was developed from the apprehension that in order to achieve environmental

protection is necessary to make changes in the applied models of production and consumption, and that environmental management and efficient use of natural resources are basic prerequisite for achieving development without environmental degradation.

The prevailing view is that the increasing environmental problems at the global level can be attributed to several factors, among which are above all rapid population growth, which has led to increasing demand for food, water and energy, accelerated economic growth and unsustainable patterns of consumption, progress in science and technology, and institutional factors that have contributed to increasing pressure on the environment and negatively impact on the state of the environment, population well-being and economic activity. Among these factors, certainly it is emphasized in the importance the technological progress that contributed to the increase of population welfare, but at the same time set new risks and threats to maintaining a healthy environment, which is primarily reflected in raising the level of pollution and hazardous wastes from the application of extensive production process loss of biodiversity and global warming. "Unsustainable technology has been the result of linear rather than cyclic thinking. The paradigm shift from linear to cyclic thinking in technological design is the crux of the shift from unsustainability to sustainability" (Vanegas, DuBose & Pearce, 2012, p. 1).

Solving global environmental problems with which the humanity is faced today requires designing of the new methods of management and decision-making in a way that inflict least harm to the environment and contributes to the simultaneous achievement of the objectives of sustainable development. In this regard, the management of technology in the context of sustainable development alludes finding ways to maximize the positive impact of technological progress on economic growth, social development and environmental protection, and minimize its negative impact on the environment and population well being

This paper is structured as follows. After the introduction, in the second part of the paper will be discussed the role and importance of technology in sustainable development. The third part of the paper is devoted to the analysis of experience in the application of technological innovations on the example of the world's leading companies, where new technologies have contributed significantly to increasing the efficiency of business. In the final part of the paper will be performed a synthesis of research results.

2. THE MAIN FEATURES OF "SUSTAINABLE" TECHNOLOGIES

As one of the driving forces of economic development, technological development today rightly occupies a high place among the factors in the realization of development strategy developed countries, while its role in accelerating the development of economies of the underdeveloped countries is irreplaceable, since it represents a factor of essential importance in laying out the future directions of development of these countries. "Technological development has a profound and long-term impact on income distribution, economic growth, employment, trade, environment, industrial structure and defence and security matters (Stoneman, 1987). The acquisition and use of science and technology (S&T) are critical for the achievement and sustenance of food security, as well as the promotion of public health and environmental quality" (Ahmed & Stein, 2004, p. 6).

The role of technology in sustainable development is great because it represents a key ingredient of change in the way on which societies produce and consume. Development and application of sustainable technology solutions is a key prerequisite for raising productivity and living standards, while simultaneously reducing the pressure on natural resources use and improvement the state in the environment area. Technological progress is, in fact, contributed to reducing the degree of dependence of man and society of the immediate environment, since the development of modern technology provide the possibility through the industrial pathway to achieve the access to new cases of artificial or raw materials which are not found in nature. In short, the technology that contributes to the simultaneous achievement of the objectives of sustainable development we can rightly be called sustainable technologies. "These technologies serve to contribute, support or advance sustainable development by reducing risk, enhancing cost effectiveness, improving process efficiency, and creating processes, products or services that are environmentally beneficial or benign, while benefiting humans" (National Science and Technology Council 1994, p. 4). Sustainable technologies differ with the following key characteristics:

1. they contribute to minimizing the use of non-renewable resources and energy, and thereby increasing their using potential for the future generations,

2. they contribute to more effectively meeting the human needs, while respecting human preference and cultural differences,
3. and finally, these technologies are eco-efficient whereas they realize minimal negative impact on the environment, which contribute to ecosystems preservation that is of essential importance for human survival on planet Earth.

There are great difficulties in defining of the environmentally sound technologies. This is especially because the environmental performances of technology depend on the nature of their impact on human society and ecosystems, but also of the infrastructure and human presumptions for technology management and monitoring of their impact. Second, the term itself is relative and liable to changes over time, whereas over time technological progress lead to the abandonment of the ones and the introduction of new environmentally sound technological solutions. Third, there are differences in the effectiveness of environmentally sound technologies between countries. For example, those technologies that represent environmentally beneficial solution for developed not necessarily mean a favourable solution for underdeveloped countries. This is particularly because the problems of development in the underdeveloped country do not appear in the same order, as in developed country, in order to underdeveloped countries could use the pattern of development of developed countries. Namely, if the technology does not correspond to local conditions and the achieved level of development, it may contribute to increasing the gap between developed and developing countries, and further burden the development problems of underdeveloped.

Despite numerous difficulties, the definition of environmentally sound technologies, which is set out in Agenda 21 (Chapter 34) indicative suggests of their key characteristics. Environmentally sound technologies are technologies that “protect the environment, are less polluting, use resources in a sustainable manner, recycle more of their wastes and products, and handle all residual wastes in a more environmentally acceptable way than the technologies for which they are substitutes” (International Environmental Technology Centre, Division of Technology, Industry and Economics, 2003, p.16). ESTs are rather systems than individual technologies, for the reason that they include in themselves and “know-how, procedures, goods and services, and equipment, as well as organisational and managerial procedures for promoting environmental sustainability” (International Environmental Technology Centre, Division of Technology, Industry and Economics, 2003, p.16). Whereas that the implementation of new environmentally sound technologies can contribute to boosting the development gap between countries, of essential importance for their effective implementation is to raising the level of development of human capital and necessary technological infrastructure in order to maximum absorb of their positive environmental impacts and minimize negative.

Agenda 21, as a comprehensive plan of action for 21st century, served as a platform for the promotion of the transfer of environmentally sound technologies in a global framework, while its implementation at the national level enable economic policy makers to make the assessment and identification of practical technological solutions from the aspect of the conveniences for sustainable development. Moreover, by emphasizing the importance of transfer environmentally sound technologies and increase the access of developing countries in development of the modern technological solutions, Agenda 21 indirectly supports the efforts of these countries to achieve sustainable development objectives, and clearly determines the place of modern technological solutions in achieving environmental protection and poverty reduction. It directly indicates to the need to leave the traditional, unsustainable technologies and transition to technologies that are sustainable and environmentally sound (Figure 1).

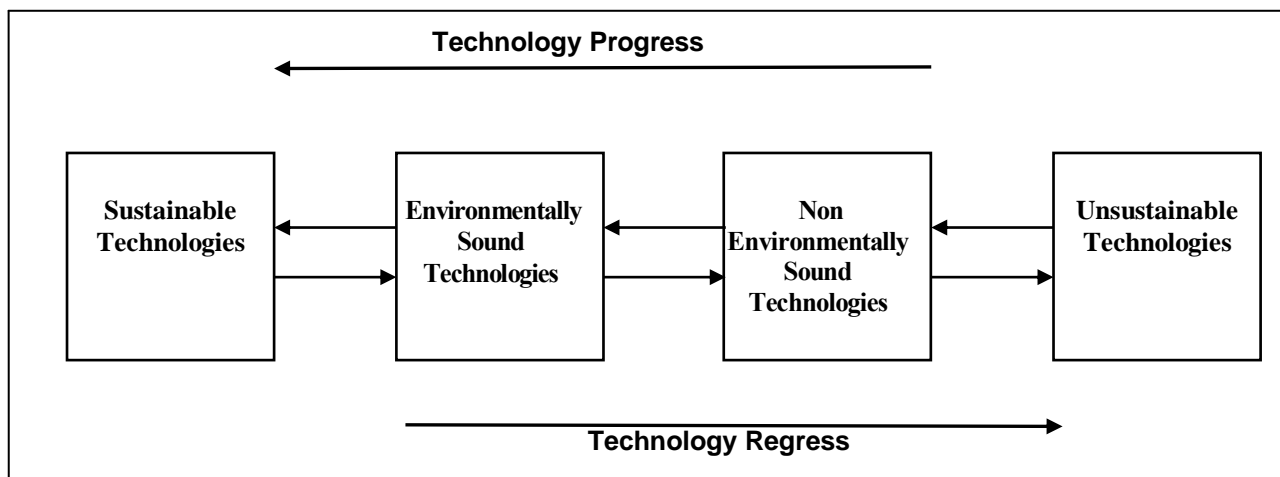

Figure 1: The Transition of Technology towards Sustainability (International Environmental Technology Centre, Division of Technology, Industry and Economics, 2003, p.17)

Therefore, “the paradigm of “sustainable development” can be viewed also as a new paradigm of technological development. The use of green technologies should be promoted, although technological optimism does not escape the need for fundamental social change and a shift in priorities. The institutional background and environmental instruments providing the right incentives play an important role in realizing the savings potential and/or the use of clean technologies” (Sunhilde, 2010, p. 30). Encouraging the transition process to sustainable and environmentally sound technologies and maximum use of their potential for the purposes of achieving sustainable development must be supported by using carefully selected instruments of environmental policy by the state authorities. The increasing use of economic instruments in environmental policies of developed countries confirms the advantages of their use in regard to the regulatory instruments of command and control approach, and the importance of strengthening the application of these instruments in solving the problems of sustainable development in developing countries and countries in transition. This is especially because in regard to regulatory instruments, economic instruments in environmental policy can provide the opportunity to realize significant economic savings, apropos they encourage economic agents to taking into account environmental issues in making their decisions, and to minimize the use of natural resources and the level of waste, but also they provide additional incentives for pollution reduction below the laid level and have stimulating effect on the introduction of new technologies for pollution control and prevention.

3. THE APPLICATION OF MODERN TECHNOLOGICAL SOLUTIONS – CASE STUDIES

During the last twenty years, many companies have realized that in order to achieve their primary motivation for the business, maximizing the profits, it is necessary to create new business strategies consistent with the goals of environmental protection and achieving sustainable development. The concept of sustainable development has imposed the need for modifying the way in which companies implement their activities, while emphasizing simultaneous the importance of re-designing technologies and the introduction of radical transformations in the technological basis of production. In this way, it encouraged the propensity of the companies to take measures of the manufacturing process innovation in order to:

1. “Filling *market gaps* as concerns technologies conducive to sustainable development, by using various schemes to narrow the gap between the private return and the return to society, between the current and future generations.
2. Supporting *dissemination of clean technologies*, low on consumption of resources, by favouring the dissemination of information and knowledge.
3. Promoting *technological diversity*, to avoid getting locked into technologies which may present long-term risks.
4. Reinforcing the *long-term innovation capacity* by favouring the development of skills and strategic prospecting.

5. Laying down procedures to *improve coherence of the various agents*, to encourage appropriation of technologies by users and by society.
6. Encouraging *citizen participation* in developing effective scenarios for a social-economic assessment of technological choices" (Patris, Valenduc & Warrant, 2001, p. 8).

According to the experience of the world's leading companies, efficient business in terms of sustainable development requires significant technological innovations. Thus, the experience of British Petroleum (BP), DuPont, Interface, Monsanto and the other refers to innovative technology management as a common basis of concrete initiatives for sustainable development. Thereby ahead of the management of the company raised serious task of creating and developing a vision and action plan for sustainable development. Traditional methods of gathering information and planning ignore some of the facts inherent in achieving sustainable development, such as discontinuous technological development and integration of key technologies in the delivery of products.

While the traditional approach to technology management is aimed at incremental improvements, the contemporary aspect of sustainable development emphasizes the incorporations of gradual improvements and radical technological changes. Incremental improvement is related to areas such as increasing energy efficiency and reuse of materials in production. In contrast, the revolutionary technological innovations are focused on completely new ways of meeting the needs of customers. In this regard, the traditional approach is limited in terms of speed or costs to implement these dual requirements. In addition to these limitations, it should be noted that sustainable development requires an interdisciplinary approach to management and technological innovation, which is difficult in the traditional approach.

Scientists, engineers, technicians and experts of other disciplines around the world are trying to respond to the challenges of sustainable development. During these efforts, in many leading companies are created new roles and responsibilities for managers of technology. In the following exposure will be render the contemporary examples of meeting sustainable development and technological innovation.

Monsanto Company, a leader in the chemical industry, are giving greater access to sustainable development by introducing significant changes in the field of technical and strategic discontinuity. In this way, it expects a significant competitive advantage inherent to a small number of companies. Developing perceptions of technology and sustainable development, Monsanto has introduced radical changes in traditional business of potato farming and create conditions for the dominant competitive position in an otherwise unchanging conditions of this market. In the modern approach to sustainable development, "*the Monsanto bioengineered NewLeaf potato*" started an initiative for protection against the destructive Colorado potato beetle and leaf virus, by a common approach. The traditional method of potato production often requires large amounts of insecticide to achieve the same level of protection and crop yield.

Monsanto has used a similar technological vision and innovation as Bt Cotton, which uses genetically re-engineering of cotton plants. While traditional cotton production involves the use of chemicals, Bt Cotton manufactures protective proteins, thus providing a more efficient way to produce cotton. Exploring new opportunities in the field of biotechnology, Monsanto has launched a collaboration with universities and laboratories, and initiated some examples of joint ventures. Meanwhile, Monsanto is especially committed to innovation plants and seeds in order to solve the problem of erosion of the upper layer. "Roundup" herbicide remains on the surface to which it is applied, limiting the erosion of topsoil, and natural biodegradation through layers of microbes. By combining sustainable development and technological innovation, Monsanto has created a viable and cost effective method dominant than the traditional.

British Petroleum, a company that several years ago oriented toward addressing issues of sustainable development, more is given to the introduction of new technologies in their business. There is an obvious transition from solid (e.g. wood, coal) to liquid fuels (crude oil) in the last few decades, and the next step is the transition from liquid to gas, by the fact that a liquid becomes a more expensive source, while gas has a much greater quantities and relatively cheaper. Business in the field of security of energy resources is moving towards renewable sources thus paving the roads to sustainability. This vision has crystallized the need for changing from the oil companies, with primary focus on petroleum refining technology, to the energy company with a portfolio of alternative technologies.

Notwithstanding the extreme shifts in business, British Petroleum does not change its attitude to the importance of oil, especially in the short term. However, following the vision of sustainable development,

the company began the transition from oil and natural gas to a wider portfolio of energy, including the development and commercialization of advanced solar technologies. Therefore, it strives to be the first company in the process of this type of transition and to become a leader in management of the energy technologies.

DuPont is a mega company in which the three business units have made significant progress towards sustainable development. “DuPont Agricultural Products” has launched major initiatives in the biotechnology arena (like Monsanto), replacing traditional costly chemical reactors used in the manufacture of polymers with biological plants that produce the desired chemicals in their cells.

Unit “DuPont’s film” is introduced even larger changes. Although seven years before this unit, which produces packaging for food, audio-tapes and substrates for printed boards, was before the abolition, by introducing a vision of sustainable development technology, situation has changed significantly. This business unit has developed a manufacturing process of polyester (80% of its business) which is regenerated polyester film in a very good product. In this way it exerts “unzips” of recycled polymers and provides a fresh starting material. At the same time, with this process is completely changed the cost structure of a mature industry.

Recently, the company DuPont has also introduced amendments to the conventional business procedure in the field of automotive paint. Historically, DuPont and Ford had a classic customer-supplier relationship in which both companies, over the quality and price, are seeking to optimize their market position. In more modern terms, these companies work together on improving the quality of colour and the whole process of painting the car. On this way were obtained significant results in the field of waste reduction and increase the quality of finished product. DuPont now participates in lowering the cost of Ford, which has not been possible in the traditional approach to selling products.

Interface, a company for manufacturing carpets and textiles engages 7300 employees in 26 factories in four continents. This company produces synthetic carpets and fabrics in the value of one million pounds every day, using as raw oil products. Instead of the supplier, Interface has become a service provider, so they stopped selling carpets and started leasing. At the end of cycle use, the carpet is returned to the company, which it is used again, reducing the net use of petroleum products. Today the company has focused on: waste eliminating, emissions reducing, the full closure of the cycle production-use-recycle using completely recycled materials, use of recycled polyester whenever possible, finding new materials that are not based on petroleum products.

In the above examples of leading companies can be identified two critical types of activities required for sustainable development: firstly, a different approach to business creating new vision and technological maps, secondly, the conversion the vision through innovation in the management of technology, by the new interdisciplinary efforts.

Successful companies are introducing new technology management systems, which are:

- low tolerance, focused on the use of developmental systems that provide ample opportunity and flexibility to use the most powerful resources,
- resource-rich, with many different types of inter-related resources,
- to learning-oriented in terms of new business and technology interaction, linking technology and business goals on the path of sustainable development.

From this it can be make a clearly difference compared to traditional approaches, which do not provide all the necessary elements for achieving success in sustainable development, i.e. and fault tolerance, and a wealth of resources and continuous learning.

Moving DuPont and Monsanto to the application of biotechnological achievements in their agricultural enterprises was not based on the conventional way of thinking. Their competitive advantage in agro biotechnology is based on innovative technology and innovative approach to various business issues. Their traditional way of response to customer needs has changed significantly. In the new conditions it was important to listen to causes of the needs of customers and to find technological solutions to respond to them. Models of thinking and planning systems that have functioned well in meeting the needs of

customers in the traditional way were too limited in the creation of biotechnology to meet the fundamentally different business requirements of sustainable development.

The formation and development of innovative vision requires a structured approach, which should consist of the following elements:

- the new decision,
- new people and thinking,
- new talks,
- new enthusiasm,
- new perspectives,
- new prototypes and models of learning and
- new knowledge networks.

A new vision occurs over time, not at one time. When a company identifies opportunities and threats in the environment, the time of their appearance and accordingly develop a vision, unavoidably is introduction of appropriate technology. This crystallizes the second element of sustainable development innovation: an creative technology management process.

Judging by the experience of leading companies, sustainable development initiatives generally require technological expertise from new perspectives and new levels of interdisciplinary collaboration. Today the product development cycle is significantly shortened, there are many products in the field of technology development, which requires a combination of traditional and existing systems. The traditional approach to managing technology and current resources can not provide sufficient technological “scope“, i.e. technological capabilities, systems, personnel and organizations, as well as interdisciplinary opportunities to fully realize the new vision (e.g. a revolutionary technology). Thus, the approach to sustainable development by DuPont and Monsanto means significant new capabilities in bioengineering and their joining with existing technology and scientific knowledge.

On the examples of leaders in sustainable development, and simultaneously the fastest growing and most innovative companies, such as Boeing, Cisco, Microsoft, can be observed a combination of benefits of existing technical and technological resources, speeding up product development and exploitation of new resources in achieving competitive advantage. These companies have taken advantage of external resources in the formation of broad-bandwidth innovation - BBI network. BBI network use the power of resources through partnerships, licensing agreements and capital in systematically products developing and innovations creating coming out of the internal framework of technology and resource base control.

Their main feature is the introduction of non-traditional entities such as:

- *“Incubators* – small, inexpensive breeding grounds for start-up companies that provide new technologies and business approaches. They operate independently and provide continuous streams of new ideas and technologies.
- *Universities* – university-based R&D centres provide excellent intellectual capital.
- *Internal technology management at other companies* – other companies can provide allied R&D, marketing, and other innovation resources that work with the BBI network in selected areas to capture value, direct programs, and cross-fertilize.
- *Venture capital* – technology innovation also requires dealmakers that look far and wide (inside and outside the formal BBI) and that can pull together the best deals. Equity partnerships are an excellent way to gain access to technology without applying internal resources” (Shelton, 1998).

Participation in the BBI provides to companies a number of benefits in addition to the obvious expansion of resources. Their new focus on “deal flow” provides several important moments in innovation:

- focus on business opportunities associated with technological improvements,
- strengthening the technical and scientific capabilities, supported by various participants sharing thoughts,
- better understanding of market and customer needs and the use of prototypes, experiments and models,

- greater sharing of risk and significantly improved access to investment funds at the stage of research, development and commercialization,
- significantly increase the flow of technological knowledge at low cost and administration immanent to traditional internal development.

The use of dynamic models or prototypes include a large number of participants in sharing the vision during the innovation process. For example, radical improvements in the development of Boeing 777 aircraft were made possible by introducing electronic prototyping in which suppliers, project engineering teams and customers simultaneously working to improve the design. This resulted in significant improvements, innovation and dramatically reduced time to commercialization.

4. CONCLUSION

In the contemporary business conditions, radical technological changes represent one of the prerequisites of sustainable development at global level. Development and application of environmentally sound technologies that contribute to the transformation of unsustainable models of production and consumption in a sustainable model of growth and development are becoming of crucial importance for the simultaneous achievement of key aspects of sustainable development. However, the application of environmentally sound technology is not limited to the implementation of cleaner production processes, but it involves also the application of such technologies which perform the evaluation and monitoring the environmental impacts of economic activities, technologies for pollution prevention and remediation of caused damage.

With the institutionalization of the concept of sustainable development at the global level was set up the request to the companies that in order to preserve their reputation and survival in the market take the necessary measures to reshape their relationship to the environment so that the objectives of sustainable growth and development have become feasible. In this context, many companies have begun with the innovation of the technological process of production, introducing new technologies into the business that are consistent with the principles of sustainable development.

It is necessary to distinguish between two types of technological innovation. First, incremental innovations, that are oriented towards cost enhancements or changes the performances in available processes, products or services, and which are characterized by lesser continually modifications in the processes or products. Second, radical innovations, that are oriented towards creation of the entirely new processes, products or services, which posses enormous potential for introducing the radical transformations in the structure of industry and which generate the appearance of the new branches as a dynamic sources of sustainable growth and development.

Experience of leading companies indicates two critical types of activities needed to ensure the proper approach to sustainable development: the creation of new visions and technological map, and convert the vision through innovation in the management of technology, aided by new interdisciplinary efforts. Thus, sustainable development initiatives generally require technological expertise from new perspectives, as well as the new levels of interdisciplinary collaboration.

Abstract: *This paper briefly describes activities connected to the campaign “Attention(!) to the Environment” – in Slovene: “Pozor(!)ni za okolje”. The campaign was initiated and sponsored by Goodyear Dunlop Sava Tires company. The goal of the campaign is to promote environmental awareness and particularly waste separation among secondary school students in the Gorenjska region (Northwestern Slovenia). The campaign was conducted for the first time in school year 2010/11 and repeated in 2011/12. The core of the campaign is a competition between schools in cleaning up municipal waste separately. However, the entire campaign included many other activities such as lectures and excursions as well as opening a Facebook page related to the environmental issue. During the course of the campaign a survey has also been conducted among the students. The survey consisted of questions asking students about their views on the environmental problems, waste treatment and particularly about their practice of waste collection at their homes and schools. The paper is particularly concerned with the presentation of the survey results.*

Keywords: *municipal waste, separate collection, secondary school students, environmental protection, reduced deposition of waste*

1. INTRODUCTION

In the transitional countries, which either became members of European Union (EU) a few years ago or they are approaching to the EU, separation of municipal waste on the source of origin has usually not very long tradition. Separate collection of municipal waste cannot be successfully performed without active collaboration of citizens. The adaptation of citizens to new waste collecting system is often connected with certain difficulties. Both motivation and information are important. At first citizens should be adequately motivated to put effort in waste separation. However, they must also have adequate knowledge that they are capable to separate waste correctly. Older people, even when they are very conscientious often have difficulties to change their long-standing habits in waste treatment. Younger people, of course, are more susceptible to changes. Therefore, it is of particular importance to invest effort in education of younger generations. There can be found many interesting and innovative approaches to education of young people on the field of responsible waste treatment in the literature (Asmatulu & Asmatulu, 2011; Harris & Probert, 2009; Kaplowitz et al., 2009; Kelly et al., 2006; Petrović & Milićević, 2006). When considering the situation in Slovenia, educational programmes for responsible waste treatment in elementary schools are well organized and effective but it seems that there exist certain possibilities to improve this field in secondary schools. In this paper a campaign entitled “Attention(!) to the Environment” is briefly presented. The goal of this campaign was promotion of municipal waste separation and improvement of environmental care among secondary school students.

2. SOME ASPECTS OF THE CAMPAIGN “ATTENTION(!) TO THE ENVIRONMENT”

The company Goodyear Dunlop Sava Tires is a company belonging to the Goodyear Group. This company is noted for investing great effort in the responsible relation to the environment which is particularly in this branch (tires production) not easy task at all. Following the policy of Goodyear corporation, they have achieved excellent results as in the last years they have extremely reduced quantities of the waste. However, Goodyear Dunlop Sava Tires would like to do something more for the improvement of environment in the region – they have decided to initiate and support also the environmental activities which are not directly connected with their production. Due to the reason mentioned above the campaign entitled “Attention(!) to the Environment” (in Slovenian “Pozor(!)ni za okolje”) has the purpose to improve the environmental consciousness of secondary school students. The campaign was performed in the Gorenjska region in the Northwestern Slovenia. The goal was that all

secondary schools from the region would participate. Nevertheless, in the school year 2010/11 the action was limited to the municipalities of Kranj and Škofja Loka. However, in the school year 2011/12 all of the secondary schools from the Gorenjska region actually participate in the campaign.

Besides secondary schools and Goodyear Dunlop Sava Tires company the partners in campaign were also all the municipalities from which derive secondary schools (Municipality of Kranj, Municipality of Škofja Loka, in 2011/12 also Municipality of Jesenice and Municipality of Radovljica), companies for municipal waste treatment and recycling, Institute of Public Health Kranj and Faculty of Organizational Sciences from the University of Maribor.

As mentioned, the campaign had goal to improve the environmental consciousness of students but it was particularly targeted in separate collection of municipal waste. The campaign included various activities as are lectures about various aspects of waste (economic waste management, waste and production, hazardous waste) and excursions. Modern and popular ways of communication like internet and facebook were used for the information of students about the campaign. However, the core of action was competition of secondary schools in separated collection of waste. Into this purpose a special commission was constituted. This commission consisted of students, professors and professionals from waste treatment companies, Institute for Public Health and Goodyear Dunlop Sava Tires. In the course of competition commission visited every school four times and during these visits which were not announced previously, bins and containers at every school were checked and the quality of waste separation assessed.

The part of the campaign was also the research about the relation of the students to the waste treatment and separated collection of municipal waste. The research was performed by a survey which was performed in two circles. The first circle was performed in September 2010, before the main part of the campaign (competition in waste separation). The second circle of the survey was performed in December 2010, after closing of the competition in waste separation. The results of the first circle of this survey are briefly presented in the continuation of this paper

3. CHARACTERISTIC FEATURES OF SURVEY

Survey consisted of 22 questions which were divided into five groups. All questions except one were of closed type offering one to five answers. The first group of questions was concerned with identification data (sex, type of secondary school, year of study). The second group of questions was related to the environmental awareness of student and their colleagues as well as their opinion about waste and separate collection. The third group contained more concrete questions regarding everyday practice of students in waste handling at their homes and the fourth group similar questions about waste handling at schools. The fifth group includes three questions which were like those in the second group concerned with student's personal view on the environmental issue.

The scope of inquiry was to get information about the relationship of secondary school students' population to the environmental issue and particularly to the separate collection of waste. It is expected that main obstacles for separate collection of waste can be recognized from the answers. This information can be helpful in searching possibility to improve the system and increase the efficiency of waste separation.

Survey was realized via internet with the open source tool Limesurvey (www.limesurvey.org) installed on swqlab.fov.uni-mb.si. Answers to survey provided students of seven secondary schools in Kranj and Škofja Loka. Total number of completed survey was 1617. This number presents a considerable part of secondary school students in Gorenjska region and therefore collected data have some statistical value. In the present paper due to lack of space some basic characteristics of answers are discussed only. Deeper analysis including statistical treatment of collected data has still to be done.

4. RESULTS OF INQUIRY

The first circle of inquiry resulted in 1617 answered inquiries. The profile of students' population was about 74% male and 26% female and relation of grammar school to the other types of secondary school was practically 50% - 50%. The greatest part of students was from the first class 41%, 21 % of students were from the second, 16% from the third and 22% from the fourth class.

Students opinion about waste and waste separation

As mentioned above the first part of inquiry (questions 4 to 9) was concerned with the students' relation to the environmental issue, waste and waste separation. All these questions were of closed type. There was only one possible answer except by the questions 8 and 9 where students were able to choose more answers. When students were asked about environmental awareness of their colleagues (Question 4) about 4 % rate it as very high, 19% as high, 60% as medium, 14% as low and 4% as very low.

The relationship of their colleagues to waste treatment (Question 5) was from the greatest part of students estimated as satisfactory (48%), 26% of students estimate it as good, 18 % as unsatisfactory and similar number (about 4%) as very good or very unsatisfactory.

Question 6 was "What kind of association you have at the word waste?" The majority of students (54 %) describe the waste as something that they would like to get rid of; 24% of students designated waste as something that has influence on the environment, 7% as a possible source of secondary raw materials, 3% as something which causes expenses and 8% do not think over waste at all. Question 7 asked students about their relationship to the separate collection of municipal waste. 58 % of students believe that separate collection is absolutely necessary, 12 % contrary believe that it is not important. 11% of students will separate waste when other people would do so, 9% think that separate collection is duty of municipal services and 8% do not think at all about separate collection.

Question 8 was about the responsibility for separate collection of waste (more answers were possible). The majority (75 %) of students are aware that everyone is responsible for waste separation, 38 % think that this is duty of municipal service, 30 % think that state and 18 % that local community is responsible for waste separation. 4% of students do not care about this. Question 9 asked about main advantages of separated collection (more possible answers). Saving of natural resources seems the most important advantage (58%), 51 % think that separate collection is important because of adequate treatment of hazardous waste, 33 % because of energy saving and 32% because of prolongation of landfill lifetime. 3% do not see any advantage in separate collection.

Waste separation in households

Third part of survey (questions 10 to 14) asked students about waste treatment at their homes i.e. in households where they live. Question 10 was concerned with the waste treatment at home and there was possible to select more answers. More than three fourth (77%) answered that they separate individual fractions (paper, glass, metal and plastic package, biological waste), 10% answered that they burn waste, 14% put all kinds of waste in the container for mixed waste and 27 % emit bulky waste in the case of collecting actions.

When students were asked to estimate the mass of waste produced daily per capita in their households (question 11) 40% could not decide for any answer, 5% do not care about this, 26 % think that mass is less than 1 kg, 23% between 1 kg and 2 kg and 5% more than 2 kg. Question 12 was concerned with the frequency of separate collection of individual fractions of waste. Answers are shown in Table 1.

Table 1: Answers on the question about frequency of separate collection of individual fractions of waste in households.

Fraction	always	often	rarely	never
Paper	63%	22%	8%	6%
Glass	58%	23%	13%	7%
Plastic bottles	57%	27%	10%	6%
Cans	47%	28%	17%	8%
Package	50%	28%	14%	8%
Biological waste	55%	23%	13%	8%

79% of students believe (question 13) that separately collected fractions are actually delivered into recycling process, meanwhile 21% think that separately collected fractions are mixed and deposited on landfill. Question 14 considered treatment of hazardous waste. 35% of students answered that they keep hazardous waste separately and emit them during the course of collecting action, 25% bring them in the collecting centre, 8% emit hazardous waste together with the other waste, 5% throw them away or pour

them in the toilet, 17% do not know how they handle with hazardous waste and 10% did not answer this question.

Waste treatment in schools

The topic of fourth group of questions (questions 15 to 19) was waste treatment in schools. When were asked about waste treatment system in their school (question 15) 21 % of students estimate it as very good, 41% as good, 25% as satisfactory, 7% as bad and 6% as very bad. In question 16 students were asked about motivation for more conscientious separate collection (more answers were possible). 34% of students answered that a greater number of waste baskets for separate collection would motivate them and 32% would like to contribute to cleaner school. More rigorous survey by teachers would motivate 9% of students meanwhile 17% answered that they could not be motivated by anything. 7% of students answered that some other things could stimulate them.

The greatest part of students (49 %) were informed about changes in waste collection system in school (question 17) when they had observed waste baskets for separate collection, 22% had got information from teachers, 3 % from other students. 7% heard announcement by loudspeakers, 3% read from the posters and only 2% were informed from the school webpage. 14% of students answered that they do not know anything about these changes. Question 18 was exception as it was of open type. Students were asked about proposals to improve their relationship to the separate waste collection in schools. 99% of students answered the question. However, because lack of space these answers cannot be discussed in the present paper. When separate collection would be successfully introduced schools can considerably lower expenses of waste treatment. Students were asked into which purpose the saved money should be used. 40% would like to use this money for excursion, 20% for educational purposes, 16% for cultural events (concerts), 15% for sport competitions and 7% for some other purposes.

Final questions

The last three questions (20-22) were like those in the first part more oriented to some general aspects of waste treatment. In question 20 students were asked about the possibility of pollution reduction with the change of habits. The majority (71%) answered that this is possible with separate collection of waste and recycling, 16% think that waste formation prevention is the most important and 3% favour waste incineration, 1% decided for some other ways. 4% think that decrease of pollution with the change of habits is not possible and 3% do not care about this.

In question 21 students were asked how they personally contribute to less polluted environment (more answers were possible). The majority of students (65%) collect the waste separately, 30% try to prevent waste formation, 20 % use paper bags or bags for repeated use, 21% cooperate in cleaning actions, 1% of students contribute in some other ways and 7% do not contribute in any way. The last question (22) asked students to estimate their personal environmental awareness. 12 % of students rate it as very high, 48% as high, 35 % as medium, 4% as low and 1 % as very low.

5. DISCUSSION

As mentioned earlier deeper analysis of the data collected during the inquiry will be performed later. The present paper brings only brief discussion of answers. It is interesting to compare the students' estimations about their own environmental awareness and environmental awareness of their colleagues. Results are graphically shown in Figure 1. It can be clearly observed that students have some better opinion about their own awareness than about awareness of their colleagues.

Figure 1: Evaluation of environmental awareness of students – 1 for their personal environmental awareness, 2 for environmental awareness of their colleagues. Marks: 1 – very low, 2 – low, 3 – medium, 4 – high, 5 – very high.

More than one half (58%) of students believe that separate collection of waste is necessary and 75% of them think that everyone can contribute to separate collection. More than one half (58%) of students think that separate collection is necessary because saving of natural resources, about one half (51%) because of adequate treatment of hazardous waste and one third believe that separate collection is important because of energy saving as well as because of landfills' life time prolongation. More than three quarters of students collect waste separately at their homes. When were asked about particular fractions the answers show that situation is similar for various fractions – something better is for collection of paper waste meanwhile collection of cans is under the average. Answers regarding hazardous waste can be reason for certain preoccupation. 5% of students answered that they mix hazardous waste with other waste, 17% do not know how they treat hazardous waste and 10% did not answer this question.

The great majority of students are content with waste treatment system in their school as only 13 % estimated it as bad or very bad. It seems that disposition of waste baskets is very important as one third (34%) of students answered that greater number of waste baskets is the most important motivating factor for separate collection and about one half of students (49%) learned about changes in waste treatment system in school as they observed baskets for separate collection. About one fifth (22%) of students got information about separate collection from their teachers. It is interesting that very small 'part of students learned about changes in waste treatment system from posters or school's web page. It can be indicative that similar part of students answered that anything could not motivate them for separate waste collection (17%) and do not know anything about changes in waste treatment system in school (14%).

Almost three quarters of students (71%) believe that separate collection is the best way to decrease pollution meanwhile 16% mentioned waste formation prevention as the best solution. Relative small part of students thinks that it is not possible to reduce pollution with change of habits or is not interested about this problem. Besides separate collection students contribute to reduction of pollution with waste formation prevention (30%), collaboration in cleaning actions (21%) or with the use of paper bags/bags for repeated use. Only 7% of students answered that do not contribute in any way to decrease of pollution.

6. CONCLUSION

The results of survey show that the majority of secondary school students are aware of significance of responsible relationship to the environment and adequate waste treatment. However, before making some conclusions the more detailed analysis and statistical interpretation of the results of survey should be done. Besides this during the competition in separated collection certain faultinesses of the waste treatment in schools as well as possibilities to improve the education system can be observed.

In the school year 2011/12 the campaign is taking part for the second time. As mentioned before, this year besides Kranj and Škofja Loka also the municipalities of Jesenice and Radovljica joined the campaign. The competition in waste separation has finished in April 2012 and inquiry started in the beginning of May 2012. It will be interesting to compare the results of competition as well as answers of inquiry for the year

2011/12 to those of the year 2010/11. In the case of such campaigns it is important that they are not taking place only once or twice but that they are organized continuously. The changes in everyday habits can be achieved only on long-term.

Abstract: *The subject of this work is exploring ways of traffic management by measuring the concentration of air pollution in urban areas. The goal of this research is to develop models of traffic management and air pollution. The method is based on 24-hour measurement of air pollution and connecting monitoring stations with Automatic Traffic Control System Centre. Based on the measuring results, signalling cycles are being activated in order to make a city traffic diversion. This way it is possible to manage air pollution in critical zones of the city and make traffic diversion to other city areas, which allows the air quality to be improved and within prescribed limits. Research Results show that in the case of Banja Luka the air quality has improved 60 minutes after the suspension of traffic in endangered areas (city centre). In order to maximize the effects of this method used for traffic management and air pollution control, it is necessary to define alternative city itineraries and conduct a population education program in time. The results of this research can be useful for companies engaged in manufacturing specialized traffic management software and also help them create new specialized software for air pollution control and forecast.*

Key words: air pollution, traffic management, air quality, pollutant measurements, SAUS, APVJGP

1. INTRODUCTION

Economy, technology and car industry development caused the increased number of vehicles in urban areas. Environmental problems in urban areas of today are numerous, causing very serious health problems and influencing the psychology of urban living. In urban areas, such as Banja Luka City, one of the main problems is undeveloped infrastructure. The Banja Luka City has no roundabout. Two transit roads pass through the city causing the increase of the pollution. Technological aspect such as the structure of the city, taxi and vehicle traffic, type of vehicles, not implemented SAUS (System of Automated Traffic Management) and APVJGP (Automated Public Transport Surveillance) systems, partial air pollution measurement, bad traffic infrastructure (no separate lines for taxi and public transport) and finally climate and meteorological factors, have direct influence on air pollution.

Small traffic infrastructure and fairly old vehicles are just some of the elements causing the increased air pollution in the city. Air pollution is also caused by certain type of vehicles, in our case vehicles that are 15.7 years old (Euro 2 Standard), (Statistics IDDEEA (2010)). The end result is ecology problems caused by increased pollution due to stop/go traffic waves and increased traffic during morning and afternoon rush hours. In order to solve the problem two possible solutions can be applied. The first is to set a traffic restriction which is not very popular solution for decreasing the air pollution in urban areas and traffic jams. The second is the method of traffic and air pollution control.

2. MANAGEMENT METHODOLOGY

Air quality level in urban areas is determined by different geographical, climate, meteorological and other factors (Knezevic, et al, 2008, 2009). Currently, the level of air quality in Banja Luka City does not match health requirements, i.e. pollution has negative impact on its population. In general, measuring results of air quality in past 3 years indicate Second Class of air quality in Banja Luka City area. Monitoring took place in 4 spots. Measuring results relating to pollution in the city centre (5th measuring spot) and measuring results relating to the pollution on no traffic day (Jankovic, et al, 2010, Knezevic, et al, 2008, 2009), show that the air quality keeps in range from Class I to Class IV., depending from the type of pollutant.

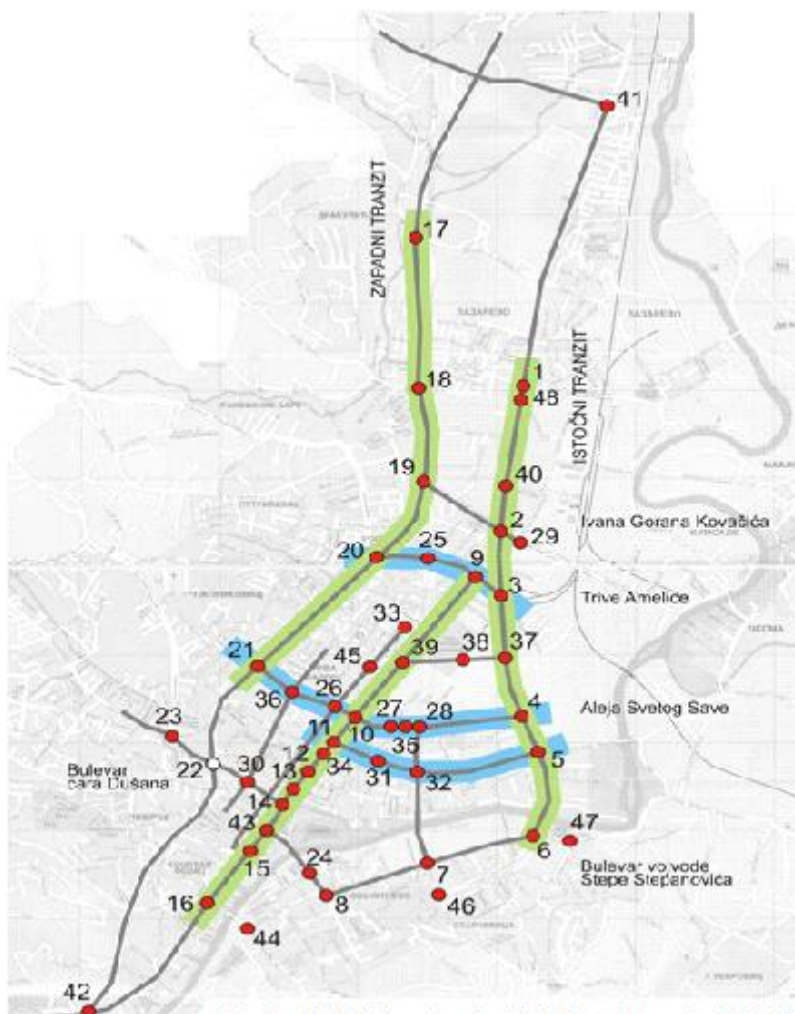

In order to apply the suggested methodology of traffic and pollution control, following actions are to be made:

- To install cable distribution system (DKR) throughout the city
- To integrate SAUS and APVJGP system

- To make a laboratory network for measuring the presence of each pollutant
- To install ArcGIS™ ESRI (Win/), Gis software-SelmaGIS
- To make professional teams for implementation of suggested actions
- To provide population education

3. THE ELEMENTS MODEL

DKR - Cable Distribution System represents an infrastructure system for data transfer and system management. This is very important issue because it also allows other elements of the system such as air pollution measuring units, air pollution street display etc., to be connected to data transfer system. For optical cable net (DKR), it is necessary to foresee a huge system which includes safety connections i.e. allows the system to function without the interruption.

Scheme 1: DKR - Cable Distribution System

The idea is to make the system work 24 per 7 and 365 days a year on online basis. Operating system must support audio or video data transfer i.e. alfa numeric information or services. It is of crucial importance to have this kind of system because it will allow the connection to the pollution monitoring network and sending information on current air pollution to street displays. In order to have emediate acces to all relevant dat, SAUS system also must provide complete database of traffic and air pollution information as well as information on the other services.

SAUS system provides both location and graphic network preview i.e. georeference vector map of urban area including georeference chart of crossroads controlled by traffic light, parking and public garage area, street cabinets with active and passive equipment, street displays, pollution measuring units on video wall.

A very important element of SAUS system is video surveillance of crossroads controlled by traffic lights and the detection. On specific locations it is necessary to install video cameras in order to achieve the following:

- Traffic and crossroad surveillance
- Driving direction of the vehicle detection (in case of driving wrong direction)
- Approaching of the vehicle detection
- Traffic jams detection
- Vehicle numbering
- Classification of numbered vehicles (it is the key element for pollution preview and the classification of pollutants is being done by Selma^{GIS} software)
- Lost cargo on the road detection
- Cross road and pedestrian surveillance

Video detection system provides detailed statistics for all required functions of detection cameras. It provides daily, weekly, monthly, quartal, 6-month and annual reports. All of this applies to air pollution statistics by pollutants). SAUS system architecture preview is given on Scheme 2.

SAUS system is advanced architectural information system for automatic traffic management (Scheme 2), that supports the following:

- reception, digitalisation and video formatting of the signal including the storage of all data related to video system and other peripheral elements such as temperature, air humidity and pollution level
- Broadcasting
- Data storage
- Client applications for video surveillance and system for independent diagnosis and maintenance

Monitoring and pollution measurement network consists of mobile EcoLabs that should be set on specific locations. Locations are determined based on traffic frequency i.e. spots with crowded streets and dense traffic during rush hours, when people are going to or coming back from work.

Monitoring and pollution measurement network is second phase in technical and organisational realisation of the model. Immediately after the realisation of SAUS system it is necessary to provide traffic counts on all crossroads and in a few iterations in order to get the exact figures of number of vehicles per hour or number of vehicles per crossroad. This will help define EcoLab locations for measuring of the pollution. (Soldatovic, 2010).

Measuring Lab - APNA 370E, (APNA 370E, HORIBA, 2012) has been used for continuous monitoring of atmospheric NO, NO₂ and NO_x. APNA-370 was selected because it uses an independent, internal dry-method to achieve the highest levels of sensitivity and accuracy. The dry method has been a preferred method for monitoring the atmospheric pollution, due to its minimal maintenance requirements and capability of continuous monitoring and instantaneous analysis of gas in its unaltered state. The APNA-370 uses a combination of the dual cross flow modulation type chemiluminescence principle and the referential calculation method. This gives it the advantages of the single-detector method plus the ability of continuous measurements of NO_x, NO, and NO₂. The design gives great stability and extremely high sensitivity (0.1 ppm F.S.)

APNA 370E is single rack-sized unit. For measuring of other pollutants such as CO, SO₂, O₃, LČ, ULČ, smoke and dust it is possible to connect mobile labs with the system. LED panels are to be installed on city entrance and other city locations displaying different information but with its main purpose to inform the population about the level of the pollution (especially NO_x). LED panels are set on city entrances in order to give the information related to city traffic such as traffic jams, car accidents, directions, speed limit warnings, temperature (T °C), air humidity (rH %), air pressure (mb), etc. LED panels are matrix colour displays with 20 mm pixel distance which are resistant to moisture and other weather and climate factors. (Soldatovic, 2010). ArcGISTM ESRI (Win/), GIS software-Selma^{GIS}

One of the most important elements of the model is the implementation of Selma^{GIS} software for graphic preview of pollutant emission on defined locations with mobile EcoLabs. Selma^{GIS} software is modular

software supported by ArcMap™ as a part of ArcGIS™ ESRI information system Windows based SelmaGIS,(2012). User interface is Windows compatible and consists of:

- Emission Factory/Emission Database
- Digitizing Tool
- Meteorology Factory
- Terrain Factory
- AUSTAL2000

Figures for pollution emissions for each pollutant (NO_2 , NO_x , PM_{10} etc.) in selected street can be obtained from Emission Factory SelmaGIS model. The system is used to determine pollutant dispersion in different seasons, vehicle structure which causes airpollution and meteorological conditions, type of source of airpollution (point sources: industries, energy production and heating industry), line sources (streets), diffuse sources (private heating, industries / energy production etc.). *AUSTAL2000* allows up to 300 x 300 grid points in the horizontal direction, i.e. the grid solution for simulation of region 25km x 25km.

Additionally AUSTAL2000 needs as physiographic parameters

- the topography height
- the aerodynamic roughness of the surrounding
- building information (building contours and building height)

AUSTAL2000 can treat the dispersion of the following gases: SO_2 , NO , NO_2 , NO_x (given as NO_2), Benzene, Chloroethane, Hydrogen Fluoride (given as F), NH_3 , Hg

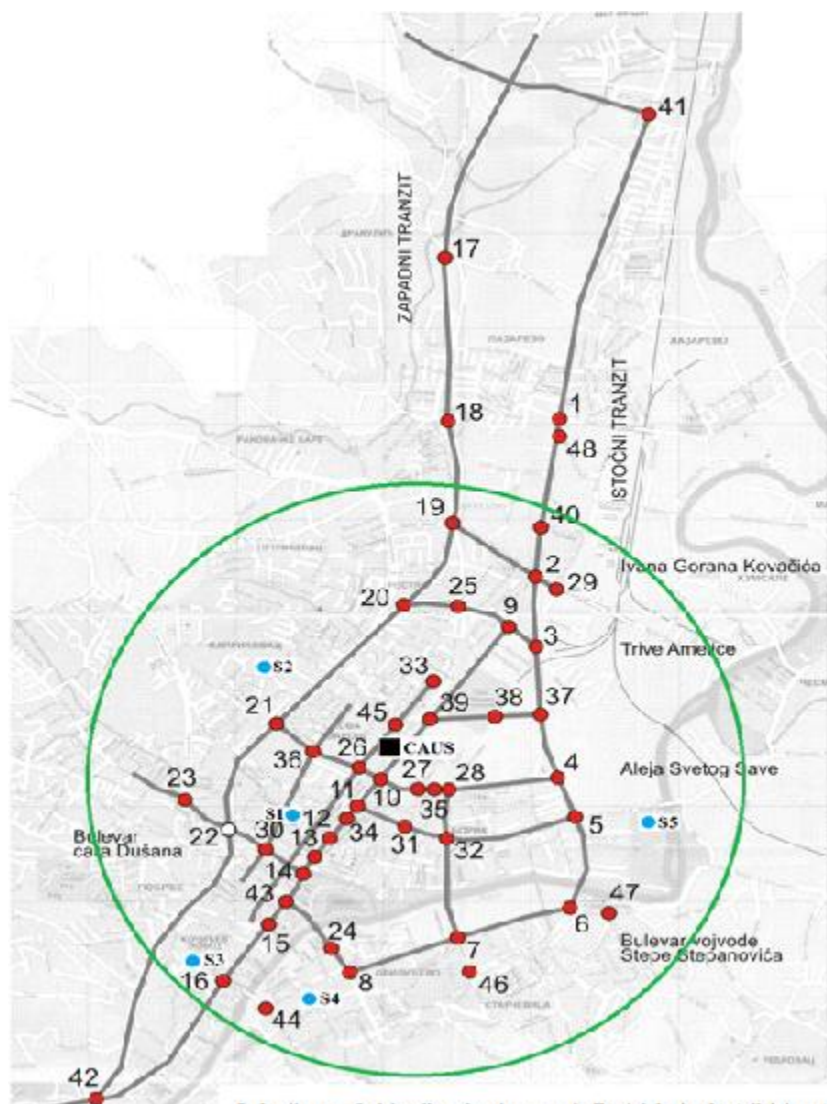

Meteorological conditions in defined area – When defining the model it is necessary to take into the account following meteorological conditions:

- Relative air humidity, (rH %);
- Air pressure, (mb);
- Wind roses, (direction, wind speed);
- Temperature, ($^{\circ}\text{C}$)

Above given parameters are being taken from Hydrometeorological Institute of Republic of Srpska and have a great impact to pollutant emissions (Jankovic, et al, 2010, Knezevic, et al, 2008, 2009). New public transport schedule, parking policy and raising the level of conscience of public transport users are of crucial importance for decreasing the air pollution up to 20%, in case of respecting public transport schedules. Constant reminding and education of the population allows rising of the level of their conscience and reducing the health problems caused by the pollution and increasing the percentage of using bicycle as a mean of transportation. New public transport schedule supported by SAUS has advantages such as pollution decrease, creating the pedestrian zones in the city centre and displacing parking areas out of the city centre to other urban areas. In order to finalize new public transport schedule it is necessary to change the old vehicles that are using liquid oil gas with new ones and, if possible, implement subway, tram or trolleybus transport system. The right means of transport should be implemented depending on the configuration of urban area and the financial resources and it is to be decided by the traffic performance study.

4. URBAN TRAFFIC MANAGEMENT BASED ON MEASURING AIR POLLUTION LEVEL

The method is based on air pollution 24-hour measurement and connecting monitoring stations with SAUS. (Scheme 2). Based on measuring results, signaling cycles are being activated in order to make city traffic diversion. This way it is possible to manage air pollution in critical zones of the city and make traffic diversion to other city areas, which allows the air quality to be improved and within prescribed limits. This method allows the implementation of automatic zero-zone i.e. no traffic zone in specific period of time.

Scheme 2: Traffic Management Model

The level of air quality in urban areas is determined by different geographical, climate, meteorological and other factors (Knezevic, et al, 2008, 2009). Currently, the level of air quality in Banja Luka City does not match health requirements, i.e. pollution has negative impact on its population. In general, measuring results of air quality in past 3 years indicate Second Air Quality Class in Banja Luka City. Monitoring took place in 4 spots. Measuring results for city centre (5th measuring spot) and measuring results in during no traffic day (Jankovic, et al, 2010, Knezevic, et al, 2008, 2009), show that the air quality keeps in range from Class I to Class IV., depending from the type of pollutant.

Example: Bus line 14-9. This bus line covers the city center. As soon as pollution reaches its critical level with nitrogen dioxide concentration in the air, the SAUS system is to suspend bus lines 14-9 relocating the traffic to bus lines 14, 30, 22, 21, 20, 19 and 2. The measuring station (S3) that covers this line and city center is within SAUS system. Bus lines 21, 36, 26, 10, 27, 35, 28, 11, 31, 32 i 20, 25, 9, 3 would be suspended automatically and the traffic would be reallocated to bus lines 19, 2, 9 and to transit road lines , 2, 3, 37, 4, 5, 6, 7, 8, 24, 43, 15, 16, 42. City center would be covered only with city and taxi transport.

This was just a sample of city traffic organized based on pollution measurement results given by S1 station. Combining other measuring stations S2-S5 it is possible to make even more alternative itineraries depending on pollution level results. The most important element of traffic management is the infrastructure adjustment of city network necessary for alternative itineraries and pictogram plan for traffic

allocation. Before the system is put into the function it is planned to conduct education campaigns in cooperation with the Ministry of Internal Affairs.

Measuring results on No Traffic Day (Scheme 3) and the day after (Scheme 4) during the period from September 22 to September 23, 2010

Scheme 3: Results of measurements of nitrogen oxides in the day without traffic

Scheme 4: Results of measurements of nitrogen oxides in the day with active transport

Years are determining second class of the air (Table 1). Taking into the consideration air pollution measuring hypothesis, measurements were done on the most frequent street in the Banja Luka City Center. Constant measurements are being done even during days with no traffic and in a specific period of time.

Table 1: Air Quality Classification

Pollutant Concentration in $\mu\text{g}/\text{m}^3$	Air Quality Class			
	Air Class 1 (low air pollution, relatively clear air)	Air Class 2 (risk zone)	Air Class 3 (high level risk zone)	Air Class 4 (critical zone)
SO ₂ (Sulfur Dioxide)	Up to 30	30 - 50	50 - 100	> 100
NO ₂ (Nitrogen Dioxide)	Up to 30	30 - 40	40 - 80	> 80
CO (Carbon Monoxid)	Up to 1000	1000 - 2000	2000 - 4000	> 4000
Black smoke or soot	Up to 20	20 - 40	40 - 60	> 60

Measurements being done on the day with no traffic and the day after with active traffic during the period from September 22 to September 23, 2010 (Jankovic, et al, 2010) gave results as given in Table 1). Decrease of pollutants has been noticed during 2 hour period (10-minute measurements in 2010), especially nitrogen oxides. The values are double during the period with regular traffic. Scheme 4 and 5.

First Measuring Day took place on 22/09/2010 and it was the day with no traffic. An average NO_2 concentration during the measuring period was $28.232 \mu\text{g}/\text{m}^3$. When comparing an active traffic and no traffic period the decrease of an average NO_2 concentration in the air was evident.

During 2-hour measuring period (no traffic period on 22/09/2010, 1100-1300) First Air Class was reached (zone of pollution border value with an average of $28.2325 \mu\text{g}/\text{m}^3$) with low polluted air, i.e. clean air. NO_2 concentration during a no traffic period was within both target and border value according to the Regulations of Border Air Quality Value (Knezevic, et al, 2008, 2009).

Second Measuring Day took place on 23/09/2010 and it was the day of active traffic. An average NO_2 concentration during the measuring period was $45.282 \mu\text{g}/\text{m}^3$, maximum NO_2 concentration value $63.878 \mu\text{g}/\text{m}^3$. Based on the Decision of Pollution Air Protection in Banja Luka City (Knezevic, et al, 2008, 2009), the air quality can be classified according to the following criteria: During 2-hour measuring period (period of active traffic on 23/09/2010, 1100-1300) 3rd Class - High risk zone (Jankovic, et al, 2010).

It is obvious that dense traffic in Banja Luka City Centre influences the air quality, which confirms NO_2 pollutant concentration during no traffic day measuring period. If we take a look at the graph with active traffic period results we can see that there is a significant increase of pollution with NO_2 . The significant increase of pollutants is noticed even with other air pollutants.

If we make data crossing of time periods (with and without traffic, scheme 5) we can see that just after 60 minutes the air quality increases i.e.

Scheme 5: Crossed data measurements with and without traffic

This 60 minute period is a turning point when the air quality i.e. Nitrogen oxide NO_2 concentration level increases or decreases. Just after 60 minutes the air quality decreases to 2nd class. If we take into the consideration the fact that rush hours in Banja Luka City are between 07:00 and 08:00 and between 15:30 and 17:00, we can be safe to say that it is possible to manage air pollution efficiently both in the City Centre and other city locations, because the traffic infrastructure makes it possible. The highest level of air pollution was spotted in rush hour period between 15:30 and 17:00, when in short period of time large number of vehicles were on the streets. From the transportation aspect, it is necessary to coordinate

alternative routes for vehicles. However standard itineraries for public and taxi transport would have stayed unchanged. In the Automatic Traffic Control System Center special itineraries would activate after the critical point, i.e. alternative lines for traffic redirection from the critical zone.

6. CONCLUSION

It is not completely possible to eliminate the air pollution in urban areas. However, it is possible to control it using air pollution measuring stations i.e. allocate polluted air throughout the city. With a support of networked measuring stations it is possible to make pedestrian zones (automatic pedestrian zone) between 1700 and 2400. This way the air quality could be improved to 1st class.

The air quality is determined by measuring results and its comparison to the standard, which helps define certain aims and take necessary steps such as:

1. Protection rate activation in critical situations (total traffic suspension using CAUS System, defining of pedestrian zone and Ecopass zone)
2. Population health risk estimation (traffic suspension)
3. Procurement of basic data for town planning (traffic infrastructure and itinerary planning)
4. Audit of citizen complaints on air pollution

Basically, air quality results taken on 5 different locations in past 3 years show that the air in Banja Luka City is of 2nd class. If we take into the consideration measuring results in S3 centre and the results on no traffic day (22/09/2010), the air quality vary from 1st to 4th class (Jankovic, et al, 2010) depending on the type of pollutant. Finally, the results of the study show that it is possible to manage and control air pollution in urban areas.

Actions that can be taken in order to support these activities and help manage air pollution are closure of parking facilities in the city centre and supporting public and taxi transportation using price policies. Currently, the parking fee in the city centre is at least 5 to 6 times higher than in other city zones and restrictions on buses to remain in city centre other except on bus stations). Quality town management enables lower fuel consumption which decreases the pollution. The reason for that is that less time would be spent in searching for available parking space. Updated information on available parking spaces on public parking lots and public garages would be presented on crossroad displays and the data would be sent by Automatic Traffic Control System Centre.

Based on measuring station network it is possible to make pedestrian zone between 17:00 and 24:00 (implementation of automatic pedestrian zone) and this way improve the air quality to the 1st level. Decreasing the traffic frequency in the city centre would help bus and taxi drivers to drive on schedule, which would also decrease air pollution.

A study allows surveillance and present reading of air quality with immediate traffic dispersion in urban area. Also, the study shows that diagnostic analyses and air quality measurement depends on meteorological conditions. In this case, wind rose has a big influence as well.

THE ROLE OF INSTITUTIONAL STABILITY AND POLICY-MAKING PROCESSES IN SUSTAINABLE DEVELOPMENT: THE CASE OF ALBANIA

Viorela Polena,

Lecturer, Aleksander Moisiu University of Durrës, polenaviorela@gmail.com

Abstract :Political stability is considerably influenced by the institutional stability within a political system. Scholars and researchers agree on the fact that institutional stability has a considerable impact on the economic development of a country and the society as a whole. Nowadays, national and international institutions are putting emphasis on the sustainable development as an element accompanying the economic, social and environmental development.

Based on this premise, this paper is aimed at presenting the relationship between the institutions and the sustainable development concept in Albania during the post-communist period. The focus of the study is the analysis of institutional stability as an important indicator in the framework of democratization processes focusing on its role on sustainable development, when the latter is incorporated in the formulation of policies. By making use of qualitative and quantitative data of the last 20-year-period in Albania, this paper argues that the low level of institutional stability has produced gaps in the implementation of sustainable development in the social, environmental and economic systems, even though in terms of the policy-making outcomes this concept is considered as an essential element.

Key words: institutional stability, institutional logics, sustainable development, policy-making process.

1. INTRODUCTION

If we attempt to compare today's world with that of at least twenty years ago, the answer would definitely be "things" have changed; political regimes have changed, societies have changed, world economy has changed, etc. Change has affected the microsystems positively in some respects and negatively in some others. Many new concepts have emerged in the course of this transition process and one of them is definitely that of *sustainable development*.

In the framework of the academic research for providing rationales and background to this concept, different definitions for *sustainable development* emerged. In the first definition given by the report of World Commission on Environment and Development (1987), sustainable development is considered to be *the development that meets the needs of the present without compromising the ability of future generations to meet their own needs*. Besides the variety of definitions to this concept, its importance cannot be put into question. It has been widely incorporated as part of the policy-making processes by many actors such as: states, national and international organizations, associations, etc.

In the last two decades, some regions and especially the Balkan region has been characterized by fundamental political, economic and social changes. The later have provided the grounds for different future considerations of the political and economic systems. Albania is part of this group of countries. After the fall of the communist regime, it entered the difficult path of democratization processes which included the reorganization of the economy and the political system as well. What is more, these changes coincided with the appearance of sustainable development as a new concept. That is why, this paper focuses on the roles that institutions themselves have had on the sustainable development in Albania. The logic that the paper attempts to shed light on is the way in which institutions involved in the policy-making process shaped the sustainable development of this country in the aftermath of the communist regime.

Nowadays, a considerable part of the literature in developing countries has been focused mostly on the relationship between politics and the economy of a country. By doing so, they further analyze economic indicators such as GDP, investments, redistribution, etc. related to the political system, its institutions, or other political indicators. As such, the quality of institutions for example, has been studied in relation to economic growth (Polterovich & Popov, 2007) or they are considered as integral to the amount spent on both the costs of transactions and the costs of transformation in the production process (Aron, 2000). Furthermore, Mamoon and Murshed (2009) put emphasis on the role of education in improving the quality of institutions. On the other hand, other authors such as Persson (2002) try to answer the question if it is the political institutions the ones which shape the economic policy. So far, little has been done in analyzing the role of the institutions within a political system regarding sustainable development, and there is almost a gap in literature focusing on this topic in the Balkans and more specifically in Albania.

The paper continues as follows: first, it provides a theoretical background of the concept of sustainable development and of the institutions involved in the process of policy-making; second, it continues with some conceptual underpinnings; third, it provides evidence on how the former has been shaped by the latter during a twenty-year-period in Albania; and finally, it presents some conclusions with future consideration for research on this topic in Albania.

2. CONCEPTUAL UNDERPINNINGS

The concept of sustainable development, even though a recent one, has grabbed the attention of many scholars and researchers, and especially international organizations which are aimed at providing assistance and support to the underdeveloped and developing countries. As mentioned above, the concept appears first in the Brundtland Report, which gives the standard definition used thereafter, and according to the International Institute for Sustainable Development, *it involves the concept of needs, namely the essential needs of the world's poor, to which overriding priority should be given; and the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs*⁴⁰. The idea of needs and limitations brings about the importance of decisions. Since the main political actors in the present world are the states, these decisions should be seen more in the light of the state institutional framework. In dealing with situations of restrictions, needs and objectives to be reached through decisions, the World Bank provides us with a structured puzzle of how the needs and objectives should be taken in consideration during the decision-making process.

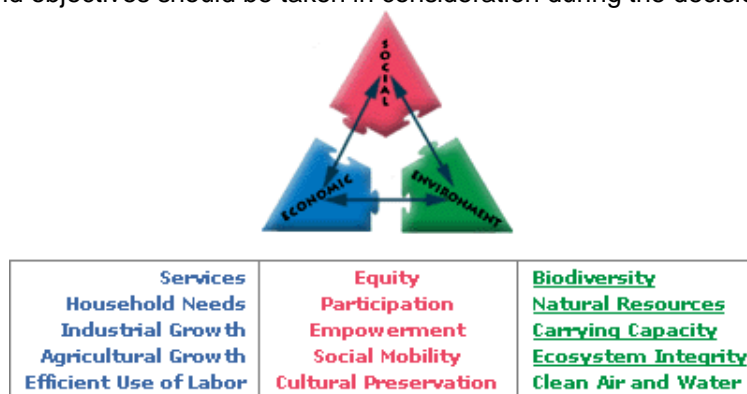

Figure 1. The puzzle diagram, Source: World Bank⁴¹

The concept of development involves the systematic interaction among the economic, social and environmental systems. However, these systems also represent the basic needs of the populations. Should there be put any priority on these needs? Kates, Parris and Leiserowitz, (2005) point out that in the Brundtland Report, *there were three quite distinct ideas about what should be developed: people, economy, and society*. A considerable part of the literature following the report has been mostly focused on the economic development since it is mostly in this system that outcomes are provided faster and the impact on the population can be measured much more easily. In the framework of such developments, a broader definition of it was provided by the Report of the World Summit on Sustainable Development (2002) which paved the way towards “a collective responsibility to advance and strengthen the interdependent and mutually reinforcing pillars of sustainable development—economic development, social development and environmental protection—at local, national, regional and global levels”.

As a result, the goal of sustainable development is to create and maintain prosperous social, economic, and ecological systems which are intimately linked: humanity depends on services of ecosystems for its wealth and security (Folke, Carpenter, Elmqvis, Gunderson, Holling, & Walker, 2002). At the core of these three pillars of the sustainable development, it is the other dimension, the institutions, which provide the input in feeding the other systems with outputs given in the form of decisions or policies. In pointing out the importance of institutions on the sustainable development of systems Gechev, points out *that the creation of an appropriate institutional framework is a necessary condition for the fulfillment of the criteria of sustainable development* (Gechev, 2008).

⁴¹ The World Bank Group. (2001) *What is sustainable development?* Retrieved from <http://www.worldbank.org/depweb/english/sd.html>

My point here is that the institutional framework includes not only political institutions but other apolitical ones as well. Both types of institutions shouldn't be considered as static in their own performance of functions, because as Holmberg emphasizes *changes in the objectives and mechanisms of functioning are important and at some extent necessary* (Holmberg, 1992). During this process, institutions in a certain state create their own internal logics which lead to certain outcomes⁴² in the decision-making process. Because of the high importance of political institutions in producing these outcomes, the paper focuses only on state institutions.

The latter, which is also the definition used for this paper, are considered as *a set of values that orient the ways in which institutions are organized, the nature of the changes that take place, the resources distributed and the technologies that are purchased and developed* (Thornton & Ocasio, 1999).

A high emphasis by recent literature has been put on the existence of the institutional logics. A group of authors cited in this paper claim that there are multiple logics which interfere within an institution. *These multiple institutional logics present different realities to their members, and by so doing they are also shaped by the actors* (Thornton, 2002). Therefore in the decision-making process, conflicting institutional logics may arise. Thornton and Ocasio (1999) *also focus on the existence of contradictory institutional logics and potential conflict, mainly when there are different groups competing over issues of status and control*. Conflict might arise not only within an institution but also among different institutions, especially if they are part of the same decision-making process in producing the outcomes. *There are multiple institutional logics, we need to attend to ongoing negotiations and conflicts that emerge within and between institutions* (Blacker & Regan, 2006). Furthermore, the importance of different present institutional logics becomes important during periods of transformation, especially in those countries which are in a transitional phase, like Albania.

I argue that, it is the important role of institutions, their nature and institutional logics that affect the way how sustainable development is carried out within the institutional decision-making process in Albania. By doing so, the institutions provide the premises for low or high considerations on sustainable development in this country. Considering the goals of the Albanian state and especially its foreign policy, the main logic which can be noticed among institutions is its aspiration towards European integration. Despite, different suggestions, comments or ideas on how integration should be involved within the policy-making outcomes, Albanian institutions incorporate in this process, issues and elements which are important to this overwhelming goal, including the concept of sustainable development, as it can be evidenced below. On the other hand, political stability is an interfering external factor that should be taken in consideration when it comes to the real implementation of the sustainable development.

3. INSTITUTIONS AND THE SUSTAINABLE DEVELOPEMENT IN ALBANIA

Institutions are considered to be a very important element in the long run perspective of sustainable development. Moreover, it is the institutions themselves which contribute to the framework and ways of carrying out sustainable development in a country. Looking back to Albania, with this specific regard, *"among many problems that Albanian decision-makers are facing today, institutional empowerment and law enforcement are the most important ones"*⁴³. This is because institutions are not only confined to framing policies in considering sustainable development, but also in monitoring the implementation of such policies. *"Even though public policies in Albania are oriented at a considerable level in incorporating the modern concept of sustainable development, reforms and other policies are slowed down by lack of implementation capabilities and monitoring indicators"*⁴⁴.

Among the variety of sectorial reforms, in this country, sustainable development tends to be more emphasized on those sectors where the impact and relationship between the systems is much more evident, such as: agriculture, tourism and economy. A recent example is that of a touristic municipality in

⁴² In this paper I use the term outcomes, as the result coming out from the policy-making process including: strategies (general or sectorial ones), decisions, plans or reforms.

Retrieved from <http://siteresources.worldbank.org/INTALBANIA/Resources/AlbaniaRuralStrategyAlbanian.pdf>

Albania (Vlora Municipality), which adapted the concept of sustainable development as part of its territorial plan⁴⁵.

During the last years, attention has been paid in the long-run analysis of factors which contribute to the sustainable development. With this regard, *specific attention has been put over roles of geography, integration into the economic world and institutions in the economic growth* (Nicol, Jano & Harri, 2003).

Figure 2. The relationship between institutional quality and national income, *Source: World Development Report, 2003. World Bank, Washington, D.C.*

“A sustainable and fast development will help in reducing the poverty. Social development will enable participation of all persons in the society” (pg. 72). This is how the National Strategy for Development and Integration incorporates sustainable development in its vision. Again at the center of sustainable development is the interaction between the economic and social systems, which is also in compliance with the Millennium Development Goals (MDGs) that Albania aspires to fulfill.

A crucial moment in the role of institutions regarding sustainable development has been the transition from communism to democracy. Thus, recognizing the importance of the institutional framework in achieving sustainable development, the Sectorial Strategy for Tourism 2007-2013 points out that *“Even though there have passed 4 years, important aspects of the strategy and action plan that still remain unfulfilled are related to: sustainable development of production, and the development of the sustainability principle in all levels”* (Strategjia sektoriale e turizmit 2007-2013/Sectorial strategy for tourism 2007-2013, pg.2).

Besides the policy-making process in providing outcomes with considerable emphasis on the sustainable development in this country, the ability to fulfill and implement these outcomes is also important. With that regard, institutional stability in the country becomes a matter of high importance. Armingeon and Careja (2008) point out that *institutional change after the institutionalization of the post-communist regime is limited and lock-in effects are strong in post-communist countries such as Albania*. On the other hand, *institutional stability is influenced at a considerable level by internal political struggles* (Feilcke-Tiemann, 2006).

The World Bank Institute which provides the Worldwide Governance Indicators for different countries, with regard to political stability provides the most recent data for Albania as well. The graph shows that the level of political stability in this country is still low.

Graph.1. Political Stability and Absence of Violence, Albania 1996-2010. *Source: Worldwide Governance Indicators for Albania World Bank Institute.*

Furthermore, institutions which are at the center of the political system will not be able to perform as efficiently as they are supposed to under low levels of political stability, especially during the implementation of policies and other institutional outcomes such as (decisions, strategies, etc.) Well-established institutions pave the way to higher institutional efficiency, thus, helping and providing support for the economic, environmental and social systems.

In the Albania's case, even though there is enough evidence in showing the institutional general support towards sustainable development, there exists a gap in information about the way how the institutional outcomes have been implemented and their impact in the country's sustainable development. Up to now, I have showed that the prevailing institutional logic of euro-integration and the need to further continue democratization processes are influencing factors in putting the sustainable development concept at the core of the decision-making process, especially in the institutional outcomes produced by it such as: strategies, reports and plans. What is more, if institutional instability is present, when it comes to the implementation process for consolidating all the systems that the sustainable development includes the situation is different. There isn't enough data to prove or show how the systems have been developed and sustained.

CONCLUSIONS

There is a general tendency among Albanian political institutions to put at the center of the decision-making process and of the institutional outcomes the concept of sustainable development. High emphasis on this concept can be seen in different sectorial and national strategies, reforms and plans. A strong rationale of this type of approach can be explained at a considerable extent by the country's euro-integration goals. Thus, the social, environmental and economic systems seem to have been at the center of the decision-making process especially during the last decade, acknowledging the importance of the resources and of the future.

On the other hand, when it comes to the implementation of these institutional outcomes, institutional stability as an indicator is of high importance. The data show that political and institutional instability is an issue of high concern. It considerably interferes in the process of implementation of those outcomes by slowing down their implementation. There is a need, for further deeper research on these rationales, in attempting to measure and evaluate the real implementation effect of the institutional outcomes on sustainable development.

IT, INNOVATIONS AND SUSTAINABILITY

Stefan Vukicevic¹, Sanja Milosevic²

¹Lund University School of Economics and Management, stefan086@gmail.com

²Microsoft Serbia, sanjadmilosevic@gmail.com

Abstract: *Today there is a growing need for questioning the use of various resources based on the limitations that inevitably exist regarding that use. This pattern is especially noticeable in dynamic and fast developing industry areas such as the area of information systems and technology. In this area particularly, it is necessary to stress how development and innovation produced in that process are affected by sustainability. This is one of the topics which this paper deals with. Also, this paper is trying to highlight the importance of that influence and how organizations are affected by it. This is done by reviewing actual research in this field of study. Special attention is given to the definition and recognition of terms such as sustainability and innovations, so that the consequences and the ways of dealing with them could be easily comprehended and accepted. The implication of this paper, that could be both academic and practical, presents us with the goal of sustainability that society and organizations will need to achieve in the future as one of the milestones of progress and development.*

Key words: *Sustainability, Innovations, Sustainable development, Information systems and technologies*

1. INTRODUCTION

One of the key characteristics of every natural resource is his limitation. This limitations transfer to today's economy and society as very strong influence. They have very important place at the beginning of every business or social activity, but also in the end as a final goal that should be achieved. On these influences can be looked from a different perspective such as ecological, social, economic, etc. Although they have various approaches, all of them are focus on same problems, and can be covered by the one term and that is sustainability.

Today's world characterizes big progress and innovations, in almost every direction. Maybe the most dynamic one is field of information technologies and systems. By looking just on previous ten years of innovations in that area it becomes clear why is that true. With information technologies and systems and innovations expansion, interaction between them and sustainability becomes stronger and more significant. To be able to examine that mutual influence between information technologies and systems, innovations and sustainability it is important first to explain some key concepts.

2. SUSTAINABILITY

Term sustainability is widely use and known, but despite that it is not simple to define it. This is the case because sustainability definition is very much determined with the point of ours views and believes. Because of that for biologist sustainability will be to preserve some species, but on the other hand for engineer sustainability will be possibility to reuse energy. Therefore, we can define sustainability in two different ways, those are weak and strong sustainability. Weak sustainability proposes that general well-being can't be decreased, which means for example that any use of natural resources is not bad while is doing well to people. On the other hand we have strong sustainability that separate resources that are created by nature, from one that people create. This means that natural resources are limited and if people transformed them, their value can't be reused again. (Jamieson, 1998; Vucetich, 2010)

Sustainability could be also observed from other perspectives according to Gladwin, Kennelly and Krause (1995) such as:

- **Technocentric view**
This point of view is similar to strong sustainability. According to this view natural reassures are exploitable without special limitations, humans are superior to nature, economy is isolated from nature and it encourages global growth.
- **Ecocentric view**

This point of view is more similar to weak sustainability. Value of this view promotes earth as alive, fragile and sensible to human's actions, where human population is already reached maximum.

- Sustaincentric view
This point of view is trying to reconcile previous two. His main characteristics are that earth and humans are connected in one system, population must be stabilized, economy and ecological system are underpinned.

Beside this definition, sustainability can be also defined from different understanding of time line. For one point of view, period that is important is present, but for the other that is future. In this sense sustainability should satisfy present needs or to satisfy needs of future generations (Jamieson, 1998). Although sustainability can be defined on more than one way, it is important to remark that every one of them is both correct and incorrect depends of perspective and beliefs. This is one of the reasons that make difficult to give one unique definition of sustainability, but common to all of them is that sustainability bring positive things to their creators.

3. SUSTAINABLE DEVELOPMENT

Sustainable development represents the processes or means that are used to achieve the goals of sustainability (Diesendorf, 2000). By observing previous definitions of sustainability it is easy to notice connection with economy, industry or in one word organizations. Primary goal for almost every organization is to obtain profit. On that way goals of sustainability often don't corresponds with goals of organizations, but still need for organizations to be sustainable is present.

According to research, main reasons for that are: competitiveness, legitimating, environmental responsibility. This reasons impact differently on organizations. First there is competitiveness which main goal, from organizations perspective, is to gain long-term profit and competitive advantage by being sustainable through managing waste and energy mater, obtain higher output for same inputs, green marketing, etc. Second reason, legitimating, refers to organizations need to adopt standards from their area of business, so that they could achieve stakeholders satisfaction. Third reason is mainly merit of strong individuals in company, and as a result gives satisfaction and feels good effect. These and other motivators don't stand alone, but they are effect by many other influences, which twist and change them and on that way change the perspective and actions of organizations. (Bansal and Roth, 2000)

After the motivation that drive companies to be sustainable is known, it is necessary to explain how they can achieve that goal through sustainable development. Here again it is come to the different way that sustainability is understood. As it is mention before, sustainability could be hard or soft. Now looking on this from the perspective of organizations, some of them give sustainability as a goal more attention in manner how to achieve it. As a result of this action it is possible to produce negative ecological impacts. Solution for this could be ecological sustainable development, which is trying to reconcile hard and soft tendencies from organizations perspective. There are four mechanisms how organizations can reach ecological sustainable development:

- total quality environmental management
- ecologically sustainable competitive strategies
- technology transfer
- corporate population impact controls

This will give to companies quality guide lines, but unfortunately this it is not often enough, because beside this there are also external factors as governments and consumer that must be involved on that way, so that true ecological sustainable development could be achieved. (Shrivastava, 1995)

4. SUSTAINABILITY AND IST

Previous description of sustainability and organizations refers to more general approach to this topic, but there is one more specific part that is very important, not only for organizations, but also to other parts of society, and that is Information Systems and Technologies (IST). Not so long ago field of IST was not of big inters for sustainability, but thanks to fast progress in that field things are now changed. First opinion

for IST was that it will just help with sustainability, now there are a lot of reasons that question that point of view (Ijab, Molla, Kassahun and Teoh, 2010). Because of this, today there is a strong bond between IST and sustainability, and need to research that bond better. As information system and information technologies complete each other, further below they will be looked as unity (Hevner, March and Park, 2004).

Relationship between IST and sustainability can be divided in two parts. First part is concerning negative effects that production, usage and disposal of IST can have on sustainability. Beside this IST can effect on sustainability in other totally opposite direction, as a great force that drive companies and society to achieve goals of sustainability. (Watson, Boudreau and Chen, 2010; Davison, 2004)

To explain how IST can help to achieve sustainability in organizations, further in text, institutional theory will be explained. Information systems supported by information technologies can act in three ways:

- automate
- informate
- transfer

Automation improves efficiency of processes by replacing manual labour with cheaper and faster automated IST processes. IST helps to inform individuals and organization by connecting different parts of a system. Transfer have important role in reorganization of systems, where as a good example is application of Internet. (Chen, Boudreau and Watson, 2008). Now when actions of IST are known, question is where these actions should be directed so that could help in achieving goals of sustainability? Answer to this question according to Thomas and Kai, (2002) is: eco-efficiency, eco-equity and eco-effectiveness. Those are three goals of sustainability that IST can improve.

Eco-efficiency represents an economic pressure on companies or individuals which force them to be sustainable so that they could achieve bigger profit. Eco-equity is time oriented and suggests that all generation should have the same chance and right to consume common recourses and effect on surroundings. Eco-effectiveness represent complete change of approaches and believes that are connected with sustainability, rather than improving individual parts of systems. (Watson, Boudreau and Chen, 2010)

Bearing in mind properties of previous IST actions and goals that could be improved, it is easy to notice how they can be pair up. So there is: automate and eco-efficiency, informate and eco-equity, transfer and eco-effectiveness. According to institutional theory suggest that by applying different types of pressures like mimetic, coercive and normative to these actions of IST, individual goals can be accomplished and at the same time sustainability. Important to say is that these types of pressures are not the only one or necessarily the right motivators. (Chen, Boudreau and Watson, 2008)

This is the case because they could be differently structured as according to Kuo and Dick (2009) there are: competitive pressures, legitimating pressures, social responsibility pressures, organizational factors and technological constraint.

Beside positive effect that IST can generate, there is also negative one. This dimension is especially important, because of growth that IST industry have. This statement supports facts that IST industry created 5.4% of global GDP in 2008 and predictions are that in 2020 this would be 8.7% of global GDP. (Soumitra and Irene, 2010). Best way to overcome problems that IST can create in field of sustainability is to distinguish them first. According to Vykoukal, Wolf and Beck (2009) there are three fields of IST that can affect sustainability and those are:

- Green Design and Manufacturing
- Green Use
- Green Disposal

Every one of those fields refers to different aspects of IST life cycle, which means that IST is always possible threat for sustainability. For example production processes can be inefficient during production, then during usage power consumption is not managed right and in the end of life cycle there could be irregular disposal. For dealing with this problems we could say that there is no wrong way to that, but only more and lees efficient one. So by improving individual aspects of life cycle, or by suggesting special approaches as implementation of Grid infrastructure, some efforts will be made toward removal of threats for sustainability. (Vykoukal, Wolf and Beck, 2009)

5. INNOVATIONS

The term innovation is used today very widely and often, but this doesn't mean that is used correct and in the right context. Simply said innovations represent something new or some newness. But newness is not necessarily an innovation and other way around. So some newness could be innovation, despite the fact that all elements of that newness are very well known, but the different application and understanding made that newness to innovation. (Slappendel, 1996)

From this it is possible to conclude that definition of innovation is more relative, than strict term. To be able to put definition in theoretical frame, Johannessen, Olsen and Lumpkin (2001), propose examination of three dimension of newness:

- What is new?
This question should define true values that distinguish innovation.
- How new?
Here the orientation is on degree that newness contributes to innovation, for example there are radical or incremental innovations.
- New to whom?
Main meaning of this question is to explain that innovation can affect different sides, such as for example: company that created innovation, customers and competitors.

As mentioned above innovations can be looked from different perspectives. Most important are perspectives of organizations and users. Organizations are among biggest creators of innovations. Besides that, organizations that don't embrace innovations, risk to fail in achieving their goals (Bower and Christensen, 1995). Because of these it is important to evaluate their relation with innovations.

Relation between innovation and organization can be looked from the individualist perspective, the structuralism perspective and the interactive process perspective. First perspective assumes that main forces of innovation in organization are individuals. For this to happen, individuals need to have predisposition for innovative behaviour. Second perspective totally opposite from the first one define source of innovation from organizational characteristics. In the end there is perspective that tries to account first two and explain that innovations in organization are produced by combining actions of individuals and structural influences. (Slappendel, 1996)

Main problem with previous explanation of sources of innovation in organization is that there are included only inner factors, without taking in consideration very important outer one, such is users. According to Bogers, Afuah and Bastian (2010), users are very often the source of innovations and their influence rise all the time. Also Von Hippel (2007) suggest that very often users of goods are one the initiate develop of new products, which can be best seen on example of rapidly changing industries such as mobile industry and open source industry. In addition to mentioned field of innovation creators, there is also one more dimension that is very important. This is relation between innovation and sustainability. Especially today mutual relationship between innovations and sustainability is very much apparent (Davison, 2008).

As sustainability today present very actual question, companies are trying to get involved in that area. One of the reasons is measures of governments, but more important one is competition. In this field companies struggle with dilemma to chose sustainability and then to be in disadvantage regard to competition that didn't chose that way. Answer to overcoming this dilemma faster lies in innovations. This connection has reciprocal character, because sustainability also represents the strong encouragement to innovate. Model that support achieving booth sustainability and innovation suggest five stages for that:

- viewing compliance as opportunity
- making value chains sustainable
- designing sustainable products and services
- developing new business model
- creating next-practice platforms

By going true these stages and achieving sustainability company will gain different opportunities to innovate, like to experiment with new sustainable materials, use clean energy, develop new packaging,

create business models that combine digital and physical infrastructure, use by-product energy. (Nimolu, Prahalad and Rangaswami, 2009)

6. CONCLUSION

Resuming everything that is previous mentioned it is obvious to see that sustainability, information systems and technologies and innovation advancing with high speed to future. On that way, fact is that they are becoming closer and more connected by each day. Although that mutual relationship could have also some negative effects, they are just small obstacles that will eventually be overcome. If this trend continues to rise at same rate, it is very possible that in future there will not be need to talk about this topic. Reason for that is because both innovations and information systems and technology will already have included as goal, in every activity, to achieve sustainability. Researching these topics from theoretical point of view helped us to recognize future trends that will inevitably occur. This will facilitate organizations to direct their efforts for progress in a way that will be beneficial both for them and also for others around them. As most researches about some topic starts first with theoretical overview, in that sense this research will highly benefit from further qualitative and quantitative research that will support this topic with appropriate data in order to gain in-depth understanding about it. These efforts will speed up shifting and applying of mentioned principles to practice.

SUGGESTIONS FOR PLANNING AND MANAGING PROTECTED AREAS, THE CASE OF TITEL LOESS PLATEAU AS A POTENTIAL GEOTOURISM DESTINATION

Ivo Mulec¹, Nicholas Wise²

¹ TIMS, Faculty of Sport and Tourism, EDUCONS University, e-mail: ivo.mulec@tims.edu.rs

² Department of Geography, Kent State University, e-mail: nwise5@kent.edu

Abstract: *The link between protected areas and tourism is vital. This mutual relationship is complex, sometimes opposing, but tourism is always a critical component to consider when planning and managing protected areas, such as potential geoparks. Sustainable tourism practices in protected areas represent long-term commitments. Protected area planners and managers can do much to build a more constructive relationship with the tourism sector. Additionally, success partly depends on actions taken by governments, for example, in updating legislation related to protected areas and tourism or introducing economic incentives to encourage sustainable forms of tourism. Nonetheless, planners and managers play a critical role by working with a broad range of stakeholders. Moreover, they can do much to ensure that tourism works for their protected area and for the people living within or nearby a geopark. Geotourism has been considered a form of niche tourism or special interest tourism, an actively growing tourism market. Vojvodina has several potential geotourism destinations—Titel Loess Plateau is one example and the focus of this commentary. This paper presents several strategic guidelines for planners, managers and other stakeholders for planning and managing the Titel Loess Plateau. This paper is a consideration of sustainable tourism opportunities with respect to local conditions and communities. It focuses on community practice and planning, implementing a management plan, and tourism services and infrastructure with the aim to guide suggestions for planning and managing the Titel Loess Plateau.*

Keywords: Protected Areas, Geotourism, Planning, Management, Titel Loess Plateau

1. INTRODUCTION

It is suggested that geotourism opportunities allow current and future generations to understand geologic phenomena specific to a particular location (Burlando et al. 2011; Dowling 2011; Newsome et al. 2011; Vasiljević et al. 2011). Geoheritage techniques, or geoparks, as such locales are considered, are aimed towards conserving natural landscapes and benefiting local/regional economies (Farsani et al. 2011; Frey et al. 2006; Hose 2007; Novelli 2005). According to Newsome et al. (2011), interests and investments in geologic tourism opportunities have been increasing in recent years as visitors are interested in seeking out diverse landscapes/viewsapes of distinct geosystems. Furthermore, it is important to focus on conserving geological heritage because it integrates scientific and cultural significances, and thus encourages planning sustainable developments to manage touristic opportunities (Hiwasaki 2003; Kavčič & Peljhan 2010).

An early definition suggests geotourism refers to “the art of explaining the meaning and significance of sites visited by the public” (Badman 1994: 429). According to Hose (1995), it is important that geoparks assist tourists in interpreting knowledge and understanding a places underlying geomorphology beyond just scenic aesthetics. This form of tourism encourages natural and cultural experiences, as historically romanticized appreciations for natural and cultural heritage is rapidly becoming a nascent economic generator for the tourism industry—especially as domestic and international tourists in recent years seek preserved destinations (Dowling & Newsome 2006; Kozak & Baloglu 2011; World Tourism Organization 2002). This increasing demand for ‘geo’ appreciations has led to the development of geotourism attractions based on geological formations, such as, and not limited to karst topography, volcanic craters, thermal springs, and waterfalls. Such physiographic landscapes, transcribed as geotourism products, have encouraged many regions to brand places around geotourism opportunities.

Geotourism destinations have been known to attract copious numbers of tourists, and poses great potential for many regions (Burlando et al. 2011; Dowling & Newsome 2006; Hose 2007; Kavčič & Peljhan 2010; Newsome et al. 2011; Pforr et al. 2006). This paper focuses on the Titel Loess Plateau located in the Vojvodina Region of Serbia. As a potential geopark, Titel Loess Plateau represents an ideal location

where future geotourism opportunities will allow visitors to experience the areas unique geologic phenomena. To further contribute to conservation practices, it is important to suggest some professional knowledge for the management of future geotourism sites. This paper begins with a brief geographic and topical overview of the region. The commentary thereafter offers and suggests some practical guidelines to assist tourism managers and subsequent stakeholders concerned with planning and managing the Titel Loess Plateau. With an emphasis on developing sustainable tourism opportunities in a manner respective of local conditions and local communities, suggestions for planning and managing the Titel Loess Plateau offered in this paper is developed around: 1. community practice and planning; 2. implementing a management plan; and 3. tourism services and infrastructure.

2. CASE STUDY: TITEL LOESS PLATEAU, VOJVODINA, SERBIA

The Titel Loess Plateau of Vojvodina, Serbia is geographically situated at the confluence of the Danube and Tisa Rivers, in the southeast of the region, directly east of Novi Sad (Figure 1). Physiographically, and according to Vasiljević et al. (2011: 113) “this isolated loess island and unique geomorphologic phenomenon, with a rich diversity of the loess landforms (e.g. loess “cave”, pyramid, gully, cliffs, etc), dominates its lower surroundings which makes it aesthetically and visually attractive.” Vasiljević et al. (2011: 113) also mention that “previously, there were no activities concerning loess conservation or geotourism at this site.” Then, by 2007, an application was prepared by the Institute for Nature Conservation of Serbia to list Titel Loess Plateau as a protected Special Nature Reserve, called Titelski breg. The environmental ministry responsible for spatial planning operations has yet to confirm when the area will be given protected status. However, in the application for the Titel Loess Plateau the Special Nature Reserve, the Institute for Nature Conservation of Serbia recognized the importance of preserving local flora and fauna. According to the Program Rada Javnog Preduzeća Titelski breg za (PRJPT) 2010 (The Working Programme of the Public Enterprise Titelski breg for 2010), 123 species of birds and 630 species of flora have been identified, and officials are putting much emphasis on protecting the areas loess landforms. It is not mentioned nor indicated what specific area will be designated as the geopark in the PRJPT report; however, the most vulnerable areas of Titel are located on the north-eastern slopes along the Tisa River (shown in images below).

Figure 1 presents the location of Titel in Serbia. In total, the Titel Loess Plateau landform covers an area of 8,197 hectares (Vasiljević et al. 2011); the entirety of this area would represent the potential geopark. Thick loess deposits ranging from 35 to 55 meters are separated by five main pseudo-complexes deposited over the last five glacial/interglacial cycles. Steep cliffs include several loess exposures (Figure 2), essential to understanding climatic and physiographic evolutions that occurred during the middle and late Pleistocene (Vasiljević et al. 2009). The suggested method for protecting the entirety of the Titel Loess Plateau is based upon the IUCN (1994) classification system, consisting of three categories. According to the PRJPT 2010, 70.6 hectares were declared Category I, which means Strict Nature Reserve/Wilderness Area, needing protection and management. An additional 264.3 hectares were declared Category II (National Park), and already has protected ecosystems and recreation management. The remaining 7,862.1 hectares are considered Category III (Protected National Monument), meaning this land is protected for the conservation of specific natural features.

To acknowledge settlements of the Titel Loess Plateau, Titel Municipality represents the only town immediately within in the vicinity. In addition to Titel, there are five villages in the periphery surrounding the Loess Plateau, these being: Šajkaš, Mošorin, Gardinovci, Lok and Villovo (Figure 1). According to the 2002 census, the Titel Municipality (this includes the town of Titel and the five villages listed), had a population of 17,600. In most settlements, except the town of Titel and the village of Šajkaš, the number of inhabitants has been decreasing over the last 20 years, common in many areas across Vojvodina. It must be noted the majority of the population has been dependent upon rural jobs, agriculture, animal husbandry, forestry, hunting and fishing. Many of these rural jobs have seen drastic declines. As a result, many of the productive population cohorts are departing rural areas, seeking service oriented employment in towns and cities. To reduce rural population declines, investments in tourism related activities will generate opportunities for area residents to gain employment in their respective rural areas without being forced to leave (Farsani et al. 2011).

At the moment there are no designated geoparks in Serbia, only protected areas. Therefore, geotourism of the Titel Loess Plateau will represent change—towards protecting the area’s natural setting and for improving economic situations. Ecotourism, geotourism, rural tourism and various types of sport tourism

were each suggested as possible types of tourism in Titel. Marković et al. (2005) were the first to suggest a geopark be designated to assist preservation efforts and tourism at the Titel loess plateau. The Titel loess plateau is significant because the geologic makeup of the area provides much insight into how these unique and important landscapes in Serbia formed as a result of natural and climatic changes during the Middle and Late Pleistocene (see Bronger 2003; Marković et al. 2008; Vasiljević et al. 2011). Moreover, such tourism techniques, according to Vasiljević et al. (2009) are encouraged to conserve Titel's natural and cultural heritage, in addition to generating employment opportunities for young people and establishing a contemporary economic base. This work contributes to earlier suggestions because no management plan assessments have been done to overview potential tourism developments of Titelski breg. Several visits to the town of Titel and conversations with stakeholders involved with Titel's future plans were important in understanding the locale and nature of problems concerning tourism development. It must be noted that local tourism officials have not yet decided what to include in the geopark. Therefore, if/when Titel becomes a geopark, the purpose of the following commentary is to suggest and present some guidelines for planners and managers to assist facilitating the potential Titel Loess Plateau geopark.

Figure 2: Images of the Titel Loess Plateau (Photographs by first author)

3. SUGGESTIONS FOR PLANNING AND MANAGING THE TITEL LOESS PLATEAU

Community Practice and Planning

Immediate community participation, involvement and awareness of tourism practices are essential for managers and planners of protected areas (Farsani et al. 2011; Hiwasaki 2003). Collectively, they can develop a sense of ownership and responsibility towards protected areas, even prior to drafting a geopark management plan. Besides local peoples living within and adjacent the Titel Loess Plateau, numerous other stakeholders interested in the geopark should be invited to collaborate, such as governmental authorities, investors and experts from a variety of academic background (such as geology, geography, history, biology, tourism management, etc.), to assist future decisions and educational approaches. Tour-related companies, whether servicing transportation or accommodation, must gain the support of local communities to assist serving the destination, engaging in sustainable practices and tourists' wellbeing.

Planning is essential to ensure Titel's desired sustainable future becomes a reality. Employing external consultants whom specialize in different fields is recommended. Furthermore, encouraging community volunteerism represents a way of connecting and exchanging ideas amongst officials and locals. To begin, a professional local destination management organization (DMO) in Titel needs to be established. This involves a local office employing tourism managers who will prepare planning and oversee procedures within and around the protected area. The PRJPT 2010 notes that, the public enterprise Titelski breg was established in 2009. Titelski breg currently employs three people, with plans to employ several more in upcoming years. An expanded management team must begin by analysing and documenting all potential and existing resources, such as available services, tourism infrastructures and finances. Titelski breg has already assessed both natural and cultural heritage in the Titel Municipality, noting events and gathering cultural, historical, archaeological, ethnographic, and other natural heritage materials for inclusion in a museum (as described in the PRJPT 2010). Additionally, Titelski breg will have to determine what and when further programs will occur, and who will assist with funding future management plans. This is where community involvement and collaborations with investors and planners becomes crucial, regarding the methods, timetables, actions and resource allocation for developing the destination.

Tourism in protected areas always produces benefits, risks and costs; however, such variables interact in complex ways (Dowling & Newsome 2006). It is the management team's responsibility to maximize benefits, while minimizing costs, when preparing tourism development policies supportive of long-term economic development. This involves maximizing local employment to promote social benefits locally, so monetary instalments exchanged reinforce the community economy. To see local economic growth over a longer term, marketing techniques must encourage and attract larger volumes of visitors, and promote increased lengths of stay to benefit local products and services (Kozak and Baloglu 2011). Vertical and horizontal integrations involve diversifying market niches aimed at attracting budget travellers and higher spending tourists (Novelli 2005). Again, community involvement becomes pertinent when planning and investing in tourism related infrastructures, especially when considering/offering local services to filter money directly into the local economy. According to Eagles et al. (2002), farmers have the potential to generate supplemental income by hosting cultural events displaying local cuisine, wine, artwork, crafts and community festivals.

Tourism developments should be designed to protect host communities. Protected areas sustained by tourism income not only create jobs and raise incomes, but also supplement benefits including improved communication infrastructure, educational and training facilities. Additionally, health care accessibility and other services become more widely available to park staff, visitors and community members (Eagles et al. 2002). In acknowledging benefits, it is important to consider risks associated with investments, local sustainability and the environment. Foremost, if the management of a protected area is not well planned, the site may be perceived as having only short term benefits by investors. Areas seen as having only short term benefits result in the rapid construction of various structures (i.e. hotels) that are not as environmentally sustainable and do not always contribute to the local economy, especially when local residents are excluded from business and entrepreneur opportunities. If locals are excluded from such opportunities, then they may also be distanced from decision making and participating in management programs/strategies. This takes away from the local attractiveness of a destination and often disconnects the community from visitors and the attraction.

Other physical risks are always present in tourism areas and must not be overlooked in natural areas, on trails and driving routes, therefore superior planning techniques can assist mitigating risk. Professional management teams from DMO's need to be constantly aware of risks, and strategically develop plans for organizing and manoeuvring visitors efficiently in times of emergency. Furthermore, to minimize risks, planners and managers need to develop a system for inventorying existing/potential hazards. Mapping

techniques are recommended here because spatial awareness of the entire site will allow for strategically allocating sign posts, access points and rerouting options. Being aware of such risks and mapping hazards allows planners to efficiently navigate emergency personnel on trails or road routes when needed.

Implementing a Management Plan

Next, the management team needs to secure resources to implement a management plan by evaluating employment, budgets, available funds and potential policy changes at least quarterly, or when attention is needed. Implementations need to be monitored to ensure that established goals written into the management plan are achieved. Therefore, frequent monitoring done by the management team must involve systematic and periodic evaluations to indicate the progress of each desired goal. Once Titelski breg's management team agrees on goals, policies and management plans, they need to communicate all viable information to stakeholders. In this regard, the most efficient method of communication is via a well designed internet site. This way information is readily available, understandable and current. Furthermore, a published document, such as a monthly or quarterly newsletter, should be posted online and also distributed amongst the community and to stakeholders who do not frequently access the internet. It is also suggested that management teams recognize community members that actively promote and sustain the management process and motivate other community members (Hiwasaki 2003). The awareness and the desire to make a difference and support a well-designed management plan will offer potential visitors a better experience, and thus ensure the destinations competitiveness.

Management plans are oriented to finances, support and supplemental funding as many protected areas have been managed through public finances (Kozak & Baloglu 2011). Unfortunately, however, many protected area management agencies have insufficient funds to effectively respond to tourism and conservation demands. Currently, most governments do not fully fund protected areas, since protected area staffs in developing countries earn low wages. Developing countries, like Serbia, can gain access to funds from international assistance programmes, non-governmental investors and independent donors. It is crucial management planners be creative when raising funds to develop a destination. As tourism generates potential income, it alone cannot generate sufficient funds for all aspects of natural and cultural heritage protection. Some potential income sources for protected areas that require consideration in management plans include: park entrance fees, recreation service fees, special events/services, accommodation taxes, equipment rentals, food sales and merchandise sales (i.e. souvenirs, clothing), in addition to outside donations and foreign aid (Eagles et al. 2002).

Zoning plans for protected areas are also important towards managing visitors within different sections of a geopark. To this regard, protected area managers need to spatially consider/identify recreational usage areas by archiving sites within the park and concentrate or disperse activities as deemed necessary. Again, well-developed mapping techniques will greatly assist spatial organizations when evaluating the entire site, and DMOs should allocate specific areas for certain uses—such as where tourism related and recreational activities are allowed, where conservation practices are required, and restricting some sites solely for scientific research. Immediate services within the geopark involve interpretation posts, transportation networks, sanitation facilities, accommodations, food/drink sales and shopping. One of the most important parts of organizing services within geoparks is providing informational and educational materials and programmes making visitors aware of natural and cultural heritage. Therefore, site management of significant places involves several considerations: the nature of the terrain and the maintenance of infrastructure, the needs of visitors, and the needs for environmental conservation and restoration (Pender & Sharpley 2005).

Providing Tourism Services and Infrastructures

This third section builds upon management planning specific to tourism services and infrastructure. Basic tourism related services for protected areas include visitor information centres, interpretative postings and accommodations. Additionally, other infrastructures include motor transportation routes and trail/path networks. All infrastructure projects developed must be strategically located, designed and operated to not be intrusive to the physical environment. In this regard, well developed management plans assist functional designs and organization of specific tourism projects to attract and cater to more visitors. Moreover, well developed management plans must identify simple solutions for efficiently maintaining recreational services at costs most effective to set budgets (Kozak and Baloglu 2011), as successes often

depend upon maintaining the geopark. Tourist services, facilities and infrastructural programmes within protected areas should act as standard-setters, promoting environmental sustainability.

Visitor information centres are often times a tourist's first stop when entering a park. However, visitor centres sometimes fail to fulfil their tasks and roles, due to poor location, out-of-date design, inappropriate messages or lack of maintenance. Having well designed facilities forge lasting first impressions and may be a deciding factor in how much time a patron spends, and if they suggest a place to others. Visitor centres are important because they are sites for revenue generation, being centralized locations for hotel accommodations, souvenir shops, restaurants, cafes, toilets and car parking. This crucial investment will inform tourists not only about the protected area, but will make them aware of such services, park safety measures and a layout of the parks recreational sites. For the aspiring Titel Loess Plateau geopark, audio-visual presentations at the visitors centre represents a proven and successful method for engaging visitors with the site and what the park has to offer; this strategy is widely used in protected area around the world. The ability to concentrate visitors in an area is important for sustaining high visitor yields and represents a crucial part of visitor management.

Visitors often require overnight accommodations. If the protected area is small, as the case with the Titel Loess Plateau, tourists will have to be accommodated in nearby towns or villages. Decisions on the location of accommodation in relation to protected areas involve issues such as finances and the influx of crowds. Wherever accommodations are constructed, it should always be carried-out in the most culturally and environmentally sensitive way. Here, cultural aesthetics and historical ambiances offer future clientele unique accommodations in quaint structures with natural vistas. Such settings potentially encourage visitors to stay longer, bringing more money into the local economy. Many home owners across the region rent a spare room of their house to tourists to gain supplemental income, often advertised with signs that read: Rooms, Sobe, or Zimmer. This type of accommodation better allows tourists to experience local culture and everyday community life.

When visitors need to be accommodated outside the protected area, there is particular need for well-developed transportation networks. Transportation infrastructures (i.e. roads, tracks, boat landings) within a protected area serve as efficient access points, providing opportunities for visitors to understand, appreciate and enjoy geoparks. Preferably, roads providing access to and within the protected area allows visitors to navigate to focal points, such as: information centres, public transportation lots and take-off points for walking trails and toilets. One downfall is motorized transport often has negative impacts, including noise and pollution, as dust can impact local fauna, damage flora and affect water quality. Transportation infrastructures often have significant impacts on protected areas, even when its primary purpose is allowing better access, unless specifically designed to reduce negative impacts on protected areas. In addition to transportation infrastructures, another difficult and expensive component for bringing tourist into protected areas is building and managing trails.

Associated with well-developed transportation infrastructures are well-developed footpaths/trails. Trails are important because they assist operational flows of visitors through the park and enhance visitor appreciations of natural areas. When constructing footpaths, it is important to consider entering and exiting points, direction plans and visitor safety regulations need to be posted. Physical concerns regarding paths are widening and erosion, path hardening and water channelling, in addition to what materials should be used for maintaining footpaths. Another issue is what types of signage and resting points should be made available along footpaths and additional facilities. Furthermore, all footpath development needs to be consistent with the nature of the terrain that it traverses. The combination of information centres displaying walking and hiking opportunities, trail accessibility from parking lots and toilet facilities, each promote visitor satisfaction. All such infrastructures must minimally intrude upon the natural environment to ensure authentic natural experiences for visitors, which acts as the attractant to encourage visitation (Pender & Sharpley 2005).

Routes, trails and paths are designed to safely manoeuvre visitors through the geopark and direct tourists to sites of interest. Signposting and other interpretable information are often used to influence a visitor's behaviour towards protected area management and their fragile eco-systems. Signposts may be simply directional or may contain interpretative educational information specific to a certain point in the geopark. Moreover, where signs are located and there included content should be carefully considered—regarding the structure of the signpost (appearance and height) and the amount of information being conveyed.

Since signs represent focal and orientation points, appropriate locations for signs are at park entrances, trail entrances, and at trail junction points, to ensure visitor safety and general whereabouts.

According to the PRJPT report, plans for more trails have been suggested, and bike trails already exist and cross much of Titelski breg. Appropriate maps with distances, lookout spots, interpretation maps and resting points need to be indicated. Future plans include the designation of a walking trail, consisting of pavement and wooden paths along the northeast sections of the park below the slopes next to the Tisa River (see images in Figure 2). This area represents one of the significant characteristics of Titel, but there is a concern of flooding. This section of the park has been known to flood and there is concern that trails may be destroyed or eroded. Walking trails atop the slopes of Titelski breg would be easier to design and maintain. Atop the slopes are old farmers' trails leading to traditional farmhouses (Salaš) and currently have been converted into spaces for rural tourism lodging.

4. CONCLUDING REMARKS

Even without the designation of geopark, the Titel Loess Plateau has a management system with baseline information suggesting site assets and potential attractions. Currently, the number of tourism activities is low, and few plans for recreational activities exist. However, before, or when, the site is potentially designated its protected status as a geopark, more management is needed to support anticipated tourism increases. A detailed management plan for the sites future development is essential for the parks development and local economic impact. Foremost, Community involvement within the Titel Loess Plateau and adjacent periphery is important for future touristic endeavours to establish lasting relationships with future visitors. Thus, activities deemed unlawful within the protected area boundaries will have to be concentrated in the periphery. Also important, the management of geoparks need to be inclusive of the local community. The community represents a gateway to the site and must be inclusive towards the planning and management of developing tourism opportunities.

DMO managers and tourism developers must build necessary tourism infrastructures, and guides need to focus on preparing itineraries which take into consideration environmental impacts and cultural significances to ensure long-term interests. Foremost, transportation networks towards and within the site needs to be efficiently organized to manoeuvre visitors. It is also important that local guides create a variety of environmental and cultural experiences to encourage tourists to stay longer periods and support promoting the site. Suggested activities within the Titel Loess Plateau involving general rural, leisurely and recreational opportunities include: nature viewing walking trails, swimming, horseback riding, boat tours, animal/bird watching sanctuaries and designating areas for hunting and fishing. Also, cultural activities such as local theatre and enogastronomic tours greatly diversify sites for visitors. All sites, potential or declared, should be first protected and then well managed to preserve these fragile areas. Preparing a professional tourism management plan for the potential Titel Loess Plateau geopark will provide this location and other future geoparks in the Vojvodina Region of Serbia to become competitive and attractive destinations in the near future. To conclude, designating Titel as a potential geopark provides opportunity to further encourage visitors to appreciate the loess plateau's natural phenomena without harming to the physical environment.

Abstract: *Traffic has a special importance, as a particular means of transport representing the sources of significant negative external effects, such as noise, air pollution, traffic accidents, land use etc. Traffic jams are a specific problem as they result in a succession of negative effects increasing the energy consumption, time loss, as well as the emission of contamination gasses. To settle the conflict of objectives by the increase of mobility and the decrease of negative environmental effects, it is important to embrace a comprehensive, integrated approach in creating a contemporary policy of transport, traffic and communication within urban development. This paper presents various types of traffic in different ways that affect the environment, the influence of radiation on the environment, and the impact of technical and technological hazards on the environment.*

Key words: *traffic, environment, effects of radiation, technical and technological hazards, pollution.*

1. INTRODUCTION

Traffic plays an important role for society as a whole because it connects the nations and regions, and thus spreads the culture, customs and other human knowledge which will be used for further economic and social development. Therefore, traffic is considered as a key factor in economic and social organization. Traffic can be seen as an industry that aims to transport people, goods and information from different places in the procurement function and the appropriation of goods necessary for life and develop the productive forces of society. Traffic has a huge significance for both the economy and social welfare. It is an essential element in the production and distribution of goods and services, and without it, we cannot think of trade and regional development. Traffic allows expansion of production and thus competition.

Modern trends on roads and air transport, lead to overloading, pollution, loss of time, health, life, and economic losses altogether. The various types of traffic have different influence on the environment. The emission in transport (especially road and air) is an important part of their overall emissions: over 90% goes to lead emission, and over 30% of the total emissions of volatile organic components. It is necessary to limit the impact of infrastructure development on land use, traffic density and reduction of the works on roads (particularly in urbanized regions), to eliminate or reduce the risk during transport of hazardous or waste materials.

It can provide:

- improved coordination of planning and investment in transport infrastructure networks and services;
- increase the competitiveness of environmentally sound forms of transport such as rail, marine and cargo transport;
- development of transport which gives priority to public transport, technical improvements in vehicle and fuel use;
- encouragement in environmentally rational use of passenger cars with the changes of traffic rules and habits.

The effective results in this field will depend on the whole complex of interrelated measures and efforts. For example, the habits of the car owner in most cases depend on the availability of other forms of transport, quality of infrastructure, price of parking and so on. The information education programs will not work if the choice is limited. The optimization of traffic types and infrastructure capabilities, network investment may also serve private interests, the interests of national economy and the environment.

2. TRANSPORT, TRAFFIC AND ENVIRONMENT

In this field there is a wide range of intervention measures which have a positive impact on the environment: technological advancements of various transport modes, fuel consumption, quality infrastructure and services that can reach the technological development of transportation systems. The short-term measures go to the three main intervention areas:

- The restriction to urban centers access for private passenger cars or heavy motor vehicle traffic, which are a major source of congestion and pollution;
- The reorganization of urban freight transport, and;
- Technological improvement of transport such as orientation to the automobile catalytic converters and better power engine efficiency.

The first intervention policy has already been implemented in many European cities. For example, access to the historical center of Milan is halved by restrictive measures for passenger cars and car parks have been removed to other parts of the city center. The practice shows that the traffic restrictions in urban areas give good results if applied to smaller areas. Larger threatening prohibited zone optimizes the access to urban areas. Another area of policy intervention concerns the reorganization of the goods distribution in cities through the implementation of logistics and combined road / rail transport. These measures are widely used in Germany in order to reduce noise and pollution.

For example, the largest Swiss retailer Migros is located in a warehouse next to its railway lines and 56% of its merchandise is distributed by rail. Distribution of goods in the local town shops remains a problem partly solved by introducing smaller trucks with engines with efficient energy utilization.

The third area of intervention is the technological improvement of the mechanical parts of cars and vehicles in general. Catalysts and technological application of similar mechanical parts can significantly reduce air pollution. The long-term measures of integrated transport policy development and the environment are numerous, and one of the most common is to improve public transport measures that are widely used in developed countries. It involves construction of the subway / light-rail transportation systems in large, and the improvement of services in smaller towns. It is also of increasing importance to regulate and improve effective communication with passengers.

3. THE EFFECT OF RADIATION ON THE HUMAN ENVIRONMENT

This area has long been neglected and even deliberately ignored by the big companies that were the main source of radiation, although it is well-known what harmful effects of electric and magnetic fields are, for instance. A French physicist and radiesthesist Bovis has differed most diverse terrestrial and cosmic radiation, even then when it is used by different devices. It is known that Chinese were able to detect cosmic and terrestrial radiation a long time ago. The Chinese emperor had the specially trained professionals who had always been there before constructors started building a residential site in order to explore it thoroughly, because it could not be built at the place where "evil spirits" came, which brought misfortune and illness according to their belief. Old Persians, Celts, Egyptians and other ancient peoples were also familiar with a healthy and harmful radiation.

We detect two types of radiation: *natural* and *artificial*. The artificial radiation involves the technical one too, and it comes from various appliances, particularly household appliances, as well as the proximity of substations, transmission lines, transformers and various other transmitters and antennas, which overloaded urban environment. Today's science directly confirms that the harmful radiation directly affects the people's health and feelings. People are constantly exposed to radiation, which comes from radionuclides in the environment. The sources are varied, and the types of radiation energy, that people are exposed to are different to. What is difficult to perceive for our senses, a reliable technique can recognize. There is the study and measurement itself, which provides insight into the nature of the processes occurring in irradiated areas, as well as a piece of information on how much a person is exposed to radiation. Cosmos is a significant source of radiation for the human kind on the Earth. The cosmic radiation is a consequence of electromagnetic waves (and charged particles) that come from the stars, or are ejected at high speed in a giant explosion. They receive an additional boost on their way through the magnetic fields in cosmic expanse acting like giant accelerators.

4. TECHNICAL AND TECHNOLOGICAL HAZARDS

In technical-technological hazards, particularly the fundamental role of accidents that occur in nuclear plants and chemical industry, are transport of hazardous materials, waste disposal, fires, industrial and car accidents. In addition to the use of nuclear energy for various means of mass destruction, it is increasingly used as an energy source since it is estimated that the supply of fossil fuels will last until 2025 (the liquid) or 2400 (the strong). The first nuclear power plant of 3 MW was built in Obninsk, a place 50 km away from Moscow, and it started its operations on 27 July 1954. The United State had its first headquarter built three years later in Illinois. At the end of 1985 there were 374 nuclear power reactors located in the world. Although nuclear plants were withdrawn, compared to the classical notion of technological industry perfection, security and reliability, such as airplanes, after all, the means of transportation should not forget that the possible failures of nuclear reactors can lead to serious consequences including the loss of lives. We know that the radioactive substances into the aquatic environment are mainly used for carrying out the time-intensive tests of nuclear weapons, and more recently for constructing a nuclear waste plant.

5. TRAFFIC SAFETY

Road safety issues occur in all countries, regardless their economic development. A problem of the organization and provision of traffic on roads and streets, has attracted a great attention in all countries, because the development of motorization is followed by large casualties and material damages suffered by individuals and social communities. A research has shown that 60-70% of the traffic accidents occur as a result of human factors (driver's misconduct or pedestrian's), 10-15% because of the malfunction of the car, and 20-40% because of the situation and noncompliant elements of the road. A number of traffic accidents and the consequences as well, depend on the weight of the composition of the road network, traffic organization, discipline of drivers and pedestrians, and the reliability of vehicles too. Increase in road safety is achieved by four factors that have a major impact on the traffic safety:

- *man,*
- *vehicle,*
- *environment and*
- *road*

A man (driver) as an active participant in the traffic, is one of the most common causative agents of disruption in road safety. According to the data in the 2004 for the European Union (25 countries) have often suffered:

- *drivers, even 62%,*
- *passengers 20%,*
- *pedestrians 18%*

It is interesting that the total number of victims are represented mostly as men (77%). There are many causes for the accident, but most frequently mentioned are:

- *alcohol,*
- *fatigue,*
- *lack of knowledge or skills for the safe management,*
- *speeding etc.*

6. PROTECTION AGAINST NOISE

The state and the general elements of the policy:

It is estimated that a large number of Europeans are exposed to the negative effects of environmental noise from various sources (traffic, industry, recreational activities, etc.). Making noise is one of the main local environmental problems with significant consequences for public health. However, only the 1993rd European Community has announced a policy change in this area in accordance with relevant solutions in the Fifth Action Program. The European Commission Green Paper (1996) explicitly defined the problem about the noise as the environmental problem. Furthermore, it led to an open discussion of policy in the field of noise and further measures. Two courses of action were set hereby: general policy in the field of noise (a common method for assessing exposure to noise, establishment of a joint index of exposure to noise, limiting the noise transfer, information exchange and experiences, improvement the of the program coherence research (in the field of noise) and emission reduction at the source (road, train, air traffic, and noise from equipment used outdoors).The most important part of EU policy in this area is aimed to reducing noise through the introduction of mandatory technical standards for products or through the establishment of emission limit values for certain products (motor vehicles, motorcycles, airplanes,

household appliances, various equipment and etc. One of the objectives set out in clause 1, Article 7. of The Sixth Community Action Programme points out the problem of reduction in the number of people who are long-term above-average level of noise affected by a particular noise from traffic.

7. MODERN EUROPEAN TRANSPORT POLICY: SUSTAINABLE MOBILITY

Today's transportation system of the European Union is faced with a growing conflict between the increased demands for mobility which has a negative impact on the environment that is becoming more and more critical, and unquestionable contribution of transport to the overall economic development on the other hand. Practically, the argument related to increased traffic congestion, poor service quality, safety prejudice to the environment and isolation of certain regions, are being confronted by the fact that confirms the economic importance of the sector: the total cost of transport in the EU amounts to about 1000 billion, the share of the gross domestic product (GDP) is over 10%, and the sector employs over 10 million people. The assessment that shows the intensity of transport in the EU is growing, both for people and goods, exceeding the GDP growth, proposes the transport separation concept from economic activity. It was discussed at the highest political level in the EU, and the fact is, that the Gothenburg European Council established the concept of economic separation and transport growth pointing it as a key factor in sustainable development strategy.

Also, the European Commission has founded and supported the project on the separation of transport intensity from economic growth, known as SPRITE project and called for political scenario of sustainable mobility, also known as POSSUM project. All these activities are a part of integrated effort to implement the concept of "sustainable mobility" in the EU, now enlarged to ten Member States. The starting point of this is the new White Book of the European Commission "European Transport Policy for 2010: "time decision".

8. CONCLUSION

The effects of intense climatic changes in recent decades are reflected in almost all parts of the world. Increasingly, disasters caused by weather conditions concern human society, but they also show a willingness to continue to mitigate climate changes or prevent them. For this purpose it is necessary to reduce emissions of greenhouse gases whose concentration in the atmosphere suddenly increased, primarily as a result of the use of fossil fuels in transport and industry. As for the transport sector, one of the main measures for achieving this goal is the diversion of cargo flows to environmentally friendly transportation industries. The development of combined land transport that best promotes the benefits of two different aspects of transport by rail and by road, is gaining importance.

The combined land transport is environmentally "friendly" mode of transport and its effectiveness is a manifold for reducing emissions, noise levels and lower fuel consumption, reduction of the number of road vehicles, or reducing congestion and the road network burden, traffic safety increase and others. For effective development and implementation of technology in the field of combined land transport in Serbia, it is necessary to create the appropriate institutional, technical and technological basis. Anthropogenic pollution of the environment and pollution itself are a result of traffic. Traffic is a major source of pressure on the environment - the air pollution and other environmental media (emissions from the combustion of fossil fuels and waste), the noise and pressures on biodiversity, land and coastal the territory due to the construction of transport infrastructure. Transportation is a major part in the overall pollution of the atmosphere of about 50% and is one of the biggest polluters today. Therefore, we must pay a special attention to the anthropogenic pollution of the environment as a consequence of traffic.

It is a known fact that the major air pollutants such as: transport (transport of people, goods transport), energy and industry (thermal power, nuclear, chemical, textile, paper, pharmaceutical, metallurgical industry, building materials and steam), are individual furnaces.

PROTECTION OF WATER RESOURCES IN RURAL AREAS OF SLOVENIA WITH ENVIRONMENTALLY ACCEPTABLE SUSTAINABLE METHODS

Davorin Žnidarič
FOV Kranj, davorinznidaric@gmail.com

Abstract: Water is the most important resource in the world - for human life, plants and animals, environment, social and natural prosperity. In Slovenia and North European countries, we have almost enough water at the moment, but some countries located south and in the Mediterranean, have a lot of problems to provide more natural and healthy water for normal life and use. We can see in Africa and some other countries in Middle East, how important water is for survival. Water deficiency has been the reason of many wars in the past and still is today, and it will, unfortunately, represent the same reason in the future, as well. Especially because water reserves drop every year for different reasons - climate changes, greenhouse gases, we must provide a solution how to reduce consumption and after that clean municipal waste waters for repeated use. In Slovenia, problems which arise yearly are the quality of water as well as an old water carried systems, where over forty percent of water has been lost. Another problem is also the quantity of municipal waste water, which must be reduced in our everyday life. In this topic we will introduce methods of "Plant Cleaning Devices (PCD)", used for cleaning devices to reduce normal drinking water and to protect areas where these resources of water exist. These methods are successfully used in practise and environmentally and naturally acceptable. The PCD applied methods which flow in nature for more than several thousand years. Methods described in this article are mostly used in rural areas where big cleaning systems are not acceptable, because of geographical and technical conditions.

Key words: water sources, municipal waste waters, plant cleaning devices, healthy water, natural methods,

1. INTRODUCTION

Slovenia has a lot of water, according to current statistics. 34 billions m³ flows every year in rivers and streams. 98% has been pumped from ground water and only 2% from flowing water on the Earth. In 2010, 125 million m³ of water was consumed in our country for various purposes. Most of the water is used for households, other are counted on table 1.

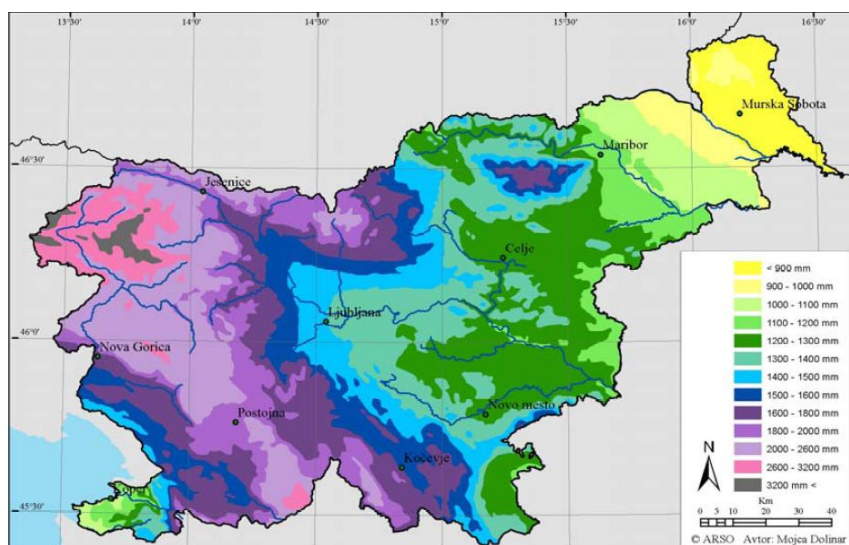

Table 1: Consumption water in Slovenia 2010

quantity/millions of m ³	consumer
85	householders
31	economy and other supporters
6	other water systems
3	water consumption for fire workers and cleaning streets

Household water consumption and water consumption in economic and non-economic activities per capita has not changed much since 2008: in recent years, total water consumption decreased by 0.2%, i.e. to 84.5 million m³ or 57 m³ per person in 2010, which is around 117 litres per person per day.

In 2010, most water per household member was consumed in the Osrednjeslovenska statistical region, 57 m³. In Gorenjska and Obalno-Kraška regions 42 m³ of water per household member was consumed, in Notranjsko-Kraška and Goriška 37 m³, in Savinjska and Podravska 36 m³, in Zasavska 34 m³, in Spodnjeposavska and Jugovzhodna Slovenija 33 m³, in Koroška 30 m³ and in Pomurska 27 m³ (SURS, 2012).

In some regions, like Prekmurje, Štajerska and also in Primorska, problems with water rise up several years. Because in this areas there is not enough precipitation, which would fill underground water sources and on the other side, water is polluted because of non-adequate agricultural preparation. For farmers and citizens, which are dependable on quantity of waters, this represents problems for their economy and normal life.

Picture 1: Precipitation map in Slovenia for period 1971-2000
(Agency republic of Slovenia for environment, 2012),

Picture 1 represents areas in the country and its precipitation in Slovenia between 1971-2000. In the North East part of Slovenia, as we can see on the map, there is less than 900mm, in the other areas, a quantity of precipitation rise between 1.000 to 2.000 mm. Almost whole West Slovenia except Primorska region, have a lot of rains. In part of Julijske Alpe this average is almost 3.200 mm. These conditions are result of south west and relative warm and moist air. Also important, for accumulation of precipitation water in groundwater, are geographical and earth structures (ARSO, 2012).

2. WATER CONSUMPTION IN SLOVENIA AND EU

Every citizen in Slovenia consumes 42m³ water per year, 117 litres per day (2010). Comparing to year 2009 consumption is lower for 16m³. If we look at European statistics, Slovenia is on the 10th place among 24 EU members (2009). The lowest consumption is in Lithuania with about 30m³ per year. On the other side the highest spenders in EU 24 are Cyprus and Ireland with 110 and 140m³.

Picture 2: Consumption water on citizens in EU24

Average water consumption in EU is between 51-75 m³, less water consume only six countries, Czech Republic, Estonia, Lithuania, Hungary, Poland and Romania. The per capita water consumption (in m³) greatly differs between EU Member States. According to Eurostat data, in EU Member States on average 70 m³ of water per capita was consumed in 2008/2009. The latest data on water consumption in one year (in m³ per capita) are available for different periods: for Belgium, Bulgaria, Denmark, Estonia, Lithuania, Hungary, Poland, Portugal, Romania and Slovenia the data are for 2009, for Cyprus, the Czech Republic, Italy and Spain they are for 2008, for Greece, Ireland, Latvia, Germany, Slovakia, Sweden and the United Kingdom they are for 2007 and for France the last available figure is for 2001. Quantity of water supplied from public water in Slovenia, for 2005 is 165.219.000 m³. And for 2010, 166.223.000 m³ (EUROSTAT,2012).

3. PUBLIC WASTE WATERS IN SLOVENIA

Uncontrolled releases of municipal water into the environment significantly affect the quality of water resources. In 2010, Slovenia produced 173,3millions m³ wastewaters from different sources. 0,3% from agriculture, forestry and fisheries, 8.6% from industrial activities (mining 9.9% in manufacturing 84.4%, from the power supply 3.9% of a building industry 1,8%), 5.2% from other activities, 34.3% of households, 51.7% and other waste water (rain water, back water...) Or 2,9% more than 2009. Over 2/3 of wastewaters are purified in 2010. Almost 73,2%, only 26,8% are unrefined. Of a total of 46.4 million m³ of untreated wastewater were 71.2% directly discharged into surface water, 28.8% in the groundwater? Treated wastewater to total 127 million m³ were almost completely released into surface waters (87%), only a small percentage of water (13%) has been released into the groundwater(SURS,2012).

Table 2: Wastewater into a source of pollution, Slovenia, 2010

Sources of wastewater	1.000 m ³
total	173.326
waste water from agriculture, forestry, fisheries	506
waste water from industrial activities	14.831
mining	1.465
Remarkable activity	12.516
electricity	575
construction	275
waste water from other activities	8.931
waste water from households	59.395
other waste water	89.663

3.1 METHODS OF TREATMENT WASTEWATER

For cleaning wastewaters we used three basic systems.

- primary
- secondary and
- tertiary

All three systems are different in the manner and degree of purification (Vuk,2010). **Primary** cleaning is based on mechanical or chemical cleaning processes, including the deposition particles of the substance. Primary treatment can be another clean-up procedure, which reduces theBPK₅⁴⁶, less than 20% and the amount of suspended solids by at least33%before release water into environment. Primary process reducing smallest part of organic pollution.

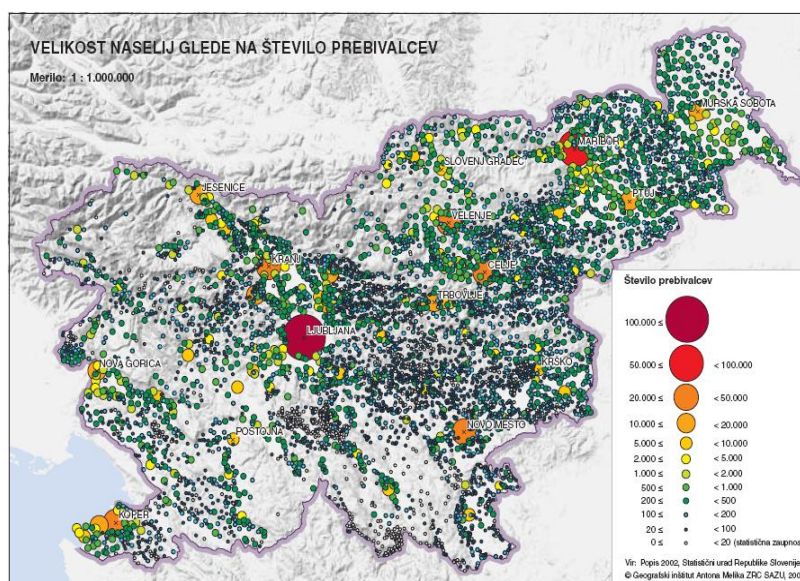

Secondary is biological and reduce organic particles and about 20 – 30% of nutrient.

Tertiary system reduce all organic and almost all nutrients. It was mainly used to reduce nitrogen and phosphorous substances. And to minimize the impact of secondary treatment (Vrhovšek, Vovk.,2009)

⁴⁶BPK₅(SLO) or BOD₅, biochemical oxygen demand, which is factor for biological pollution in water

4. SOLVING THE PROBLEMS OF ABSTRACTION AND WASTEWATER

In general, Slovenia is characterised by high proportion of dispersed settlement. 6.028 villages are mostly located especially in mountainous and hilly areas. These areas represent 30.5% of the whole territory inhabited by 38.5% of the total population. In areas with less than 2.000 PE⁴⁷ live 52.3% of all residents. Slovenia has 98.4% of such settlements. Legal frameworks for areas less than 50 PE do not provide public services in the care of drainage and sewage, but they leave people alone. Also, individuals are left to costs associated with solving the problems of urban waste water, which often leads to poor and inadequate systems. Appropriate solutions exist, but are left to local communities and individuals, who often opt for environmentally inappropriate technological solutions and cost (SURS, 2010).

Picture 4: The size of settlements in terms of population
(Anton Melik Geographical Institute, 2012)

4.1 ERM – ECO REMEDIATION METHODS

The regulation of wastewater treatment, which includes utilities, is now used by many processes. Among them, over the past few years, there is the most efficient way through ERM⁴⁸ processes, which include PCD⁴⁹ in the context of small sewage treatment plants. PCD became permitted technology, the government adopted a decree on the emission of waste water discharged from small sewage treatment plants, which are defined in the Act as a cleaning device, with a capacity of less than 2.000 PE. In remote areas or in areas where the installation of conventional water treatment plants is impossible due to geographic or other restrictions, PCD represent the best solution (Žnidarič, 2011).

4.1.1 PLANT CLINING DEVICES-PCD

Ecoremediation methods have an essential role in addressing the negative environmental interventions of the past. This means inadequate regulations of rivers and streams, and wetlands areas that have historically represented a habitat for plants and animals. PCD also enable us to revitalise the stagnant water sources for irrigation and drought prevention, in different areas that were previously reclamation of land by drainage. (Žnidarič, 2011).

⁴⁷PE population equivalent PE is a parameter indicative of load expressed as a unit and PEB60 g / (capita per day) is obtained by dividing the actual load expressed in g BPK5/day the value of 60 g / (capita per day.)

⁴⁸ERM is abbreviation for Eco Remediation Method

⁴⁹PCD or Plant Cleaning Device is natural system to cleaning wastewater, particularly in rural or dispersed areas

PCD eliminate water pollution and promote the preservation of water resources and their arrangement. It is important for:

- protection of water used for abstraction or intended for public drinking water supply or for the manufacture of beverages.
- reduction and more careful use of water
- maintenance of the quantity and quality of groundwater
- renaturation of water bodies
- reduction of pollution of water bodies

PCD consists of sandbank beds that are separated from the surrounding area with foil. Substratum and plants in beds have been used for purification. Important parameter in PCD is the flow time of waste water through substrate and plants roots, where microorganisms reduce pollutants in the water.

PCD is divided into two basic types:

- surface flow, or the free surface or **FWS** (free water surface) and
- by an underground stream or **SSF** (subsurface flow)

Waste water flows on the surface or just below it and slowly percolate through the substrate. Treatment plants in this way, exploiting the properties that such systems are utilized in nature. As in the swamps and backwaters of rivers. Irrigation plants which are inhabited with algae's and microbe processes allows to cleaning water.

Primary weakness of this method of cleaning is that water comes into contact with air and the potential option to spread of vermin and odour. The positive side of this method is on the other side, that we can observe the system and, if necessary, take immediate action.

Plants used in the device are separated by the treatment plant:

- emergent macrophytes
- the free float and
- rooted floating and submerged macrophytes

How plants and used in PCDs, depending on pollutants and their concentrations in the water load. We can see on picture 4. and 5..

polluted water flowing over the surface effect and slowly percolate through the substrate.

4.1.1.1 PCDs WITH THE SURFACE FLOW

This system consists of a shaft, which is a substrate in which they are rooted macrophytes. Laden water flows through the substrate below the surface so that in this case does not come into contact with oxygen and the potential odor. The difference between the surface and underground flow, and CW, is that the latter represents a greater surface area for biofilm development macrobic and thus more effective treatment. Plants used for these princes PCDs are: *Phragmites australis*, or common reeds, *Typhalatifolia* or two rushes and broadleaf *Scirpus lacustris* (Vrhovsek, Vovk, 2009).

Picture 4: PLC with the surface flow (LIMNOS, 2010)

4.1.1.2 PCDs UNDER SURFACE FLOW

This system consists of a shaft, where is a substrate in which macrophytes are rooted. Water flows through the substrate below the surface, and in this case does not come into contact with oxygen and the potential odor. The difference between the surface and underground flow in PCD is, that the latter represents a greater surface area for bio film which enabling cleaning of waste water.

Plants used for these processes in PCDs are: *Phragmites australis*, or common reeds, *Typhalatifolia* or two rushes and broad leaf *Scirpus lacustris*.

Picture 5: PCD under surface flow (LIMNOS, 2010)

4.2 MECHANISMS OF TREATMENT IN PCD-S:

Mechanisms are interrelated and include:

- settling of suspended particles of insoluble parts
- filtration and chemical precipitation
- chemical transformation
- adsorption and ion exchange across the surface of plants, substrate, sediment and plant waste
- decomposition and transformation of pollutants and nutrients through the microbial and plant
- predation and natural die off
- biological reactions:
 - photosynthesis
 - respiration
 - fermentation
 - nitrification
 - denitrification and
 - microbial removal of phosphorus (Vovk, 2008)

4.2.1. CONSTRUCTION OF URBAN WASTE WATER TREATMENT USING PCD

Constructed wetlands (PCDs) mimics the self-cleaning ability of nature. Operates without mechanical and electrical equipment. The system consists of several successive basins insulated with foil and filled with the substrate. With the participation of micro-organisms and wetland plants as well as active, pre-planned role of physical and chemical processes, the water is cleaned to the required standards for the sustainable way through the natural flora. Microorganisms on the roots cleaned 80% and plants 20% waste waters.

Waste water is captured in septic pits or special jaws of liquid is swept in treatment plants, where the water clean. To provide a major share of cleaning bacteria that live on, or between the roots of specific types of plants. Only this can make maximum use of the natural environment in which we intend to put PCD. Thus increasing the efficiency of the device, since the bacteria and plants have adapted to the work environment.

For 1PE is required from 2 to 2.5 m² (LIMNOS, 2010). For family with 4 persons, we need 12m² place (10m² and 2m² more, because of 20% losses in winter). And its costs about 3.500 EUR in Slovenia. Which contains material, documentations, monitoring and work on the building PCD.

Picture 6: System for individual houses (Davorin Žnidarič, 2011)

PCD or Plant Cleaning device (**picture 6**) is a natural system cleaning wastewater, especially in rural or dispersed areas.

- 1 existing septic pits, septic tanks
- 2 PCD filtered garden - secondary treatment phase
- 3 cleaning garden
- 4 polishing garden
- 5 purified effluent (pool or surrounding area)

5. CONCLUSION

We must protect water because of us and our future generation. Methods exist, but they must be ecologically and environmentally acceptable. Plant Cleaning Devices are one of the best and successful devices. They are suitable for rural and scattered areas where other systems cannot be set, mostly because of geographical or other reasons. Our article /introduce only one solution to protect natural resources with ecological and suitable systems. But everything is in our deliberation. When we will change relation to the nature and its sources, we will rescue our lives and our future.

MANAGING INNOVATION – A FACTOR OF COMPETITIVENESS IN THE GLOBAL CONTEXT

Denis Bugar¹, Gordana Tomić², Aleksandra Tomić

¹ Higher School of Professional Business Studies, Novi Sad, Serbia, denis.vps@gmail.com

² Belgrade Business School, Belgrade, Serbia

Abstract: *In this paper, the authors highlight the importance of innovation for the global competitiveness index in the example of the European Union countries. Over the past period, the importance of innovation has been increasingly pronounced, which leads to a revolution in business and economy. Besides the success of knowledge-based economy, innovations also enable people, communities and countries to enhance their impact on business, politics and society. The World Economic Forum defines competitiveness as a set of institutions, regulations and other factors which determine the level of productivity of a particular country. The indicator of the level of competitiveness is called GCI (Global Competitiveness Index - GCI) and deals with measuring average values of numerous microeconomic and macroeconomic components.*

Key words: *innovation, global environment, innovation index, global competitiveness index*

1. INTRODUCTION

The new focus of competition is innovation as the ultimate source of differentiation and market success. Research and development activities of companies are increasingly clustered in order to overcome their resource requirements.

Pervasive pressure of competition causes companies to be in a good form. Improvement of products, production processes, efficiency increase, greater market power and influence and development potential represents the processes for which companies strive in order to survive in intense competitive struggle and increase their competitive advantage. It is precisely for these purposes why companies use innovation and invest in research and development so that they can be adequately utilized.

Such activities can affect the growth of competitiveness and recognition which can conquer new markets and sales growth, which further leads to more spending on research and development to keep pace with other market players and the environment in which they operate.

2. THE IMPORTANCE OF COMPETITIVENESS FOR ECONOMIC DEVELOPMENT

For creating competitive advantages the strategy of the national economy, by which a certain country mobilizes and develops its production capacity to achieve economic development and international competitiveness, is also very important. It is essential that the government creates an environment that stimulates companies to gain competitive advantage. For this reason, the purpose of this study is to highlight the importance of a positive link between innovation and the creation of global competitiveness in the example of the European Union countries.

In calculating the GCI a well-balanced average of many different components is used. Each component represents one aspect of a complex reality, which is called competition. These components are grouped into 12 columns, which are called the *12 pillars of competitiveness*. These pillars are divided into sub-indices; "General requirements", "Improving efficiency", "Innovation and sophistication factors" that are organized as follows:

- Basic requirements:

- Institutions
- Infrastructure
- Macroeconomic stability
- Health and primary education

- Improving efficiency:

- Higher education and training
- The efficiency of goods markets
- Labor market efficiency
- Financial market sophistication
- Technological readiness
- Market size

- Innovation and sophistication factors:

- Sophistication of business
- Innovation

Table 1. Overview of GDP per capita in EU countries

Country	GDP pc - 2009 (US\$)	GDP pc - 2010 (US\$)	GDP pc ¹ (%)
Sweden	43,403.916	48,874.608	0.48
Germany	40,831.659	40,631.243	3.96
Finland	44,555.810	44,488.643	0.25
the Netherlands	48,188.414	47,172.140	0.91
Denmark	56,051.559	56,147.143	0.27
UK	35,315.270	36,119.846	2.94
Poland	11,298.879	12,300.126	0.97
France	42,409.874	41,018.597	2.90
Latvia	11,465.612	10,694.594	0.04
Austria	45,685.879	44,986.583	0.45
Bulgaria	6,421.320	6,334.337	0.12
Greece	29,328.084	27,301.544	0.44
Slovenia	24,450.310	23,705.694	0.08
Portugal	22,027.594	21,558.780	0.33
Lithuania	11,055.520	11,043.838	0.08
Italy	35,250.810	34,058.720	2.39
Hungary	12,893.958	12,879.296	0.25

Source: <http://www.imf.org/external/pubs/ft/weo/2011/01/weodata/index.aspx>

¹ GDP per capita as a percentage (%) of the total worldwide number

The influence of each of the pillars of competitiveness varies from country to country, depending on the stage of economic development of the given economy. There are three stages of economic development: "The stage driven by factors", "Efficiency driven stage" and "Innovation-driven stage." These stages are taken into account when calculating the index, giving different weights to pillars (http://www.famns.edu.rs/skup2/radovi_pdf/vucenov_cosic.pdf).

World Economic Forum provides a detailed assessment of the productive potential of countries around the world. The report contributes to understanding the key factors that determine economic growth, help to explain why some countries are more successful than others, especially when it comes to increasing the levels of income.

Competitiveness contributes to innovation, business and overall economic growth. But if the competitiveness is poor in the market then the national economy suffers. Competitiveness is defined as a set of institutions, policies, and factors that determine a country's level of productivity.

The table shows GDP per capita in EU countries. One of the most important and most frequently used indicators of the level of economic development of a certain country is **gross domestic product** – GDP. Luxembourg has the biggest GDP per capita of 108,831,704 US\$, which can be seen in the graph, while Bulgaria has the lowest GDP of 6,334,337 US\$.

Behind Lukseburga are Denmark, Sweden, the Netherlands. These countries are among the top twenty most competitive economies in the world. Romania, Latvia, Poland by Bulgaria have the lowest GDP per capita. Bulgaria is located at 71 place, Romania is at the 67th place and Latvia takes 70th place in the global competitiveness index.

In Bulgaria in 2010 there was a fall of GDP per capita compared to 2009 from 6,421,320 US\$ to 6,334,337 US\$. Ireland recorded a decline of GDP per capita from 49,863,415 US\$ to 45,688,759 US\$, while Luxembourg recorded an increase from 106,550,822 US\$ to 108,831,704 US\$. Behind these figures on increase and attained level of GDP per capita, there are substantial changes of main drivers of development and major structural changes in the economic systems of individual countries.

Their dominant driver of growth is innovation while investments and factors driving the development have much smaller effect on the development. Innovation and innovative activity in these countries is reflected in both the technological-productive as well as entrepreneurial-managerial sphere.

Most EU countries have higher annual GDPpc than 17,000 USD, which means that they are in the third phase of development, i.e. innovation driven economy. Their knowledge-based economy offer high paid jobs and highly valuable products and services. These countries have a high innovative capacity and high competitive skills.

From the tabular and graphical representation we can see the ranking of EU countries according to the global competitiveness index. Scandinavian countries, Germany, Great Britain, France and the Benelux countries (Belgium, the Netherlands and Luxembourg) are at the top of the list and all are in the top 20 most competitive economies in the world. Sweden is on second place as the most competitive economy which is two places higher than the previous year and its GCI is 5.56. Germany is on the fifth and its GCI is 5.36. But the sources of their economic strength are different. Most other EU countries are among the 50 most competitive economies at the global level but there are five member states that do not have good results of competitiveness. Greece has bad economic indicators and it is found on the 83rd place which is 12 places lower than the previous year and its GCI is 3.99.

This economic decline of Greece in 2010 is due to severe deterioration in its macroeconomic environment which is caused by poor institutional adjustment and low efficiency of the market. The group of countries in the middle of the table whose rank is from 29th to 50th place and whose competitiveness index ranges from 4.74 to 4.34 is very significant. Here most countries have a worse position than the previous one. Bulgaria is located at 71st place which is five places higher as opposed to the previous year.

The first twenty states of the EU has GCI index over 5.00. From the table we can see that Sweden, which is in the second place, has a very high level of competitiveness of 5.56. The results of the index of competitiveness show that Poland with 4.51 GCI and the countries above it have a high level of competitiveness that ranges from 4.51 to 5.50. GCI shows that good institutions and competent and skillful

macroeconomic management, together with education and a focus on technology and innovation, represent successful strategies for achieving competitiveness in the growing global economy.

Table 2: EU Global Competitiveness Index

Country	Rang 2010.	Score	Rang 2009.	Change 2009.-2010.
Sweden	2.	5.56	4.	↑ +2
Germany	5.	5.39	7.	↑ +2
Finland	7.	5.37	6.	↓ -1
Netherlands	8.	5.33	10.	↑ +2
Denmark	9.	5.32	5.	↓ -4
the UK	12.	5.25	13.	↑ +1
France	15.	5.13	16.	↑ +1
Austria	18.	5.09	17.	↓ -1
Belgium	19.	5.07	18.	↓ -1
Luxembourg	20.	5.05	21.	↑ +1
Ireland	29.	4.74	25.	↓ -4
Estonia	33.	4.61	35.	↑ +2
Czech Republic	36.	4.57	31.	↓ -5
Poland	39.	4.51	46.	↑ +7
Cyprus	40.	4.50	34.	↓ -6
Spain	42.	4.49	33.	↓ -9
Slovenia	45.	4.42	37.	↓ -8
Portugal	46.	4.38	43.	↓ -3
Lithuania	47.	4.38	53.	↑ +6
Italy	48.	4.37	48.	
Malta	50.	4.34	52.	↑ +2
Hungary	52.	4.33	58.	↑ +6
Slovakia	60.	4.25	47.	↓ -13
Romania	67	4.16	64.	↓ -3
Latvia	70.	4.14	68.	↓ -2
Bulgaria	71.	4.13	76.	↑ +5
Greece	83.	3.99	71.	↓ -12

3. THE ANALYSIS OF CONTRIBUTION OF INNOVATION TO THE COMPETITIVENESS OF COUNTRIES

In addition to macroeconomic stability national economies must have and microeconomic stability in order to be competitive. Business activities in these national economies benefit from well-developed institutional framework and accountability within public institutions, and excellent infrastructure is an additional positive feature of the business environment. In recent years, innovation is increasingly gaining in importance which creates a revolution in business and economics. Recognizing the key role of innovation for growth and development of each country, the Confederation of Indian Industry together with INSEAD (The Business School for the World) and Canon India has developed the Global Innovation Index.

Table 3. Comparing Global Competitiveness index and Global Innovation index

Country	Global Competitiveness index	Global Innovation index
Sweden	2.	5.
Germany	5.	8.
Finland	7.	3.
the Netherlands	8.	13.
Denmark	9.	10.
the UK	12.	14.
France	15.	19.
Austria	18.	20.
Belgium	19.	15.
Luxembourg	20.	16.
Ireland	29.	22.
Estonia	33.	37.
the Czech Republic	36.	27.

Latvia	70.	77.
Bulgaria	71.	92.
Greece	83.	79.

Source: http://www3.weforum.org/docs/WEF_GlobalCompetitivenessReport_2010-11.pdf

The objective of measuring this index is to show the growth of innovation by the states, as well as to detect any obstacles that prevent the full profits of innovation for companies, government, and population (http://www.famns.edu.rs/skup2/radovi_pdf/vucenov_cosic.pdf).

Global Innovation Index classifies countries according to parameters such as "The institutions and their policy of doing business", "Human Capital", "Infrastructure", "Technological sophistication", "Business Markets", etc. The index has been in use since 2007 and compares 130 countries while using more than 90 indicators looking at different aspects of innovation.

The basic principles on which the Global Innovation Index (GII) is based:

1. There is a difference between input and output between measuring innovation in the economy. Inputs are factors that contribute to facilitating innovation while outputs show the results of innovation within the economy.
2. Global Innovation Index observe five input factors: Institutions and their policies, Human capital, General and IT infrastructure, Sophistication of the market and Business sophistication.
3. Third GI shows three output factors that make the results of innovation of economies: Knowledge development, Competence and Wealth creation.

In addition to Global Competitiveness Index, the World Economic Forum shows the Global Innovation Index, which is also measured on a scale of 1 to 7

From the given table we can see that if we compare countries that have a competitiveness index ranking to the 30th place these countries rank to 22nd place with the innovation index. Countries whose competitiveness index is ranked up to 50th place have innovation index which rank to 50th place but one country holds 54th place. Up to 83rd place of the competitiveness index, innovation index is up to 92nd place.

From the table we can see that countries whose competitiveness index is up to 30th place and also have a high index of innovation. Finland, which is on the 5th place of competitiveness index is on the 3rd place of the index of innovation. Sweden, which takes 2nd place in the competitiveness index has a 5th place when it comes to the index of innovation. Benelux and Nordic countries compensate for the small size of the market with constant innovation. By constant innovation, countries that have a high index of innovation also have a greater competitiveness index.

Because of this economies should be based on constant innovation. By constant innovation companies achieve competitive advantage which results in microeconomic stability.

Research and experimental development (R & D) comprise creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of a man, culture and society and the use of this fund of knowledge to devise new applications (*Lynch, Harrington, Stackpoole, Shimiyev, Doyle & Lee, 2002*).

Research is collecting knowledge about various phenomena and then selection of the relevant knowledge that helps us in solving problems. In these days of globalization Research and Development become a priority and a risk. Investment in research and development does not always mean that we will gain. Those who do not invest, they will drop out of "race" in the market very soon and will be taken over by competition, because in terms of strongly expressed competitiveness which is caused by the increasing number of participants in the global market, competitive advantages are changing and disappearing in a short period of time.

States and organizations need to invest in R&D to create a society based on knowledge, innovation and modern technologies. Investment in R&D does not only economic development of each country but results in a reduction of inequality of entire regions (*Huggins, Izushi, Davies & Shougui, 2008*).

Applied knowledge, science, education and research and development become the dominant factors in the development of modern economy and its competitiveness. It requires international cooperation because of the presence of a globalization and environment where innovation, originality and knowledge are the primary factors of development is necessary to achieve competitiveness.

We can conclude that investments in research and development, which increase every year, have had positive impact on the innovation index, speaking for all members of the European Union. Changes in the index of innovation caused by the increasing percentage share of gross domestic product in investments in research and development. Looking at the relationship between the index of innovation and global competitiveness index, we can conclude that there is a positive correlation. The change of the global

competitiveness is index caused by the growth of the index of innovation, which confirms the fact that the growth of competitiveness of an economy depends on the growth of innovation.

Innovations are the key drivers of long-term competitiveness, national prosperity and global economy. Innovative leaders in the EU are Sweden, Germany, Finland, Netherlands and Denmark, whose innovation performance are well above the average of EU countries. In the long run, innovations contribute to increasing GDP and increasing spending on research and development which further encourages innovations that contribute to competitiveness, economic development and improved living standards. In short term, states should support the development of innovations by all their measures.

4. CONCLUSION

Generally, when innovations are implemented, they must bring positive results to our environment, economy or society. They allow the reduction of production costs, new business organization, the introduction of new products. We must invest in research and development to keep pace with other market players. Significant investments in research and development are among the most important factors that enable many world economies to improve their ratings and increase GDP. States should invest in R & D to create a society based on knowledge, innovation and modern technologies in order to participate in market competition. Companies that appear on the market and apply innovation will be more profitable, more efficient, will provide new products which enables their prosperity, that is, they will be more competitive.

The problems of production management, which is connected to the concept that integrates and manages all production and service operations in businesses, can be solved by innovation whose application includes promotion or development of products, services, processes, technology, new ways of work organization which further increases productivity, improves quality products and services that contribute to the competitiveness of the organization.

Abstract: *This paper presents the results of a research study conducted in the area of Technology and Innovation Management (TIM) education in Serbia. A questionnaire-based mail survey was used to collect necessary data. The survey targeted two populations – professors who teach TIM courses at state and private universities, and practitioners who are responsible for managing technology. The results indicate that the curriculum of TIM requires prioritization and changes, and that business executives need to be better educated in different TIM knowledge areas. Some of the results obtained may be a consequence of small sample groups, and the future intention of the authors is to expand the samples, as well as to further examine and verify the findings presented in this paper.*

Keywords: *Technology Management (TM), Innovation Management (IM), education, Serbia, TIM knowledge areas, research*

1. INTRODUCTION

Technology management (TM) simply defined is “the process of effective integration and utilization of innovation, strategic, operational, and commercial mission of an enterprise for gaining competitive advantage”. (Badawy, 2009) The US National Research Council defines management of technology as “linking engineering, science, and management disciplines to address the issues involved in planning, development, and implementation of technological capabilities to shape and accomplish the strategic and operational objectives of an organization”. (Nambisan, 2003) The TM field has emerged from its relative obscurity during the 1970s and 1980s to mainstream business management during the 1990s (Nambisan and Wilemon, 2002). Managing technology and innovation has emerged as distinct and crucial functional area of business organization with specific strategic and operational roles.

Orientation towards strategic management issues in the practice of firms today is evident, with a focus on dealing with problems of long-term survival, growth and development in the uncertain and turbulent environment. Operational tasks and the capability to perform operations according to defined criteria are considered as a necessity and competence that firms develop today as a “must”. Organizations are focused at dealing with the problem of “what” to offer as new value (products and services), and “how” to perform the necessary operations, which points to the significance of strong links and interweaving of the strategic and operational dimensions of the key firm operations. Technology at the base of firm operations determines the new value offered in the form of products and services (answer to the question “what”) and the processes by which the output is created (answer to the question “how”). (Levi Jakšić, 2011)

The perspectives of micro and macro management of technology and innovation are becoming more closely related in an integral approach, as a significant dimension of the new technology and innovations management paradigm. TIM, as specific set of competencies in the competency based competitiveness approach, is recognized as the critical success factor for firms, sectors, economies and regions. The integral TIM concept is focused at managing technology as external force and internal factor of the firm meaning that both the innovative and technological infrastructure and the technology and innovative capacities of the firm are taken into account. Managing technological diversification is a significant dimension of the new paradigm leading to operations competitiveness of the firm closely related to its innovative capabilities. The success rate in the implementation of new technology and the development of new ideas for its application is an organizational challenge. Essential to technology management success is how we manage the innovation

process and the development of technology, and technology utilization in business and industry. (Badawy, 2009)

The strategic alignment of technological assets with a company's direction and management is a major issue in terms of impacting profitability and growth. Unfortunately, there have often been important mismatches between the graduates of universities and the skills needed by today's technology-based organizations (Nambisan, 2003, Mignogna, 2002). In highly dynamic environment, there is a constant need to research the knowledge and skills needed in practice and their compatibility with current programs at different educational levels.

2. RESEARCH BACKGROUND

The last two decades of historical development have shown a rise in the research interest in the field of technology and innovation management. That is clearly seen by the steep rise in the number of published works and authors that deal with these problems in theory and practice and by the results they have achieved. The rise is also seen in number of diverse educational programs in this field. In the US and in a few Western European countries, TM programs are now housed under the various academic schools (business, engineering, science, etc.) and have considerable diversity in their themes, focus, and course offerings. (Nambisan, 2003) Research studies in this field have been oriented at investigating TM and IM study programs and their relevance for practice. These studies have used different approaches and different expert and research groups.

Members of IAMOT (International Association of Management of Technology) and MINT (Management of Innovation and New Technology) were used as a research groups in the study conducted by Yanez et al. (Yanez, 2010). The authors wanted to answer three questions: 1. Did a body of knowledge for Technology and Innovation Management education make sense for the stakeholders in the field? 2. Do they have the right topics, and, if not, what was missing? 3. Are there any differences in the relative perceived value of some groups of these topics to an educational program? The results showed that some of the "most commonly found topics" were not included in their knowledge areas. They have developed the ranking based on *Knowledge discipline importance* to TIM education and the best ranked areas were: Strategic TIM, Innovation Management, Integration of Technology and Business Strategy, Fundamentals of TM, R&D Management, Product development management, Knowledge management, and Technology entrepreneurship. (Yanez, 2010)

The study conducted by Mallick and Chaudhury explored TM education in MBA programs in the United States (Mallick, 2000). Research has identified knowledge and skills that are necessary for effective TM. The study showed that there was general agreement between professors/academicians and executives/practitioners as to what knowledge and skills are important for effective TM. They were: knowledge of business strategy and competition, strategic role of technology in business, new product development (NPD), and understanding the issues related to implementation of new technology.

In the qualitative study (Levin, 2008) realized jointly by academics and technology managers from a number of large industrial firms, 27 technology management routines were identified. They were organized into a framework consisting of four categories: producing scientific and technological knowledge, transforming knowledge into working artefacts, linking artefacts with user requirements, and providing organizational support. According to the authors, this study is valuable for academics also, providing a descriptive baseline of the TM routines used in large corporations.

A global study of graduate TM programs involved over 50 universities and recognized the following key issues: TM programs are still evolving, industry involvement has increased, IT, related knowledge and international perspectives are becoming crucial, technology management education is important a graduate and undergraduate levels. (Nambisan, 2003) Liao classified TM methodologies using eighth categories: TM framework, General and policy research, Information systems, Information and communication technology, Artificial intelligence/expert systems, Database technology, Modeling, and Statistics methodology. One of the conclusions from the survey was that TM methodologies tended to develop towards expert orientation and that TM applications development was a problem oriented domain. (Liao, 2005)

There is still an evident need for research in this field, having in mind the dynamics of technological change, especially in production and services based on ICT implementation. These studies are very important today

as the role of university is changing. University has an indirect impact on entrepreneurship (Levi Jakšić, 2011, Levi Jakšić, 2012), playing a key role in high education and having the central mission of developing study programmes, with curricula and module syllabi that will prepare the future highly qualified work force to contribute with the highest capacity to the creativeness, innovativeness and entrepreneurship in the sustainable development of the economy and society. This is the crucial social responsibility of universities today. (Philpott, 2011)

Innovation and opportunity at the base of entrepreneurship is viewed in the perspective of the critical role of institutions in the promotion of innovation defined by national innovation systems, and universities are cited as critical institutional actors in national innovation systems. (Mitra, 2012) Therefore the role of TM and IM educators is of crucial importance. They are attempting to better serve their students' professional requirements and meet industry needs. (Nambisan, 2003)

The field of Technology and innovation management (TIM) has been studied in the Republic of Serbia at state and private universities for many decades. The first introduction of this field in undergraduate faculty programmes was in 1971 when the first generation of students at University of Belgrade, Faculty of organizational Sciences (UB FOS) studied Technological Systems as one of the compulsory modules. Today, many programs and modules are housed under the state and private universities. The relevant modules, disciplines and faculty branches, are presented in Table 1.

Table 1: Overview of faculties teaching the TIM modules at state and private universities in the Republic of Serbia

The changes in syllabus of TM modules at UB FOS were in line with the development of the scientific field and the research topics in the environment. Comparative overview of changes in TIM scientific field and introduction of new thematic units into relevant modules - Managing technology (TM) from 1987 to 2005 and Management of technology and development (MTD) from 2006 until present, are presented in Table 2.

Table 2: New findings in the academic field of TIM and thematic units at relevant modules at UB FOS (based on Levi-Jakšić, 2011a)

3. RESEARCH DESIGN

Target population, method and objectives: In order to examine the knowledge needed in TIM practice and their compatibility with the current programs at different educational levels in Serbia, a mail survey was conducted in the period February – April 2012. The survey targeted two populations – professors who teach TIM courses at state and private universities in Serbia (presented in Table 1) and business executives/practitioners who are responsible for managing technology in the industry of Serbia. This approach firstly allows comparison between the areas of TIM that professors considered important for curriculum and areas considered necessary by practitioners. Secondly, as the field of TIM in Serbia does not have a standardized curriculum and as there is no consensus on its content, it needs efficient prioritization. Professors have the primary responsibility for curriculum development in business schools. They teach what they consider to be important for students to learn and students learn what professors intend to teach. But, the voice of practitioners should be present as a guide to any professional program. They are in a better position to identify the needs that are relevant to the challenges they encounter in their everyday practice. (Mallick and Chaudhury, 2000)

Survey instruments: A questionnaire-based mail survey was used to collect the necessary data. Two separate survey instruments were developed for two targeted populations. Firstly it was made for professors who teach TIM and then some topics were modified to make it suitable for practitioners. Questionnaires were divided into two parts. The first part was focused on information related to university/faculty affiliation, methods used for teaching and the background of the respondent (for professors) and on information related to organization and the background of the respondent (for practitioners). The second part consisted of 37 knowledge areas, which were divided into five main groups: 1. Basic concepts of TM and organization development, 2. Strategic role of technology in business, 3. Strategic technology management, 4. Operational management, 5. Links of TM and other disciplines. The respondents were asked to rate the importance of each area using five-point Likert scale (1 = Not important at all, 5 = Very important). Professors were also asked to rate the coverage of each area in their curriculum (1 = Not covered at all, 5 = Very well covered) and the practitioners to rate their proficiency in each area (1 = No proficiency at all, 5 = Very good proficiency). They were also asked to give additional comments to the survey. Less than 2% of the respondents gave additional comment, so it can be concluded that the knowledge areas in the questionnaire were well covered.

Data collection: A database of the professors who teach TIM related courses in Serbia was made. Survey instrument was mailed to 44 professors. Twelve completed questionnaires were returned, resulting in 27% response rate. In order to reach the second targeted population, questionnaire was sent to 310 companies in Serbia. Thirty-four completed questionnaires were returned, resulting in approximately 11% response rate.

4. RESULTS AND DISCUSSION

4.1 Essential knowledge areas of TIM – importance, coverage, proficiency: professors vs. practitioners

Table 3 presents the findings related to the knowledge areas relevant for TIM and the responses from both groups: professors and practitioners. For each knowledge area in column 1 respondents were asked to rate

its importance in managing technology. Columns 2 and 8 present the average importance ratings for professors and practitioners, respectively. Professors were also asked to rate the coverage of areas listed in column 1 in their programs. The average coverage ratings for all respondents are presented in column 4. Practitioners were asked to rate their proficiency/knowledge in all areas listed in column 1. The average proficiency ratings are presented in column 10. The differences between importance and coverage level of all listed knowledge areas is calculated to obtain a level of deficiency for each area and are presented in column 6. In the same way, column 12 presents deficiency between the importance of knowledge areas to practitioners and their proficiency in those areas. The rankings of knowledge areas based on professors' importance ratings, coverage and deficiency are presented in columns 3, 5 and 7, respectively. The rankings based on practitioners' ratings of importance, proficiency and deficiency are presented in columns 9, 11 and 13, respectively. Items in column 1 are presented respecting their importance rank by professors.

The rankings in the column 3, based on professors' importance ratings, reveal that the top ten important knowledge areas are: Corporate, business and functional strategies, Technology strategy, Competitive strategies, Integrating business and technology strategies, Technology forecasting, Innovation processes, R&D management, Entrepreneurship, Performance management of technology and organization, Measurement and control of technology efficiency in the organization. The least important knowledge areas include Business - production - technological systems, Internal value chain model - primary/secondary operations and Legal aspects. Column 5 indicates that the best covered areas in TIM courses are Entrepreneurship, Creativity and product, service and process development, Technology strategy and Technology forecasting. Knowledge areas with the lowest coverage levels are: Legal aspects, Internal value chain model - primary/secondary operations, Basic business functions and operations, Sustainable development and Performance management of technology and organization. These results show that the best covered areas are some of those that professors marked as the most important, but some important areas are not covered sufficiently. Top five areas in which the TIM courses are most deficient (column 7) are: Performance management of technology and organization, Measurement and control of technology efficiency in the organization, Corporate, business and functional strategies, Sustainable development and Financial aspects. Areas in which courses are the least deficient are: Globalization, strategic alliances and partnerships, Organizational structure, The meaning of the concept of technology management in the organization, Technology and value creation in the form of products / services and Creativity and product, service and process development.

The rankings in column 9, based on practitioners' importance ratings, reveal that the top ten knowledge areas are: Financial aspects, Information technology and business, The acceptance/adaptation of new technology for the organization, Creativity and product, service and process development, Integrating business and technology strategies, Acquisition of technology – ranking and selection of technology, Knowledge Management, Sustainable development, Technology and value creation in the form of products / services and Business – production – technological systems. Results show that Models, qualitative and quantitative methods as a support, Globalization, strategic alliances and partnerships, Internal value chain model - primary/secondary operations, Competitive strategies and R&D management are the areas that practitioners ranked as the least important. This is a worrying fact, because some of these areas are actually the most important in today's business world. Column 11 indicates that the top five areas in which practitioners consider themselves as most proficient are: Internal value chain model - primary/secondary operations, Management of technology portfolio and R&D projects, Marketing aspects, Globalization, strategic alliances and partnerships and Technology forecasting. The respondents consider themselves as least proficient in the following areas: Sustainable development, Internal factors of the organization and Acquisition of technology – ranking and selection of technology. The highest deficiency is present in Intellectual property rights, Sustainable development and Technology transfer, which is another worrying fact because these are some of the most emerging topics in today's business.

The given analysis shows the results within separated populations, and indicates the knowledge areas that should be reexamined first. The results show that there are relatively strong deficiencies between importance of knowledge areas to professors and their coverage in the courses. Differences are present also in the importance of knowledge areas to practitioners and their proficiency in those areas. Thus, these results confirm that on one side, the curriculum of TIM needs prioritization and changes and, on the other side, business executives need to be more educated in technology and innovation management.

4.2. Relative importance of TIM knowledge areas: professors vs. practitioners

A comparison of importance ratings between the sample groups – professors and practitioners, using t-test, identified only five statistically significant differences ($p < 0.05$), in the following knowledge areas: *Management of R&D* ($p = 0.049$), *Measurement and control of technology efficiency in the organization* ($p = 0.037$), *Technology strategy* ($p = 0.025$), *Corporate, business and functional strategies* ($p = 0.023$) and *Competitive strategies* ($p = 0.005$). In order to see the level of these statistically significant differences, eta-square was calculated for each of the five areas. Results showed that there is a high influence for Competitive strategies ($\eta^2 > 0.14$) and medium influence for other four areas ($\eta^2 > 0.06$), which shows that these areas are the ones that should be reexamined first. The obtained result may be the consequence of the small sample groups. The intention is to expand the samples in the future and to examine and confirm the preliminary findings given in this section.

5. CONCLUSION

The study presented in this paper confirmed that there is a constant need to research the knowledge desirable in practice and their compatibility with current programs at different educational levels. This is specially the case in the field of Technology and innovation management where there is an evident rise in number of diverse educational programs. The dynamic field of TIM and turbulent market conditions in Serbia are the major challenge in itself. The survey of the knowledge needed in TIM practice and programs at different educational levels in Serbia revealed significant differences in educational programs and respondents' attitudes. The field of TIM in Serbia does not have a standardized curriculum and faculties have considerable diversity in their themes, focus, and course offerings. Based on the survey, the least important areas for practitioners and the areas where practitioners have the lowest competence are some of the most emerging areas in today's business. We can conclude that: 1. The curriculum of TIM needs prioritization and changes, hearing the voice of practice, and 2. The business executives need to be more educated in different TIM knowledge areas. In addition to curriculum changes, seminars, conferences and other forms of knowledge transfer are needed. This research can be considered as a research in progress and some of the results obtained may be the consequence of the small sample groups. Nevertheless, the results are showing that further research is needed. They can be considered as action alerts, also. The future intention of the authors is to expand the samples under consideration and to further examine and verify the findings presented in this paper. With a large sample, it would be possible to examine the relationship between respondents' educational and professional background and their attitude toward specific TIM knowledge areas.

Abstract: *The majority of the existing e-learning systems are faced with problems due to a non-standardized data model, unstructured content and education platform incompatibility. Such systems contain educational content that is formatted in a single system, this way being useless in others, making them incompatible systems. These facilities are therefore not used in other systems. This is a basic deficiency of the existing e-learning system. For these reasons it is necessary to carry out the standardization process of e-education. With the rapid expansion of various forms of e-learning, the market has been overwhelmed by a large number of platforms from different vendors (LMS - Learning Management System), whose main purpose is storing, managing and distributing learning materials to the end users, students.*

Key words: *e-learning standards, SCORM standards and definition, SCORM components, meta data and standardization of e-learning.*

1. INTRODUCTION

The development of quality instructional materials for learning needs a considerable expenditure of time and money and is therefore very important that the teaching materials presented are compatible with various platforms for e-learning, their versions and operating systems on which they have been built.

Before the advent of learning material standards, the producers had the same materials to create multiple versions in order to cover the different systems. The materials which were created in one school could not be used in another one because it has a different platform for e-learning. All these have significantly influenced the increase in prices or prevented the handout of teaching materials to educational institutions. Therefore, a need arose to define standards that will accept a platform for producers and creators themselves.

In that case, all the teaching materials were consistent with this standard and also based on the standardized platform for e-learning. The first standards were being made by the IMS Global Learning Consortium and the World Society of Electrical and Electronics Engineers the IEEE. In January 1999 the large US organizations launched an initiative whose role was to determine precisely the standardization of teaching materials for learning to be generally accepted.

Their initiative was joined by a large number of educational institutions and interested companies. The first task of ADL-a practical definition of standards and the recommendations was to create teaching materials for learning. The result is a document given to the specification of standards, called the SCORM with the current versions of SCORM.

2. SCORM STANDARD-DEFINITION SCO

SCORM standard introduces the concept of shared content object SCO (Sharable Content Object), which is the basic unit of learning materials (Eng. Learning Object). SCO is the equivalent of one lecture, the electronic exchange and it can consist of a text, images, video sequences and even the interactive content such as flash or java applications.

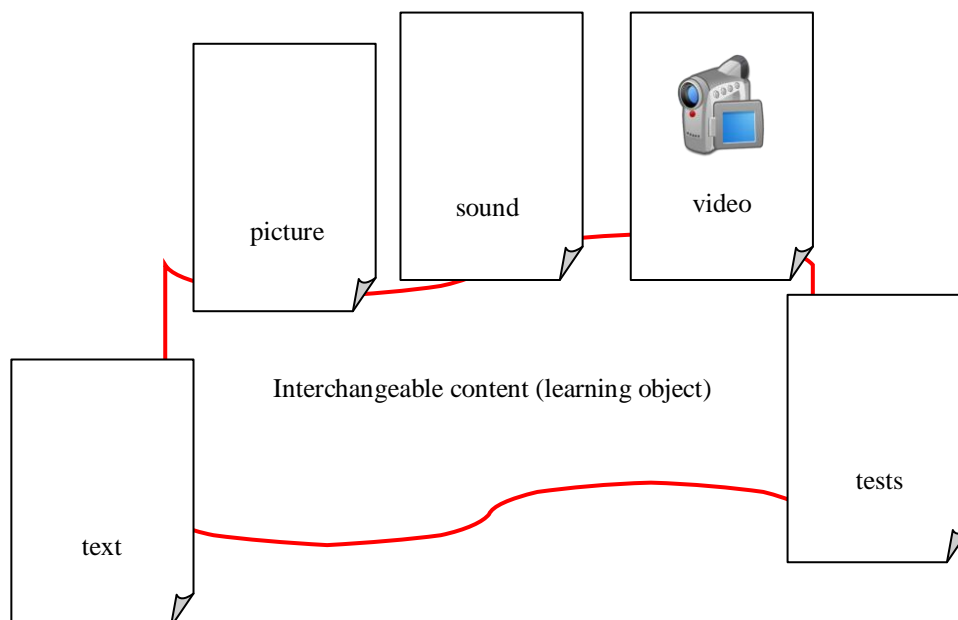

SCO is described by metadata, which allows finding the lessons in various technical and pedagogical criteria.

Each SCO should represent a logical and complete whole, which is not too extensive and that can fit into the whole e-course. These lessons may include lectures or tests with different types of responses (single or multiple choice, completing, etc.). Structuring of electronic course content is done by selecting and arranging the SCO in a specific order.

2.1. STANDARDIZATION OF ELECTRONIC MATERIALS

The majority of existing e-learning systems are closed systems. They include courses that are created and authored tools for a particular system. These facilities therefore are not be used in other systems. This is a basic lack of existing e-learning system.

For these reasons it is necessary to carry out the standardization process of e-education. The main task of the standardization process of e-education is to develop a standardized data model and standardized structure of the educational content that will enable their use, regardless the tools they were created by and the environment they will be located in. This involves cooperation between different LMS.

Picture 1: Learning objects (Sharable Content Objects - SCO)

Electronic educational materials are usually made within a standard known as SCORM (Sharable Content Object Reference Model). SCORM is a set of standard web-based technologies and protocols that allow the authors of electronic course content and to exchange information (Sharable Content Objects - SCO) in different LMS. Content objects that are interchangeable (SCO) may be: sound, image, text, video or any other electronic medium. The basic concepts of standard e-learning and SCORM model are:

- **Durability**

Once created a material can be used during the relevant time period in spite of the outdated version of software and hardware (which provides that, despite technological progress, they can be used as educational material designed for e-learning, if they are made by the SCORM standard)

Learning materials can be exchanged between different LMS systems (Platform for e-learning). Once designed electronic learning materials at any SCORM compatible platform can be delivered regardless the tools that are being designed and educational platform.

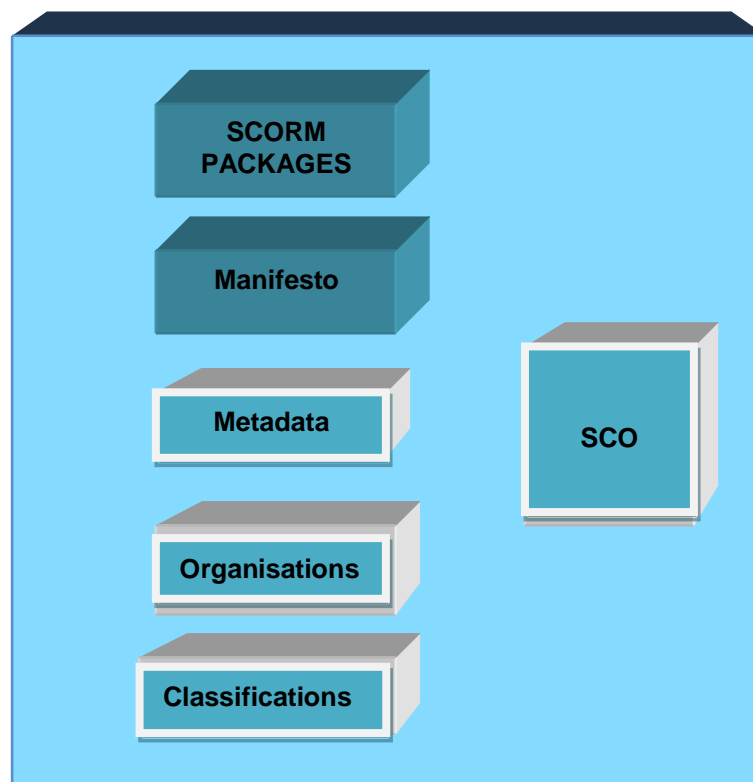

- **Reusability**

Each SCO can be repeatedly used as a part of various educational entities, in different contexts and for different learning objectives.

- **Accessibility**

SCORM materials can be classified and find thanks to meta data. A complete SCORM package is described in the manifesto.

The picture shows the structure of the SCORM package:

Picture 2: The structure of SCORM packages

The **manifesto** describes the entire package through a structured XML document. Reading the manifesto, LMS receives all information about the content of the package, the organization structure and collection of resources included.

Metadata contains a descriptive and administrative information about the package, as well as the information that defines the package for compliance with the SCORM standard.

Organizations represent one or more activities that can be inserted as needed. This list of activities is the manner and sequence that will provide student with resources. SCORM package must have at least one organization.

Classification of attributes describes the package and their use. They are to be included in the catalog and global search. A SCO is typically composed of multiple files (html, flash, video and audio, interactive media ...) that the student follows as common or interactive lessons, and may represent different types of tests.

SCO can be treated as a mini web site with their directory structure and content. All links in the SCO framework must be relative to be independent of the physical location of distribution. Standard SCORM contains proposals for:

- Formatting content (Lesson content is divided into learning objects (learning objects))
- Describe the content (metadata to describe learning: types of educational content, the level of interaction, the target group, length of learning, etc.).

2.2. SCORM COMPONENTS

SCORM components are units of educational content that is delivered to students:

- *The basic elements* - the basic unit of educational content (text, images, Java applets, audio).
- *Learning objects* (Sharable Content Objects - SCO) that comprises the smallest indivisible unit of educational content being delivered to students (web pages).
- *Aggregation of content* - area teaching a course or a structured set of SCO-components with defined behavior. The most commonly used to group related educational content.

2.3. META DATA

A growing number of educational facilities are available in the Internet environment, hence, there is the need of simple tracing enabling their reuse. For the purpose of locating simple, educational resources meta-data (metadata) is being applied.

Metadata are "data about data ". They give information about the group of data that make up an educational facility (document, image, content modules, etc.). Most are encoded in the programming language XML (eXtensible Markup Language) and describe the educational facility, or other digital source used in the educational process. Meta-data have a role to facilitate re-usability and interoperability, usually in the LMS. Each component is being developed for the purpose of defining a set of meta-data in order to be used later as the same resource, creating the appropriate design patterns for components of the course to be used for entering a pre-determined set of meta-data. Thus created and completed, they are meant to be put in the appropriate place to keep the folder structure, exchanging themselves with other team members-developers who will create these documents. The specification that defines the elements required by the type of components:

- type,
- the author / owner / publisher,
- description,
- language,
- date,
- terms of distribution,
- format and pedagogical attributes (educational style, the style of interaction).

3. THE ROLE OF TEACHERS IN THE SYSTEM OF DISTANCE LEARNING

Standardization of e-learning:

The main role of standards in the implementation of e-learning is reflected in the tendency to develop standardized data model and standardized structure of the educational content enabling their use regardless the tools that created them and the environment within which they are being used.

Standardization process to ensure the following properties of e-learning:

- *interoperability*, which ensures the possibility of electronic exchange of materials between different LMS systems,
- *reusability*, which involves the use of educational materials in different courses for different students or whatever authoring tools are used to create them including LMS systems as well.,
- *manageability*, where we observe the system's ability to record relevant information about student and program content,
- *accessibility*, indicating the possibility that the author and students from any location can access the contents of e-learning and
- *durability* , which provides the functionality of the system in case of being upgraded and improved.

Creating standards is often a long-lasting process that takes place through the following four iterative steps: Research and development in order to find possible solutions to problems, development of specifications, testing and activation of pilot programs and accreditation by official bodies.

Developing standards in the field of e-learning to deal with many organizations, institutions and initiatives such as: AICC (Airlaine Industry CBT Committee), AIMS (IMS Global Learning Consortium), ADL (Advanced Distributed Learning), ALIC (Advanced Learning Infrastructure Consortium), ARIADNE (Alliance of Remote Instructional Authoring and Distribution Networks for Europe), CEN (Committee European de Normalisation, European Committee for Standardization), IEEE (Institute of Electrical and Electronic Engineers), ISO (International Standards Organization), GESTALT (Getting Educational Systems Talking Across Leading edge Technologies), PROMETEUS (PROmoting Multimedia access to Education and Training in European Society)...

At the initiative of the Department of Defense (The U.S. Department of Defense) and the Directorate of Science and Technology, White House (The White House Science and Technology Office) is an initiative created ADL (Advanced Distributed Learning), whose greatest contribution in the field of standardization is reflected in the development of SCORM reference model (Sharable Contents Object Reference Model-Reference model of tradable content objects). SCORM is a standard in the legal sense because it is not accredited by an official body that verifies the effectiveness of the applied set of specifications and

standards. It was drafted in collaboration with standardization bodies such as AICC, IMS and IEEE to integrate their specifications into one cohesive, usable, comprehensive model defining the key interrelationships between their standards.

The first version of the ADL's SCORM documentation was turned towards the content of courses that are conducted through the Web, and aimed to provide the following:

- the ability of LMS systems to initiate the content that is made by different manufacturers and tools to exchange data with the content,
- the ability of LMS systems from different vendors to launch the same content, feasible to exchange data with that content during its execution,
- the ability to more LMS products/environment feasible approaches to the common stock of content a
- the ability to transfer the entire course from one LMS to another system.

SCORM recommendations define meta data for the educational content; model of organization and packaging of educational content – the structure of the course (content packaging); communication mechanisms between learning content and LMS systems, which define data model that manages the LMS, the method of initiating and delivering content.

4. CONCLUSION

The central place in the structure of the educational content that is compliant with SCORM recommendation takes an interchangeable object content (SCO - Sharable Content Object). Its understanding is based on the concept of learning object that is an independent, discrete part of the educational content to practice the one and the only one educational goal. The interchangeable content object is the object of study that consists of one or more basic units of educational content, having the ability to locate the LMS API adapter. Based on SCORM specification, there is a determined hierarchy of educational components. At the lowest level there are: the basic unit of educational content that are presented in the form of text, images, audio or other types of data in digital format. Their combinations can create information objects that represent concepts, facts, principles, processes and procedures.

MANAGEMENT OF MULTICHANNEL RELATIONSHIP BETWEEN RETAILERS AND CONSUMERS

Jelena Koncar¹, Sonja Lekovic²

¹Faculty of Economics Subotica, jkoncar@ef.uns.ac.rs

² Faculty of Economics Subotica, sonjalekovic@ef.uns.ac.rs

Abstract: *Multichannel relationship is built between consumers and retailers that use more than one channel to interact with the target market. Multichannel retailing is currently one of the most interesting areas in marketing channels. Multichannel approach to building customer relationships is of great importance in maintaining regular, loyal customers, as well as in achieving competitiveness and winning new consumers. The development of a multichannel relationship between retailers and consumers is a complex process, and when properly applied can dramatically increase the sale of products and service of retailers at the appropriate market segment. Combining marketing channels through multichannel approach enables better business performance.*

Keywords: *multichannel marketing, marketing channels, electronic commerce, retailer, consumer*

1. INTRODUCTION

The development of multichannel marketing gives consumers access to more marketing channels as a choice to buy products. Using one or more marketing channels, retailers provide consumers with more options and thus become more attractive to consumers and win new consumers. The exponential growth of electronic marketing channel gives retailers new opportunities to reach geographically distant consumers, 24 hours, seven days a week, reviewing the product before going to the retail store, etc.

In building a multichannel relationship between the retailer and the consumers, the following questions need answers:

- Which marketing channel should we use for the customer relationships development?
- How to coordinate and manage the implementation of sales in certain channel (pricing, inventory management, product distribution, etc.)?
- What is the impact of electronic marketing channels on purchasing products in the retail store?
- How to achieve an optimal mix of marketing channels in multichannel relationship with consumers?

Multichannel retailers face many problems in the implementation of selling the product because one marketing channel is a direct competitor to the other marketing channel. Therefore, one channel can exert a direct impact on increasing sales of another, while the relationship between marketing channel depends on the decisions of consumers in which channel will purchase the products.

2. INTERDEPENDENCE OF INDIVIDUAL CHANNELS IN DEVELOPMENT OF RELATIONSHIP BETWEEN RETAILERS AND CONSUMERS

The development of multichannel approach provides good consumer relationships, consumer loyalty, winning new consumers, which will have multiple effects on the income of retailer from sale. Thanks to this approach, the retailer has a view to customers' needs in the multichannel way, improving relationships with customers as a whole. Specifically, in one channel (e.g. e-commerce site) the consumer's need is identified, the consumer becomes familiar with the product, its characteristics, retail stores where the product can be bought, while still not fully prepared to buy in an electronic shop. Then, the decision to buy consumer makes

in the retail store, where he/she meets a physical product. However, following purchase of the same product, the consumer will likely do after receiving the catalog to home address for ordering the product from the same retailer.

The management of multichannel relationships with has to make a decision on the optimal channels, among the growing number of different marketing channels. To increase sales, achieve greater market share, increase sales income for retailers' profit, makes retailers to perform multichannel strategy. The ultimate goal is the synchronization of customers' information and interactions through its channels in order to comprehend better the needs of customers (Arakin, 2008, p. 193). The main characteristics of marketing channels are shown in Figure 1. The value added by sales determines characteristics of individual marketing channels, participated in the retailer's sales force and channel specific transaction costs. In building relationships with consumers, the retailer determines the optimal mix of channels.

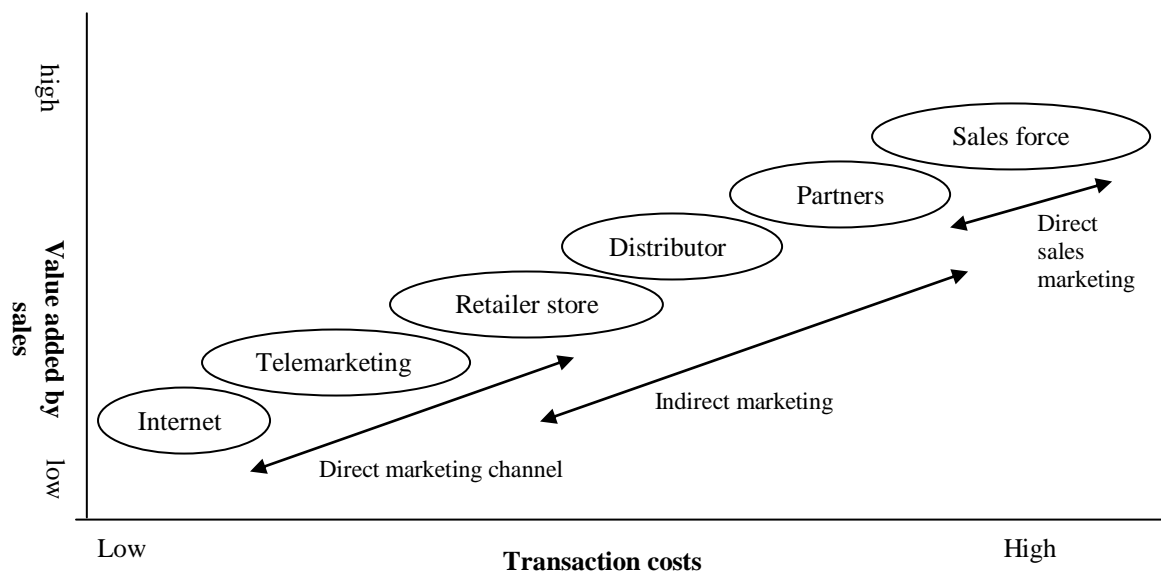

Figure 1: Characteristics of Marketing Channels (Lovreta, Koncar, Petkovic, 2011, p. 186)

If the retailer decides to sell in retail stores with the inclusion of one direct channel, for example, the option of electronic sales, which has low value-added sales, but low transaction costs for the retailer and the consumer, direct marketing channel will initially have an impact on increasing sales in the retail store. Direct marketing channel will be used to introduce products to consumers, compare prices, product choice and marketing channels. In case of the Republic of Serbia, 41.2% of households use the Internet, and more than half consumers, the 58.5%, use the Internet to be informed about the products of retailers and manufacturers (Upotreba informaciono-komunikacione tehnologije u Republici Srbiji 2011., p. 9).

What the impact of one marketing channel will be to increase sales in another channel, that is, how much sales and share of each channel depends on the level of implementation and development of the retailer's relationship with the consumer in a particular channel. The retailer can have multichannel consumer relationships at different levels of development. Interrelationship between the levels of development can be summarized as follows (Vanish, 2011, p.14):

- 1) 0 level - limited presence;
- 2) 1 level - reactive and experimental;
- 3) 2 level - defined and repeatable;
- 4) 3 level - controlled and measured;
- 5) 4 level - optimized and innovative.

Retailers with limited presence of multichannel relationships with customers have limited implementation of electronic commerce, mobile commerce and direct marketing. These new marketing channels are not considered as crucial for retailer's business and have no significant impact, nor are substantially used by consumers to purchase products, but they exist as a potential option to purchase the product. At this level,

multi-channel relationship between retailers and consumers is undeveloped, and the consumer dominantly purchases products at the retailer store.

At the first level, retailers react to the impact of environment, competition and consumers, i.e. external factors that pull use of technology in building relationships with the consumer. Therefore, the use of electronic commerce, mobile commerce and direct marketing is the result of the environmental impact, but without a precise plan of keeping the multichannel relationship between the retailer and the consumer, or the results of implementation of these relationships.

When multichannel relationships with customers become clearly defined and with repeating retailer uses them as essential for establishing an interactive relationship "1:1". Technology is changing the nature of the retailer-consumer interaction (Berman and Evans, 2010, p. 44). The potential of new marketing channel is visible in the further development and implementation of multichannel performance, and the acceptance by consumers.

Control and measurement of multichannel consumer relationship implies the existence of the retailer's integrated approach. The retailer, who has clearly defined goals to be achieved and results of multichannel relationships, devotes attention equally to each marketing channel by which he establishes relationships with the consumer. The application of multichannel marketing profile should contain information, which is provided by online and offline customers' experience (Koncar, 2011, p. 531). At this level, individual marketing channel does not represent a competition to another, but contributes to the achievement of synergy of channel goals.

The last level leads to the spread of individual channels, which can endanger the whole retail system. It is therefore necessary to make decisions about optimization of multi-channel consumer relationships, in order to achieve the efficiency of each channel. The new innovative approach in each of these channels needs to achieve efficiency in contact with the consumer.

In the multichannel management of relationship between the retailer and the consumer, the retailer must keep in mind that some consumers want to purchase electronic, and are willing to wait for products to reach them. On the other hand, a huge number of consumers want to dispose the product immediately when purchase it in retail store. For this segment of consumers, it is not acceptable to wait for product to be shipped, and they are satisfied with the level of interactions in the retail store. What is crucial for retailers is to provide to consumer a variety of convenient ways to buy a product, and, thereby, build good multichannel relationships with consumer.

3. THE IMPACT OF ELECTRONIC COMMERCE IN MANAGEMENT OF MULTICHANNEL RELATIONSHIP BETWEEN RETAILER AND CONSUMER

Electronic commerce represents the use of the Internet and Web to transact business. More formally, digitally enabled commercial transactions between and among organizations and individuals (Laudon and Traver, 2012, p. 49). The development of electronic commerce have the effect of changing the retailer's existing marketing channels, as well as the emergence of new retailers who sell only on the Web. The retailer, who introduces an electronic channel, must take into consideration the consistency of the existing system. Most multichannel retailers benefits theirs performance "clicks and bricks", and thus show the range of products on their websites. The famous multichannel organizations are Wal-Mart, Sears, JCPenney, Staples, OfficeMax, Costco, Macy's, Target and other brand-name merchants. Consumers have access to products from home and the ability to get information and buy products electronically, or do their shopping in a retail store. The multichannel consumer behavior shows that 22% of consumers like browsing products online and buy the same retail facility, a 21% compares prices of different online retailers (Berman and Evans, 2010, p. 175).

Electronic commerce has enabled access to retail customers without time and geographical constraints. In building a multichannel relationship with the consumer, electronic commerce provides information about the needs, identify new needs, collect relevant data on each individual consumer, and all thanks to an interactive relationship, "one on one." Interactivity is a technology that allows for two-way communication between merchant and consumer (Laudon and Traver, 2012, p.54). The dynamics of interactivity will have a profound impact on the concept of the market management, and thereby the relations of retailers and consumers. Interactivity allows the definition of a completely individual and variable assortment, depending on the

preferences of consumers. Consumers are, basically, multichannel beings with many demands, whereby, a successful business concept should fully cover all of the multichannel orientation.

Because of the complexity of multichannel approach, the retailer performance in a "click and brick" must ensure the availability of products in the electronic channel and retail store, and price policy consistency, automatic recording of inventory to meet customer needs in each channel. Two approaches of implementation of multichannel strategy of building relationships between retailers and consumers are "top-down" and "bottom-up" (Vaish, 2011, p.14). The "top-down" concept takes into account the views of all interest groups and dimensions: mobile channels, electronic channels, and various aspects of the electronic channels such as content, experience, business intelligence, etc. In the "bottom-up" approach, we take into account the data, which are available within the organization structure and its possibility of implementing multichannel strategy in dealing with customers.

Multichannel strategy becomes dominant in the world's leading retailers, because of its large extent influence on the improvement of business performance. The experience of developed-market countries shows that retailers who are implementing and utilizes multichannel strategies in marketing channels, have better business performance than those who do business with only one channel.

Today, electronic commerce is becoming a key factor in the expansion of multichannel strategy of retail development in Serbia. The leading indicators of future development of electronic commerce in the Republic of Serbia are the degree of economic development, the Internet infrastructure, as well as the educational level of the population. Products that consumers most often buy electronically in Serbia are: books, newspapers and magazines (23.9%), clothing and sporting goods (19.8%), household products (19%), electrical appliances (10.3%), drugs (8.7%), computer software (8.3%), hardware components (7.1%), housing (5.2%), other travel arrangements (5.2%), games and equipment for the game (4.2%) and other (Upotreba informaciono-komunikacione tehnologije u Republici Srbiji 2010, 2012).

The above data indicate that electronic commerce in the Republic of Serbia becomes a key factor in the development of multichannel retailers and consumers in marketing channels. Interactivity has a profound impact on multichannel marketing on the global market. Personalization and customization of e-services to consumers in the interconnection of multichannel retailers, depends on the possibilities of the Internet and electronic commerce technology. The future expansion of e-services will depend on the capabilities of e-commerce to transform their services in a personalized service to meet the needs of individual consumers. Previous experience of market-developed countries indicates that customers are multichannel marketing users through interactivity that provide an individual offer for each customer. The ultimate goal of developing the profile of a multichannel marketing is the synchronization of information about consumers and their interaction, with the aim of better meeting the demands and needs of consumers.

4. CONCLUSION

Multichannel occurs when retailers in their market performance use more than one type of channel in order to win the target market segments. Multichannel strategy becomes dominant in the business world's leading retailers because it affects business performance improvement compared to single channel marketing. The implementation of multichannel strategies creates a synergy that should create an adequate supply of multichannel consumers. The growing importance of retailing in marketing channels has focused on the application of multichannel strategies. In Serbia, e-commerce is increasingly becoming a factor in the development of multichannel strategies. The importance of electronic commerce in marketing channels will increase in the future in Serbia, and, above all, thanks to the multichannel approach.

Abstract: *A new trend in the development of modern information and communication technology is the cloud computing, a model that is built on the basis of the convergence of several IT concepts: virtualization, distributed software applications, data centers, Web2, grid computing ... The work includes a cloud computing model with all its characteristics and its possible application in e-governance in order to provide efficient, economical, and intelligent services to end users.*

Keywords: *cloud computing, model, e-government, information and telecommunication technologies, architecture*

1. INTRODUCTION

Today, in order to meet the growing demands of our clients, the state administration business is increasingly based on modern information and communication technologies, that is to say Internet technologies. By the application of modern information and communication technology-ICT models, in e-government, it becomes a user-focused administration that enables better, faster and more efficient sophisticated public services to citizens (in rural and urban areas), business systems, public institutions... E-government with its basic models: Government to Government G2G, Government to Enterprise-G2E, n to Business G2B and Government-to-Consumer G2C, becomes a reality in achieving efficient and effective operation of the entire state administration. Public administrations in developed countries have begun to increasingly translate their e-government models into cloud computing models, which are the new innovative information technology that has a trend of exponential growth. Using the cloud computing model increases the productivity of e-government, reduces the costs by reducing information resources needed to run the standard e-government services, increases flexibility, scalability, interoperability, accessibility...

2. E-GOVERNMENT

Throughout the literature, there are many definitions of what constitutes the concept of electronic government. For the needs of this work, we will mention the following three:

"Electronic government refers to government's use of technology, particularly web-based Internet applications to enhance the access to and delivery of government information and service to citizens, business partners, employees, other agencies, and government entities". [1]

World Bank definition: "E-Government refers to the use by government agencies of information technologies (such as Wide Area Networks, the Internet, and mobile computing) that have the ability to transform relations with citizens, businesses, and other arms of government. These technologies can serve a variety of different ends: better delivery of government services to citizens, improved interactions with business and industry, citizen empowerment through access to information, or more efficient government management. The resulting benefits can be less corruption, increased transparency, greater convenience, revenue growth, and/or cost reductions.

Definition of the Working Group on E-government in the Developing World: E-government is the use of information and communication technologies (ICTs) to promote more efficient and effective government, facilitate more accessible government services, allow greater public access to information, and make government more accountable to citizens. E-government might involve delivering services via the Internet, telephone, community centers (self-service or facilitated by others), wireless devices or other communications systems.

E-government implementation models

There are four basic e-Government models, based on Internet technologies that need to provide access to services and information 24 hours a day, seven days a week to citizens, business systems and employees in public administration:

- *Government to Government-G2G*, Public Administration Service, based on Internet technology that enables efficient and effective conduct of specific activities (information exchange, reporting, regional planning, transfer of funds, database integration, knowledge base ...) between various government organizations and agencies at all levels.
- *Government to Enterprise-G2E*, a service that enables employees in public administration through the intranet to perform tasks (document management, executive info systems, enterprise resource planning ...) in a functional, efficient, reliable and high quality manner.
- *Government to Business-G2B*, public service administration, which may include two-way interactions and transactions: government-to-business (G2B) and business-to-government (B2G). In these models, the communication or execution of certain operations (procurement, supplies, proposals and bids, sales data, rules and regulations ...) is done using the Internet and extranets.
- *Government to Consumer-G2C*, government provides numerous services to their citizens: tax payments, paying fines & tickets, voter information, birth & death certificates, reservations classes & facilities, complaint tracking, public information...

2.1. E-government architecture

The e-government architecture defines the standards, infrastructure components, applications, technologies, business model and guidelines for electronic commerce among and between organisations that facilitates the interaction of the government and promotes group productivity.

Figure 1 shows the architecture framework of e-government which is divided into four layers: access layer, e-government layer, e-business layer, and infrastructure layer.

- *Access layer*, a layer that allows end users to access various information services and e-government. They consist of online and offline channels or routes of distribution through which products, services and information are used, accessed and communicated by multiple technologies (web sites, mobile phone, digital TV...).
- *E-government layer*, an integrated e-government portal, used for the electronic interaction between: government and citizens, government and business, government and its employees, and government and government.
- *E-business layer*, this layer is focused on using ICT applications and tools to harness a networks of trust, knowledge sharing and information processing that takes place both within and between organizations [10]. Practically, it integrates front-end e-government layer applications, such as online catalogues and transaction interfaces in the government portal with back-end activities such as existing databases and data warehouses.
- *Infrastructure layer*, a layer that should provide a unique, effective and reliable access to desired information and e-government services (e-portal) via the Intranet to all users from its: computer systems, telephones, cell phones, digital TV, public information points ...

The logical connection of each layer will facilitate the exchange of data and services between and within public sector organisations, as well as support the consistency of government data and transactions from and to users.

Most countries in the world, whether they are developed or developing, allocate significant funds for the acquisition of modern IT infrastructure to implement in the e-governance model, in order to improve providing information and services to citizens, business systems and employees ... The construction of modern e-government avoids traditional service delivery and operational processes become more efficient and effective.

In the further text, the United Nations E-Government Development Survey 2012 will be briefly presented and commented, more specifically: regional averages in e-government development, world e-government development leaders 2012 and emerging leaders in e-government development. Table 1 and Figure 2 (graph) show regional averages in e-government development.

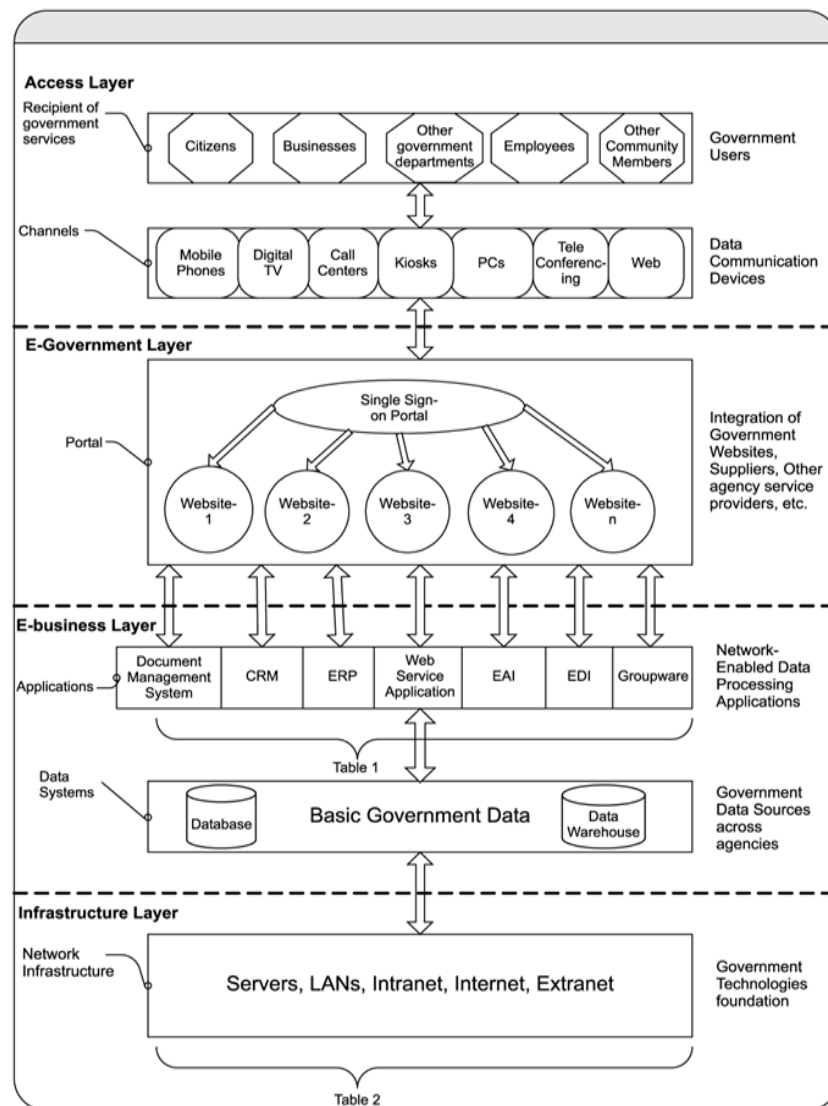

Figure 1: Framework of e-government architecture [4]

Table 2: Regional averages in e-government development

Rank	Continent	E-government development index-EGDI*
1.	Africa	0.2780
2.	Americas	0.5403
3.	Asia	0.4992
4.	Europe	0.7188
5.	Oceania	0.4240
World average		0.4882

* E-Government Development Index is a composite index comprising the Web measure index, the Telecommunication Infrastructure index and the Human Capital index.

In Table 1 and Figure 2 we can see that Europe has the biggest e-government development index 0.7188, America is second 0.5403, third place is taken by Asia with 0.4992, Oceania is in the fourth place with 0.4240 and the last one is Africa with 0.2780. E-government average development index in the world is 0.4882.

Figure 2: Regional averages in e-government development

The following table and figure (graph) show ten developed countries in the world that represent leaders in e-government development.

Table 2: World e-government development leaders 2012

Rank	Country	E-government development index (EGDI)
1.	Republic of Korea	0.9283
2.	Netherlands	0.9125
3.	United Kingdom	0.8960
4.	Denmark	0.8889
5.	United States	0.8687
6.	France	0.8635
7.	Sweden	0.8599
8.	Norway	0.8593
9.	Finland	0.8505
10.	Singapore	0.8474

Figure 3: World e-government development leaders 2012.

In Table 2 and Figure 3 we can see that the e-government development leader is the Republic of Korea with 0.9283 e-government development index, Netherlands is second with 0.9125 e-government development index, United Kingdom is in the third place with 0.8960 e-government development index, fourth place is taken by Denmark with 0.8889 e-government development index, United States occupy fifth place with 0.8687 e-government development index followed by: France 0.8635, Sweden 0.8599, Norway 0.8593, Finland 0.8505 and Singapore 0.8474 e-government development index.

Emerging leaders in e-government development are given in Table 3 and Figure 4 (graph).

Table 3: World e-government development leaders 2012

Rank	Country	E-government development index (EGDI)
1.	Austria	0.7840
2.	Iceland	0.7835
3.	Spain	0.7770
4.	Belgium	0.7718
5.	Slovenia	0.7492
6.	Monaco	0.7468
7.	Russian Federation	0.7345
8.	United Arab Emirates	0.7344
9.	Lithuania	0.7333
10.	Croatia	0.7328

Figure 4: Emerging leaders in e-government development

Among the emerging countries, Austria is the first with 0.7840 e-government development index, followed by: Iceland 0.7835, Spain 0.7770, Belgium 0.7718, Slovenia 0.7492, Monaco 0.7468, Russian Federation 0.7345, United Arab Emirates, 0.7344, Lithuania 0.7333 and Croatia 0.7328. Based on the analysis of the presented results we can conclude that Europe is the world leader in developing e-government according to United Nations E-Government Development Survey 2012.

3. CLOUD COMPUTING

Cloud Computing is created on the basis of the convergence of several concepts of modern information technologies (virtualization, distributed software applications, data centers, Grid computing, standardization, Web2 ...) in order to increase efficiency and reduce overall operating costs. Throughout the literature there are many commonly accepted definitions of what constitutes the concept of cloud computing and for this occasion we cite the definition of the U.S. National Institute of Standards and Technology-NIST "Cloud computing using a computer model that allows the network access if necessary, to shared set of flexible

computing resources (networks, servers, data storage, applications and services) that can be provided quickly and release management with minimum effort and interaction with the provider. It describes the cloud computing model through three service models: Software as a Service-SaaS, Platform as a Service PaaS and Infrastructure-as-Service IaaS, four models of application: private cloud, cloud community, public cloud and hybrid cloud and the five basic features: self-service to request, the broad band network access, resource pooling, rapid elasticity and measured service. [7]

3.1. Architecture, service models and the application of cloud models

The architecture of the cloud

For successful implementation of new business models based on cloud computing are needed and new technological platform for the development and execution of business and software solutions. Large systems in the domain of IT: Google, Microsoft, IBM, Cisco, HP, Dell, Oracle, VMware... developed a scalable and flexible architecture, enabling successful assignment and delivery of information resources and services to consumer demand. Figure 2 shows the models (NIST Cloud Computing Reference Architecture and IBM Cloud Computing Architecture CC-RA), an open, modular and layered architecture of cloud computing with the basic elements of structure: the consumer cloud, a cloud provider, carrier cloud, cloud and cloud auditor broker (NIST) and by cloud services, cloud service providers and the development of cloud services (IBM). [4]

Figure 2 shows the models Cloud Computing Reference Architecture - NIST, an open, modular and layered architecture of cloud computing with the basic elements of structure: the consumer cloud, a cloud provider, carrier cloud, cloud and cloud auditor broker.

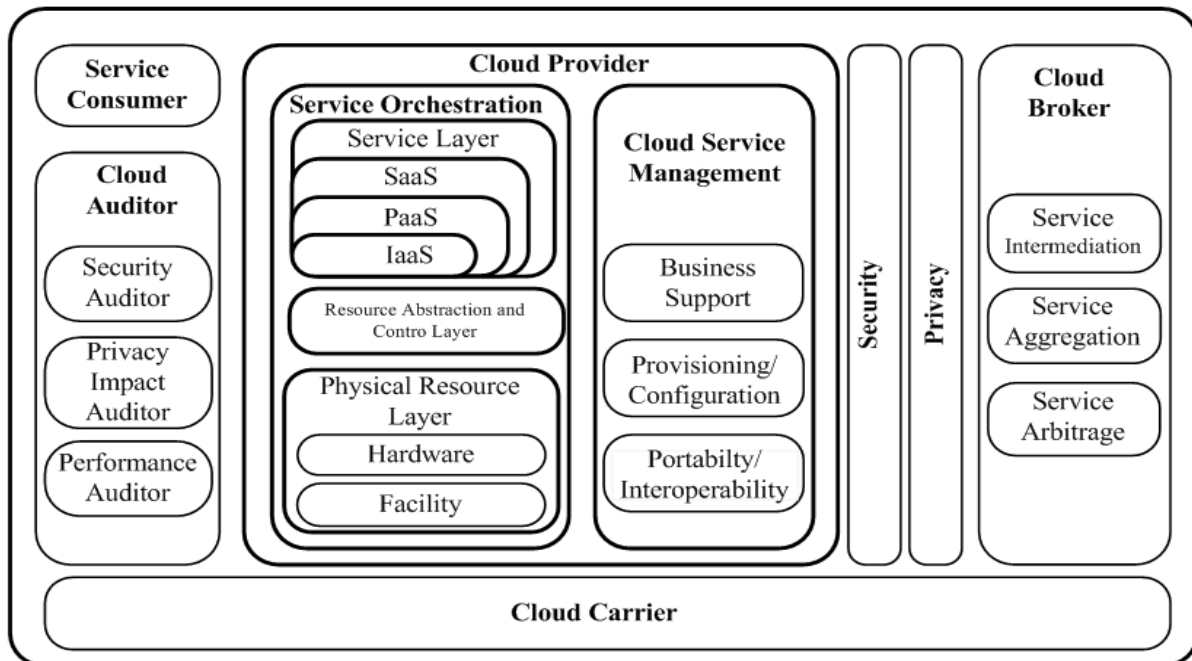

Figure 5: Models of cloud computing architecture

NIST model in the cloud computing architecture is characterized by the following characteristics:

- *Cloud consumer* or user, the system can be a business or individual users who use the services or the services of cloud providers. Business users and related service providers are regulated by SLA (Service Level Agreement).
- *Cloud provider* may be an individual person, business entity or system that is responsible for providing end-consumers.
- *Carrier cloud* or transmission cloud is the agent in charge to ensure successful connection and transfer of cloud between cloud services providers and consumers.
- *Cloud broker*, the person who manages the use of performance and delivery of cloud services, negotiate and establish business relationships between providers and consumers of cloud services. It should be noted that in other representative cloud computing architecture (VMware vCloud Architecture, IBM RA CC, Windows Azure, etc.) there is no cloud broker.

- *Cloud audit*, the party may conduct an independent assessment of: the quality of cloud services, quality of performance and quality of the cloud safety.

Models of cloud services

Service cloud computing services include three basic models:

- Software as a Service-SaaS;
- Platform-as-a-Service-PaaS and
- Infrastructure-as-a-Service-IaaS.
- **Software as a Service-SaaS**, represents software applications in the cloud that were implemented as a hosted service provider to whom users access the Internet with its various computer systems to obtain and use certain software applications. User depending on the cloud provider has available a large number of software applications from various manufacturers for electronic mail, sales, finance, accounting, human resources, document management, social networking, content management, office management systems, customer relationship management - CRM, systems for enterprise resource planning – ERP...
- **Platform as a Service PaaS**, the user provides the ability to use tools and resources on a cloud provider platform and with support by its developers, system administrators and developers elect, appoint, develop, test and manage their own software packages and configuration of the operating environment.
- **Infrastructure as a Service IaaS**, the user (system administrators, developers) to provide access to the necessary basic computer resources: virtual computer systems, data centers, storage, networks, etc. to be used with your choice of operating systems and software applications in the process treatment. Infrastructure as a service to respond to trends of growth in the cloud computing model must be distinguished: scalability, security and reliability.

In cloud computing, there are four models:

- Private cloud;
- Public cloud;
- Hybrid cloud and
- Community cloud.
- **The private cloud**, a model application of computing in the cloud within a business system where IT professionals develop their own integrated and scalable cloud infrastructure (server consolidation, virtualization, data centers, standardization, etc.) that can be placed inside or outside the business system, business system. Access to and use of infrastructure clouds have employed in the business system.
- **The public cloud**, as opposed to a private cloud model, the computing infrastructure of the public cloud model is available and open to the public through the Internet business systems and individual users.
- **The hybrid cloud** model is a synthesis of private, public and common clouds, which remain unique entities interconnected by standardized or proprietary technologies that enable transmission of data or applications.
- **The community cloud**, a model where the cloud infrastructure used to control several operating systems that have common interests in the form of secrecy, security, integration services, etc.

Figure 6. shows the application of the cloud computing model in e-government.

Wyld D. and Maurin R. offer Ten Predictions for the Cloud-Enabled Future of Government:

1. Cloud computing will take off at the local and state levels through mostly rogue, “under the radar” initiatives over the next few years.
2. At the federal level, there will be a coordinated move to cloud computing, but with inevitable tension between agencies.
3. There will be two to three incidents a year worldwide with potentially massive security breaches, involving much media attention and attendant calls for greater regulation and oversight of cloud providers.
4. There will be much cooperation between private sector firms (seeking to be cloud service providers) and government agencies, with far more data and applications than expected today transitioning to the cloud over the next decade.

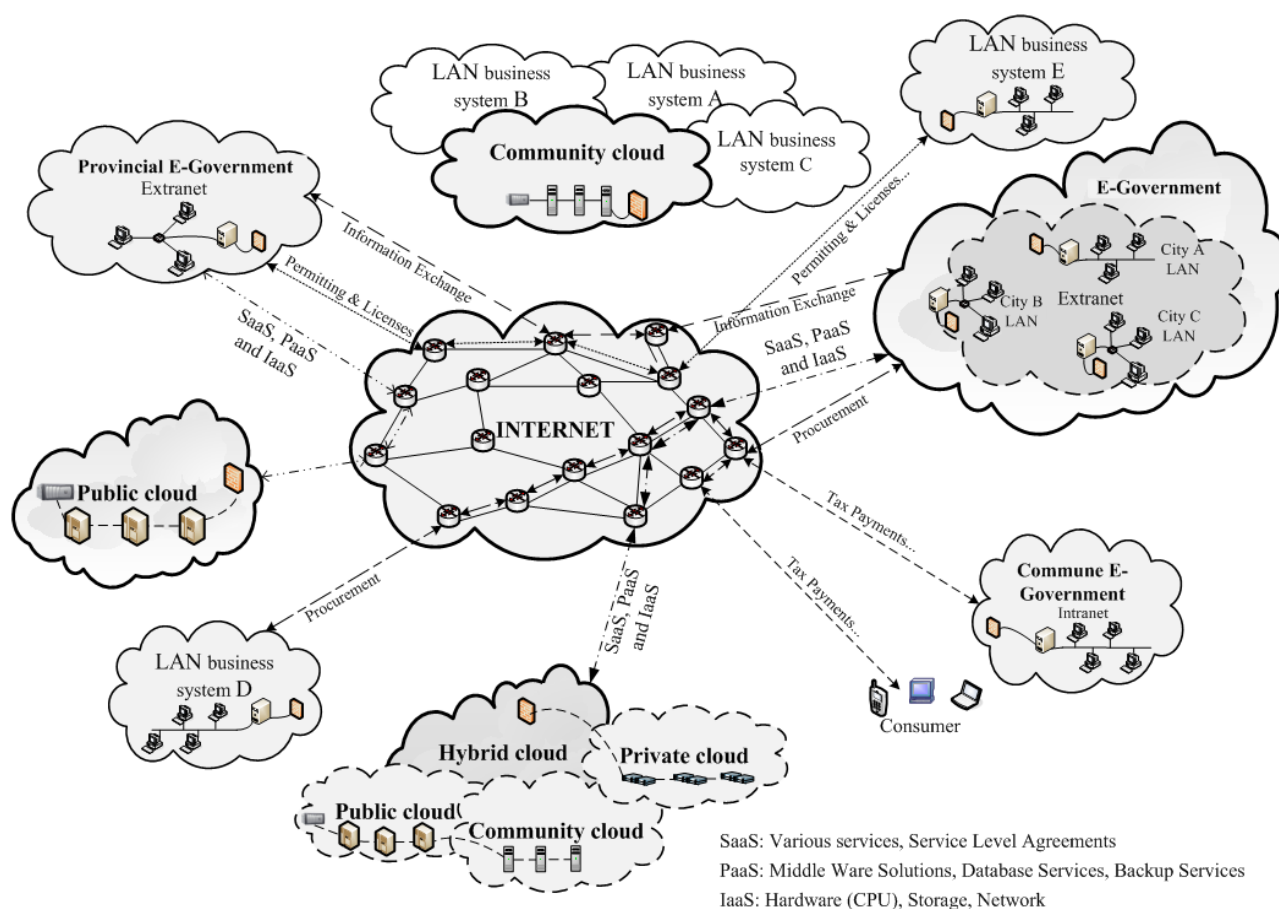

Figure 6: The application of the cloud computing model in e-government

5. Budget pressures will continue to drive more and more government IT to hybrid and even public clouds, as more and more former internal IT functions-and assets (hardware, software, data, and support personnel)—are outsourced, with billions in procurement dollars shifting to the cloud.
6. There will be greater use of cloud computing, in everything from health care and education to the military and national security.
7. Free cloud offerings—even beyond the e-mail, storage, and application functions found today—will be a significant part of IT portfolios in most governmental agencies.
8. The spillover effect of government use of cloud computing will include faster agreements among major cloud providers on standards and cloud interoperability protocols.
9. There will be significant legal action arising out of governmental uses of cloud computing, and legislation addressing both IT and business needs and consumer fears and protections will be a major focus over the next decade.
10. The “democratization of technology” brought about by cloud computing will impact the quality of our individual online lives, the growth of businesses, and the pace of innovation, benefiting us all.

4. CONCLUSION

In recent years the world trend in developed and developing countries is the abandonment of traditional ways of providing information and services by government institutions and the transition to e-government models that are based on modern ICT. The next step that should make e-government more efficient and more effective is the application of the cloud computing model. Cloud computing models represent a new phase in the dynamic development of IT infrastructure and services. They bring a fundamental shift and provide better delivery methods and efficient use of computing resources compared to conventional methods that were applied in the business. Using the cloud computing model in e- government, creates new values through: lower total operating costs, faster time deployment, increased efficiency, greater flexibility, dynamic scalability, higher level of security, rapid development of innovative services...

THE GROWTH OF SOFTWARE INDUSTRY IN THE WORLD WITH SPECIAL FOCUS ON BOSNIA AND HERZEGOVINA

Munir Zahirovic, Hadžib Salkić,

¹ University "Vitez", Travnik (BiH); munir.zahirovic@gmail.com

² University "Vitez" Travnik, BiH; hadzib.salkic@unvi.edu.ba

Abstract: *This paper presents the essential features of the software industry, its growth, elaborates on the characteristics of a company that manufactures software, gives an overview of possibilities and indicates the perspective of the software industry at the macro and micro level which is the main objective of this paper. This paper also elaborates on the technological, as well as some important economic factors important for the software industry, especially for countries in transition. Finally, it gives an overview of the software industry in Bosnia and Herzegovina and gives some conclusions.*

Keywords: *software industry, the growth, the strategies of software industry's development, the perspective of the software industry*

1. INTRODUCTION

The increasing demand for software for various purposes has caused the appearance, growth and development of software industry. Since its main task the production of software, it inevitably has a major responsibility for its success or failure. Each industry has its own characteristics and dimensions. Same is with the software industry. The dimensions of this industry and its degree of development vary from country to country. Consequently, some states are more advanced in developing software and software engineering than others. Since that, we can make the difference between the classification of some countries in this segment. Software industry is characterized by substantially constant growth and development both on local and global levels.

2. SIZE CHARACTERISTICS OF THE SOFTWARE DEVELOPMENT

The size of firms for software development is characterized by two important features: a) the number of employees, and b) the size of the capital. On this basis, we can conclude that a firm or company which has higher capital and a number of qualified employees has increased opportunities for better and higher quality software development, and therefore the possibility of higher earnings and achieve higher profits. However, sometimes even a firm with a fewer employees can make a big profit.

In the world today there are firms of different sizes, ranging from those whose number of employees can be counted "on the fingers of one hand" to those that employ tens of thousands of workers. Large firms and companies achieve a large gain, which contributes to better and faster growth and development of certain countries.

Software produced by certain company can be used not only at local but also at global level. On this basis, the company opened the doors to a large market and thus big profits.

This leads to greater needs for further development and improvement of the software so that he must be always a step or two ahead of the competition. To achieve this, we need to engage a larger number of experts of different profiles. Positive effects on the economy of certain country are more than obvious, hence the need to stimulate the firms involved in software engineering.

The importance of this can be illustrated by numerous examples and one of them is the Oracle company, established in 1977 in the United States. It now employs 104.569 workers. By comparison, in October 2011 B&H has registered 693.964 employees. Oracle is present in over 145 countries worldwide, its net earnings

in 2007 was \$4.2 billion order in 2011 reached a figure of 8.5 billion dollars.[3] By contrast the House of Peoples of the Federation of B&H (FB&H) has adopted a budget for 2011 in the amount of 1.699 billion.[4]

3. DIFFERENTIATION OF SOME STATES IN THE ADVANCEMENT IN SOFTWARE DEVELOPMENT AND SOFTWARE ENGINEERING

Countries are not in the same degree of commercial, economic, technological, cultural and other advances, therefore, among them some differences occur. The same is in the development of software industry. Some countries are world leaders in production of the major software providers and exporters, while other countries belatedly joined the race.

Some states have dropped out of the race due to certain internal or external factors, as is the case with the former Yugoslavia, which is due to internal conflicts and splits, and as such ceased to exist. Some states do not realize the importance of the software industry, so they are not paying attention or bring legal framework that would encourage the development of software engineering, and therefore the software industry. The constellation of the above, the state of the world would be, in terms of software engineering development, production and export of software, could classify into several groups or categories:

- first category consists of countries: U.S., EU, Canada, Australia, Japan, India, Israel, Ireland,
- second category consists of only two states that are in a transitional phase, namely China and Russia,
- third category consists of countries such as Brazil, Costa Rica, the Philippines, Malaysia, Korea, Pakistan, Mexico, Poland and Romanian who recently have made significant progress in this field,
- fourth category consists of countries such as Cuba, Jordan, UAE, Egypt, Iran, Bangladesh, Indonesia and Vietnam that have only begun to engage in this important race.

Tables would look like this:

Classification of countries in terms of progress in the development of software engineering and software sales	
1. category	U.S., EU, Canada, Australia, Japan, India, Israel, Ireland
2. category	China and Russia
3. category	Brazil, Costa Rica, the Philippines, Malaysia, Korea, Pakistan, Mexico, Poland and Romania
4. category	Cuba, Jordan, UAE, Egypt, Iran, Bangladesh, Indonesia and Vietnam

Table 1: Classification of countries to progress in the development of software industry and software engineering

The question is which of these categories include B&H? Unfortunately, neither one of these. If you just compare B&H with some of the countries from the fourth category such as Egypt, it is clear that B&H does not fall into any of these categories.

Ministry of Communications and Information Technology of the Arab Republic of Egypt was established in December 1999 and, in its plans for the next five years, had a goal to reach the Egyptian software exports worth 500 million dollars. That failed, but by 2006 profit worth 200 million dollars.[1] B&H does not have any similar plan or development strategy on this issue which can be clearly seen by visiting the official government websites. What remains B&H is to use the experience of advanced countries in this field in order to move with progress and technological revolution that may have positive economic consequences for its entire development.

4. GROWTH OF SOFTWARE INDUSTRY

The software industry is a branch of computer industry. In the U.S., it occupies third place, immediately after the automobile and electronic industries. Otherwise, the U.S. leading this industry in relation to other countries. In 2008, the U.S. took a significant share of the packaged software market. Their share was \$136.6 billion, or 45.9% of the world market. Therefore the U.S. is the largest single market of packaged

software in the world. Nevertheless more than half the world market packaged software is located outside the United States.

Figure 1: Profits shares of some countries in the world market of packaged software in 2008

In 2008, the PC software market has taken 30% market share, or \$ 88 billion of the total packaged software market worth 297 billion dollars.

Figure 2: The total market value of packaged software in 2008, in millions of dollars

It is interesting that the extraordinary progress in computer sales was recorded in Brazil, Russia, India and China (abbr. BRIC countries - Brazil, Russia, India and China). In the period between 2009 to 2012 they recorded growth of 43%, which amounts to more than 66 billion dollars. In the same period in U.S., Central, Eastern and Western Europe and Japan together recorded a growth of 2%. At the same time sales of packaged software in the BRIC countries experienced growth of 44% which is close to \$22 billion. Also, at the same time the United States, Central, Eastern and Western Europe and Japan together have experienced an increase of only 15%.

5. SOFTWARE INDUSTRY IN B&H

The software industry in B&H has not developed and doesn't have a significant economic impact on the development of national economy. At the last time, Bosnia and Herzegovina has made some progress in developing the local software industry. B&H has recognized a number of jobs related to IT and software industry, one of which is a software engineer. However, it is indicative that B&H has no national strategy for developing the software industry. Nevertheless, in B&H there are companies that are engaged in developing application and system software, designing, implementing and maintaining information systems, such as: IT Systems - Sarajevo, UNITRADE SOFT, Ocean, Djikic Ltd. (...).

Figure 3: Sales growth of computers and packaged software in the world

According to some reports in the B&H in the end of 2002, there were about 200 companies from the IT sector, and their numbers through 2005 years has grown at 2587.

Furthermore, in these reports, states that 70% of companies in this sector with mostly or completely domestic capital, and only 30% of companies have different missions and representatives of foreign firms. It is stated that more than 20% of companies in the IT sector in BiH achieve an annual turnover in excess of 5 million.

Also the report states that at the end of 2005 in B&H more companies from the IT sector engaged in software sales (35%) than selling computers (30%), and that, according to a survey conducted by UNDP, as much as 62% of these companies have in their offer domestic software production, and on average have the commercial offer more than five different software solutions. However, this report includes not only software company engaged in developing application and system software, but it includes all the IT companies engaged in the sale of computers, or repair (...).

Unfortunately there are not many official statistics on the domestic software industry, as well as data on the number of employees in these firms, the profit generated, etc. Notwithstanding the absence of this information can come to the conclusion that the profit realized by the company at the state level is not significant, based on the following:

- due to the small number of software companies,
- they are mostly small-scale firms that employ fewer workers (Djikić company employs 13 permanent employees and has a network of collaborators).

However, there are some external analyzes, research and forecasts for Bosnian market of information technology and software industry. Thus, according to a UNDP report, the total market value of information technology in B&H in 2007 amounted to 187.38 million, of which 10.3% share of the software or about 19.3 million dollars.

With the numerous problems encountered, domestic software industry suffers huge damage that piracy causes it, which, although prohibited by law, continue to spread, so that these firms, in addition to the small Bosnian-Herzegovinian market, have even lower profits because of pirated sales of their works.

In addition, the domestic software industry is faced with the problem of competitiveness. The big international software companies offering their products localized, which makes local software producers that, as stated in the UNDP report, enter the phase of software development leaving the phase of analysis and design phase, and after the development phase of software, testing is not performed. This mode is referred to the company managers justify their desire to offer you a cheaper product as possible. Most software companies in B&H, especially smaller ones, offers to the market inexpensive software that does not meet all user requirements, which results in frequent interventions in the software, even in the stage of implementation. This mode makes the ICT industry in the increasingly uncompetitive both within B&H and in markets outside B&H.

In 2010, the IT market in Bosnia and Herzegovina reached a value of 166.99 million U.S. dollars, which represents some progress compared to 2007. Whatever, IT market in B&H grew by 5% compared to 2009. Delivery of IT services and software are recorded growth of 5.6%, while the overall hardware fell by 2.1%.

6. KEY ASSUMPTIONS FOR DEVELOPMENT DOMESTIC SOFTWARE INDUSTRY

For the development of any industry in any country requires particular preconditions to be fulfilled. Otherwise, all efforts on the development of these industries is futile. B&H is trying to develop many kind of industries. As in Bosnia began to develop the software industry needs to lead the care of her and her development. Accordingly, it is necessary to implement the main preconditions for the development of domestic industry which could be summarized as follows:

- 1) establish a separate ministry for information technology and telecommunications,
- 2) developing a strategy for the development of domestic software industry,
- 3) adoption of legal regulations that will regulate this area,
- 4) provide support to local government software industry both financial and otherwise,
- 5) ensure that copyright is not only legal on paper, but also through the practical implementation of that law,
- 6) educate experts in different areas of information technology,
- 7) establishment of technology parks,
- 8) organization of scientific seminars on software engineering and software industry under the auspices of the state,
- 9) provide a positive climate for the development of domestic software industry and attract foreign investors,
- 10) favoring the domestic IT industry in the public procurement process.

This would be some of the preconditions for the development of software engineering and domestic software industry. In addition to these there are other assumptions and preconditions to be fulfilled, however, the above-mentioned preconditions are the basis and only when they, or most of them are met, a software engineering in B&H, as well as local software industry will be able to run faster, better and better develop and find their place in the local and global markets.

7. CONCLUSION

If one compares the data of the profits of software in the world market for some years in the period 1997-2008, he can see its steady growth.

Table 2: Total profits of packet software in the world market

Year	Total profits of packet software in the world market
1997	122 billion U.S. dollars
1998	135 billion U.S. dollars
2002	220 billion U.S. dollars
2008	297 billion U.S. dollars

In just eleven years, the world's software industry profits more than doubled, even when adjusted to a billion dollars, then these data clearly show that the software industry in the world has very good perspective. Even in a period of world crisis (recession), some countries experience growth and increased profits from year to year.

Development of software companies and software industries may find fertile ground in any place in the world if they fulfill at least the most important preconditions for the development of software industry and reduce risks in its investments.

Abstract: *This paper gives insight into the architecture of NFC service life cycle management solutions - one of the key components of the NFC ecosystems. NFC enabled phones equipped with secure elements, combined with NFC enabled infrastructure – readers and POS terminals are surely prerequisites, but are insufficient for the use of NFC technology in its full potential. There has to be a secure way to download, install, personalise, upgrade and delete an application on a secure element, without the need to go to the service provider's or mobile operators' stores. Solutions for the application life cycle management, the so called "TSM solutions", provide means for managing the NFC service life cycle "over the air" (OTA) by using the mobile operators' wireless infrastructure. This work presents the basic concepts that "TSM solutions" are built upon and emphasizes its role and importance in NFC ecosystem. The paper is intended for "TSM solution" providers, mobile operators, financial institutions, service providers, as well as other actors participating in NFC ecosystem.*

Keywords: *Near Field Communication (NFC), TSM solutions, OTA application life cycle management*

1. INTRODUCTION

Near Field Communication (NFC) is wireless technology, allowing very short-distanced data transfer (up to 4cm), with speed rate of 424Kb/sec. Operating on 13.56 MHz, NFC is based on the same principle as RFID technology - electromagnetic induction. It was initially developed by Sony and Philips, afterwards it has been standardized by ISO (ISO/IEC 18092, ISO/IEC 21481) and ECMA (ECMA 340, ECMA 352). NFC standard incorporates variety of existing standards such as ISO 14443 (Type A and B) and Felica, which makes NFC enabled devices compatible with existing wireless infrastructure.

Integration of Near Field Communication technology in mobile phone, turns mobile phone into multifunctional device – in new sense of those words. NFC extends mobile phone functionality from basically communicational device towards device that can replace one's wallet (cash and credit/debit cards), home and office keys, identification documents (id cards) and all kinds of tickets (tickets for public transport, tickets for theatre or football game) (Figure 1). What NFC actually brings to mobile phone is the ability of device to interact with its surroundings. Interaction takes place in "near field" – short distance up to 4 cm. By simply "tapping" NFC enabled device to NFC tag or NFC enabled reader, user can read smart posters, make proximity payments, provide identity (access building or log in to PC), or use ticketing service.

NFC device can work in three operational modes: card emulator, reader/writer and peer-to-peer mode. In card emulator mode device acts as contactless smart card, replacing existing plastic smart cards. In reader/writer mode NFC device can read or write to smart tags (i.e. smart posters), while peer-to-peer mode is used for two NFC devices wishing to exchange content (Ok, Aydin, Coskun and Ozdenizci, 2011).

In order to use security sensitive NFC services, such as mobile payment, or identification, besides NFC chip, mobile device needs to have kind of trusted execution environment (TEE) – a place where sensitive data and applications can be stored and ran in secure fashion. It is a piece of hardware, called "secure element" (SE), and it can be provided in three form factors (Figure 2):

- **UICC card**

Advanced type of SIM card. Besides communication applications (USIM, CSIM) it can contain applications intended for general purposes (payment, public transportation, etc).

Figure 2: **Applications of NFC technology** (Oberthur, 2010)

- **Secure microSD card**
MicroSD card with TEE.
- **Embedded secure element**
Embedded secure element (eSE) is a secure chip “embedded” to phone’s motherboard, being integral part of mobile phone electronics.

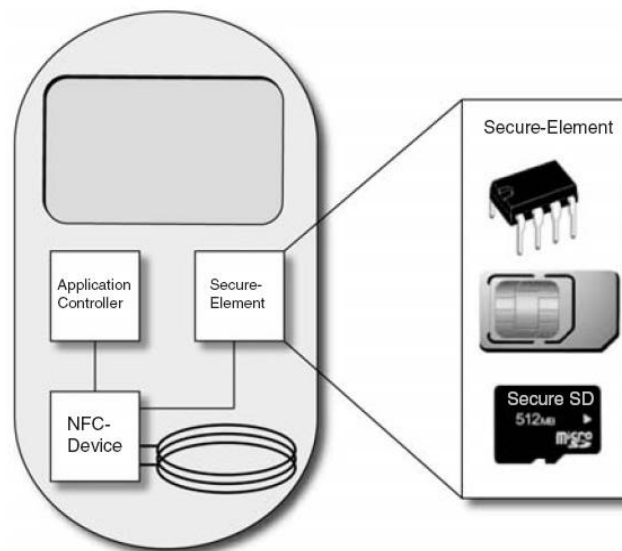

Figure 3: **NFC enabled device with secure element** (Finkenzeller, 2010)

Regardless of SE type used for NFC services, it is very important to allow different service providers to host their applications on the same SE. Otherwise, end-user could end up with several secure elements, which would create complexity, resulting in bad user experience and slowing down adoption of NFC services.

In order to use sophisticated NFC services one has to have NFC enabled mobile phone, with SE hosting security sensitive applications. There is also a need for NFC enabled infrastructure such as NFC tags and readers. However, NFC enabled infrastructure, combined with NFC phones with secure elements, is not enough for successful implementation and use of NFC services. There are some open questions such as:

1. How to manage life cycle of applications on secure element (how to load, install, personalize, lock, unlock, upgrade or delete application on secure element or application on handset²)?
2. Who has rights to manage application life cycle?
3. Should there be some kind of agreement between service providers (SPs), phone manufacturers and mobile network operators (MNOs)?
4. Does user need to go to service provider's store each time he wants to use new NFC service?
5. What happens when user loses or damages his mobile phone or secure element?
6. What if user changes secure element?

To find proper answers to these questions, we need to understand environment for using NFC services, called NFC ecosystem, its actors and their complexed relationships.

2. NFC ECOSYSTEM – ACTORS, REQUIREMENTS AND ROLE OF TSM

NFC ecosystem is environment intended for using NFC services. It consists of:

- **Actors**
Actors are real world entities such as banks, public transport operators, MNOs, mobile phone manufacturers, SE manufacturers and end-users. Each actor can have one or more roles attached. Role can be viewed as a set of responsibilities.
- **Infrastructure**
Infrastructure consists of hardware (NFC tags and readers, NFC enabled mobile phones, secure elements, wireless infrastructure such as base stations, servers, etc.), software (that runs on mentioned hardware), communication channels, protocols and standards for data exchange between devices (GSM/UMTS, SMS, Internet, ISO/IEC 18092, TCP/IP, etc.).
- **Business agreements**
Business agreements define business relationship between actors, such as sharing expenses and profit or creating appropriate business models.
- **Technical agreements**
Technical agreements are based on business agreements and refer to technical aspects of functional implementations (i.e. technical agreement defines way of personalization of application on SE, or message exchange format between different actors in ecosystem).

As shown in Figure 3, main actors of NFC ecosystem are service providers (SPs), mobile network operators (MNOs), SE manufacturers, mobile phone manufacturers and end-users³. Service providers are companies who want to offer more effective services to their customers by using NFC technology. Examples of SPs are financial institutions (banks), public transport operators, theatres, museums, merchants, government bodies, etc. MNOs are telecommunication companies providing mobile network functionality, used for communication via cell phone. Phone manufacturers are companies that produce mobile phones such as Nokia, Research in Motion (RIM), Samsung, Motorola and Sony Ericson. Companies like NXP, G&D, Gemalto and Oberthur are examples of SE manufacturers – actors that produce different kinds of SE. The last, but not the least, are end users, that “consume” NFC services.

² NFC service is usually composed of one or more applications running on secure element, and one or more applications running in the memory of mobile device. Applications running in mobile device memory are usually intended to be user interface for accessing appropriate service application on SE.

³ Figure 3 shows only main actors in NFC ecosystem. Real ecosystem has many more actors.

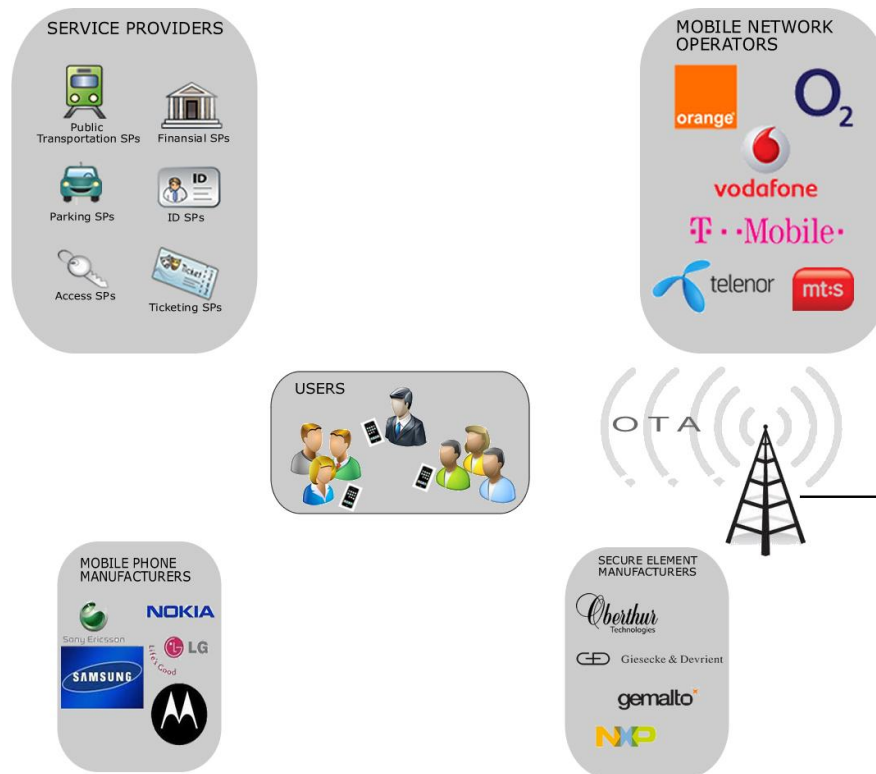

Figure 4: NFC Ecosystem

In NFC ecosystem each actor has its area of responsibility. MNO controls wireless infrastructure - so called "Over The Air" (OTA) infrastructure, bank holds financial instruments such as user's bank account, SE manufacturer is in charge of SE, while mobile device manufacturer holds control over mobile device functionalities. In order for NFC service be functional, each actor must give "green light", in its area of jurisdiction. Let's take NFC mobile payment service for an example. If end user wants to enable mobile payments using his handset, he refers to his bank, requesting activation of mobile payment service. In order to allow payment service, bank needs to check out end-user's mobile phone and secure element from technical point of view. To do that kind of check, bank needs identifiers of mobile phone (IMEI⁴) and secure element, which can be retrieved from end-user's MNO, based on his phone number. So, bank must have a way to ask for IMEI and SE identifier from MNO. MNO, from the other side, must have a way to reply to the end-user's bank request, sending IMEI and SE identifier. When received, identifiers of mobile phone and SE need to be forwarded to device manufacturer and SE manufacturer, respectively. This means that bank needs to be able to communicate with device manufacturer as well as SE manufacturer. Based on SE identifier, SE manufacturer sends data regarding technical capabilities of secure element to the bank. Using the same logic, device manufacturer will send data about technical capabilities of mobile device. If end-user's SE and mobile device meet the requirements for activating NFC payment service, bank refers to MNO again, asking for download of payment application to user's SE. MNO takes application code and, using its OTA infrastructure, downloads application code "over-the-air" to the SE in user's mobile phone. In the last step MNO notifies all actors about successful operation on SE. This simplified example shows essential need for communication between actors in NFC ecosystem.

Prior enabling communication, actors need to establish business agreements and technical agreements. Business agreement means setting commercial model – defining revenue sharing, pricing for technical service management functions (responding to request, sending data), pricing of "renting" space on SE, etc. Technical agreement refers to communication details (initiating connection, message exchange format, etc), supported modes for SE content management, supported SE types, etc. If each actor would have to make agreement with each other actor, it would lead to chaotic business environment, with low level of scalability and rather proprietary than standardized communication interfaces. In order to decrease complexity, and support standardization (interoperability) and scalability, MNOs association - GSMA proposed creation of Trusted Service Manager (TSM) role, which is supposed to be a link between all other actors, especially SPs

⁴ International Mobile Equipment Identity (IMEI) is mobile phone identifier. It is used from GSM network to identify valid devices.

and MNOs, that are competitors in NFC ecosystem⁵ (Global Platform, 2009). Instead of direct interaction, actors of ecosystem interact using trusted intermediary – TSM (Figure 4).

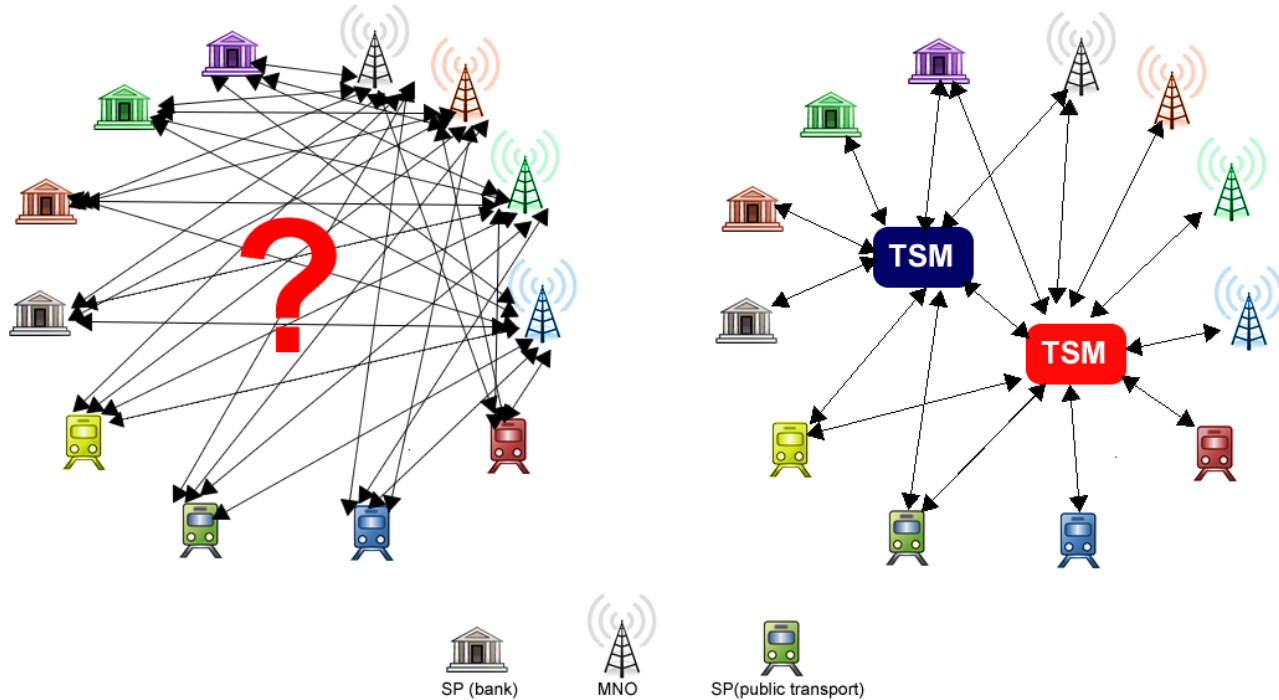

Figure 5: Role of TSM in NFC ecosystem

From technical aspect, TSM provides Trusted Third Party which guarantees security and confidentiality between SPs and MNOs, and offers 24x7 high availability services for all actors of ecosystem (Veran, 2008). From business point of view, TSM is one-stop shop for service providers to offer NFC services to their customers, no matter what MNO they belong to (Veder, 2008).

3. TSM SOLUTIONS – SYSTEMS FOR OTA NFC SERVICE LIFE CYCLE MANAGEMENT

Traditional payment and information networks rely upon service provider's card terminal being on-line (i.e. ATM), while customer token (i.e. credit card) is not on line. In traditional payment networks all personalisation is done before issuing smart card to the end user. After personalisation smart card is issued "as it is", with unlikely possibility of adding new applications, or upgrading existing ones. All this traditional ways of managing secure element are just not good enough for NFC services, because NFC ecosystem needs to be dynamic environment, allowing applications to quickly transit from one to another life cycle state.

One of the essential features, that brings value to the users of NFC services, is the concept of "On-Line User". It means that user and its token (secure element) are 24x7 accessible, which makes possible for service provider to communicate with SE almost constantly. This is very convenient for the highly dynamic environment such as NFC ecosystem, because user doesn't have to go to SP's stores and wait there in long queues in order to get new or upgrade old NFC service – all those activities are performed using wireless (OTA) infrastructure, often even without end-user's knowledge of ongoing changes on his device and/or SE.

System (solution) for OTA life cycle management of applications on SE is enabler of concept of "On-Line User". These solutions are often called "TSM solutions", because of specific role of TSM in ecosystem. Despite this commonly accepted colloquially nickname of system, it would be wrong to comprehend TSM role as implementer of all functionalities of system – on the contrary – TSM mainly acts as trusted message dispatcher, while other actors implement system functionalities.

Use cases, that system for OTA management of NFC service life cycle must implement, can be divided in two main groups (Global Platform, 2011):

⁵ Because of being competitors, MNOs and SPs often have difficulties in finding mutually acceptable business model, which happened to be one of the biggest obstacles for NFC mass rollout.

- **Use cases related to NFC service**

Technical use cases that cover OTA management of NFC service life cycle (deployment, locking, unlocking, update, upgrade and deletion).

- **Use cases related to end-user**

During the service life, end user can encounter events or situations that have impact on service. Such events are: SE/mobile device changed, SE/mobile device lost or stolen and maybe recovered later, etc.

Use cases related to NFC service are:

1. NFC service deployment
2. NFC service activation
3. NFC service lock
4. NFC service unlock
5. NFC service upgrade
6. NFC service data update
7. NFC service undeployment

Use cases related to end-user are:

1. SE changed
2. Mobile phone number changed
3. Mobile device changed
4. Lost or stolen mobile device
5. Recovered mobile device after a loss
6. Get a new mobile after a loss
7. Mobile subscription termination
8. MNO swap
9. Temporary suspension of NFC services

Global Platform (2011) and Association Française pour le “Sans Contact” Mobile – AFSCM (2009) give detail description of use cases mentioned above.

As shown, management of service life cycle in NFC ecosystem is based on stakeholders interaction (communication) – actors need to communicate with each other and exchange messages in reliable and interoperable way. Considering the fact that these actors come from different business environments, with heterogeneous systems, as appropriate environment for implementation of NFC service management systems, Global Platform (2011) recommends Service Oriented Architecture (SOA)⁶, using Web services as SOA implementation technology. Main two reasons are interoperability and loose coupling⁷. This means that communication of actors in NFC ecosystem should be implemented using Web services.

Web service is software system designed to support machine-to-machine interaction over the network (Wikipedia). Interaction is based on message exchange using Simple Object Access protocol (SOAP) - XML based protocol for exchange of structured informations. On one side of web service is entity that provides service – “service provider”, while on the other side is entity that “consumes” service – “service consumer”. In order to clarify using web services for communication implementation in NFC ecosystems, we can refer to the above mentioned example of user wanting to enable NFC mobile payment on his phone (Figure 5). After receiving request for enabling NFC payment service, bank needs to “talk” to TSM using web service. Bank, as a web service consumers, requests user’s mobile equipment check (phone and SE) from TSM, as a web service provider. In next step, TSM acts as web service consumer, by calling another web service provided by MNO (MNO is service provider in this step), in order to obtain IMEI and SE identifier. Same logic applies

⁶ Service Oriented Architecture (SOA) is a set of principles and methodologies for designing and developing software in the form of interoperable services. These services are well-defined business functionalities that are built as software components (discrete pieces of code and/or data structures) that can be reused for different purposes (Wikipedia).

⁷ Loose coupling between two software components occurs when one (depending) component depends only on the interface of the other component. Depending component has no knowledge of the concrete implementation of interface functions, so implementation of functionalities can change, without effecting dependant class, as long as interface specification is respected.

for web services used for communication on relation TSM – SE manufacturer and TSM – mobile device manufacturer.

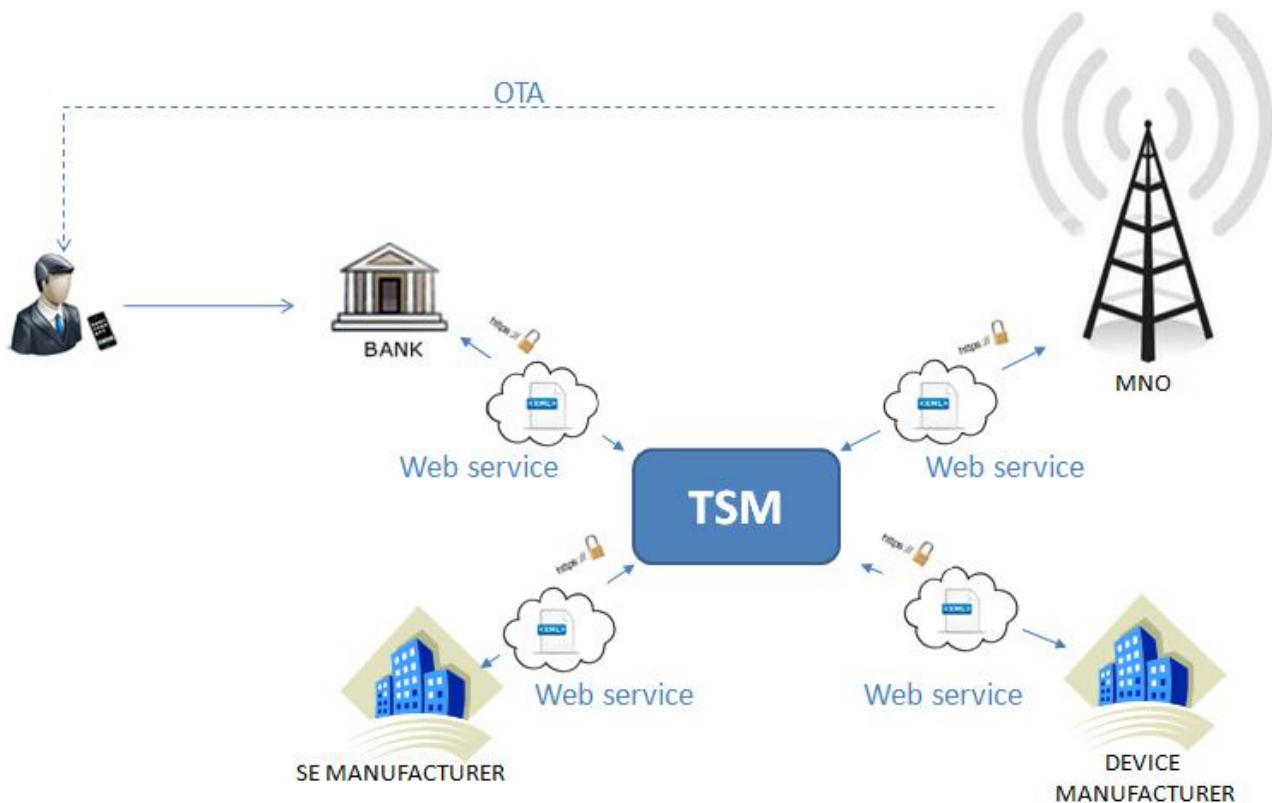

Figure 6: **Communication of actors using web services**

4. TSM SOLUTIONS' SECURITY

Instead of using physical cards, TSM solutions are used to manage smart card applications, hosted on the SE of NFC device, over the wireless network. Therefore, TSM solutions have to meet high security standards, like those of ordinary smart card issuers, producing, personalizing and distributing smartcards (Madlmayer, Langer, Kantner, Scharinger and Schaumüller-Bichl, 2009). In order to provide end-to-end security in NFC ecosystem, one has to deal with several different aspects of security such as: security of SE, security of SE application and UI mobile application, security of TSM, security of the OTA provisioning, security of NFC device, security of NFC interface, etc. In this work, focus is on the TSM security.

Considering that TSM solutions are systems based on actors' interactions using web services, security of TSM solutions comes down to web services' security. Threats such as message alteration, breach of confidentiality, "man in the middle attack" and denial of service need to be addressed, when SOAP (XML) message exchange is involved.

In order to cope with these challenges, appropriate security techniques must be applied. Security techniques can be implemented on transport layer, SOAP message layer or both – transport and SOAP message layer. The choice often depends on application requirements (Web Services Interoperability Organisation-WSI, 2005).

For security implementation on transport layer, combination of SSL/TLS protocol and HTTP protocol is used, which provides integrity and confidentiality of whole SOAP message, transported using HTTPS. In this case, the entire HTTP message – header as well as body containing SOAP message – receive integrity and confidentiality protection. However, confidentiality and integrity are in the effect only during HTTP session – there is no protection of message once received (and possibly queued by the web service consumer or requestor). Because protection is applied to the entire message (partial protection can be applied), transport level security is unsuitable for SOAP topologies involving SOAP intermediaries.

Security techniques implemented on SOAP message layer provide integrity and confidentiality to a portion or combination of SOAP message content using XML Digital Signature and XML Encryption techniques outlined in SOAP message security specification (OASIS, 2006). In this case, confidentiality and integrity are in effect during as well as after message transmission (beyond HTTPS session), being suitable for providing end to end confidentiality despite SOAP intermediaries.

5. EXISTING SOLUTIONS

There is evident trend of increasing demands for TSM solutions. Companies, positioned as security and smart card solutions providers, such as Gemalto, Giesecke & Devrient, Oberthur, Bell Id and First Data, are also TSM solution providers. MNOs and SPs are forming alliances with TSM provider companies, in order to get their solutions for NFC service life cycle management. Bellow are presented examples of such partnerships.

In September 2009, First Data formed strategic partnership with company SK C&C – mobile technology and ePayment leader – aiming to develop TSM solution by mid of 2011. Proof that this partnership had been successful was participation of First Data, as a TSM solution provider, in project with Google named “Google wallet”.

In the December 2011, Gemalto was chosen by the american MNOs consortium “ISIS” (joint venture of three biggest wireless service providers in USA – Verizon, AT&T and T-Mobile), in order to provide TSM solutions that will be appropriate for the needs of USA market.

One of the biggest telecommunication companies in the world Telefónica, on 2nd December 2011 announced choosing Giesecke & Devrient’s solutions called “TSM Enabler” as a platform for providing TSM services for its partners in NFC ecosystem.

6. CONCLUSION

In order to create NFC ecosystem that will enable use of NFC services in their full potential, it is crucial to provide solutions for remote (OTA) management of NFC service life cycle. These solutions, also called “TSM solutions”, are based on communication of actors. These actors are coming from different industries and are based on heterogeneous platforms, so the most appropriate environment for implementing interactions is Service Oriented Architecture, using Web services as SOA implementation technology.

Although we are witnessing raised interest for obtaining TSM solutions from MNOs and SPs, it seems that all existing solutions are limited to just a few ecosystem participants. There is no real openness for new actors. This lack of scalability origins from absence of stakeholders willingness to change and adopt to new business environment, rather than technical attributes of TSM solutions. It is very important that communication interfaces within existing TSM solutions are being based on standards, so other potential participants could easily join, which, having in mind significant profit NFC services are bringing along, is a chance worth effort.

MODERN TENDENCIES IN THE DEVELOPMENT OF TOURISM- TIMESHARING - WITH REFERENCE TO LEGAL ASPECT

Danijela Glusac¹, Jelena Vojnovic², Milica Stankovic³

¹ Higher School of Professional Business Studies, Novi Sad, Serbia, daniglu@sbb.rs

² Higher School of Professional Business Studies, Novi Sad, Serbia, jelena.vps@gmail.com

³ Higher School of Professional Business Studies, Novi Sad, Serbia, milica.stankovic.vps@gmail.com

Abstract: *In the process of globalization, the growing integration of the economy and society in the world results from a very fast expansion of tourism. Timesharing is a serious rival to some of the traditional forms of tourism businesses. In this paper the authors start from the basic characteristics of timesharing, its types, economic benefits and the legal framework of this phenomenon. In our opinion, timesharing represents a new concept in tourism, and a new way of providing tourist services, but at the same time it represents an effective way of attracting the capital and an interesting way of investing into future holidays. Due to the complexity of timesharing in tourism of the modern age, in this paper we approach the problems from the economic as well as the legal aspect.*

Key words: *timesharing, tourism, types, benefits, contract*

1. INTRODUCTION

By studying the innovations in the tourism sector throughout the life cycle of tourism services we can come to many conclusions. Their use in the coming decades should allow for the expansion of quality and quantity of using tourism services. Despite the widespread belief that innovations in services often do not occur or that they do not exist at all, innovations in tourism are numerous and frequent, but more complex than innovations in some other sectors or industries. The competition, globally, more and more influences tourist destinations forcing them to innovate. Services in developed economies produce two thirds of new values and participate in employment and this share is increasing, while the share of production tends to decline. Regardless of the economic effects of services, the study of innovation did not deal with this field - service innovations to a great extent. In fact, in this area there are several key questions which have been raised: whether and how innovative the services are, what kind of connection exists between service innovation and product innovation and what the relation between innovation and economic performance services is. However, to this date it is considered that the innovations are associated with the changes in technology (Stosic, 2007).

2. DEFINING TOURISM

There are several definitions of tourism. Unkovic and Zecevic (2007) state that "tourism is the sum of phenomena and relationships arising from the travel and stay of non-residents, insofar as they do not lead to permanent residence and are not connected with any earning activity" (p.11). This is considered to be the most acceptable definition of tourism, and it was adopted by the International Association of Scientific Experts in Tourism, and it is the work of Swiss authors Hunziker and Krapf.

Regarding this definition, we may conclude that there are factors that influence the development of tourism. According to some authors, the basic factors of tourism are following (Dobre, 2005): The Movement factors, the factors of the Offer, the Mediatory factors.

We may conclude that tourism as an economic activity differs from other activities according to its characteristics and specificities. Therefore, it is necessary to point out the specificities that characterize tourism: heterogeneity - complexity of the structure, seasonal business on the tourist market, the specificities of the components, work non-productivity (Dobre, 2005).

The managers of the tourist enterprises have to bear in mind these characteristics when making decisions about planning, organizing and controlling, so that they could contribute to the development of tourism. In the last few years, new ways of spending free time appeared on the tourist market. Among them, timesharing is of the utmost importance.

3. THE TERM AND FORMATION OF TIMESHARING

Timesharing is a relatively new term, which takes a special place in the global tourism. The Timesharing industry is reported to be one of the fastest growing sectors of the tourism industry and its significance within the tourism sector brings great benefits to the host communities, the hoteliers and the timeshare owners. There are different explanations and definitions for the term "timesharing". The term "timesharing" is a concept that follows the changes on the market, which represent the grounds for the growth and development of timesharing, and which is the exact reason why the timesharing concept can be differently defined. Bakic, Tomic, Muhi and Kovacevic (2010) define timesharing as a "ownership of certain shares of accommodation facilities, where a form of share considers purchasing time (one or more weeks) in pre-determined number of years (exp. 25, 30, 50, 80, 100 and more) in specific units of accommodation facilities" (p.18). Timesharing industry was originally created in 1960. when Alexander Nette began offering shares in a hotel he managed in Ticino, where ownership gave the buyer the right to use the holiday properties owned by the company on a regular basis. His concept led to the development of the Hapimag company, which is still the main promoter of the European timesharing industry. The concept is based on the fact that an individual cannot afford skiing or staying in the luxurious suites in the Alps, but if a group of friends unite, gather their money, and agree to share an apartment, in that case they can afford the purchase. During one year the right to use the shared flat, i.e. apartment for the first week has one of the friends, the second week the other until all of them use their right to the shared property. However, according to Edmonds (1991), Timesharing, as we know it today began in 1967 from an enterprising hotelier in the French ski resort known as the "Superdevoluy". This new business venture was advertised by a popular slogan: "Why rent the room? Buy the hotel, it's cheaper!" At the beginning of the 70s, several cases where apartment hotel building investors could not close the financial construction of building the apartment hotel were recorded. It is then that the investors started using timesharing system and instead of selling apartments, they started selling time spent in using them (Tutic, 1994). The phenomena of massive tourism resulted from the impossibility to satisfy the needs, thus the problem tried to be solved by building and purchasing holiday homes, which had its negative sides such as big expenses, as well as the possibility of a theft or burglary when nobody was at home. All of these influenced the blossom of timesharing at the beginning of the 80s. On behalf of timesharing we can point out some of the positive aspects: feasibility - vacation owner will always have a free place for vacation. We can also point out the possibility to change the vacation place every year; purchased timesharing units the buyer can rent, sell, or leave as an inheritance; via timesharing, the trader collects other people's capital to finance his own activities and expend his own capacities; saving money - by purchasing timesharing you do not have to worry about the prices during the season i.e. you have the accommodation provided at any time of the year at the same price. The consumer satisfies his needs by receiving the same or higher service quality, and he gets all that by spending less money. Inflation does not affect timesharing users because they gained their rights to use the propriety over a longer period of time.

The basic characteristic of timesharing is to ensure that the consumers possess capacities which in normal conditions, based on their incomes, they would not be able to afford. It mainly concerns luxurious products, i.e. luxurious hotels, villas, houses, yachts, airplanes. Due to the popularity of this concept, specialized companies have developed. The main function of these companies is to provide the consumers with the necessary capacity and provide the conditions for using these capacities in special destinations, i.e. they enable the owners to exchange time lease and give them the possibility of staying in different destinations all around the world.

Hotel chains also have a significant role in the area of timesharing industry. Hotel chains use up-to-date technology to manage the resort facilities that are included by the new systems of ownership. The leading hotel chains are Marriot Co, Hyatt, Sheraton and Hilton Ritz.

These economic effects have affected certain governments (Greece, Tunis, Morocco, Israel, Egypt) to support the development of this system. Some of the reasons for the support were: regional development, the development of tourism, employment, etc.

4. TYPES OF TIMESHARING

Universally accepted form of timesharing does not exist. Looking at the standard models and schemes of timesharing relations will help us understand the extent of offered possibilities. The standard forms of timesharing can be divided into two basic groups. The first group consists of forms with which you gain the right of ownership or co-ownership (owner (co-owner) or proprietary timesharing). The buyers gain the co-ownership of a specific accommodation unit within the scope of specifically determined complex, with determined order of using the accommodation during the year and obligation of signing in the property registry. There are several ownership variations, among these the most frequent ones are timespan ownership, interval ownership and fee simple.

Timespan ownership is a form of timesharing ownership where the unit of co-ownership is placed. Each co-owner is the owner of ideal part of accommodation unit and has its exclusive right of ownership in a specific period of every year, which is determined by the plan of using the tourist facility. Interval ownership implies rotating the ownership among the owners, and the right of ownership is determined by that rotation, at the end, the users become co-owners of the facility. In the case of fee simple, every owner has the absolute right of ownership in the agreed period of every year (Kessler as cited in Micovic, 2011). The basic characteristic of the other group of timesharing is to establish the right of using the tourist facilities. Establishing timesharing relations by means of clubs is the most significant aspect of nonproprietary (user's) timesharing. The club membership timesharing is the form of timesharing present in many countries (England and Germany). In these cases, users do not gain the right of ownership - co-ownership of a certain tourist facility, but they gain "the ownership of time stocks." By purchasing a time stock a person becomes a member of the timeshare club complex, which was founded by other owners. The stock certificate of ownership is given to every buyer of time stock, who has enclosed the contract (Zindovic, 2011). The next modality of the user's timesharing is timesharing via participation in the economic society. The economic (stockholder) society is created from this form of timesharing, the society where the buyer becomes a shareholder or stockholder and thus gains the right to enjoy in a specific unit and to use the common parts of a facility with the rest of the stockholders during the specific period of a year. This is all regulated by the contract of society founding and statute (examples: Switzerland and Italy) (Zindovic, 2011). One of the first companies founded according to this concept is the Swiss company called HAPIMAG. Since 1963, Hapimag has been offering flexible rights of residence at a range of travel destinations. Today, Hapimag has over 5300 apartments in 57 resorts and residences in 16 countries. All Hapimag properties are financed from shareholders' equity. This successful business model has enabled Hapimag to withstand every economic crisis of the last 50 years. Since 1963, Hapimag has been offering flexible rights of residence at a range of travel destinations. There is one simple idea underlying Hapimag's business model: joint investments and individual use. Members invest together in resorts and residences, which are currently 57 in number and which they can use individually according to their own requirements. Their need for rights of residence determines the size of their investment (Hapimag, 2012).

5. THE ROLE OF EXCHANGE

Exchange has become an essential part of the timeshare product. The Exchange companies are like brokers between consumers. They give timeshare owners the ability to swap their timeshare for another - at a different time, location or both - with the confidence that they will receive another high-quality holiday. Typically, a timeshare purchaser in an affiliated resort joins the exchange company automatically at the time of purchase. Their exchange company then acts like a timeshare bank. If the consumer chooses not to use the week they have bought, they deposit it with the exchange company and can subsequently withdraw equivalent weeks - at other times and/or at other resorts - which have been deposited by other members. The leading company in the exchange of the tourist resorts is RCI (Resort Condominiums International). For more than 37 years, RCI has been at the forefront of the timeshare exchange industry, transforming the holiday experience for resort developers and owners alike. As the global leader in holiday exchange, RCI is known industry-wide for being a trusted associate as well as a full-service, single source service provider for our clients' needs. We strive to make dream holiday reality for our 3.8 million members and to work with developers to help enhance their sales and profits by expanding the utilization and enjoyment of their leisure real estate products. We help our resort affiliates move their business forward, and together, we continue to advance the leisure real estate industry as a whole (RCI, 2012). RCI require members to deposit a week in their bank before offering an exchange and generally only offer a week/resort of similar or lesser trading power than that banked. They charge an annual membership fees (with discounts for longer periods) plus an exchange fee. RCI has been increasingly criticized for their failure to provide a good choice of exchanges or

even, in some cases, any choice whatsoever. To become a member of RCI you must own a week in one of its affiliated resorts. RCI also has two "Points" systems notionally independent of their "weeks" system as well as numerous sister companies offering rental of holiday accommodation. RCI, the world's largest timeshare exchange company and a part of Wyndham Worldwide, has signed its first affiliation agreements in Serbia, adding two new resorts to its portfolio of over 4,000 affiliated resorts worldwide: Club "Satelit" and "Kraljevi Konaci" resort. RCI members can now choose from two attractive resorts in this diverse and vibrant country (The Timeshare Blog, 2008).

6. THE MAIN PLAYERS IN THE TIMESHARING DISTRIBUTION

Pantazis (2003) states that "the Timesharing distribution system consists of various players. Their individual role is crucial for the success of the industry. According to WTO (1996) and OTE (Organization for Timeshare in Europe) the following explains who are the main participants in the industry's distribution chain when it comes to planning, development, commercial and resort management phases of a Timeshare development. On one hand, there is the Developer. The Developer is a real estate or construction company that owns some kind of physical property, which is to be sold on a Timeshare basis. Some of the developers plan the project, choose the location and build the complex. Other developers purchase existing hotel or an apartment block, or change the already build resort for the Timeshare use" (p.19).

The two most famous companies that are responsible for the promotion and selling, i.e. commercial aspects of Timeshare intervals are Sales and Marketing company.

The Holiday Exchange Companies are the ones that offer their clients, the Timeshare owners, the opportunity to exchange their interval for another, in an affiliated resort.

The so-called Management company is in charge of the maintenance and management operations of the resort. The developer may employ and train the required staff on his own or go to a specialized management company.

The association established by the resort developer is called Owner's Association. This association is more concerned with resident's issues and it operates like a residents association for a block of apartments. The association was formed by the owners of the Timeshare intervals in the same resort, and its main purpose was to protect owner's interests. They deal with issues such as the level of annual service charges and the provision of sinking funds for major future repairs and refurbishment.

The companies that are specialized for organization and division of the Timeshare developer entities are called The Resale companies. They are aimed at selling to the open market weeks and properties, which had been previously purchased by the individuals who subsequently wish to sell (Panatazis, 2003).

7. THE PRICE

The price of timesharing accommodation unit can be very different. Mostly, the price is affected by the location and time criteria and other factors such as the type of product (whether the accommodation is in bungalows, villas, apartments), also other contents which are offered (receptive factors, such as food, sport, recreation, entertainment, amusement conditions, etc.) the quality of the product (how are accommodation units equipped, interior and exterior design), then image, fashion and prestige (Bukvic, 2004). Bakic et al (2010) argue that "timeshare unit selling price includes the following structure: cost of accommodation units (30-50%), marketing (35-40%) and other expenses included in profit and the like (30-35%) (p. 19). Calculations show that it is cheaper to spend a vacation via timesharing system, than to have your own house or a holiday home since the fixed expenses are extremely high. Timesharing is attractive not only for the users, but for the companies as well. These companies deal with timesharing and gain the profit throughout the whole year by using a precise system of management.

8. THE MARKETING OF TIMESHARING

Whatever the timeshare product or enhancement introduced into the resort timeshare sale, the marketing of such products in the resort timeshare world has increasingly become an art and science unto itself.

Bakic et al. (2010) argue that Promotional activity is a very important instrument in business policy for selling timeshare capacity. Most productive ways to promote timesharing are:

- Through specialized journals for timesharing ("Holiday Timesharing", "International Timeshare News") to inform readers and inform stakeholders about the latest news and benefits in the industry. Through "Word of mouth" concept. The recommendation was an incentive to buy in more than 50% cases.
- Internet as a means of promotion. This type of promotion has proved to be the fastest and most productive. The advantage of the website is reflected in the fact that it can present to buyers as many information, in easy way. Potential buyers can visually experience what is the offer like, how much it costs, location and other features (p.19). In addition, direct mail is used to be one of the principal means of generating potential prospects for Timeshare, particularly for off-site offices. The nature and the quality of the direct mail vary. For some companies, well-presented mail and high quality brochures, are sent to potential buyers while others simply inform them that a free gift has been won and it has to be collected personally by visiting the office on a certain date. Direct marketing, which includes direct mail and telephone marketing is a very popular tool. The consumers in general have little knowledge or understanding about timesharing which in accordance with no natural desire to buy the product, leads the marketers to offer them incentives to induce their visit to the point of sales.
- Off Property Contacts (OPCs): OPCs are the individuals who fill timeshare presentations with potential buyers by pitching them on the beauty of timeshare ownership and, often, offering a thank you gift for attendance. OPCs may be direct employees of a timeshare company or may be part-time contractors. These workers operate from high-traffic tourist areas, such as hotels, shopping malls, beaches and stand-alone local sites. OPCs do not sell timeshare units. Sales agents conduct presentations and perform all sales.
- Fly-Buys or Mini Vacation: This method has become one of the most popular ways of marketing Timeshare and still continues to grow in importance. The potential prospects are given the opportunity of taking a short break or a low cost holiday at a Timeshare resort, subject to attending a sales presentation. This offer is made through direct mail, tele marketing or with OPCs.

9. THE EXPERIENCES OF TIMESHARING IN OTHER COUNTRIES

In Europe about 1.4 million families own timeshares, and about 620 companies, which have their own business in that sector, have estimated annual profit of 2 billion euro (Marviss services, 2011). Within many years of tourism tradition in our country, but not only with that tradition, "health spa resort" after a long period of "dry" years, is again on the upward path towards the development. If we take into consideration that Serbia has a large number of spa resorts, we can conclude that there exists the capacity for the development of timesharing. What is necessary for the development of timesharing is the existence of attractive spa, health resorts, archeological sites, etc.

So far, the experiences have shown that the timeshare centers must satisfy certain conditions in order to be positioned and sold at the tourist market. The conditions are following:

- Location must be in an attractive area (both natural and social attractions are desirable);
- Availability and diversity of different catering facilities (restaurants, taverns, pizzerias, fast food restaurants, etc.), as well as supplying facilities for tourists (supermarkets, groceries, etc.);
- Developed traffic infrastructure in the area (most of all the road network), as well as the access roads;
- Availability of various partial tourist products from the area of sport, entertainment, recreation, amusement, culture, etc.;
- Exclusive offers (most often it is asked for "peaceful" locations near famous tourist centers, as well as "isolated" locations so as to avoid the overlapping of the segments – tenants and "ordinary" tourists);
- Relatively higher quality of interior design (very often with luxurious furniture);
- It is desirable for the number of hotel accommodation units to be incorporated in the system (for a relatively shorter staying – one or two days);
- The worked out system of maintenance (cleanliness, phone plug-in, TV and etc.);
- The worked out system of management (tenancy, exchange, resale, promotional activities (Bukvic,2004);

Destinations that do not satisfy the above-mentioned conditions have small chances of success on the market. Precisely, there is a specific number of destinations that did not succeed because of neglecting some of the above-mentioned factors, they could not go further than the introduction phase. These factors

are in the center of interest for those who are developing the system, as well as for those who are appearing as users (tenants).

The most recent timeshare statistics as compiled and provided by the American Resort Development Association (ARDA) indicate that there are 1,548 vacation ownership properties in the USA. Seven percent of all households own more than 7.2 million intervals with the average cost of a timeshare interval being \$20,468. The majority of timeshares owned are points based systems. Resort occupancy stands at 79.7% and nine out of every ten timeshare owners are current on their timeshare loans and maintenance fees (Timeshare Trends Blog, 2011). These firms have created projects specifically geared toward the timesharing market. According to John Nicolls, former senior vice president with Hyatt, today's timesharing unit is a complete apartment rather than simply a hotel room. "The most important aspect of a timesharing project is that it should be designed and built for that purpose," said Nicolls. In developing its timeshare properties, Hyatt has found it desirable to locate them adjacent to a successful resort. "Usually, the best strategy is to get the hotel up and running and a few years later start the timesharing project. It is important that they be located near a successful resort hotel, because that generates the traffic and the leads you need to sell the timeshares," said Nicolls.

Specific period of time had passed until the timesharing industry found its base in Asia. According to the research, currently there are four countries in the region that have more than ten timesharing resorts (Malaysia, Indonesia, Thailand and Australia). As Smith and Vecchi (2010) state that in Asia is still present only small number of the purpose-built resorts with respect to The United States which have a large number of the purpose-build resorts.

Currently in Malaysia, there are about 30 timesharing resorts, in Indonesia about 20, and in Thailand about 15. However, this is only temporary. Each of the countries mentioned above has its own plan which is based on the further stimulation of timesharing. For instance, in Malaysia exist defined plans according to which they will build 11 timesharing resorts. In Indonesia, in Bali, they have already started building the purpose-build resorts. It is necessary to point out that the existing resorts apart from high quality content, which refers to possibility of using golf course or going to the beach, have a high standard of personal services.

Timesharing in Asia is arising. Several factors are influencing Asia to become the area that will experience the expansion which was previously seen only in The United States. The growth of the middle class and prosperity, the arising need for the vacation, elimination of the currency control, decreasing control of the government when business activities are concerned, removing the obstacles for the inflow of foreign investments are just some of the factors which induce the development of the timesharing in Asia. With respect to Asia whose markets are unsaturated with small investing expenses, the markets in the USA are saturated with high expenses and low margins. European markets regardless of a good geographic and demographic base, with respect to Asian market, are regarded as less suitable for investments due to the excessive regulations.

Asian industry has to decide whether it will define timesharing product as an investment or as a consumer's product. Furthermore, there should be a specific jurisdiction, on a state level. Therefore, it is necessary for the government to take the initiative to ensure that the timesharing will become a healthy part of vacation in Asia's industry. The users, ownerships, local communities and any other institution or a person dealing with timesharing can benefit from it.

10. THE SHORTCOMINGS OF TIMESHARING

One of the product's disadvantages often mentioned by its critics and not seldom adopted by prospective buyers is the high acquisition price combined with the long-term (up to 60 years) period of fulfillment of the owner's right.

As mentioned above timesharing has many positive impacts on the tourism industry, but it may also have some negative impacts. One of the main problems occur when the marketing of Timeshare is taking place on site, at the resort area. This involves different forms of persuasion by OPCs and sales people, which often use sale activities that are regarded as aggressive. These aggressive sales practices have resulted in strong opposition from consumer organizations and have caused criticism from the media. Another negative impact of the timesharing and the whole tourism industry is the damage of the local societies and environments particularly in overcrowded and undeveloped destinations (Pantazis, 2003).

Regardless of the criticism addressed to timesharing, it represents a large contribution to the national economies.

11. LEGAL FRAMEWORK

The development of services and the expansion of tourism represent the basic characteristics of the new age. Tourism refers to every aspect of our society. It affects the development of the economy, the way the citizens live and their standard of living, it leads to the opening of the new working places and general prosperity. Due to its nature and characteristics, tourism includes a wide variety of phenomena that occur before, and that go deep into economic, ecological, social and legal aspects of life.

In the process of providing tourism services a large number of participants appear, among them are tourist agencies, traveling agencies, recreational organizations et al., all of which give their contribution to providing tourism services in their own ways.

There are two tourism services that we can differentiate: travel packages (or contracts about travel organization) and timesharing. In business practice timesharing was formed as an unnamed contract, a part of the autonomous contract law. In these regions the timesharing contract was implemented into legal system by adopting the law which gives the right to time share a tourist facility. According to the Article 1. Subpart 2. the law defined the right to time share a tourist facility as a right to use a certain tourist facility, according to its purpose for a certain number of years, in a certain period during a year, under the conditions specified in the contract of sale. What is characteristic about this law is that the object of this law was under public property. The period of using a certain facility could not be less than 5 years, nor longer than 30. The time spent using a certain facility was determined to a period of 7 days.

Brief application of this law led to the great interest of renting apartments in Kopaonik. Our legislator defines timesharing as a contract of using a time shared immovable property, timesharing is a contract according to which the vendor is bound to give one or more immobile properties once or more times to the consumer to use it, and the consumer is bound to pay the compensation for it and the contract is closed for the period less than a year or with a possibility of tacit prolongation of the contract. The solution from our already existing law as a subject of timesharing it induces real estate (immovable). However, Directive 2008/122/ec of the European parliament and of the council of 14 January 2009 on the protection of consumers in respect of certain aspects of timeshare, long-term holiday product, resale and exchange contracts as subject of timesharing it induces "overnight accommodation". This kind of formulation refers to immovable property as well as movable ones. However, our legislator used the formulation "immovable property where you can spend the night". The aim of the directive is that the EU member states harmonize their regulations in order to facilitate the functioning of the internal market and allow the consumers to conclude the contract on the entire territory of the EU. In addition to this, the aim of the directive is to protect the buyers and to highlight the main issues that need to be taken into account when signing the contract (Vilus, 2007).

The law nature of timesharing

The greatest similarity timesharing has with the rental agreement, taking into account that in both of them the right to use the property, which is limited, is constituted; that the landlord takes over the responsibility to maintain the property during the period of using it and that after the expiry period the consumer has the obligation to give the property back to the landlord.

Furthermore, the host is obligated not only to hand over and make it possible for the people to enjoy in the tourist apartment, but also to enable the use of all the appliances and facilities intended for the general and common use by the guests in the apartment area. Moreover, the host is obligated to keep all the guest's possessions, which were brought or handed over, safe. When compared with tenants, the guest is not obligated to pay for small expenses and repairs which were made by the regular use of the apartment and its appliances. In the case of the rental agreement, according to the law, the lease is paid semi-annually if the property is under the lease for one or more years, but if it is under the lease for a shorter period of time it is paid at the end of that period. Compensation according to timesharing is paid at the expiry date when the consumer may unilaterally terminate the contract (Micovic, 2011).

Caric (1996) points out that "timesharing is different from the lease contract, mainly due to the fact that via timesharing one cannot transfer or gain the full and unlimited right to use other people's property, but it is time parceled right which is being agreed upon and which assumes common use of the property by several people" (p.70). The difference between timesharing and the contract of sale is in the fact that the consumer,

according to the contract for time shared immovable property only gains the right to use the property, but do not gain the absolute right of ownership over the property (Draskic as cited in Micovic, 2011). Lately, in our country as well as in the others, there is the growing need to differentiate timesharing from the concession contract. Their common feature is that they can provide time and content limited right to use the property. Caric (1996) points out that "their differences are crucial because the concession contract refers to the use of renewed economic wealth and goods in the general use, while timesharing may refer to every economic property, although timesharing contract is more often closed in tourism" (p.70). The main characteristic of timesharing which makes it specific and separates it into a special institution of the contract law is the time limit. Therefore, we justify the stand that we are dealing with a specific, *sui generis* contract. Zindovic (2011) emphasizes that "due to the economic significance and the relations which can be formed from this contract, we consider that this contract cannot be classified into traditional contracts of civil and economic law, but it represents the contract *sui generis* of the service right" (p.312).

Timesharing in our law has a law obligation effect. By concluding timesharing, an obligation relation is formed between the vendors (the ones who give the immovable property) and the consumer as the carrier of the right to use the immovable property in a specific time period, according to which the two parties gain rights and obligations. On one side, the vendor has the obligation to hand over the immovable property and keep the consumer's things safe. While, on the other side, the consumer is obligated to pay compensation to the vendor for using the immovable property and other services, to take a good care of it and to return the property to the vendor after the expiry date. The obligations of the vendor do not only refer to the obligations set by the contract, but as well as the preliminary contract.

According to the Article 111. Consumer protection law from 2010, the vendor is obligated to precisely inform, in the appropriate time span, the consumer about the data listed in the standard informative forms for timesharing, whose content is legislated by the Government, on the proposition of the Minister and the Minister authorized for tourism businesses. In the case of conclusion the contract, these data become its integral part and they cannot be changed, unless both parties specifically agree in a different way, and if the changes are made in case of a force majeure.

Therefore, the vendor is obligated to provide the notice from the Article 111. Subpart 1. of the relevant law to the consumer without the compensation, the notice should be given in written form or on the permanent medium which is easily available to the consumer, in a clear and understandable way. In the same way, before the contract conclusion the vendor is obligated to inform, in the appropriate time span, the consumer about any change of the data, which will be specially stated in the contract if it should be concluded.

The legislator emphasizes three information which the vendor is obligated to notify the consumer, in appropriate time span, before the conclusion of the contract.

- The consumer's right to unilaterally terminate the contract.
- The deadline during which the vendor can unilaterally terminate the contract.
- The prohibition of paying in advance before the expiry date during which the vendor can unilaterally terminate the contract.

Considering the fact that the contract is closed according to the already prepared forms, it is clear that it is the formulary (adhesion contract). In the Annex of previous Directive 94/47/EC the minimum content of data was legislated which the contract must include. Many neighboring countries have explicitly stated in their legal texts exactly what a contract must include. That practice has not continued with the new Consumer protection law from 2010, but it is left for the legislation to arrange obligatory timesharing contents.

It should be emphasized that the contract of enabling the exchange of the time shared immovable property is regulated by the law. This contract is said to be the one by which the vendor is bound to include the consumer in the exchange system of time shared immovable property, and the consumers can reciprocally concede for a specific period the rights from the contract of time shared immovable property, but the consumer is bound to pay the compensation for that.

The consumer can unilaterally terminate the contract, i.e. preliminary contract of time shared immovable property, contract of permanent facilities for rest, contract which offers help during the resale, and the contract which enables the exchange of the time shared immovable property without the obligation to state the reason for the termination, during the 14 days from the day of receiving the concluded contract.

Popovic (2010) emphasizes that “ despite the fact that timesharing contract has a short history, in the couple of previous years it was very significant in the practice, especially in the Western Europe countries, therefore it will on the basis of this legal business in tourism developed countries achieve a significant financial impact” (p.115).

12. CONCLUSION

Despite the scepticism in the past about the innovations in tourism, the innovations in tourism are becoming more evident. In the future, the tourists will dictate the terms, technology will stay the key factor, and the forms of providing tourism services (first of all we think of timesharing) will not disappear from the market, but it will appear in innovative forms. We consider that emphasizing the basic characteristics of timesharing experiences in other countries and legal legislatures is useful for considering the possibility of developing that system in Serbia. We should not forget why timesharing was in the first place established in our country. Our timesharing system was formed as an ‘emergency exit’, when the possibility of engaging foreign capital via so called mutual investments with foreign business partners fell into a dead end. It was created in the hope that our timesharing system will represent a significant system of tourism investments in our country. However, even today we can see the possibility of adopting timesharing in our country, provided that we use the timesharing experiences around the world, come up with a very good organization, and take into account all the natural beauty and the position of Serbia.

Besides the possibility of raising funds, the positive role of timesharing is that tourism capacities will be used for many years, which is an important prerequisite for successful business. Furthermore, in the traditional business lack of financial resources for the advertising system is constantly appearing, but in timesharing system this is not the case, except at the very beginning. Timesharing gives an interesting possibility to the consumers that the apartment can be rented or sold to anyone else during the week when consumers are using it, and it can be replaced through an organization for a similar apartment in Vietnam, the Dominican Republic or Jamaica. As far as the legal nature of the contract of timesharing is concerned, the contract is the creation of autonomous contractual economy law and is similar to the sales contract rental agreement, contract of leasing and concession contract. In the Law on consumer protection there are several articles devoted to tourism.

² Politecnico di Milano, marin.jovanovic@mail.polimi.it

Abstract: *The purpose of this paper is to propose a framework to depict the issues, opportunities and challenges the automotive ecosystem is facing while driving toward sustainable mobility. Research was based on a thorough analysis of contemporary articles, journals and books in this field as well as on several interviews with representatives from top automotive suppliers and OEMs in Italy and Germany. With the concept of e-mobility which is increasingly becoming more prominent within automotive industry, new business opportunities are arising. For those players who wait too long in joining the e-mobility race, a potential share could be significantly smaller. The central point is that in the years to come, the automotive industry value chain will be reshaped towards a car usership model. Perceiving a car as a mobility product where the car itself represents just a piece of the holistic mobility package is the anticipated direction. A portfolio of business models has been analysed starting from the car as a product striving to a future holistic mobility approach. The arrival of electric cars is no longer a question, we could just argue its adoption rate and the course of technology and business development. As any disruptive innovation, the new value chain will bring many white-space opportunities, as well as challenges. Only those players who proactively think in this direction will be the ones taking advantage and leading the way in the new generation of sustainable mobility.*

Keywords: *automotive, sustainable mobility, business models, car usership, value chain, e-car*

1. INTRODUCTION

The purpose of this paper is to propose a framework to depict the issues, opportunities and challenges automotive ecosystem is facing while driving toward sustainable mobility. Through comprehensive research and interviews with automotive executives and leaders at automotive OEMs and suppliers, we are trying to:

- Identify current automotive industry business models and anticipate changes over the years to come
- Connect megatrends that are having a strong impact on the automotive industry; trying to appoint innovation as an answer to most of them
- Determine relevance of sustainable mobility for automotive industry
- Explore and position new entrants as well as existing players in the business model and value creation
- Identify where will the new opportunities emerge; how the business model will realign by proposing a classified framework
- Identify patterns of success and failures in today's automotive industry
- Perceive holistic mobility approach and mobility package as a solution

The perspectives in this report are intended to benefit and encourage mutual cooperation among all players within extended circle of future automotive business model. We are convinced that once the new ecosystem is established, automotive industry will be capable to meet the triple-bottom line challenge: people-planet-profit.

2. MAJOR TRENDS

Sustainable mobility comes with three major trends that will greatly affect the automotive sector in the following years: environmental issues, rising urbanization and overall changes in the customer behaviour.

Environmental concerns are at the top of the list of challenges facing the automobile industry today, overcoming even the cost reduction which has been the primary goal so far. "While cost reduction remains very important, the automotive industry's emphasis is on the environment and the demands that it puts on innovation," said Chris Murphy (DuPont Automotive, 2008). People are becoming more and more environmentally aware. They are increasingly expecting sustainability and eco-friendliness in the automotive industry and placing these concepts as the main points for differentiation and improvement of brand image.

There is an on-going trend of moving people to live in cities. By 2050, 70% of the world's population is expected to live in urbanized areas. With the growing trend of urbanization, the number of mega cities will rise to up to 30 in 2025, where almost 8 out of 10 mega cities will be in the emerging markets (*Fédération Internationale de l'Automobile - FIA, 2011*). Having in mind that emissions and environmental standards are continuously being tightened and are affecting regulations in mega cities, the sustainable mobility will have a great impact on demand, margin structures and business models in the automotive sector. In defiance of the fact that cars are currently being designed to meet the current urban habits and customer needs, not everybody wants to have his own car anymore. The world is moving from car ownership to car usership. With this in mind, there is a greater focus on the intelligence mobility services (car-sharing, car-pooling etc.) and new business models that come with it. This is why today's automotive market will soon develop in the mobility market, forcing the existing market players to adopt and give an opportunity for the new ones to evolve.

As a result of globalization and ever increasing connectivity among people, we have sailed into the world of the empowered customer. Power has shifted to the customers and thus compressing margins and creating new paradigms. These new generations of Internet-empowered car buyers are more demanding and they have placed the negotiation power in their corners. Customers have unlimited access to the information and can instantly share it with the rest of the world. Through social networks and mobile commerce the relationship between buyers as sellers has changed dramatically, where customer expectations regarding the service quality, price and delivery are striving to the highest level. OEMs that recognize this empowerment and the importance of additional mobile services are more likely to gain and maintain the competitive advantage in the future.

3. FROM CAR OWNERSHIP TO CAR USERSHIP

Automotive industry value chain has to be reshaped to address emerging mobility needs as well as changing customer behaviour and habits. Customer is smarter, enlightened with all sorts of information which are instantly available on demand.

Internet is becoming a part of daily life where staying connected is recognized and accepted concept which helps people all around the world regardless the application area. Connectivity is becoming an intrinsic part of a vehicle and more importantly outside of a vehicle. It is certain that automotive business model needs to undertake major changes due to a size of the technology shift and already mentioned pressure towards sustainability products.

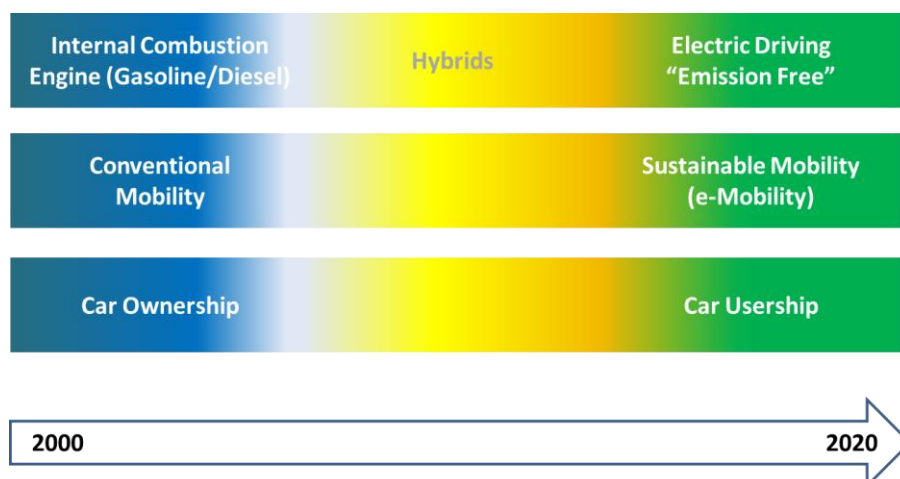

Figure 1: Changing concepts of mobility and car ownership

In the same way, automakers have to bear in mind decreasing importance of a car as a status symbol. In the years to come concept of mobility will overtake the factual car ownership with a smarter and more convenient transportation models to reach from point A to point B, what is a direct attack for automaker's revenue streams. From the finance perspective, in the era of IT intelligence and ubiquitous connectivity, traditional car concept is a highly depreciation asset which has to undertake changes.

On the other hand a substantial part of the customer base is emotionally tied to the car they own or they'd like to buy, what makes this issue significantly more complicated. Moreover, we could say that the conditions are pretty much the same with other industries where smart application and services are overtaking the traditional markets but within an automotive ecosystem a unique approach has to be invented simply because motor cars cannot be replaced by electric cars. The entire business model will expand and offer opportunities beyond the traditional value chain.

It is very likely to see new entrants like infrastructure providers, utility companies, suppliers, TIME (telecommunications, information technology, media and entertainment) or new service providers fighting for the customer's mobility budget.

Having that in mind it is reasonable to believe that radical innovation like moving to e-car concept involves shift on more than one dimension. There are three main dimensions triggering the change:

- Product innovation – sustainable growth of the industry converging to e-car and e-mobility concepts
- Customer innovation – changing needs and habits
- Business model innovation – changing the way value is created and shared

An innovation that occurs along one dimension is expected to be incremental, while connecting the dots along two or all three dimensions will result in a new business opportunities and it is much more likely to be disruptive. Taking into account the size of the technology shift required and customers' uncertainty concerning high costs, low mileage and undefined usability, it is up to the industry to attract customers into electric cars – push strategy.

Every innovation is facing customer resistance in the early phase; electric cars are not excluded from this practice. Technology risk from the customer viewpoint represents the main threat for the successful adoption of electric cars. Therefore, making the shift together with an innovative business models will make the transition from the concept of ownership to usership far easier for OEMs. Furthermore, perceiving a car as a mobility product where car itself represents just a piece of the holistic mobility package is the right standpoint. Total cost of ownership/usership is another critical turning point on the way to e-car. TCO/TCU has to be the reason to outweigh the traditional car concept and create momentum. Customer is going to evaluate benefits from the features like pay-as-you-drive, car2go, car-sharing, car-pooling and others yet to be invented and support the concept as a respectable pay-off. Once the early adopters approve the usership business model arriving at around 16% of the market, early majority will jump in and there will be no going back (KPMG, 2012).

4. FUTURE BUSINESS MODELS

As stated above, owning a car will have a diminishing role in the mind of the future customers. With the increase of ecological awareness more rational approach to mobility is going to be developed, regarding the sustainability and an overall improvement of the lifestyle. This will lead to growing customer expectations in the field of traffic and mobility concepts. Taking into consideration the conflicting priorities in this field, it could happen that only few of the OEMs will manage to sustain profitable in the long run by focusing only on product related features and profit streams. That is why the automotive industry players have to challenge and shake up their current business models in order to satisfy ever demanding mobility requirements and secure sustainable margins and profit streams for the future development. By 2020, an automotive will transform to mobility market and realign the existing business models.

During our research, we have identified portfolio for possible business model that will emerge in the near future. As you can see in the figure below business models are deployed between two concepts - car and mobility. First axis the "mobility concept" describes two extremes of mobility offerings to the customers. It ranges from basic mobility to the holistic mobility which is reflected in expanded mobility, increased convenience and improved lifestyle services. The second axis denotes the car concept in the future business

model landscape. From one side there is a physical ownership of the car and mobility is inevitably connected to the car itself, while the other side is completely opposite. Instead of owning a car there is a concept of car usership. Together with this concept a lot of new areas for mobility business models arise.

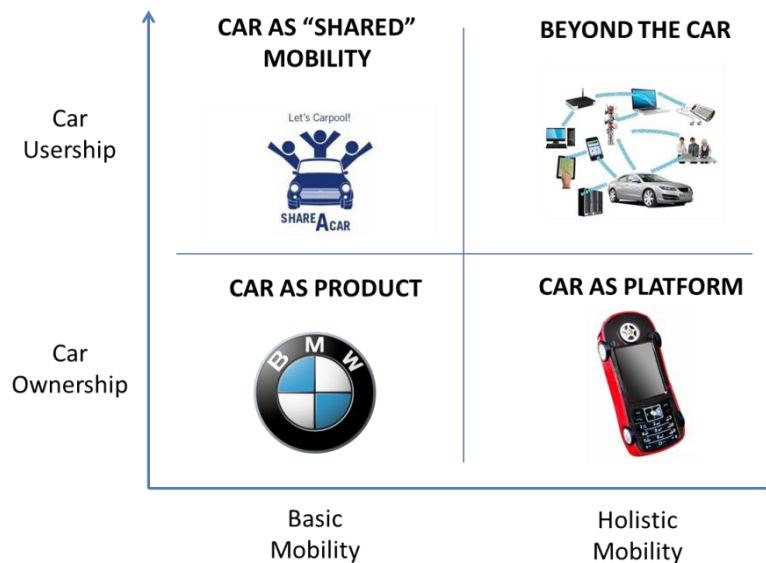

Figure 2: Portfolio of possible business models

These four possible business models represent the end-points in the future mobility market. Although it's possible that some of the market players take these extreme values as their future business strategy, it is more likely that the mixture of these models is going to be the right solution for majority of the players.

Car as product is a business model that largely corresponds to today's car manufacturer. Main competence lies in the state of art technology for producing variety of products, ranging from engine to chassis and lightweight construction parts. What distinguishes this model from the others is a manufacturing excellence that enables the production of high quality and cost effective products. In order to maintain its competitiveness this players have to continuously develop innovative, sustainable and green technologies. The main market segment to focus on is a technology savvy customer who seeks for comfort, independence on one side and eco-friendliness on the other, and they are willing to pay a premium price to acquire the product. Since the main profit stream in this model is coming from sales of the product itself, it is expected that premium vendors will evolve and concentrate on specific market niche. In addition few players who succeed in maintaining necessary margin and economies of scale will take the leadership in the future automotive landscape.

Car as platform is a model that can be seen in today's telecommunication industry. Although there is an inevitable link with the core product, the main emphasis is being moved to service portfolio offered to the customers. What we can witness today in telecommunication industry is that companies are giving cell phone products for free in order to see the additional packet of their services. The similar concept can be expected in automotive industry. Car is going to represent just a platform for enabling a vast number of services around it offered to a customer along the whole product lifecycle. The main difference with the previously mentioned concept lies in technology development. While players focused on car as a product invest in technology innovation and use state of art technology, car service providers use the existing technology and have a low impact on product-based innovation. All the processes beyond their core competencies are outsourced.

This concept is primarily targeting the customer who is still seeking the concrete product to satisfy his/her mobility requirements, but as the same time search for additional services around the core product. Revenue streams in this case are coming from a multiple business opportunities emerged during the whole product ownership cycle. Partnerships, value creation and money distribution among the major players in the industry are characteristics of this model.

Car as "shared" mobility moves the focus from the product itself to the sustainable transport and mobility solutions. In this business model car is seen as just one of the means to satisfy the future mobility demands. Customers will have the possibility to create a multi-modal ways of mobility by using public transportations

and other non-individual transportation means. Car innovation set place in the area of cost-efficiency and practicality. The concept of “shared” mobility will take place. The player will focus on providing mobility solutions without producing a car itself. The main drivers of this model come from reduced cost and increased flexibility for all the customers that just need to move from place A to B. We are moving here from car ownership to the pay per use approach. This will give opportunity to the development of so called collaborative commuting – “We is the new I” (*Smart Mobility magazine*, 2011). Car sharing concept will become the number one mobility solution. It is similar to car rental but mainly for a short distances and regular mobility requirements. Some of the typical representatives of these models are Zip-Car and Car2Go from Daimler Company.

Beyond the car model completely separates the concept of mobility from the car itself. Necessary infrastructure, car, train schedule, parking, an airline, hotel, meetings, online commerce, video conference, connectivity, CO2 reduction, smart phones, tablets are all ingredients in the future mobility requirements that need to be met. It is up to the companies and business model actors to manage them in the effective way in order to create a nice blend of services which will satisfy the customer needs at the highest level.

The main competence of these players lies in the expertise of managing compound relationships with customers and expanding the cooperation and partner networks beyond the automotive industry in order to provide a unique portfolio of additional services. Goal is to provide all the mobility necessities in a customer everyday life. Companies should focus on the segments who doesn't have the need to own the car, on the contrary they see a car as a burden and potential cost generator. The status symbol is being required through a variety of additional mobility services providing along the way. It's not the car that is going to be sold anymore, but the solution to mobility issues required by the customers – more time, lower cost, ecological awareness, better quality of life etc. Automotive manufacturers will move from the car to the lifestyle providers.

5. REALIGNED VALUE CHAIN

Without a question lifecycles between the traditional automotive and e-car industry differ in its fundamentals. In the new automotive age technology suppliers play highly important role and they should closely collaborate with the OEM. The automotive value chain will be considerably different in months and years to come with the high level of uncertainty what is going to lead and control the major technologies and changes in the electric value chain. It may be OEMs, the utility companies, infrastructure providers or maybe some other intermediates. Hard times have come for the automotive stakeholders because reshaping of the value chain is indispensable action towards not grow but existence in the business.

According to KPMG survey 54 percent of respondents believe electric component suppliers will gain a more significant role by 2025, however the survey underestimates the importance of emerging concepts and business models (*KPMG International*, 2012). Still, electric vehicles are gaining the momentum, especially in the last 12 months when they've gone from the strategic long term objectives directly on the streets. Unconventional partnerships are made in order to support new business model to achieve complementary services. Electric vehicle value chain became reality.

Many uncertainties and risks are still influencing the industry mainly because of high electric car prices, complex transition process, missing infrastructure, atypical cooperation needed between OEMs and power producers and still extremely high battery prices. On the other hand, technology for electric cars is available today but the unique silver bullet solution is missing to put all the pieces together. Overall up-front costs are remaining very high for the end customers of e-cars. Essentially, the Total Cost of Ownership paybacks have not been well-articulated so far. For both consumer and fleet managers the initial costs of electric vehicles compared to that of internal combustion engine (ICE) are still incomparably high. Governments are responsible to facilitate and trigger the first move with incentives towards large scale e-car production. In order to influence successful electric vehicle rollouts more cross-sectional cooperation is needed, predominantly between OEMs and power suppliers.

Furthermore, some automakers and vehicle-sharing businesses perceive the mobility concept as part of the electric vehicle offering and value distribution. Business model innovation might be even more important than the technology itself. What the world is searching for is actually a self-sustainable value chain for electric vehicles. In the initial phase, one of the solutions could be a new business processes with the focus on electric car integration to traditional energy billing system including all mobile electricity expenditures one

could make; leasing electric cars, park and charging stations, other mobility web 2.0 brokers and intermediates and finally battery leasing and switching concepts.

Changed provision market is expected to occur as the number of e-cars is increasing. Similarly, the utility companies will create a new revenue stream regarding delivering and charging the electricity. If we try to conceptualize, electric vehicles are adding a great deal to the overall fluctuation in value distribution. An electric vehicle in the grid system will increase considerably electricity revenues over the life of the vehicle. Correspondingly, from the battery supplier point of view, shift to lithium-battery is adding in approximately 10.000 € to the cost of the e-car. Current batteries packs enable up to 100 km before they need to be recharged. Companies that can design and produce these batteries with the same performance at half the current cost will garner a competitive edge. Companies across the value chain are competing to hit this new revenue stream while governments are more and more perceiving battery technology as strategically vital. Revenue stream will be shifting to companies that can provide charging, maintenance and other services yet to come. New service revenue streams will essentially come from services such as infrastructure, communications, retail, media and advertising.

To survive and prosper, all stakeholders should take the necessary steps needed to stay in the game of electric vehicle value chain. The transformed value chain will take the following distribution of value starting from the development and promoting of e-mobility services, building and operating e-mobility, selling and delivering and finally the chain will be closed with service and billing management.

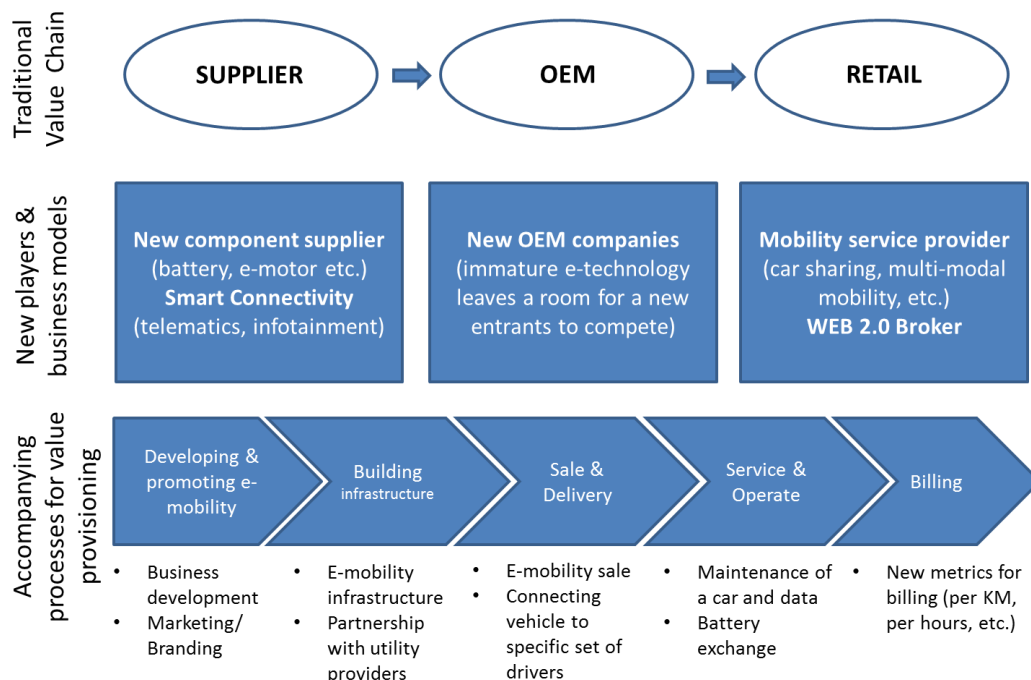

Figure 3: Realignment of the automotive value chain

As any disruptive innovation, the new value chain will bring many white-space opportunities as well as challenges. Only the stakeholders that proactively think in this direction will be the ones taking advantage and leading the way in the next generation.

6. CONCLUSION

Sustainability will have the major impact on demand, margin structure and value chains in the automotive industry. As a result a change in the industry structure can be expected, meaning that existing and new entrants will have to adapt to the new framework and emerging business models in order to achieve sustainable success. The arrival of the electric cars is no longer a question, we could just argue about the adoption rate and course of the development.

THE ANALYTIC HIERARCHY PROCESS (AHP) APPLICATION IN EQUIPMENT SELECTION

Abstract: *In those papers, we propose a method for decomposing a decision problem into its constituent parts and building hierarchies of criteria using the AHP concept. The mentioned concept is also used to improve and facilitate group decision-making. Our method is performed through four steps: structuring a decision problem and the selection of criteria, priority setting of the criteria by pairwise comparison (weighing), pairwise comparison of options on each criterion (scoring), obtaining an overall relative score for each option. We intended to show one of the various ways to identify difficult decisions to decision makers. Strengths and weaknesses are also included in order to provide an overall picture.*

Keywords: *AHP, methodology, decision, method, criteria*

1. INTRODUCTION

The **Analytic Hierarchy Process (AHP)** is a structured technique for organizing and analyzing complex decisions. Based on mathematics and psychology, it was developed by Thomas L. Saaty in the 1970s and has been extensively studied and refined since then.

It has particular application in group decision making, and is used around the world in a wide variety of decision situations, in fields such as government, business, industry, healthcare, and education.

Rather than prescribing a "correct" decision, the AHP helps decision makers find one that best suits their goal and their understanding of the problem. It provides a comprehensive and rational framework for structuring a decision problem, for representing and quantifying its elements, for relating those elements to overall goals, and for evaluating alternative solutions.

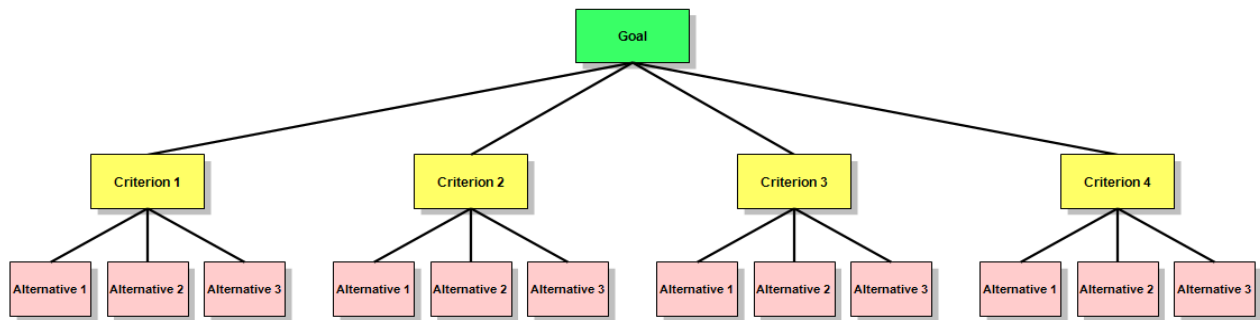

Users of the AHP first decompose their decision problem into a hierarchy of more easily comprehended sub-problems, each of which can be analyzed independently. The elements of the hierarchy can relate to any aspect of the decision problem—tangible or intangible, carefully measured or roughly estimated, well- or poorly-understood—anything at all that applies to the decision at hand.

Once the hierarchy is built, the decision makers systematically evaluate its various elements by comparing them to one another two at a time, with respect to their impact on an element above them in the hierarchy. In making the comparisons, the decision makers can use concrete data about the elements, but they typically use their judgments about the elements' relative meaning and importance. It is the essence of the AHP that human judgments, and not just the underlying information, can be used in performing the evaluations.^[2]

The AHP converts these evaluations to numerical values that can be processed and compared over the entire range of the problem. A numerical weight or priority is derived for each element of the hierarchy, allowing diverse and often incommensurable elements to be compared to one another in a rational and consistent way. This capability distinguishes the AHP from other decision making techniques.

In the final step of the process, numerical priorities are calculated for each of the decision alternatives. These numbers represent the alternatives' relative ability to achieve the decision goal, so they allow a straightforward consideration of the various courses of action.

Several firms supply computer software to assist in using the process.

Picture 1

2. METHODOLOGY

The AHP, as a compensatory method, assumes complete aggregation among criteria and develops a linear additive model. The weights and scores are achieved basically by pairwise comparisons between all options with each other (ODPM, 2004).

Note that AHP, as all MAVT methods, can only be applied when the mutual preferential independence axiom applies.

3. PROCESS

The basic procedure to carry out the AHP consists of the following steps:

1. Structuring a decision problem and selection of criteria

The first step is to decompose a decision problem into its constituent parts. In its simplest form, this structure comprises a goal or focus at the topmost level, criteria (and subcriteria) at the intermediate levels, while the lowest level contains the options.

Arranging all the components in a hierarchy provides an overall view of the complex relationships and helps the decision maker to assess whether the elements in each level are of the same magnitude so that they can be compared accurately. An element in a given level does not have to function as a criterion for all the elements in the level below. Each level may represent a different cut at the problem so the hierarchy does not need to be complete (Saaty, 1990).

When constructing hierarchies it is essential to consider the environment surrounding the problem and to identify the issues or attributes that contribute to the solution as well as to identify all participants associated with the problem.

2. Priority setting of the criteria by pairwise comparison (weighing)

For each pair of criteria, the decision maker is required to respond to a question such as "How important is criterion A relative to criterion B?" Rating the relative "priority" of the criteria is done by assigning a weight between 1 (equal importance) and 9 (extreme importance) to the more important criterion, whereas the reciprocal of this value is assigned to the other criterion in the pair. The weighings are then normalized and averaged in order to obtain an average weight for each criterion.

3. Pairwise comparison of options on each criterion (scoring)

Analytic hierarchy process (AHP)

For each pairing within each criterion the better option is awarded a score, again, on a scale between 1 (equally good) and 9 (absolutely better), whilst the other option in the pairing is assigned a rating equal to the reciprocal of this value. Each score records how well option "x" meets criterion "Y". Afterwards, the ratings are normalized and averaged.

Comparisons of elements in pairs require that they are homogeneous or close with respect to the common attribute; otherwise significant errors may be introduced into the process of measurement (Saaty, 1990).

4. Obtaining an overall relative score for each option

In a final step the option scores are combined with the criterion weights to produce an overall score for each option. The extent to which the options satisfy the criteria is weighed according to the relative importance of the criteria. This is done by simple weighted summation (see the previous chapter).

Finally, after judgements have been made on the impact of all the elements and priorities have been computed for the hierarchy as a whole, sometimes and with care, the less important elements can be dropped from further consideration because of their relatively small impact on the overall objective. The priorities can then be recomputed throughout, either with or without changing the judgements (Saaty, 1990). Remark: Especially in the case of complex sustainability issues the compensability among criteria can be problematic. The idea of 'musts' and 'wants' initially developed by Kepner and Tregoe (1965) and referred to by De Brucker et al. (1995) is a possibility to 'weaken' the compensatory nature of AHP (or other MCA methods), if necessary. An option that does not satisfy one or more 'musts' is considered infeasible and is eliminated from further consideration. The remaining options are then evaluated based on how well they meet the 'wants' (objectives to be maximised).

4. REVIEW

4.1 Evaluation of results

Policy processes:

AHP can effectively support decision making with regard to complex sustainability issues and can help to recognize and define a problem in detail. It is widely used to decompose a decision problem into its constituent parts, which are then structured hierarchically. Multiple and even conflicting goals can be taken into consideration. Furthermore, the paired comparison approach forces decision makers to consider each individual trade-off in the decision problem, which can be a lengthy task. As a result, AHP delivers a ranking of options which facilitates the selection of a policy option. AHP is less suitable for the implementation and the evaluation of implemented policy options.

Sustainability aspects:

AHP is capable to compare long-term impacts, independently of the gauge year. Further sustainability aspects such as (de-)coupling, adaptability, (ir-)reversibility can be incorporated as criteria to compare alternative policies. Also the impacts on distributional effects over different groups/sectors/regions can be included in AHP as separate categories. AHP can compare impacts independently of the global dimension and can be applied to spatial data. Environmental, economic and social impacts can be simultaneously covered by AHP.

Operational aspects:

Manpower and time needs as well as the costs for applying the tool are difficult to estimate and depend highly on the subject. The same goes for data needs and data availability. In general, much data is needed to estimate the impacts, whereas the required amount of expert judgement to explain the results is medium. Qualitative and quantitative data can be incorporated.

The methodology for AHP is clear, straightforward and well documented. Since the approach requires complex calculations, corresponding software supports the users.

Under some circumstances, ranking irregularities can occur when AHP or some of its variants are used. But sensitivity analysis allows the decision maker to assess how alternative ratings would change if criteria weights were changed. AHP can support the modelling of risk in a variety of ways. Particularly, the modelling of relative rather than absolute probabilities and the use of risk adjusted values can provide new opportunities for decision support. No specific time scale is associated with AHP and there are no limitations regarding the geographical coverage.

4.2 Experiences

AHP has been very successful in gaining the acceptance of practitioners, possibly owing to the helpfulness of the hierarchical problem presentation and the appeal of pairwise comparisons in preference elicitation (Salo and Hämäläinen, 1997). The range of reported practical applications is extensive (Vargas, 1990) and includes

Resource Allocation, Strategic Planning and Project/Risk Management. Ramanathan et al. (2001) proposes namely the AHP to address the need for considering multiple criteria and multiple stakeholders in Environmental Impact Assessment (EIA).

Gomez-Limon & Atance (2004) used the AHP technique in order to reveal the preferences that citizens assign to the different possible objectives of the European Common Agricultural Policy (CAP). This methodological approach has been implemented among citizens of Castilla y León (Spain).

AHP as one of the presented MCA methods was not applied during the case study of Sustainability-A-Test. With regard to the topic of the case study, the Biofuels Directive and the Energy Crop Premium, AHP could have been used to decompose and present the policy problem in a multicriteria fashion, and later on to support the stages of policy options description and evaluation.

4.3 Combinations

Although AHP is a decision-making methodology in itself, its ability to elicit accurate ratio scale measurements and combine them across multiple criteria has led to AHP applications in conjunction with many other decision support tool and methodologies. AHP has been used in combination with, linear programming, integer programming, goal programming, data envelope analysis, balanced score cards, genetic algorithms, and neural networks (reported in Millet and Wedley, 2003).

A'WOT (Kurttila et al., 2000) is an example of a combination specially developed for the purposes of practical strategic planning. The approach in which the SWOT (Strengths, Weaknesses, Opportunities and Threats; Wheelen and Hunger, 1995; Hill and Westbrook, 1997) forms the general framework, and the AHP is applied within this framework in order to bring quantitative analysis capacity into the planning process, has been given the name A'WOT. It has also been tested in strategic natural resource planning in state forestry in Finland (Pesonen et al., 2001). As only preliminary tests have been made so far, the method is bound to evolve further, and new versions will be developed (Kangas et al., 2001).

AHP can also be used to compare the impacts of alternative policies generated by other tools like physical assessment tools, modelling tools and environmental appraisal tools. It can be applied in conjunction with stakeholder analysis and, finally, AHP is capable to support the evaluation of alternative policies/plans/projects in SIA and SEA.

4.4 Strengths and weaknesses

The strengths and weaknesses of the AHP have been subject of substantial debate among specialists in MCA.

4.4.1 Strengths:

The advantages of AHP over other multi criteria methods are its flexibility, intuitive appeal to the decision makers and its ability to check inconsistencies (Ramanathan 2001). Generally, users find the pairwise comparison form of data input straightforward and convenient.

- Additionally, the AHP method has the distinct advantage that it decomposes a decision problem into its constituent parts and builds hierarchies of criteria. Here, the importance of each element (criterion) becomes clear (Macharis et al. 2004).
- AHP helps to capture both subjective and objective evaluation measures. While providing a useful mechanism for checking the consistency of the evaluation measures and alternatives, AHP reduces bias in decision making.
- The AHP method supports group decision-making through consensus by calculating the geometric mean of the individual pairwise comparisons (Zahir 1999).
- AHP is uniquely positioned to help model situations of uncertainty and risk since it is capable of deriving scales where measures ordinarily do not exist (Millet & Wedley 2002).

4.4.2 Weaknesses:

Despite the popularity of the AHP, many authors have expressed concern over certain issues in the AHP methodology.

Many researchers have long observed some cases in which ranking irregularities can occur when the AHP or some of its variants are used. This rank reversal is likely to occur e.g. when a copy or a near copy of an existing option is added to the set of alternatives that are being evaluated. Triantaphyllou (2001) proved that rank reversal is not possible when a multiplicative variant of the AHP is used.

According to Belton (1986) and Belton and Gear (1997) a key issue for the AHP ranking reversals is the interpretation of the criteria weights. However, the AHP and some of its variants are considered by many as the most reliable MCDM method.

The AHP–method can be considered as a complete aggregation method of the additive type. The problem with such aggregation is that compensation between good scores on some criteria and bad scores on other criteria can occur. Detailed, and often important, information can be lost by such aggregation.

With AHP the decision problem is decomposed into a number of subsystems, within which and between which a substantial number of pairwise comparisons need to be completed. This approach has the disadvantage that the number of pairwise comparisons to be made, may become very large ($n(n-1)/2$), and thus become a lengthy task (Macharis et al. 2004).

Another important disadvantage of the AHP method is the artificial limitation of the use of the 9–point scale. Sometimes, the decision– maker might find difficult to distinguish among them and tell for example whether one alternative is 6 or 7 times more important than another. Also, the AHP method cannot cope with the fact that alternative A is 25 times more important than alternative C (see also Murphy, 1993; Belton and Gear, 1983; Belton, 1986). Due to the discussion on the scale’s restrictions, Hajkovicz et al. (2000) modified the procedure in their study by using a 2–point–scale, due to time constraints placed on decision makers. So the decision makers only indicated whether a criterion was more or less important or equally important to its partner.

5. A WORKED EXAMPLE

The AHP deals with problems of the following type.

A firm wishes to buy one new piece of equipment of a certain type and has four aspects in mind which will govern its purchasing choice: expense, E; operability, O; reliability, R; and adaptability for other uses, or flexibility, F. Competing manufacturers of that equipment have offered three options, X, Y and Z. The firm’s engineers have looked at these options and decided that X is cheap and easy to operate but is not very reliable and could not easily be adapted to other uses. Y is somewhat more expensive, is reasonably easy to operate, is very reliable but not very adaptable. Finally, Z is very expensive, not easy to operate, is a little less reliable than Y but is claimed by the manufacturer to have a wide range of alternative uses. (This is obviously a hypothetical example and, to understand Saaty properly, you should think of another case from your own experience.)

Each of X, Y and Z will satisfy the firm’s requirements to differing extents so which, overall, best meets this firm’s needs?

The firm has four factors in mind: expense, operability, reliability and flexibility; E, O, R and F respectively. The factors chosen should be independent, as required by Saaty’s mathematics. At first sight, E and R are not independent but, in fact, what is really shown is that the firm would prefer not to spend too much money but is willing to do so if the results justify it. We first provide an initial matrix for the firm’s pairwise comparisons in which the principal diagonal contains entries of 1, as each factor is as important as itself.

	E	O	R	F
E	1			
O		1		
R			1	
F				1

There is no standard way to make the pairwise comparison but let us suppose that the firm decides that O, operability, is slightly more important than cost. In the next matrix that is rated as 3 in the cell O,E and 1/3 in

E,O. They also decide that cost is far more important than reliability, giving 5 in E,R and 1/5 in R,E, as shown below.

	E	O	R	F
E	1	1/3	5	
O	3	1		
R	1/5		1	
F				1

The firm similarly judges that operability, O, is much more important than flexibility, F (rating = 5), and the same judgement is made as to the relative importance of F vis-à-vis R. This forms the completed matrix, which we will term the Overall Preference Matrix (OPM), is:

	E	O	R	F
E	1	1/3	5	1
O	3	1	5	1
R	1/5	1/5	1	1/5
F	1	1	5	1

The eigenvector (a column vector but written as a row to save space), which we will call the Relative Value Vector (RVV), is calculated by standard methods (see Annex A) as (0.232, 0.402, 0.061, 0.305). These four numbers correspond, in turn, to the relative values of E, O, R and F. The 0.402 means that the firm values operability most of all; 0.305 shows that they like the idea of flexibility; the remaining two numbers show that they not desperately worried about cost and are not interested in reliability. The CR is 0.055, well below the critical limit of 0.1, so they are consistent in their choices. It may seem odd not to be interested in reliability but the RVV captures all the implicit factors in the decision context. Perhaps, in this case, the machine will only be used occasionally so there will be plenty of time for repairs if they are needed. We now turn to the three potential machines, X, Y and Z. We now need four sets of pairwise comparisons but this time in terms of how well X, Y and Z perform in terms of the four criteria, E, O, R and F. The first table is with respect to E, expense, and ranks the three machines as :

	X	Y	Z
X	1	5	9
Y	1/5	1	3
Z	1/9	1/3	1

This means that X is considerably better than Y in terms of cost and even more so for Z. Actual cost figures could be used but that would distort this matrix relative to others in which qualitative factors are assessed. The eigenvector for this matrix is (0.751, 0.178, 0.071), very much as expected, and the CR is 0.072, so the judgements are acceptably consistent. The next three matrices are respectively judgments of the relative merits of X, Y and Z with respect to operability, reliability and flexibility (just to remind you, X is cheap and easy to operate but is not very reliable and could not easily be adapted to other uses. Y is somewhat more expensive, is reasonably easy to operate, is very reliable but not very adaptable. Finally, Z is very expensive, not easy to operate, is a little less reliable than Y but is claimed to have a wide range of alternative uses):

Operability:

	X	Y	Z
X	1	1	9
Y	1	1	3
Z	1/9	1/3	1

Eigenvector (0.480, 0.406, 0.114), CR=0.026

Reliability:

	X	Y	Z
X	1	1/3	1/9
Y	3	1	1/3
Z	9	3	1

Eigenvector (0.077, 0.231, 0.692), CR=0 (perfect consistency)

Flexibility:

	X	Y	Z
X	1	1/9	1/5
Y	9	1	2
Z	5	1/2	1

Eigenvector (0.066, 0.615, 0.319), CR= 0.

The reason that Y scores better than Z on this criterion is that the firm does not really believe the manufacturer's claims for Z. The AHP deals with opinion and hunch as easily as with fact. The final stage is to construct a matrix of the eigenvectors for X, Y and Z:

	E	O	R	F
X	0.751	0.480	0.077	0.066
Y	0.178	0.406	0.231	0.615
Z	0.071	0.114	0.692	0.319

This matrix, which we call the Option Performance Matrix (OPM), summarises the respective capability of the three machines in terms of what the firm wants. Reading down each column, it somewhat states the obvious: X is far better than Y and Z in terms of cost; it is a little better than Y in terms of operability, however, X is of limited value in terms of reliability and flexibility. These are not, however, absolutes; they relate only

to the set of criteria chosen by this hypothetical firm. For another firm to whom reliability was more important and who wanted to avoid expense, the three machines might score quite differently. Those results are only part of the story and the final step is to take into account the firm's judgements as to the relative importance of E, O, R and F. For a firm whose only requirement was for flexibility, Y would be ideal. Someone who valued only reliability would need machine Z. This firm is, however, more sophisticated, as, I suspect, are most firms, and has already expressed its assessment of the relative weights attached to E, O, R and F in the Relative Value Vector (0.232, 0.402, 0.061, 0.305). Finally, then, we need to weight the value of achieving something, R, say, by the respective abilities of X, Y and Z to achieve R, that is to combine the Relative Value Vector (RVV) with

the Option Performance Matrix (OPM). Technically, the calculation is to post-multiply the OPM by the RVV to obtain the vector for the respective abilities of these machines to meet the firm's needs. It comes out to (0.392, 0.406, 0.204) and might be called the Value For Money vector (VFM). In matrix algebra, $OPM \cdot RVV = VFM$ or, in words, performance*requirement= value for money. In those terms, this suggested method might have wide applicability. The three numbers in the VFM are the final result of the calculation, but what do they mean?

First, in simple terms, they mean that X, which scores 0.392, seems to come out slightly worse in terms of its ability to meet the firm's needs than does Y at 0.406. Z is well behind at 0.204 and would do rather badly at satisfying the firm's requirements in this illustrative case. Secondly, the three decimal places are, in practical terms, illusory, and X and Y are equal at 0.4. A coin could be tossed but, in the real world, it might be sensible to go for X as the option putting least pressure on cash flow. Thirdly, and perhaps most importantly, the vector of the relative merits of X, Y and Z follows ineluctably from judgements made by the

firm as to its requirements and by their engineers as to the capabilities of differing machines. There is a strong audit trail from output back to inputs. Of course, anyone who understands the AHP mathematics might be able to fiddle the judgements so as to guarantee a preferred outcome, but that is unavoidable except by vigilance.

6. CONCLUSION

Through this paper we presented a methodological approach which implies structuring criteria of multiple options into a system hierarchy, including relative values of all criteria, comparing alternatives for each particular criterion and defining average importance of alternatives. The goal of using this method is to single out and offer one out of several decisions. It should be done by setting apart unnecessary decisions and choosing the ones that has the biggest impact on the main goal. AHP method offers meaningful and rational framework for structuring problems, presentation and quantification of elements that make a problem. Techniques of putting together these elements and techniques of evaluating alternative solutions enable directing towards a final solution.

MARKETING COMMUNICATION STRATEGY OF REUSABLE BRANDED BOTTLE EQUA ON THE EX-YUGOSLAVIA MARKET

Branka Novčič¹, Tina Šegota²

¹Faculty of Organizational Sciences, novcicb@fon.bg.ac.rs

²ZkotZ d.o.o., tinasegota@gmail.com

Abstract: Awareness about ecology, waste reduction, harmful chemical compounds in plastic and overestimated price of bottled water, have all created potential buyers for reusable products. The aim of manufacturers was to quickly meet buyers' need with the production of reusable, trendy, and economical bottle for water.

This case study presents a practical example of Slovenian company ZkotZ d.o.o. and its leading brand for reusable plastic bottles for water, EQUA. Authors of this case study present implementation of marketing communication strategy on the ex-Yugoslavia markets.

This case study is designed to present different methods marketing communication strategy for a new concept of reusable and ecological product. The differentiation of targeted markets is minimal due to the fact that all of them belong to an ex-Yugoslavia region and therefore share similar preferences and awareness about ecology. The case study particularly emphasizes representing a new product and its communication forms, used to raise awareness about health and ecology that could be transferred to similar markets.

Keywords: marketing strategy, communication, brand, EQUA, bottle, ecology, lifestyle

1. INTRODUCTION

January 16th 2012, Ljubljana, Slovenia, miss Tina Šegota, marketing manager for EQUA brand, brand owned by ZkotZ d.o.o. Company, was working hard during the weekend to put together annual marketing plan for 2012. While Miss Šegota was on her way to work, she could not help herself not thinking about the fact that she noticed - company had excellent sale results in the last quarter of 2011. Brand EQUA recorded rapid growth, by introducing innovative communication strategy to Slovenian Market, and by entering new markets such as Croatian market. The only thought that was rushing through mind while she was preparing for Monday morning board meeting, was what a great potential EQUA brand has on ex-Yugoslavian market. Miss Šegota was so excited that she needed to share this great potential for company's growth with her colleagues.

"We should focus more on ex-Yugoslavia market if we want to achieve our goals. Also we should adapt EQUA's marketing communication strategy for specific market if we want to attract new customers" - was the most common feedback that Miss Šegota received from her colleagues. She also presented this proposal for position on ex-Yugoslavia market to Mr. Anže Miklavc, CEO of ZkotZ d.o.o. Company in board meeting.

After the meeting Mr. Miklavc was sitting in his chair, drinking his favourite coffee, and thinking about Miss Šegota's just proposed. He picked up the phone and revised his final decision – "I think that your proposal has great potential. Also, I agree that we need to plan our marketing plan for ex-Yugoslavia market. But we also need to think how to reposition EQUA brand on Slovenian market and retain our consumers."

2. COMPANY BACKGROUND

The ZkotZ d.o.o. company was established in year 2009 as a part of Ljubljana University Incubator, and today counts 7 employees. The company is fully owned by Anže Miklavc who is also the founder of the company. Presently, the company owns brands EQUA, Ushakes and Outbox. EQUA is an international brand with the headquarters situated in the capital of Slovenia, Ljubljana.

At the moment EQUA brand has the strongest presence on only two markets, Slovenian and Croatian market, but is also present on several other markets including Austria, Finland, Germany and The Netherlands. Having in mind business results that EQUA brand achieved in last year and market potential for this kind of product, the CEO of ZkotZ d.o.o. is thinking about expanding their business to some new markets in year 2012.

Organizational structure of the ZkotZ d.o.o. company

Company counts 7 employees, and each of them has its own position and field of business to cover. Employees' positions and field of business that they cover are as following:

- ❖ *CEO* – in charge of company's core business activities, the highest level of responsibility, final decision maker;
- ❖ *Project manager* – in charge of new projects (expanding the product portfolio), event management (the first Pillow fight in Slovenia), media relations;
- ❖ *Marketing manager* – in charge of all marketing activities on ex-Yugoslavia markets, relationship management with B2B key accounts on ex-Yugoslavia markets, communication with sales channels and distributors;
- ❖ *Creative director* – responsible for all visual communications and ideas related to products and brand's visual communication;
- ❖ *Manager for Dutch market* – in charge of all business activities on Dutch market, including marketing activities and support to distributors;
- ❖ *Manager for Austrian and German market* - in charge of all business activities on Austrian and German market, including marketing activities and support to distributors;
- ❖ *Manager for brand Ushakes* – in charge of all business activities on Slovenian market, including marketing activities and support to distributors.

3. PRODUCT PORTFOLIO

Company ZkotZ d.o.o. owns three brands: EQUA, Ushakes, and Outbox. The most successful brand is EQUA, which has the greatest share in company's annual profit, around 80 %. Even though brand Ushakes was created before brand EQUA, company decided to introduce EQUA brand based on the results of market research on the Slovenian market.

Chart 1: Share in company's annual profit by brands for 2011

EQUA is the biggest and the strongest brand of the company. It was created in April 2010. At the moment brand EQUA is the main focus of the company. It represents environmentally friendly reusable bottle for water. It is an excellent alternative for any kind of plastic bottles, in same time it encourages consumers

not to use regular plastic bottles, which usually end up as waste. It does not take up valuable landfill space like wasted plastic bottles and the best thing about EQUA is being friendly to users' health and to the environment. What makes EQUA bottle more suitable to use is the material EQUA is made of which does not contain harmful chemical compound bisphenol A (later referred to as BPA), which could be found in regular plastic.

EQUA's philosophy is very clear: "We care about the world and our main focus is to operate our business in a sustainable way." Its philosophy is also communicated in brand's slogan "For your health and nature's wealth".

Ushakes is a healthy meal substitute which contains more than 20 vital vitamins, minerals and other crucial nutrients and comes in two basic variations: sports edition flavoured with vanilla and banana, and diet edition

flavoured with vanilla and strawberry. With daily consumption of all the nutrition crucial for users' normal body and mind function, everyday stress immediately transforms into challenge. Not only users feel and look great, their performance and productivity are also brought to the highest level.

Outbox is brand that focuses on video production – preparation of audio and video ads and material.

About brand EQUA and its products

The brand name consists of two words *eco* and *aqua* which together form EQUA. The name stands for ecological, reusable and trend products. At the moment main product presented by the brand is reusable plastic bottle for water names after the brand. The EQUA bottle can be used for different purposes and at various situations: at home, in the office, during sport activities or even while having a walk through the city. On top the bottle is very practical, light and easy to use on a daily basis. Slogan of the brand "For your health and nature's wealth" directly represents the EQUA bottle which is healthy and eco-friendly.

The EQUA bottle is one of the best alternatives for regular plastic bottles. The latter are made of materials which can react with the content of the bottle if used regularly. Therefore the content in a regular plastic bottle could become dangerous for consuming and it could seriously jeopardize consumers' health. What makes the EQUA bottle more suitable to use is the material the product is made from and which does not contain harmful chemical compound BPA. Each bottle carries the "BPA free" certificate that guarantees that consummation of content from the EQUA bottle is 100 % healthy and harmless for both human and environment. The EQUA bottle is meant for long-term and is recyclable.

Additional ecological aspect of brand EQUA is cooperation with local ecological organizations. By purchasing EQUA bottle, consumers' are donating 10 % of net profit to ecological organizations.

Product characteristics: All EQUA bottles are made of high quality material tritan copolyester, which contains a mold release derived from vegetable based sources. The material is branded Eastman Tritan which is one of the best manufacturers of harmless plastic material. Its most outstanding features are excellent toughness, hydrolytic stability, and heat (100 °C) and chemical resistance. Bottles from EQUA collection can be filled with liquids, which do not exceed 110 °C temperature. The bottles can be washed in dishwasher.

Normally, unnecessary emissions are used for production, transport and storing of a regular plastic bottle. They are also harmful for the environment and have consequences to our health. There are not any extra emissions used for production of tap water, which is simply the most ecological and the cheapest to drink. Official certificate indicates that the bottle is made out of "food contact materials", which are intended to be in contact with food or drink.

At the moment there are 13 different bottle designs (See Picture 1). Product size: 400 ml and 600 ml.

Picture 1: *The collection of EQUA bottles*

4. BUSINESS SEGMENTATION

EQUA bottles are being sold through different distribution companies across the region. For example, through distribution companies specialized for supermarkets, fitness centres, gift shops, office stores, pharmacies, etc. At the moment brand EQUA is present on Slovenian and Croatian market. There is no difference in both markets therefore both are divided into B2B and B2C segments (See Picture 2).

B2B segment

B2B-1 (sellers)	B2B-2 (users)
Retail stores	Big and small companies
Designer product stores	Banks, post offices and telecommunication companies
Gift shop	Tourist offices, tourist information centers, travel agencies
Pharmacies and drugstores	Pharmaceutical companies
Fitness, aerobics and yoga centers	Water filter companies
Eco and bio stores	Municipalities, universities, elementary and secondary schools, student clubs
Bookstores	The organizers of various events: conferences, sports events, children's workshops, ecological events
Toy stores	
Office material stores	
Gas stations	

B2C segment

In the B2C segment sales are conducted via web store.
Consumer groups, for which the product is most appropriate:

- Eco-conscious individuals.
- Athletes (professionals, amateurs and recreational).
- Parents with young children, pregnant women and mothers with babies.
- People who work in offices.
- Students.

Picture 2: *Market segmentation for brand EQUA*

5. MARKETING COMMUNICATION ON EX-YUGOSLAVIA MARKETS

Brand EQUA combines ecology and lifestyle. When communicating with its target markets there is a strong need to combine ecology, lifestyle and fun.

Communicating ecology

When emphasising ecology, there are several benefits that have to be communicated. First and foremost important is the benefit of “BPA free” certificate, which is present on every EQUA bottle and is the biggest benefit for EQUA’s customer (See Picture 3). The certificate stands for its fine quality material, which enables customers to fearlessly drink non-contaminated drinks.

Picture 3: *EQUA’s “BPA free” certificate*

The second ecological benefit is the bottle being the best alternative for regular plastic bottles. Main topic is that the bottle if used daily, could replace 169 regular plastic bottles used by the customer when buying soft drinks or bottled water.

Those two benefits are mostly combined in EQUA’s communication. Both are usually communicated in PR messages addressed to ecological and health magazines, whose readers are eco-conscious individuals and parents with young children, pregnant women and mothers with babies.

Ecological attitude of the brand is shown through “10 %” concept, in which 10 per cent of net profit of each sold bottle is donated to local ecological organization. In year 2010 EQUA decided to cooperate with Slovene ecological organization *Ecologists without borders*, which organizes the largest environmental project World Cleanup in Slovenia. The cooperation continued through the years and in 2012 EQUA

decided to make customized bottle for World Cleanup in Slovenia (See Picture 4) to help the organization raise finances for the project.

Due to the fact that in 2012 brand EQUA entered Croatian market, it carried forward the same model of "10 %" concept. Therefore EQUA decided to cooperate with Croatian ecological organization Žmergo, which organizes the largest environmental project World Cleanup in Croatia. This is the first World Cleanup project in Croatian and EQUA made customized bottle for World Cleanup Croatia (See Picture 4) to help the organization raise finances for the project.

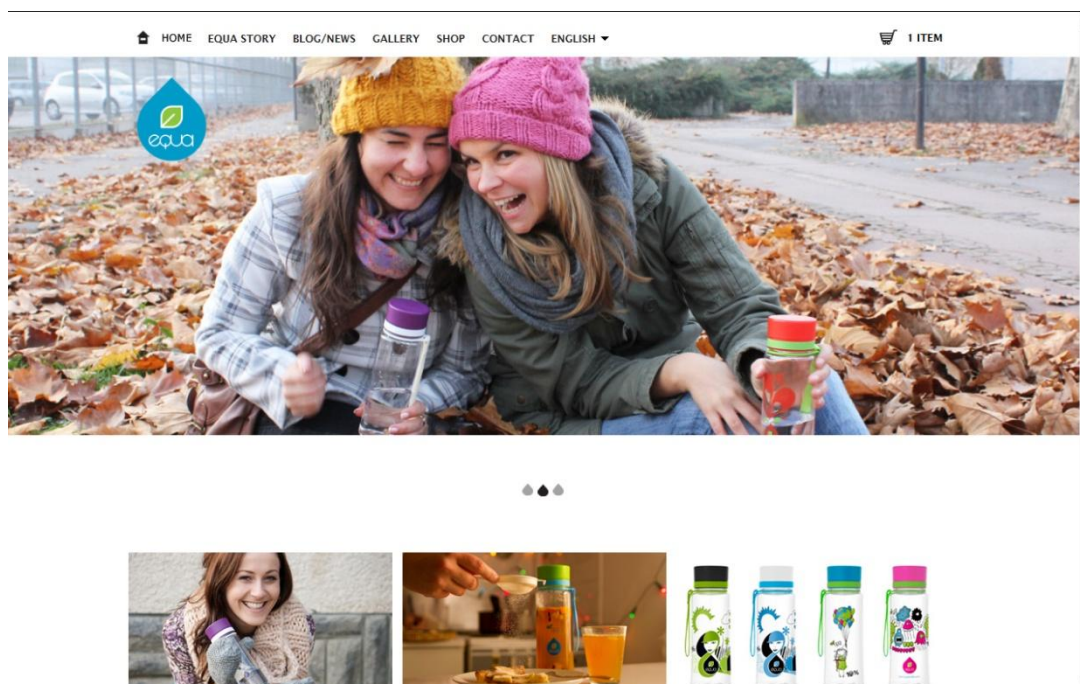

Picture 4: Customized bottles for World Cleanup 2012 events in Slovenia and Croatia

Communicating lifestyle

EQUA's lifestyle is all about trends, fun and fashion. Its designs are created to enable each individual to find the bottle which will meet its preferences and enable self-expression. Therefore EQUA's collection is being upgraded at least once a year to constantly follow design trends and customers' preferences.

Recently EQUA started to communicate the lifestyle by using the phrase *myequa*. This stands for using EQUA products daily and at various situations and to enable to user to express trendy and ecological attitude.

The implementation of the phrase began with the upgrade of EQUA's web page in February 2012. The web page uses internet name www.myequa.com (See Picture 5). The web page has five different languages: Slovene, Croatian, English, German and Dutch. It is designed to communicate happiness, the use of EQUA bottles in various situations and to give its users as many information they need.

Picture 5: Brand's web page www.myequa.com

The funny side of EQUA brand is communicated in events. In October 2011 EQUA and Radio Antena co-organized the first Pillow fight in Slovenia. The event took place at Students' Arena, a three day event in Ljubljana, where young people have the opportunity to listen to different lectures, take place in workshops and get useful information about student's life. Pillow fight was communicated via Facebook, in PR messages, in Radio Antena, and outdoor ads and fliers placed around Ljubljana's faculties (See Picture 6). Special pillows were made for the event and were given to participants. The event in Slovenia got lots of media coverage including TV, radio, magazines and web pages.

EQUA is going to organize Pillow fight every year and its goal is to make this event traditional. In 2012 Pillow fight Slovenia is going to take place at Students' Arena event as in year 2011 and Pillow fight Croatia is going to be organized in Zagreb for the first time. Both events will take place in October. The aim is to connect EQUA brand with youth and fun.

Picture 6: Pillow fight 2011 advertisement

One of the main communication channels for EQUA is Facebook. EQUA has 4 different Facebook profiles, but only three are active. These three profiles aim to communicate with different public in their own language and are named after different markets. Among active ones there are *EQUA – pijem zdravo, darujem za naravo* for Slovenian customers (active for two years), *EQUA – for your health and nature's wealth*, which communicates in English and German language and is meant for Austrian, German and countries excluded from ex-Yugoslavia region (active for two years), and there is *EQUA Hrvatska* for Croatian customers (active since the end of December 2011). Non active is *EQUA Serbia*, but it is soon to be activated.

On Facebook EQUA strives to be fast in answering fans requests and questions. This channel is used to provide news about the arrival of new designs and products and to give different tips about EQUA lifestyle.

To reach its fans EQUA also uses several social media channels as Twitter, Flickr, LinkedIn, Vimeo, Youtube, but Facebook is its priority. Flickr is the second most used social media channel where EQUA posts its visual content communicating happiness and variety.

In February 2012 EQUA decided to increase the number of fans on EQUA Hrvatska's profile by organizing prize game "Share Love and Get EQUA" (See Picture 7). The "Share Love" game lasted for 14 days and followers were invited to share daily posted pictures on their walls and therefore compete for daily prize. EQUA Hrvatska's fan base increased by 1.104 unique new likes and at the moment counts 2.029 unique likes. Because of the success of "Share Love" game on Croatian Facebook page it was later on conducted also on Slovene Facebook page.

Picture 7: "Share Love and Get EQUA" Facebook prize game layout

6. CONCLUSION

Company ZkotZ d.o.o. launched brand EQUA in the time of economical crisis in Slovenia. But despite the political and economical troubleshoot; brand EQUA received great appreciation among its users. EQUA is an example how a good product, its well thought marketing communication strategy and fast response to customers' needs could prosper in billowing economy.

The same as many Slovene companies, EQUA decided to enter ex-Yugoslavia markets due to the similarities and conjoined history. Marketing communication practices, which were firstly implemented in Slovenia and showed good results, were duplicated to Croatian market. Those have a good potential to be duplicated also to other ex-Yugoslavia markets EQUA is going to enter. Nonetheless, successful marketing communication practices from ex-Yugoslavia markets are also going to be implemented to Slovenian market, and the results will be compared to discover the small differences of the markets.

Due to the fact that EQUA is a young brand which enables two types of communication – ecology and lifestyle mixed with trends and fun – EQUA strives to constantly participate in raising environmental awareness and to communicate healthy lifestyle.

INFORMATION TECHNOLOGIES IN CONTEMPORARY SCHOOL MANAGEMENT SYSTEM, CASE STUDY

Miroslava Jordović Pavlović¹, Siniša Randić², Lidija Paunović³

¹Technical school Užice, miroslavajp@gmail.com

²Technical Faculty – Čačak, rasin@tfc.kg.ac.rs

³University of Belgrade, Faculty of Organizational Sciences, lidijapaunovic@elab.rs

Abstract: Improvements within the management system of schools as part of an ongoing process of improving the education system, have reached a certain level. This paper aims to observe modes, levels and specific problems in application of information technologies in informing, information sharing and collaboration as important aspects in ensuring quality in control of the processes that occur at school. Some deficiencies in application of information technology within these processes have been identified, and alternatives to solving them have been offered. The solution discussion was performed according to the parameters that were extracted as important in the problem analysis. A school that is recognized in Zlatibor region and elsewhere in Serbia for its advanced development tendencies was selected for the case study. The proposed solutions are practically applicable in any work collective.

Key words: management, education, information technologies, groupware software, teamwork

1. INTRODUCTION

As Stjepan Staničić pointed out in his Current trends in school management, management in education can be defined as coordination of human, physical and financial resources in the education sector to achieve the goals set by the state, local and school educational policy, legislation system and concepts and projections of the education development (Staničić, 2008).

Modern approach to the development of schools, especially in terms of quality assurance of the processes that take place within the institution, requires also the development of appropriate software solutions for effective monitoring and control of the process. The school managements in Germany, Denmark, Ireland and the Benelux countries apply special software for the process management, which allows simultaneous monitoring and coordination of different processes, ensuring optimization of the schools' functioning. (Rottluff, 2008)

Previous efforts for a more intensive application of information technology in the educational system of Serbia involved the application of various software solutions and internet in teaching, electronic Grade Book, accounting programs, e-mail application, the application of EIS and others. New products constantly come onto the market and in combination with existing products realize a new functionality (Saračević & Mašović, 2011). This paper will show the current status and ways of monitoring several distinct processes within the school and offer several solutions for improvement.

2. GENERAL OVERVIEW OF THE COMPANY

It was on February 27, 1960 when Technical School Užice was opened. Its establishing emerged from the need for education of personnel for the economy and public services in mechanical, electrical, metallurgical and construction sectors. In 2010, it celebrated its fifty year anniversary. The period from the year 2002 on has been marked by participation of the school in various projects, intensive arranging and equipping of the school, the introduction of new educational profiles, but also by continuous training of teachers in modern teaching methodologies.

Several years back, there have been from 1050 to 1150 students in the school; this academic year the enrolled students attend classes in 40 regular classes, whereas there are 32 in the four-year education (11 pilot classes) and eight classes in the three-year education, including two experimental ones. In 2003, the school entered the first phase of the Reform of vocational education in which, through CARDS I, the European Union through the European Agency for Reconstruction and Development financed the reconstruction of the school building, procurement of modern teaching devices and equipment for experimental educational profile – a machining operator, but also the training for modern methods of work

within the school. Internal and external carriers of change, in addition to the director, passed a series of seminars that helped the employees start using new ways of working in educational practice. In August 2006, the school entered the second phase of the Program of reform of vocational education as one of four schools in Serbia, where the European Agency for Reconstruction funded the introduction of new educational profile in the sector of information - communication technologies, a telecommunication electrician. The program was successfully completed in May 2008. Apart from the obtained equipment, the teachers have undergone a series of training that enabled them to apply modern forms of work in their teaching, aiming at gaining functional knowledge by the students and facilitating their involvement in work after they complete secondary education. A Seven-member school delegation paid a study visit to the Vocational school, "Otto Brenner" in Hanover in October 2007.

Technical School Užice was the Saint Sava award winner for the year 2006. Serbian Chamber of Commerce and Regional Chamber of Commerce Užice awarded Technical school the plaque for its contribution to the economic development of the region and the Chamber system in 2007 and the plaque "Captain Misa Anastasijevic" for the results achieved in the promotion of entrepreneurial culture and creativity in 2009.

At the moment, the school is implementing the project "Regional centers of competence ReCeKo - Serbia" in which the school has been involved since September 2009 as one of 12 schools in Serbia. The project aims to develop vocational schools into the regional centers of competence for vocational education. The project is being implemented in cooperation with the Ministry of Education and with the financial support of German organization for technical cooperation - GTZ. The school delegation visited "MM school for multimedia and information technology" in Hanover, Germany, which should become a partner school in the project realization. Since March 2010, the school has been involved in the project "Modernization of Vocational Education" implemented by the Ministry of Education with technical and financial support from the European Union (IPA 2007), as a continuation of the Program of reform of vocational education, whose three phases were implemented over the past six years. The school is undertaking activities to include itself into the program International recognition for young people - MEPI.

During the past decade, the school timely recognized modern tendencies in the development of vocational education and engaged itself in many projects - so today Technical school is recognized in the wider region for its work and success.

3. SPECIFIC FIELD OF OPERATION

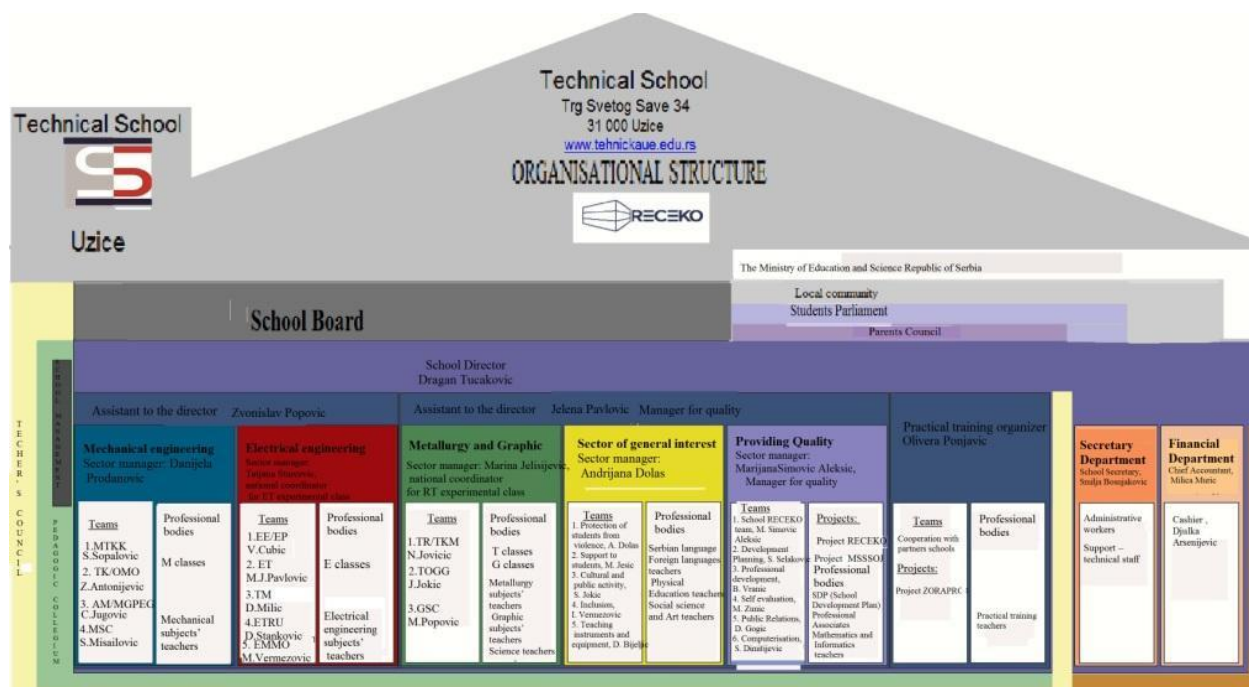

The fields of education and service delivery in education today differ much compared to the ones that existed several years ago. According to the current Strategy for the Development of Vocational Education in Republic of Serbia, adopted by the Government, institutions for vocational education and training develop and implement programs and modules of various types in accordance with appropriate standards, i.e. programs of initial vocational education, trainings and programs for professional development and knowledge updating, which are customized and intended for different target groups (youth, adults, employed, unemployed, people with special needs). The ultimate goal remained the same - successful student and successful teacher; however, the methods used to obtain these, roughly called, "final products" are significantly different than they used to be. The school management has to select the most productive methods to achieve the ultimate goal.

4. SPECIFIC DECISIONS AND PROBLEMS

Quality improvement and modernization of educational work in secondary vocational education involves the introduction of new program contents and organizational innovations (Komlenović, 2004). Being aware of the specificity of educational activities, but also the historical and cultural heritage, it should be noted that the introduction of innovations, which go beyond the usual understanding of school, is a potential source of problems. In this context, the imposition of new standards in communication between the subjects of the educational process will be one of the challenges for the transformation of schools in Serbia. Therefore, the development of activities to implement the measures in terms of improving educational services, in addition to finding optimal organizational and methodological solutions, must be accompanied with aspects of motivating all subjects as well.

4.1 THE CHANGE OF THE ORGANIZATIONAL STRUCTURE

In accordance with ReCeKo project which anticipates introduction of innovations in the areas of organization, management and financing of vocational schools, the following organizational structure of the school was established in 2011:

Picture1: Organizational structure of the Technical school Uzice

Managers were appointed, teams were formed, the new structure became established and key performance indicators were put in place in accordance with the ReCeKo project:

- Self-responsible school that in measurable way, constantly improves the quality of its work and contributes to regional economic development.
- More intensive and better direction of learning opportunities of vocational schools in Serbia to local and regional needs
- Standardization and quality in accordance with the EFQM model

As it was said in case study Building high performance teams, done by the firm Human Synergistics With the overall aim of developing a culture of collective achievement, the focus is 'empowerment', 'personal responsibility' and 'team decision making', which is completely applicable here. Overarching this is a clearly defined set of 'core values', designed to guide everyone's behavior. These are: integrity, participation, teamwork, continuous innovation and personal development.(Human Synergistics, 2010)

The new organizational structure of management in its first year of implementation has led to a more efficient division of labour in comparison to the previous organization, as well as to a layered division of responsibility, which was the objective. However, some problems in the lower layers of the organization were reported.

The critical issue here was the need to take on more staff to meet increasing volumes, but at the same time reduce expenditure. The two were clearly not entirely compatible unless something is changed in the way the operations were managed. Put bluntly, there needed to be a profound increase in productivity.

4.2 PROBLEM ANALYSIS

Before approaching the observation of problems involved with the process of organizational adaptation of the education system at the level of basic organizational unit such as a school, it is necessary to review the resources which Technical school in Uzice brings into this process. Bearing in mind that communication -

information aspects of education have a significant place in the considered changes, a particular attention has been paid to the information - technology and multimedia resources.

The school has following resources:

▪ **Human resources:**

Table 1: Human resources

Professional profile	Number of executors		Education degree							
			VII2	VII1	VII	VI	V	IV	III	I
Teaching staff	Teacher	94,7	1	1	82,3	9,4	1			
Internal and external change carriers	Internal	0,2			0,2					
	External	0,2			0,2					
Managing staff	Director	1			1					
	Assistants to the director	1,5			1,5					
	Practical training organizer	1			1					
	Sector managers	1,5			1,5					
Professional associates	Psychologist	1			1					
	Pedagogue	1			1					
	Librarian	2			2					
National coordinators for experimental classes	Electro-Telecom technician	0,3			0,3					
	Recycling Technician	0,2			0,2					
Administrative staff	Secretary	1			1					
	Administrative workers	1,5						1,5		
Financial staff	Chief Accountant	1						1		
	Cashier	1						1		
Support technical staff –	Caretakers	2					1	1		
	Hygienists	14								14
Total executors		125,1	1	1	93,2	9,49,4	2	24,5	4,5	14

14

▪ **Material-technical resources:**

Table 2: Material-technical resources

Resource	Total no	Area (m ²)
Classrooms	11	487
Specialized classrooms	19	1150
Laboratories	8	372
Workshops	5	440
Gym block with two rooms	1	653
Library with reading room	1	70
Conference hall	1	35
RE-CE-KO office	1	35

▪ **Information - technology (IT) and multimedia equipment**

Table 3: Information-technology (IT) and multimedia equipment

Type of equipment	Where is it used?	Number of items
Personal Computer	in teaching	105
Personal Computer	out of teaching	18
Video beamer	in and out of teaching	4
Graph scopes	in teaching	6

For monitoring and controlling of the processes that are happening in the school Director, sector managers and team leaders use the same tools as the employees use to exchange information and for being informed generally:

- meetings and telephone as key players
- electronic mail as a further step
- shared folders within the network (it is used by a small percentage of employees)
- web site: www.tehnickaue.edu.rs

The employees are accustomed to all these ways of communication. In most cases, all participants must be at the same place and at the same time.

The analysis of the school specificities in terms of :

- existing resources
- the organization of the lessons (work in two shifts)
- schedule mismatch of the teachers – teams' members
- communication styles
- specific obstacles faced by employees in their work

the following problems are distinguished:

1. teachers don't have their own space to work
2. insufficient number of computers for teachers' needs
3. educators perform major part of their work on professional preparation and responsibilities as members of the teams out of the institution
4. team meetings are held mainly in the evening, after the afternoon shift, when the efficiency of employees is significantly reduced
5. the employees stress unsatisfactory level of mutual communication and cooperation
6. the employees stress unsatisfactory level of communication and cooperation with other structures in the school
7. the employees stress unsatisfactory level of communication and cooperation with clients and parents
8. lack of interactivity of the school's web site
9. inertia of the education system in the procurement of new computer equipment

The question is whether it is possible:

- That each employee achieves the established 'core values'
- To achieve effectiveness of teams
- That the team leader has a good insight into the work of his/her team
- That the sector manager has a good insight into the work of teams.
- That the school Director has a good insight into the work of sector

without use of the advanced information and communication technologies? Because only high-quality, accessible and maintained information may be key to business success .

E-mail, though very effective, has a number of limitations; shared folders also have a number of flaws. Unfortunately, the experience gathered in recent years clearly shows that for modern and efficient school operations former selection of the information and communication technologies is less and less sufficient.

It is time to move a step forward.

5. ALTERNATIVES

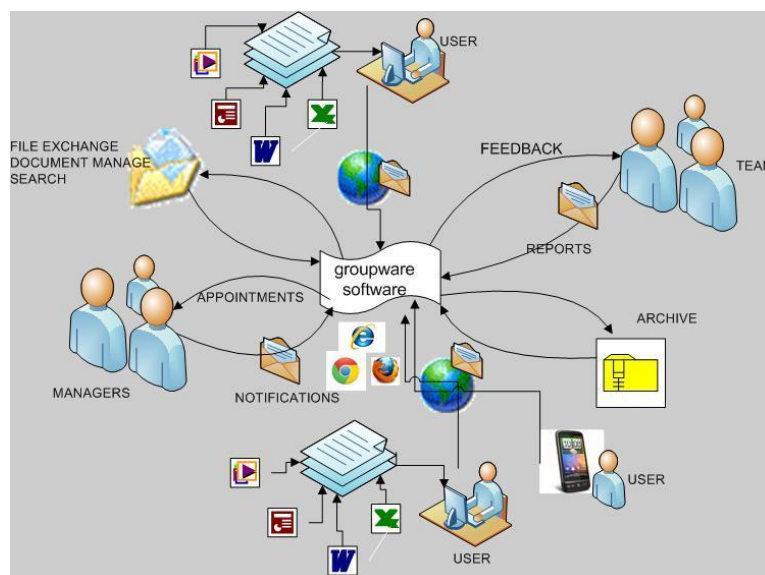

What is needed for more efficient operation?

- Document Management
- Information management
- Projects Management

It can be performed by certain software, let's call it "collaboration software", the software that raises the level of communication within the organization, regardless of whether it is the: client-server architecture, solutions based on Web technologies, solutions, whose use is enabled through the Cloud.

The software should solve several problems:

- the availability and reliability of information
- ease of monitoring more activities that are performed at the same time
- document management, and just as importantly, organized and safely stored business information which can be used to analyze previous business results and allow making better business decisions

Picture 2: Infrastructure of the collaboration software

Table 4, shows some of the possible alternative solutions, which feature separation by categories.

Table 4: Comparison of the possible solutions

software name	price	multiple users in the same time	capacity	supported file formats	mobile access	technical knowledge	security
wiki	free	editing	without limit	/	available	minimal	weak
Google Docs or Google Apps	free	share open edit	5GB for storage	.doc,.docx .xls,.xlsx .ppt,.pptx .odt,.pdf ...	available	very low	password protected
Microsoft Skydrive	free	share open edit	7GB for storage	Microsoft Office, OneNote	available	very low	password protected
Facebook group	free	editing	/	.doc,.docx jpeg,...	available	very low	strong
Teamwork hosted	2500euros per year	comfortable environment	without limit	many	available	low	password protected

We will start the analysis with the commercial software. Their common feature is that they are of comfortable graphic design and provide a range of additional tools for communication and collaboration (for example, software support for the whiteboard). For this analysis, we chose Teamwork, as representative of medium expensive software. Teamwork is a proven, reliable and friendly web based project management solutions for handling work in any field. Teamwork is often chosen by universities as supporting application for project management courses. It is mainly a tool for collecting work data in real time, while the projects are running. It also provides several tools to estimate work to be done. This type of software would completely satisfy all the requirements of "collaboration software", previously exposed, and even provide greater functionality for convenient work of the employees.

Wiki pages have two very good features - unlimited capacity and minimal technical knowledge required for using the service; however three of the seven extracted features are not good enough. Multiple users cannot use the service at the same time, users enter data in a given environment, which means that the solution does not support multiple file formats and there is no data protection against unauthorized alteration, in this case it is only possible to restore the previous version, but this feature excludes the possibility of selective allocation of rights to specific users, which we have singled out as an important feature in consideration of general characteristics of "collaboration software".

The formation of groups on the social network Facebook is certainly a kind of solution, but it introduces the problem of socio-psychological nature in terms of its use, so it will not be specifically commented on here. SkyDrive and Google services are quite similar in their characteristics; the only difference is the capacity for data storage. SkyDrive is more preferable there. The good sides of both of these services are that they provide all basic functions that we have selected as important for "collaboration software", and that they are free. They do not give such comfortable graphical interface, nor additional features, but we must say they are satisfactory option for free services.

6. DISCUSSION OF THE SOLUTION

The school has approached the process of organizational changes comprehensively and with consideration of all relevant parameters. Of course, it was taken into account that, in our conditions, this is a pioneer attempt and that the solutions adopted would significantly influence needs to change the existing practices in our education process.

Generally, school's requirements are such that it is necessary to meet the terms of the following parameters:

1. The rate, since the school budget is very limited and buying software would certainly not have been identified as a priority
2. The possibility that multiple users work simultaneously on the same document, because this option saves time needed for meeting
3. Document capacity
4. Number of supported file formats, depending on the needs especially in the field of vocational subjects where number of current file formats can be rather big and demanding
5. The possibility to access documents and information by mobile devices, as the percentage of employees with those requirements increases
6. Technical knowledge required to use the software service is an important parameter because there are employees who have lower level of skills in the use of information technology, especially among the older members
7. Data security is important in terms of unauthorized access and permission of access to a specific set of information and documents.

The school was to assess which parameters are most important to it and make choices accordingly, being sure that any of the solutions would result in more or less higher level of communication than the present one, and thus increase the effectiveness of teams, including the sector. Normally, free software was considered first. Wiki pages were rejected because of the weak security, which is not acceptable for most of the files, and because the environment for file formats is not comfortable. The formation of groups on the social network Facebook was rejected because of the reasons of socio-psychological nature, previously mentioned. The choice was on Google services or Microsoft SkyDrive. Features of these two solutions, as previously mentioned, are very similar. Technical school Uzice chose the solution SkyDrive. The possibility of

integration with some of the Microsoft educational software later on and better help support determined the choice. The decision was made shortly before writing this paper, so the effects of the implementation can be the subject of another analysis.

However, the necessary requirements will be met by introducing SkyDrive based collaboration software. The possibilities that this software offers, are defined through the next several paths.

What does this collaboration software bring in relation to the previous solutions for the communication of the teams members? What does this collaboration software bring in relation to the previous solutions for monitoring and controlling the process of performing the tasks and aims done by team leaders? The team is working on a task, all are granted certain rights, which control the visibility of information and documents. Team leader establishes rights for the team members. The information is also placed on the "wall" of the document, and in accordance with the rules of conduct, co-workers are able to see it immediately and respond to it. If someone is a member of several teams, all relevant information will be shown on his/her wall. Another gain in relation to e-mail is that it is easy to track changes. Suppose that a team member wrote a document and put it on the portal of his/her team. All team members can look at it and possibly make amendments or changes. The new version, but also any old one, will still be available to everyone, and it will be known who changed it, when and what was changed. So if a team member wants to look at the document after a while, he/she will not be in a dilemma whether the electronic mail attachment, which he found is indeed the final version or at some point someone may have forgotten to send it to him. Team leader can monitor the level of performance of each team member. With this software that employees use at school or home, the problems numbered from 1 to 6 are overcome.

What does this collaboration software bring in relation to the existing solutions in monitoring and controlling the effectiveness of teams' work for the sector managers? Team managers and the sector manager may form a new communication group, which would work on similar principles as described above. The sector manager defines access rights.

What does this collaboration software bring in relation to the existing solutions in monitoring and controlling the processes that are ongoing in the school for the school director? The Director and the sector managers may make the highest hierarchy group in the collaboration software. Problems given in numbers from 7 to 9 will be moderated by these solutions.

7. CONCLUSION

The new organizational structure in the management system, strategically established and organized teams and set 'core values' for each employee have led to increased efficiency and productivity of the school in carrying out its activities. The implementation of software solutions aimed at optimizing the processes occurring within the teams and especially within the sectors will raise the accomplished levels of efficiency and productivity further more; at the same time the employee satisfaction will also be raised. The employees will be able to perform part of their obligations anytime and anywhere; they will be able to establish communication and cooperation with other team members in an easy and reliable way.

PROFITABILITY EVALUATIONS OF INVESTMENTS IN REGIONAL LANDFILLS IN REPUBLIC OF SERBIA

Dušan Saković¹ Miloš Ilić²

¹Hidrozavod DTD ad Novi Sad

²ERSTE Bank ad Novi Sad

1. INTRODUCTION

Investments in environmental protection are the obligation of each country. Proper removal, disposal and recycling of waste must be established as a practice, primarily because of environmental reasons, that is to create a better and healthier environment for living. Adequate disposal of various wastes directly improves living conditions in the region in which to build the landfill because the waste is passed directly to the sanitary area which is designed in a way that prevents any negative impacts on local soil, groundwater, rivers etc. In addition, construction of a sanitary landfill at the same time includes removing all illegal dumpsites in the region and divert their waste into one location. Investment in environmental protection, and in that context, in the construction of regional landfills is one of the main conditions for joining the European Union. All laws, acts, measures adopted must be harmonized with EU directives, in accordance with this, all objects that are used in environment management must be built according to European standards.

Investments in regional sanitary landfills require large resources to be invested in infrastructural facilities at the landfill and equipment used for collecting and recycling waste. Raising the necessary funds, especially in transition countries such as Serbia is not easy. Because there are multiple interests in the improvement of living environment, and for the construction of landfills, the structure of investors in construction is often varied. Apart from local and state Governments, investments often include foreign donors and private creditors. Some are primarily interested in the improvement the environment, local government and donors, where as creditors are primarily interested in making profit, that is maximizing return on the investment. No matter what the goal is, all investors are interested in landfills ability, either as an independent, private enterprise, and either as part of local government, to operate positively, to exert its own income, which will be sufficient for the smooth functioning in the lifetime, which is extremely long.

Precisely because there is more potential investors, before entering into the financing and construction of the landfill future business and financial analysis must be conducted. The essence is to make adequate financial structure so that local authorities can hold on the burden of the investment, then to attract donors and in the end to make private investors satisfied with the achieved interest rate. To approve the financing of such a large project cost effectiveness analysis of the investment should be carried out. The most widely used methods for this purpose is the calculation of Net Present Value of the project and the calculation of Internal Rate of Return.

The aim of this study is to show that investment in the regional landfills in addition to being good for the local community and state in terms of environmental improvements, it is also economically profitable for all participants in the project, because modern landfills, as private or public companies, may independently collect revenue and thus operate independently realizing profits for its founders. To support this view, the study will present financial analysis of future functioning of two regional sanitary landfills in Serbia, whose construction is in progress. These are: Regional Landfill in Northbacka-region (Regional Landfill Subotica) and the regional landfill in the eastern part of Serbia (Regional Landfill Zajecar). All data presented in the study come from preliminary designs which are made for the construction of the landfills. Company Hidrozavod DTD ad Novi Sad was engaged in designing these projects and their managers allowed us access to data published further in the text.

2. WASTE MANAGEMENT STATUS IN SERBIA

Waste management in Serbia is inadequate and it possesses public health and environmental hazards. Only about 60 % of produced municipal waste is collected in Serbia (around 2.4 million tonnes per year). The collection is organized in urban areas mainly, and organized collection is missing in rural areas, except in AP

Vojvodina. Up to now, land filling was the only waste treatment method. Last years, and from year to year more and more, several other waste treatment methods are implemented, like recycling, waste combustion in cement kilns, composting, producing energy from biomass, etc. The existing disposal sites generally do not meet the technical requirements of sanitary landfills and their capacity in most municipalities is already exhausted. In addition to the registered landfills there are 4,481 illegal dumpsites of different size in rural areas. Dumpsites present a potential risk for ground and surface water and soil, due to the high concentration of organic matter and heavy metals.

The Government of the Republic of Serbia adopted first National Waste Management Strategy (NSWM) in 2003, and adopted new revised version, foreseen for period 2010-2019, in april 2010. NSWM 2010 follow the same approach as previous NSWM, but give updated list of the waste management regions and more detailed scheme for different waste streams. According to the NSWM 2010, 26 waste management regions are envisaged to be established. The NSWM also includes Action plan for its implementation with precise administrative and technical measures and deadlines for their realization. Regarding progress made in terms of policy and legislation harmonisation with the EU, waste management is one of the Government of Serbia priorities.

According to short-term objectives of the Strategy on Waste Management 14 regional landfills have to be constructed up to 2014. The considered study covers financial aspects of two of 26 SWM regions, foreseen by Strategy on Waste Management 2010: the city of Subotica region and (Bačka Topola, Kanjiža, Mali Iđoš, Senta, Čoka and Novi Kneževac). Total number of the population in this region is 280,025, census 2002. And the city of Zajecar region and six municipalities (Knjazevac, Boljevac, Bor, Kladovo, Majdanpek and Negotin). Total number of the population in this region is 265.541 censuses 2002.

3. DYNAMIC METHODS AS AN INSTRUMENT FOR RATING COST-EFFECTIVENESS OF PROJECTS

The sum of discounted net cash flows (Net present value) represents a principle indicator of profitability. A positive NPV shows that a project will bring profit to its investors and that it is justifiable. And the opposite, a negative NPV points that a project will generate losses and that it is not justifiable to consider it for realization. In that sense the NPV can be considered as elimination criteria in the project evaluation process. The formula for calculating NPV is (Mikerevic, 2005 p. 168):

$$NPV = \frac{FV}{(1+k)^n} \quad (1)$$

NPV- Net Present Value

FV-Future Value

k-discount rate

n-number of periods

If the cash flows have different annual amounts, as is the case with the projects presented, summarizing the discounted annual cash flows must be conducted in order to obtain a net present value at the end of the project. This is done by the formula (Mikerevic, 2005 p. 171):

$$NPV = \sum_{t=1}^n YA_t \left(\frac{1}{1+k} \right)^t \quad (2)$$

YA-Year amount

t-current year

k-discount rate

The Internal Rate Return, on the other hand, represents a relative indicator measuring a project's average profit rate of return. The more IRR ends up above the discount factor, or a referent acceptable threshold of the rate of return, the more acceptable and the more attractive project becomes. In principle, if the IRR is below the discount factor the project is not financially acceptable and the other way around, if it is above it, the project is financially acceptable. Since the IRR may be set at different levels depending on investor's preferences and their readiness to accept a particular rate of return, these criteria is considered selection criteria. Its basic purpose is to help investors make the right decision in terms of alternative uses of available

capital. IRR is the discount factor that reduces NPV to zero and is calculated by the formula (Krasulja, 2000 p. 303):

$$C = \sum_{t=1}^n \frac{R}{1 + IRR^t} \quad (3)$$

C-Present value

R-Yearly net cash flow

IRR- Internal rate of return

n-Number of periods

IRR formula is almost identical as the NPV formula, but the difference is that, in NPV calculation discount factor (k) is pre determined, whereas in IRR calculation NPV is reduced to zero value, in order to find the discount factor or the IRR. Finding IRR can only be done as a result of higher or lower number of attempts. The IRR can only be approximated couple of times and then found.

4. IMPORTANT ISSUES FOR THE ANALYSIS

The financial analysis aimed at the calculation of the adequate net return indicators, has the following basic steps to elaborate the financial analysis:

- calculation of the investment cost,
- calculation of the operation cost,
- calculation of the estimated revenues,
- calculation of the discounted cash flow as the base for calculation of IRR (Internal Rate of Return) and NPV (Net Present Value).

In order to evaluate acceptability of the project a projection of its annual cash flow has been made and then used to calculate the Net Present Value of the project (NPV) and its Internal Rate of Return (IRR). Future costs and revenues flow have been discounted by applying a discounting factor which reflects opportunity costs. Financial analysis and evaluations of the projects are based on several key assumptions, amongst which the most important are as follows:

Time horizon

A time horizon of a project, its expected life cycle duration, is an important part of any analysis and evaluation of the project. It often impacts a final judgment about the project: longer duration of the project means longer cash flows and due to discounting effects a higher Net Present Value.

The logic behind the project's time horizon is based on its assumed economic life cycle, that is, the period in which it can create economic benefits to its investors and/or the community. In this sense, the end of a life cycle is, in theory, defined as the moment when all invested resources would be depreciated and financial liabilities finally covered. In real life, this moment is defined as a moment in time when it is possible to sum up all project's effects (all financial inflows and outflow) and reach the final judgment about whether the investment has been justifiable or not.

Guide to Cost Benefit Analysis of Investment Projects prepared by the Directorate General of Regional Policy of the European Commission based on the OECD's analysis from 1993 – suggests that the time horizon for a project of construction of the regional landfill is 30 years (p.100). For projections of cash flows and their discounting and calculation of the most important indicators of the project acceptability: NPV and IRR we will use period of 33 years for regional landfill in Subotica and 24 years for regional landfill in Zajecar. Also in the study, because of the page limitations, will not be shown every year of the landfills life, thus only the data from several years are shown.

Prices used in the calculation

Financial analysis is based on tariffs expressed in Euros as fixed prices from 2011. as the base line year for the calculation of all indicators. This is a usual approach in financial analyses and it is not used only in situation when changes in relative relations between prices of particular inputs (raw materials, reproduction materials, services, etc.), or outputs (products/services) are expected with certainty for instance due to administrative control of tariffs and the like.

Given the character of investments and the structure of planned inputs and outputs we may accept the assumption of fixed prices and the fact that it will correctly reflect the relations between the mentioned inputs and outputs. On the other hand, fixed prices enable avoiding general fluctuation of prices and exchange rates (frequent oscillations and weakening of the dinar against euro during a long period of time) which pose a real risk due to the current macroeconomic situation in Serbia.

Exchange rate used in the calculation

When the work on the projects began the official exchange rate was 1 euro to 103 dinars therefore we kept the same rate until the end of the work. Using the same exchange rate in calculations of financial indicators enabled consistency and comparability of all indicators and results in the study.

Discount factor in financial evaluation

Discount rate or factor which is going to be used in this financial analysis is 5%, which is also suggested by the above mentioned „Guide to Cost Benefit Analysis of Investment Projects“ of the European Commission. Such discount rate is appropriate for infrastructural projects whose primary goal is not achieving high financial effects but, primarily, creating conditions for the improvement of surrounding community.

5. FINANCIAL ASPECTS OF PROJECTS

Before we determine the Net Present Value and Internal Rate of Return, it is necessary to recognize the individual components that have an impact on the profitability of projects. In that sense we should analyze investments in a landfill, especially in the first phase related to the construction of the largest part of the landfills. In addition to successfully determine the Net Present Value we must carry out a projection of costs and revenues for the prescribed life of the landfills and examine their structure and dynamics. Especially important for assessing the cost-effectiveness is an overview of sources of financing projects. Here we must make a difference between borrowed and own funds of the municipals, also the calculation of the NPV and IRR has to be conducted from investments point of view and from municipals point of view. Characteristics of investments in environmental projects are grants awarded by various funds in the EU and funds of the Government of Serbia, which if excluded from the NPV and IRR analysis greatly increase the profitability of projects.

Investments projection

Investments in the regional landfills consist predominantly of investments in fixed assets. The major activity of the future landfill companies will refer dominantly to services, so it will not need large stocks (if any) of raw materials, inventories, etc. At the same time the nature of the operations is such that it will not assume many and frequent payments to the suppliers and other partners as well as large payables, and based on that, frequent financial outflows. Because of these reasons, the future companies generally will not need large working capital. Simply recapitulation of the investments without the list of specific fixed asset items and for the purpose of the financial analysis structures them into the four following categories:

- Land;
- Buildings and infrastructure;
- Equipment;
- Other (including interest).

Table 1: Investments in fixed assets, in 000 Euros Subotica

Income projection

The Landfill companies are going to generate revenues from the two main groups of activities:

- Collecting solid waste and charging the existing (or maybe extended) group of clients for the service; and
- Selecting and recycling collected SW and selling it to different buyers.

The initial, somewhat, simplified but yet realistic assumption has been that around 50% of the so-called recyclable waste will be processed at the local level, therefore this part will never end up on the regional landfills. In other words, total amounts of waste will be reduced for this part. The other half of the recyclable waste will be received and recycled at the regional landfills.

Table 4. show revenue calculation based on revenues from receiving and land filling the solid waste coming from municipalities in the regions. The calculation has been done based on estimated movement of total

amounts of MSW generated in the Regions. The other source of revenues will be revenue from recycling of the waste which will be received at the landfills.

Table 4: Calculation of total revenues of regional landfills

Sources of finance

Sources of financing the construction of regional landfills in Serbia are generally structured from several sources, domestic and foreign. Since this is a large amount of investment that the municipality can not finance by themselves and bearing in mind that this is an investment in environmental protection, EU usually approve grants for this kind of projects. The rest of the funds is collected from municipal revenues, the Serbian Government, foreign and domestic loans.

The success of the first investment phase, out of six, is crucial for the final implementation of the Project. This is the phase where, practically, the whole sanitary landfill will be built and serviced with equipment, while investments in the phases that follow will pertain, primarily, to additional construction, expansion and maintenance.

Cash flow for calculating NPV and IRR

Cash flow used to calculate the Net Present Value – NPV and the Internal Rate of Return – IRR (Economic Flow of the Project) has been formed with the basic goal to evaluate acceptability of the projects from the viewpoint of invested resources.

6. RESULTS AND CONCLUSION

Net Present Value/Internal Rate of Return on total investments in project

Based on the discounted net cash flow the basic indicators of financial effectiveness: net present value, internal rate of return and net present value rate have been calculated and presented below:

Table 9: NPV, IRR and NPV ratio on total investment

ITEMS	Subotica	Zajecar
Net Present Value of the Project (NPV)	6,524.616 Euros	2,111.433 euros
Internal Rate of Return of the Project (IRR)	6,1%	5,7%
Net Present Value (NPV) Ratio	20,2%	130.6%

Indicators are positive and thus showing that the project are, under given circumstances, acceptable from the viewpoint of the investor (Regional Landfill Company):

- Positive Net Present Values shows that the projects will enable invested funds to be returned;
- Internal Rate of Return is 6.1% and 5.7% which are above the threshold defined by the discount rate of 5% also confirms acceptability of the projects from the viewpoint of the investor. Obtained rate of return is favorable, particularly since this is an infrastructure project which, as any project of its kind, does not yield high direct returns but, as a rule produces high social effects.
- Net Present Value Rate compares invested funds and discounted cash flow of the project during its life cycle. This ratio for the investment into the regional landfill Subotica is 20,2% which points that the invested fund will be returned as 20,2% higher. This ratio for the investment into the regional landfill Zajecar is 130.6% which points that the invested fund will be returned as 130.6% higher.

Net Present Value/Internal Rate of Return on Shareholder's Equity or Funded Capital (public/private)

Capital effectiveness analysis has as its goal to show effectiveness of the analyzed project from the viewpoint of the investor's equity/capital. The logic of such analysis and evaluation is based on the fact that projects with a wider community support due to their external social effects do not always have to be fully acceptable in terms of sources of funds.

The above mentioned methodological guide emphasizes that such projects are supported by special funds of the EU and their grants which reduce investor's risks and thus make return on their investment easier. With this many financially unacceptable projects from the viewpoint of investors become acceptable and many socially desirable projects, which would not be funded without the EU support, come to life.

The Capital effectiveness in the projects for the regional landfills in Subotica and Zajecar have been evaluated based on the corrected cash flow presented in Table 7. and 8.

Table 10: NPV, IRR NPV ratio for Equity

ITEMS	Subotica	Zajecar
Capital Net Present Value	32,940.211 Euros	17,199.192 euros
Capital Internal Rate of Return	28,8%	11.9%%
Capital Net Present Value (NPV) ratio	709,4%	287.7%

The correction pertains to changed amount of „Investments“ where all grants have been excluded (expected international and domestic donations) allowing obtained Net Present Values and Internal Rates of Return to reflect equity effectiveness– in this particular case those are local governments which founded the regional landfill. As the above presented table shows, the key indicators of the equity effectiveness are more favorable compared to the indicators of the project effectiveness.

Since all calculated indicators of profitability have a positive value, as the study had showed, the conclusion is that investing in building regional landfills in Serbia is profitable from every point of view, especially municipals due to grants and loans from the EU funds.

Abstract: LEGO is one of the leading brands in the global toy industry nowadays. This case study provides information about current marketing strategies of the LEGO Group. In addition, primary and secondary target groups are described, as well as the key differences among them. Furthermore, three alternatives for innovative marketing strategy by 2015 are presented. The first marketing strategy considers product innovation, the second strategy discusses the export strategy to Latin America countries and the third strategy refers to interactive marketing strategy for The LEGO Group. Eventually, this case study should help students to better understand strategic marketing decisions by using innovation as creative dimension on one side, and results considering the marketing investments of all marketing campaigns until 2015 on the other side of the approach.

Keywords: The LEGO Group, toy industry, product innovation, export marketing strategy, interactive marketing strategy.

1. INTRODUCTION

The LEGO Group is engaged in the development of children's creativity through playing and learning. Based on the world-famous building block, LEGO brick, the company today provides toys, experiences and teaching materials, organized in 25 product lines, in more than 130 countries. The LEGO Group has approximately 10,000 employees, and it is the world's third largest manufacturer of play materials. (11)

Everything started in Denmark in 1916 when Ole Kirk Christiansen opened a carpentry shop, and in 1932 began making carved wooden toys. Two years later the company was named LEGO (a combination of two Danish words, "leg" and "godt," meaning "play well"). In time, plastic materials were steadily replacing wooden ones. The ancestor to the common LEGO block was invented in 1949. After hearing criticism that no company made a comprehensive toy system, in 1954 Ole's son Godtfred assembled a list of 10 product criteria for LEGO's toys, including that they have lots of compatible components. The company launched the first LEGO play set in 1955, and soon afterwards LEGO became one of the most popular toys in Europe. After the fire in LEGO's warehouse in 1960, the company completely ceased production of wooden items in favor of plastics.

Luggage-maker Samsonite began manufacturing and distributing LEGOs in the US in 1961 under license. LEGO's first LEGOLAND park was opened in Billund, Denmark, in 1968. The company introduced the more complex LEGO Technic model sets in 1977 and the popular LEGOLAND Space play set in 1979. The first LEGO Imagination Center was opened in Minneapolis in 1992, and the second followed in Walt Disney World five years later.

In the 1990s growth of the video game industry far outpaced the growth of the construction toys market, and LEGO suffered. With profits reductions, in 1998 the company sealed an agreement to start the production of building kits and figures based on the popular Star Wars movies and Walt Disney's Winnie the Pooh. In 2001, LEGO started cooperation with software company Microsoft Corporation in creation of children's online games. In 2003, LEGO entered into the arts and crafts market with the introduction of CLIKITS: a fashion design system made up of a variety of kits allowing girls to design room decor, picture frames, jewelry, and fashion and hair accessories.

Nowadays, LEGO is actively engaged in online video game business. In early 2010 LEGO extended its licensing agreement with Warner Bros. Home Entertainment Group through 2016. The deal related to LEGO video games being played across multiple platforms, gives traction to titles LEGO Star Wars, LEGO Batman, and LEGO Indiana Jones. Collectively, LEGO has sold nearly 50 million units of the games worldwide so far. (12)

As mentioned before, LEGO already produces TV shows, educational materials, and merchandise including books, video games, and computer game software. Fears in the industry concerning toys made in China, which have had an unusually high number of recalls in recent years, could boost LEGO's bottom line further. However, LEGO only has a part of its production operating in China.

2. INDUSTRY OVERVIEW

According to Global Toy Market Estimates: 2011 Edition, global toy sales grew by nearly 5% (4.7%) in 2010 to US\$83.3 billion. While the growth was driven by strong performance in the Asia region, which increased at a rate nearly double the average (9.2%), the U.S. market remains the largest market with sales of nearly \$22 billion, followed by Japan, China, the UK and France. The toy market remains very concentrated within these top five countries, which captured just over 50% of total global sales. Additionally, strong growth exists in emerging markets, with the BRIC countries (Brazil, Russia, India, China) showing growth of 13%.(10)

The toys and games industry is a veritable playground for a select group of global players. The industry is dominated by two US toy makers: Mattel (Barbie, Hot Wheels, Fisher-Price) and Hasbro (G.I. Joe, Tonka, Playskool). Further, other large companies, such as Japan's Bandai Co. (Digimon) and Sanrio (Hello Kitty), as well as Denmark's The LEGO Group, generally generate revenues in the US\$1 billion-and-up range annually. Most of these companies have achieved success in the industry by creating cross-culturally appealing brands that are supported by marketing campaigns to market products to a vast number of countries.

US chains also lead the global toy retail market, with discount retailers such as Wal-Mart Stores (the nation's #1 toy seller), Kmart, and Target, as well as Toys "R" Us. Some specialty toy sellers have fallen prey to big box discount stores (who now begin their holiday volume discounting much earlier in the season). Most toy retailers also have an online presence, although many toy e-tailers, did not survive the dot-com fallout.

The advent of the "tween" market (kids from 7 to 14 years of age) has shortened the life span of some toys like Barbie, while setting up online communities where kids can interact with other peers through characters. Nevertheless, retro toys are making a comeback. Adults who once played with the originals are now introducing these toys to their children, exposing a whole new generation to these brands.

The Internet has opened up a new realm of interaction between kids and their toys. Action figures and dolls have their own web sites that feature story lines, bios, screen savers, message boards, and games.

Some industry suppliers aim for the mega hit through licensing deals. However, licensing has become an option to approach with caution. Hasbro paid some US\$600 million and a 20% royalty for rights to the second series of Star Wars movies, only to be stuck with unsold inventory after some of the releases. Moreover, Mattel's deal for Harry Potter books and movies was a much more modest US\$20 million guarantee and 15% royalty. Companies have since been more conservative when shelling out licensing money.

Beyond licensing, companies are looking for growth in untapped markets. Large opportunity exists in the considerable number of children who have not yet heard from the likes of Mattel, Hasbro, and their kin. Toy makers have historically targeted American children, who on average acquire about US\$400 worth of toys each year. The average for children outside the US is US\$34. However, companies cannot ignore the facts. There are some 60 million children in the US. India, for example, has 400 million potential toy consumers and China has 300 million children. In the future, successful suppliers to the toy industry may have to attract the attention of children around the world if they hope to sustain growth.

Nevertheless, governments are shining a spotlight on the industry and have created new legislation aimed at better policing consumer product safety.

While keeping their sales outlets current, toy companies must constantly seek to score the next big hit. The toy makers continue to vie for consumer attention by churning out more interactive toys. Companies have also been looking to make a splash with creative or educational toys. (3, 14, 9, 19)

3. MAIN COMPETITORS OVERVIEW

Main LEGO's competitors on the global level are US toy companies, Mattel and Hasbro.

Mattel was founded by the Handlers and Matson in 1945 in Southern California, US. The company tends to focus on its core brands and licensing deals. The most famous and best-selling brand in the Mattel family is certainly Barbie. Since the appearance in 1959, Barbie has dressed up Mattel's portfolio and has spawned countless accessories. The platinum blond remains the most popular doll worldwide, as one is sold every two seconds somewhere in the world. Mattel's reported net sales in FY 2011 were US\$6,2 billion, with an increase of 7% in comparison to FY 2010. (15)

Hasbro was founded by the Hassenfeld Family in 1923 in Rhode Island, US. The maker of Milton Bradley (Candy Land, Scrabble) and Parker Brothers (Monopoly, Trivial Pursuit) games, trading cards ("Pokemon", "Harry Potter", and "Magic: The Gathering"), and action figures. In 2011, Hasbro generated net revenue of US\$4,3 billion, with an increase of 7% comparing to net revenue in 2010. (6)

4. TARGET GROUP PROFILE

The LEGO Group often insists it is not childish. That means that children are not their one and only target group. Their goal is to encourage the child in all of us. *The motive behind the word Lego bringing out the inner child is a serious one: look how many great inventions were conceived in the spirit of play.* It can be concluded that LEGO has opened up a whole new universe of potential for the humble plastic brick and its components for very wide target groups, which are described below:

Generation C kids (born 1995-2012)

Gen C kids will grow up with a highly sophisticated media and computer environment and will be more Internet savvy and expert than Gen Y members. These generations read books from Kindle and iPad, and value friendships through Facebook and Twitter. How to address them? The interesting aspects that describe Gen C are content, creation, connection and choice of the products. They want to create and control content, since they are interested in storytelling the company is ready to offer. They need to hear a brand story. Furthermore, they want an openhanded approach, including involvement in brand creation and offer of a variety of toys (e.g. Nurse Barbie, Hollywood Barbie, etc.). For example, the toy manufacturer LEGO has successfully used customer comments and conversations from the LEGO Club website to design new products. Survey results prove that beside overwhelming Internet effect, children still appreciate family and friends the most, following by pets and all kinds of toys, respectively. Children are already emotionally connected to toys, thus the task is to sustain such close relationship. (5)

Decision Makers (Parents)

Parents are the ones who decide about the purchases of toys. However, the fact is that children have influence on them, although different shopping goals of both sides should be considered. On one side, kids want to have interesting and popular toys, while on the other side, parents are interested in educational and creative value of the toys. Another important trend that can be identified is that moms are especially concerned about safety and quality of the toys. Consequently, environmental and health issues are aspects that toy companies should consider closely nowadays. (5)

AFOLs - Adult Fans of Lego

As mentioned previously, Lego is not only observed as a childish toy. The fact is that Lego is an intellectual and creative construction toy dedicated to people of all ages. Because of that, there is this specific niche group of customers. What is special about them is that they understand the functional and educational dimension of LEGO bricks. AFOLs are nostalgic about the childhood, and their LEGO collections keep their inner child awake. Finally, it has been proven that AFOLs are the most loyal customers, and in that sense there is a need for strategic thinking about their needs and wishes. (1)

5. MARKETING STRATEGY ALTERNATIVES

How LEGO organizes innovation?

The LEGO Group's mission is "Inspire and develop the builders of tomorrow." Its vision is "Inventing the future of play." LEGO organizes innovation through three large areas:

1. Functional groups
2. Concept lab and product and marketing development
3. Community, education and direct communication

Functional groups deal with core business processes that enable innovation in other processes. Core processes include sales, operations and financial planning, while consequently enhanced processes are forecasting and marketing planning.

On one side, concept lab department develops completely new products and play experiences. On the other side, product and marketing development department develops the next generation of existing products and existing play themes, packaging and campaigns. Areas of innovation can be defined as messaging (advertising campaigns and websites), offerings (products and packaging) and platforms (toys' technology elements).

Community, education and direct communication support customer communities and gathers ideas from them. Moreover, this department manages LEGO retail chain and online store, while offering improved educational and playing experiences. Areas of innovation can be divided into customer interaction (communities and customer services), sales channels (retail and direct selling) and business model (evaluated through pricing and revenue).

On the product side, the LEGO Group focuses on creating innovative new products from concepts developed under the title "Obviously LEGO, never seen before." The company plans to come up with such concepts every two to three years. The latest example is LEGO Games System, which is family board game (a new way of playing with LEGO bricks) with a LEGO attitude of changeability. The company also intends to expand LEGO Education, its division that works with schools and kindergartens. It will also develop its digital business as the difference between the physical world and the digital world becomes more and more blurred and less and less relevant for children. (18, 20, 17)

Export Strategy

The LEGO Group has chosen a strategy that is based on a number of growth drivers. One is to increase the market share in the United States. Many Americans may think they buy a lot of LEGO products, but they buy only about a third of what Germans buy, for example. Thus, there are potential growth opportunities in the U.S. market.

The LEGO Group also wants to increase market share in Eastern Europe, where the toy market is growing very rapidly. In addition, it wants to invest in emerging markets, but cautiously. The toy industry is not the first one to move in new, emerging markets, so the LEGO Group will invest at appropriate levels and be ready for when those markets do move.

Latin America is a "promised" market for toy makers. Most of the countries in Latin America are recording growth in the middle-class segment. Accordingly, rapid rise in spending per child is creating new opportunities for the toy makers looking to expand in emerging markets. For instance, in 2011, Brazil's middle-class, if defined as households with an annual disposable income of over US\$15,000, numbered 32.4 million households, a figure which puts Brazil in fifth place globally in terms of number of middle-class households, ahead of France and the UK. Similar situation has been reported in households in other parts of Latin America. (4)

Moreover, LEGO's biggest competitor Mattel has indicated that Brazil and Mexico are being their second and third largest foreign markets in 2011, respectively. The overall revenue of nearly US\$1 billion has been coming from Latin America. Based on macroeconomic indicators presented in Table 1, it can be concluded that disposable income in all countries in this region is rising. Besides, CAGR is significantly high for all

countries, especially for Argentina, Brazil and Uruguay. This indicator can be attractive for other toy makers in the world.

What kinds of toys are particularly popular in Latin America? Mattel has the leading position in Brazil, holding robust 30% of market share, following by Hasbro and local toy makers. Adapting to local cultural habits and trends has proven to be a great move. Regarding this fact, Mattel's investment in localized toys like Dora La Explorada, paid off. Unsurpassed favorites like action figures and model vehicles will continue rising in sales, because they are desired by the children who watch television. Nevertheless, construction toys are expected to enjoy strong growth until 2015, due to larger number of working mums and hectic life they are living in.

Yet, what is very surprising is the absence of massive chained international retailers, such as Toys "R" Us in most of the Latin's countries. For example, toy retailing is more fragmented in Brazil compared to the US or Europe. The largest toy stores include Ri Happy and PBKIDS, both of which expanded aggressively over 2005-2010. However, sales through traditional toy stores accounted for only 32% of all toys sold in Brazil in 2010. A significant 13% share of toy retailing is represented by department stores and a further 11% by variety stores, such as Americanas or Leader. Similar case is with other previously mentioned markets. Finally, online retailing is growing, and this is definitely an open space for innovations and new players. (4)

Table 1: Disposable Income in Latin America, 2008-2011 (4)

US\$ per capita, fixed 2011 exchange rates					
Country	2008	2009	2010	2011	CAGR (2006-2010)
Uruguay	7,040.3	7,256.0	8,341.4	9,341.3	12%
Brazil	5,892.0	6,478.4	7,308.5	8,058.4	11%
Chile	6,705.8	6,886.9	7,363.1	8,039.6	8%
Mexico	6,450.0	6,267.3	6,795.6	7,257.5	5%
Costa Rica	4,904.9	5,125.9	5,578.2	5,997.0	10%
Argentina	3,670.3	4,078.8	5,008.2	5,892.1	19%
Venezuela	2,758.8	3,481.8	4,375.3	5,661.1	31%
Colombia	3,950.6	4,109.5	4,314.2	4,608.4	7%
Peru	3,004.9	3,121.7	3,324.2	3,599.3	8%

The LEGO Group will also expand direct-to-consumer activities (sales through LEGO-owned retail stores), online sales, and online activities (such as online games for children).

Chart 1: Market size in 2010 and spend per child (0-14-year-old) (4)

Interactive LEGO's approach

Defining successful digital presence is extremely important part of Lego's marketing strategy. There are many integrated interactive marketing campaigns delivered by The LEGO Group. Table 2 shows some of the crucial Lego's on line activities ranking by establishment date.

Table 2: The LEGO Group' on line activities (from 1998 to 2011) (7,8)

Year	On line action introducing by The LEGO Group	
1998	LEGO MINDSTORMS - a series of kits containing software and hardware to create small, customizable and programmable robots	http://mindstorms.lego.com
2000	LEGO STUDIO PRODUCT – was developed by The LEGO Group and partners with Steven Spielberg which allowed users to create stop-motion animation using their LEGO bricks.	http://www.lego.com/studios/
2000-2001	LEGO BIONICLE – leading by innovation it was the first truly TRANSMEDIA APPROACH undertaken by the company. The BIONICLE.com site was the digital hub for all IMC communication activities. Connected product, print, video, in-store and packaging in ways never before seen in the toy industry.	http://www.bionicle.lego.com
2004	LEGO DIGITAL DESIGNER – a computer program that allows users to build models using virtual LEGO bricks.	http://ldd.lego.com/
2005	LEGO Factory (later DesignByMe) - a service allowing people upload the models built in LDD to the LEGO website, design their own box design, and order them for actual delivery	http://designbyme.lego.com
2005	LEGO Star Wars: The Video Game Named “ Game of the Year ” from Kidzworld.com, was developed by The LEGO Group teams and Travelers Tales Games	http://starwars.lego.com
2007	LEGO co-creation with kids - Kids who submitted good ideas were given credits in gaming and videos. The result was a dramatic increase in traffic, time on site and NPS numbers	/
2007	LEGO Mars Mission: Crystalien Conflict – the flash-based Command and Conquer style game.	http://www.toybrixandblox.com/games/lego-mars-mission-crystalien-conflict-game/
2008	LEGO Star Wars Movie Making Contest Users - create a stop-motion animation featuring LEGO SW characters more than 1000 entries in three categories	http://www.legostarwarsmoviemakingcontest.com
2009-2010	LEGO Unity platform for creating online games and 3d interactive content on the Web, PC, Mac, Wii™ and iPhone	http://unity3d.com/
2009	LEGO Power Miners- it's new underground theme. They decide to embrace kids' love of “potty humor” to create affinity with the brand. Good example of viral marketing.	http://www.youtube.com/watch?v=6RK1xHiglfs
2010	LEGO Universe- a massively multiplayer online game developed by NetDevil. The servers were shut down permanently on January 30, 2012.	http://universe.lego.com
2010	LEGO augmented reality application - to show users what is inside the box	http://www.youtube.com/watch?v=nYNkVKKOxW4&feature=player_embedded
2010	LEGO Atlantis - it's new underwater theme. An extensive teaser allowed boys to explore the bottom of the ocean and discover various items. Backed by a 45-minute movie, there was plenty of content to play with.	http://atlantis.lego.com
2011	LEGO Build Together - a website that offers fathers and sons ideas on how they can enjoy LEGO bricks together.	http://buildtogether.com/
2011	LEGO Spinjitzu Scavenger Hunt for iOS devices Game Goals: Create buzz Take Ninjago to go; Incentivize interacting with physical products. Slogan: Ninjago goes mobile!	http://www.148apps.com/tag/lego-ninjago-spinjitzu-savenger-hunt/
2011	LEGO Life of George Combine an iOS app + bricks to recreate items that George finds on his travels	http://www.youtube.com/watch?v=1DHZwSOVKBY

Many of these actions were successful for the LEGO Group. LEGO Mars Mission had more than 40 levels and discussing the performance 66% return rate, with play time higher than 17 minutes in comparison to the average one. It is considered as the most successful flash game in LEGO.com history. Also, LEGO mobile performance showed highest rank in App store: #4 total installs to date: 8+ million in 2011.(7) On the other hand, LEGO Universe did not succeed because LEGO's management has not been able to build revenue model for their target group, and therefore, has decided to close the game.(2)

6. WHAT IS NEXT?

Despite a downturn in the economy, LEGO has logged revenue increases while its traditional toy rivals saw sales slide. The company points to the success of its classic toy lines - LEGO City, LEGO Creator, LEGO Technic, and LEGO Star Wars - for the rise in revenue. Geographically, LEGO expects moderate sales increases in its North American and Western Europe markets. As for the lowering production costs, LEGO implemented strategy related to moving production operations from Denmark, Switzerland, and the US to mostly lower-cost countries, such as the Czech Republic, Hungary, and Mexico.

Having in mind LEGO's current innovative activities, future steps in this field should be defined. As mentioned previously, both product and communication sides have room for further improvements and innovations and thus, proper analyses should be conducted in order to make the best possible choices.

Chart 2: LEGO Growth Model

Digital experts from the LEGO Group are thinking about future steps in defining interactive marketing strategy. They have many possibilities but they should think about the priority until 2015: dynamic digital objects, interactive display, stronger application integration, stronger presence in social media, more engagement with parents or even more interactive campaign.

Abstract: Military industry in Serbia is made up of several enterprises that are mainly oriented to the production of lightweight, semiheavy and heavy artillery. The most interesting products are infantry ammunition, anti-tank ammunition, ballistic equipment, automatic and hunting rifles and grenades. Although there is a demand for all products named above only two products are intended for export. Those are grenade launchers and automatic rifles.

Export of arms is in the jurisdiction of the Ministry of Foreign Affairs, Ministry of Finance with the approval of the Ministry of Defense. Only after fulfillment of appropriate standards, rules and collect the permit requirement, the specific company or factory-supplier, can export produced weapons, where for the transport of these products vehicles available to the Army of Serbia are used.

Limitations that exist in this problem are related to amount of grenade launcher and rifles that can be transported from the factories. Additional limitations are the amount of products that has to be delivered to specific buyer and transportation vehicles provided by the Army.

The goal of this case study is to help Ministry of Foreign Affairs to find optimal number vehicles needed for transporting selected products which will reduce cost of transport, by applying the linear and nonlinear programming.

Key words: Linear programming, integer programming, military supply chain management, military logistics, operational research

1. INTRODUCTION
Operational research or management science originated during World War II as a formal discipline. At that time it was used for coordination and deployment of the radars. The results were surprisingly successful, which led to application in other military departments such as navy, aviation and land forces. After the war methods and models of operational research were developed not only for military but also for use in other areas of human activity mainly for business use. [6 p.18]

One of the major sub disciplines in modern operational research is supply chain management and logistics. But there are some differences between Corporate and Military supply chain management (SCM).

Differences between corporate and military scm

The main goal of corporate SCM is to adapt overall business process to enable the profitable transformation of materials or products into finished goods and their distribution to meet demands (Figure 1: Corporate SCM).

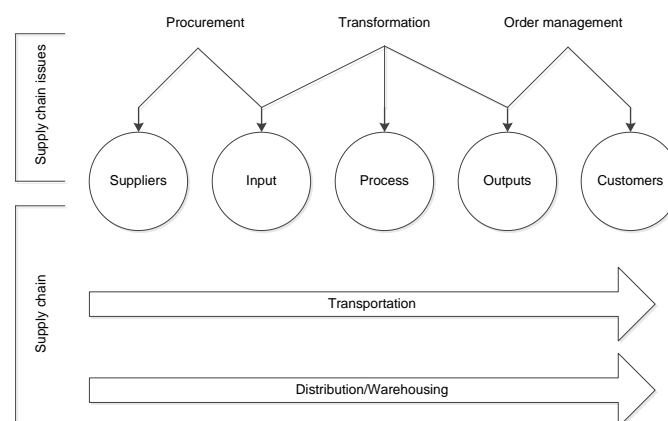

Figure 1: Corporate SCM

Also there are some external factors such as globalization, government regulations, environment, competition etc.

Military SCM, on the other hand, does not adapt to make profit. It is results-oriented in that sense that it integrates supply, maintenance and transportation functions with the physical, financial, information and communication networks to satisfy military requirements in shortest possible time with shortest expenses. There are, also, differences in external factors. Soldiers (Customers) needs are priority, Ministry of Defense regulations, environment, deployment, mission requirements etc. (Figure 2: Military SCM).

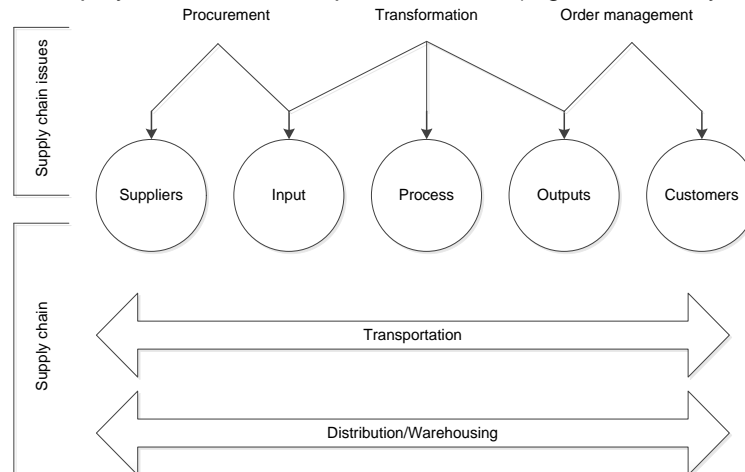

Figure 2: Military SCM

Another significant difference is relates to the number of intermediaries. Corporate SCM consists of several one way communication steps Manufactures -> Wholesalers or Distribution Centers -> Specific Distributor -> Retailer -> Customer, while Military SCM have two way communication and no intermediaries. From factory or specialized enterprise product goes to warehouse or depot and from that point directly to military unit.

Nevertheless, both military and corporate SCM are using for same problem. That is, optimization of available resources to operate in planned or unplanned events.[8, 9,10, 11 pp.253-257]

2. PROBLEM

Six Serbian enterprises has the permit for producing military equipment from Ministry of Defense . Those are:

- „Zastava oružje“ from Kragujevac;
- „Sloboda“ from Čačak;
- „Krušik“ from Valjevo;
- „Prvi Partizan“ from Užice;
- „Milan Blagojević“ from Lučani;
- „Prva Iskra“ from Barič.

About companies

All of these enterprises are oriented on developing and production of lightweight, semiheavy and heavy artillery. Among the most interesting products are infantry ammunition, anti-tank ammunition, ballistic equipment, automatic and hunting rifles and grenades. Although there is a demand for all products named above automated rifles and grenade launchers are of interest.

„Zastava oružje“ is joint stock company that employs over 2000 workers. They developed a wide range of products that are exported to over 40 countries in the world. It is 95% autonomous in production (only 5% are imported resources). Quality of their products is ensured with SRPS ISO 9001:2008 and SNO 9000/05 certificates. Beside military weapons, they have civilian program which includes: sporting rifles, pistols, air rifles and small-bore rifles. „Zastava oružje“ is focused on export which is proven by fact that export makes 95% of the product placement. By decision of the Ministry of Defense of the Government of the Republic of Serbia, they became a part of Defense Industry of Serbia in 2003.[\[4\]](#)

„Sloboda“ is ordnance founded in 1948. Their focus is on quality control and continuous investments in materials. Beside producing arms and ordnance, „Sloboda“ possesses its own laboratories specialized in

various kinds of measurements such as length, pressure and angle measuring, and in these laboratories all mechanical and chemical properties of materials are tested. The received certificate ISO 9001:2000 is the best indication of the high standards and quality of their products and services.[\[3\]](#)

„Krušik“ is producer of hunting ammunition which have about 60 employees. They have 58 machines and units for production at its disposal. It also has an organised Test Station as a function of research, development and quality assurance. The market potential of the FR Yugoslavia and its neighbours, as well as the competition, make „Krušik“ stand firmly in the position of the leader among the ammunition producers in this area, which means that 50% of its production satisfies the domestic market, and the remainder is directed to export and defense production.[\[7\]](#)

„Prvi Partizan“ is ammunition factory founded in Užice in 1928. They supply Serbian Army and Police, many foreign Armies and it also produces hunting and sporting ammunition, that is being sold all over the world. The factory has four production facilities, employs more than 600 workers and it takes important part in economy of its region. Today, „Prvi Partizan“ is modern factory, competitive with the most known world manufacturers, which in its production program has wide range of commercial and military calibers, pistol and revolver ammunition of the highest quality. Following the market requirements, with the strategy of permanent expansion of products range, Prvi Partizan continuously works on Research and Development of new products in this field, on research of new production programs, and on improvement of quality system, which is established in accordance with ISO 9001:2000.[\[5\]](#)

„Milan Blagojević“ is enterprise that belongs to defense industry with modern facilities that produces the products of the highest quality, well known to the world. The Company has 85% of export oriented business and accomplishes a successful cooperation in the field of the export of its products and services, with more than 30 countries around the world. Also, uses very high quality of raw materials from worldwide known suppliers. The main production program includes more than 20 products of special and commercial domain such as single base powder, double base powder etc.[\[1\]](#)

„Prva Iskra“ is company that begun with work in 1946 when started the production of TNT. Since then they developed their production program and today produces explosives DNT, Hexogen, Octogen etc.[\[2\]](#)

Limitations

Ministry of Defense in cooperation with the Ministry of Foreign Affairs and Ministry of Finance has signed an agreement about joint military exercise with the five former Yugoslav republics: Slovenia, Croatia, Bosnia and Herzegovina, Macedonia and Montenegro. Every country that signed agreement has obligations. Republic of Serbia will export automated rifles and grenade launcher to the appropriate military headquarters.

Every country has its own needs for weapons. They are given in Table 1.

Table 1: Demand for military equipment (in units)

Country Product	Slovenia (Ljubljana)	Croatia (Zagreb)	Macedonia (Skopje)	Montenegro (Podgorica)	Bosnia and Herzegovina (Sarajevo)
M21	840	1250	910	750	1000
BGA30	390	530	220	100	320

These products are produced in the „Zastava oružje“ enterprise but, for security reasons they are distributed in warehouses of the other companies.

Automated rifle M21 has caliber of 5.56 mm and it is basically a „Kalashnikov“ system, which is made only in one version. Whole industry can produce annually 5000 units intended for export. 54% of the total production capacity (2700 pieces) are in the warehouse of the factory „Zastava oružje“, 1200 pieces are in a factory „Prva iskra“, 800 pieces of stock are in the factory „Prvi Partizan“ and the remaining 300 rifles are stored in the factory „Krušik“. Price of one rifle is 1000\$ and its volume is 0.06 m³.

Grenade launcher is made as infantry weapon which also can be produced only in one version. The total production is allocated in the following manner: 800 pieces are stored in the factory „Sloboda“, 400 pieces in a factory „Prvi Partizan“, 300 pieces in a factory „Krušik“ and the remaining 100 pieces stored in the factory „Milan Blagojević“. Price of one grenade launcher is 2728\$ and its volume is 0.2 m³.

Ministry of Foreign Affairs, in cooperation with Ministry of Finance and Ministry of Defense, is responsible for every kind of export of military equipment. Regulation by Ministry are strict and only after fulfilment of those regulations the specific company or factory-supplier can export their products. According to the agreement, one of the companies' obligation is to pay costs of transportation. On the other hand, the obligation of the military is to provide, due to economic reasons, train wagons. Military can provide three types of train wagons, 5 closed wagons, 5 opened wagons and 3 platform wagons. All of train wagons are located in Belgrade. Closed wagons are of type Hbills-z (227), opened wagons are Eas-z (595) and both have effective volume of 65 m³. Platform wagons are of type Rs-z (390) and their effective volume is 120 m³.

Having the wagon capacities in mind, we can calculate how much weapon can fit in each type of wagon (Table 2).

Table 2: Maximum number of weapons that can fit in appropriate wagon

Wagons Product	Closed wagons (Hbills-z 227)	Opened wagons (Eas-z 595)	Platform (Rs-z 390)
M21	1083	1083	2000
BGA30	325	325	600

Cost of transportation is different from factory to factory because of destinations distance. Cost per kilometer is variable and depends of total transported weight. In this case, maximum capacity of available wagons is 10 t. Price per kilometer is 15 RSD. When we multiply distance with 15 RSD we get total cost of transportation from factory to specific military headquarters. Some of prices are omitted because they are too high, i.e. there is at least one better transportation path. Because „Milan Blagojević“ from Lučani is nearest to „Prvi Partizan“ every transportation will go through Užice, not directly from Lučani (Table 3).

Table 3: Cost of transportation from factory to military headquarters (in RSD)

Country Product	Slovenia (Ljubljana)	Croatia (Zagreb)	Macedonia (Skopje)	Montenegro (Podgorica)	Bosnia and Herzegovina (Sarajevo)
Barič	4410	3330	3765	3480	2865
Užice	5130	4410	3765	2355	1785
Lučani	/	/	/	/	/
Valjevo	4770	3615	/	/	1860
Kragujevac	5490	4410	3045	/	/
Čačak	5490	4410	3330	/	/

When train delivers military equipment, it has to return to the start location (factory). However, cost of returning empty train are lower than transportation costs. Price of returning are given in table 4, and they are calculated by multiplying distance with 8 RSD. Before returning to Belgrade wagons need to be examined and cleaned, which cost 1000 RSD.

Table 4: Cost of transportation from military headquarters to factories (in RSD)

Country Product	Slovenia (Ljubljana)	Croatia (Zagreb)	Macedonia (Skopje)	Montenegro (Podgorica)	Bosnia and Herzegovina (Sarajevo)
Barič	2352	1776	2008	1856	1528
Užice	2736	2352	2008	1256	952
Lučani	/	/	/	/	/
Valjevo	2544	1928	/	/	992
Kragujevac	2928	2352	3045	/	/
Čačak	2928	2352	1776	/	/

Since all train wagons are located in Belgrade, there are cost of arrival of train wagon from Belgrade to appropriate factory. Those cost are calculated by multiplying distance (number of kilometers) and 8 RSD (table 5).

Table 5: Cost of transportation trains from Belgrade to factories (in RSD)

From \ To	Barič	Užice	Lučani	Valjevo	Kragujevac	Čačak
Belgrade	0	1264	1264	736	1096	1080

Since Barič is part of Belgrade, there are no costs of transportation from Belgrade to Barič. Also, since Lučani are close to Užice, costs for Užice and Lučani are the same. Costs of returning wagons from factories to Belgrade are the same as from Belgrade to factories.

Since the Ministry of Finance of the Republic of Serbia accepted to cover the costs of transportation, it is necessary to determine the number of wagons of all three types, in order to minimize that the total transportation costs is minimal.

3. ALTERNATIVES

The main performance in military SCM is time of delivery. Delays in transportation can lead to tragic consequences. Because of that and the fact that railway traffic in Serbia tends to be late, the Army should analyze the alternative ways of transportation.

One option is road traffic. Advantages of road transport compared to rail transport are flexibility in the choice of the roads and the vehicles for transportations as well as the possibility of transporting weapons without going to Belgrade. However, there are some disadvantages. The main disadvantage is the fact that road transportation costs more since it is necessary to provide a large number of people and vehicles for one shipment. Another problem that may occur is the determination of the best road for transportation. Factors that should be considered are road conditions, traffic jams etc.

Second option is air traffic. This kind would definitely be the fastest, but the most expensive one. The main problem in this kind of transportation is number of airports in Serbia and the distance from factories to the airports. Airports that should be considered are "Nikola Tesla" in Belgrade which is international civil airport, "Ponikve" in Užice and airport "Lađevci" near Kraljevo which are military airports. Other airports are either too far or unequipped.

Water traffic should not be considered, because most of the factories don't have exit to wide enough rivers and there are no direct ways to destinations.

³University of Belgrade, Faculty of Organizational Sciences, marija.stepic@gmail.com

Abstract: *Marijana Knezević, engineer of organizational sciences, and Vasa Despotović, agricultural engineer, spent their entire childhood playing in the dusty Kajmakčalanska Street in Bakčine, the hamlet of Ramnice. Ramnice is a large village near Belgrade. Like all other parts of Serbia, their village is affected by apathy, a disease that misleads people and gives them false appearance of a bleak situation. In order to regain control of their lives and to improve life of their fellow citizens, Marijana and Vasa decided to focus their skills on the development of their community. Soon, the idea of reviving, once successful agricultural cooperative was formed.*

Unused farms should be converted into orchards. Problem of dividing available farmland into agricultural cultures should be solved using linear programming. The goal is to maximize profit. After the harvest, it is necessary to find a way to keep the products fresh, until they reach customers. There are two options. The first one is the construction of warehouses for the products. The second option considers purchasing or renting trucks, which will transport products to the customers. Closed transport model should be used in the analysis. Usage of Vogel method (method of least differences) is recommended for the determination of the initial solution and Modi method (potential method) for verification of optimality.

Keywords: *linear programming, operational research, agriculture, transport model*

1. DESCRIPTION OF THE PROBLEM

"Now, when we have won them over, everything else is a piece of cake!" Marijana sighed and looked at her associate Vasa. They were coming out of the meeting with representatives of Ramnice, a large village near Belgrade. The meeting was about reviving the largest agricultural cooperative of Belgrade's suburbs.

Marijana Knezević, engineer of organizational sciences and Vasa Despotović, agricultural engineer, who spent their entire childhood playing in the dusty streets in Kajmakčalanska in Bakčine, the hamlet of Ramnice. Neither one of them had an opportunity to apply their knowledge, although some time has passed since they graduated. Like all other parts of Serbia, their village too is affected by apathy, a disease that misleads people and gives them a false appearance of a bleak situation. Unemployed or low income, with no hope that it will get better, people feel helpless and listless. In order to regain control of their lives and improve life of their fellow citizens, Marijana and Vasa decided to focus their skills on the development of their community.

The idea of reviving the once successful agricultural cooperative was formed. Marijana and Vasa made the necessary soil analysis, feasibility study and made plans for planting fruit. It is necessary to obtain the consent of farmers and provide their assistance in achieving these plans. All farmers must participate and be ready to follow directions of agricultural engineer. The problem is the farmer's mentality. They are not receptive to new ideas and their general attitude is "I don't care if he's got a degree, no kid is going to tell me what to do!". Their stubbornness is hard to overcome and that is why Marijana and Vasa felt nervous about exposing their ideas at the meeting.

However, faced with the impossibility of product placement on the market and huge losses due to lack of organization, the farmers were more than willing to accept any proposal that would provide them gains. The new agricultural cooperative would provide customers, like food factories, with large quantities of fruit, flour and corn. The plan is to plant fruit on unused farmland. Each farm must comply with the plan presented by agricultural engineers, who are employees of the agricultural cooperative. The plan is designed based on a soil analysis.

Ramnica is one of the largest villages of the district. It has 9000 inhabitants, of which 6000 are working age population, and 2000 of them are unemployed. Unemployed workers have different qualifications and 1000 of them can be employed in the processing of agricultural land.

Farmers decided to give an opportunity to young enthusiastic people, hoping that they will succeed in bringing new jobs and increasing gains. Marijana and Vasa agreed with the farmers to present a final plan at the next meeting. Content of the final plan consists of list of cultures that need to be sown, number of employees, amount of total costs and methods of storage or transportation of products after harvest. If the results of the analysis are satisfying, execution of the plan will commence.

2. THE CURRENT SITUATION

Ramnica's area covers 5918 ha. The agricultural area occupies 3418 ha of the total area.

Table 4: Distribution of cultures on occupied agricultural area

Name	Area [ha]
Orchards + strawberry plantations	140
Wheat	900
Corn	710
Soybean	24
Vineyards	100
Animal husbandry + forest	1000
The total agricultural area occupied	2874

Free or unused farms need to be converted into orchards. Cultures that will be planted are plums, cherries, sweet cherries, peaches, apples and pears. The relief is characterized by the variety of forms, alternation of mountain and lowland areas. There are different types of soil – chernozem, smonitsa, eutric, cambisol, clays and sand. These types of land are suitable for growing all 6 cultures. Distributions of cultures need to be determined regarding the benefits and characteristics of soil types. The rolling hilly and mountainous areas, even steeper slopes, are perfect for growing plum orchards. That is why it was decided to plant plums on at least 60 ha of suitable land. Slopes and gentle slopes, facing south, southeast and east are best for growing cherries, so these are the areas where cherries will be planted. Cherry should be planted on at least 80 ha. Sweet cherries need a lot of light and open space, so suitable soil needs to be provided and sweet cherries will be planted on at least 70 ha. Since early spring frosts are a normal occurrence in these parts, peaches should be planted on the north side. Trees will be slightly longer in the rest period, but the majority of the buds will remain in a good, vital state. Therefore it is possible to plant peaches on maximum 150 ha and they should be planted on at least 50 ha. In order to develop the production of apples, a decision has been made to plant apples on at least 90 ha. Chernozem and brown forest soil are important for growing pears, so pear orchards should be planted on at least 70 ha.

In the spring, all orchards require pruning and upkeep, painting and sprinkling trees with fungicides and insecticides. It is also necessary to maintain the health and productivity of the trees. Peaches, cherries and sweet cherries are being harvested in the spring. Plums, apples and pears are being harvested in the fall when it is also necessary to prune fruit. In order to ensure the highest yield orchards require 7 days work per week (30 working days per month; no work during winter). The daily working rate is 800 dinars.

For protection of the fruit from pests it is necessary to use different types of fungicides and insecticides. Some of the fungicides and insecticides that are being used are BOTRYSTOCK, PRESING, VITRA WP, RIZA 250EW, WIZZZAARD, CYREN 480EC and PYRINEX SUPER 420EC. It is also necessary to use different products for plant nutrition during the year, all in order to ensure the highest yield. Plant nutrition products are VERASOL and HERBAGREEN. The average cost of products for nutrition and protection is 800 dinars per 1 ha area.

Table 2: Price of products and average yield of cultures

Name	Price [din / kg]	Yield [t / ha]
Plum	45	3375
Cherry	45	132.35
Sweet cherry	135	34
Peach	54	375
Apple	50	450
Pear	126	476.47

After the harvest, the main problem is finding a way to keep the products fresh, until they reach customers. This can be achieved with adequate storage or with transportation to the customer immediately after harvest. The Fund for development of the Republic of Serbia has awarded grants totaling 150 million dinars for the development of agricultural cooperative and therefore the whole village. Those funds can be used in 2 ways. First one is the construction of warehouses for the products. The second option considers purchasing or renting trucks, which will transport products to the customers.

Option 1: Building a warehouse

The amount of fruit after the harvest will exceed current accommodation capacity of the village. It is essential to find a solution for this accommodation problem, because the nature of fruit is very sensitive and the period of time it can stay fresh is short. Good storage will preserve the quality of fruit as long as possible. A modern type of storing fruit is controlled atmosphere (CA) storage, which corresponds to international standards. Building this kind of a warehouse is more expensive, but it would provide cooperation with foreign food factories.

Only one type of fruit can be stored in each chamber of this storage. The storage period significantly depends on the biological specificity of the fruit. Therefore tangible differences occur in the durability of sorts. CA storage uses changed atmosphere within the chamber that consists of lowering the proportion of O₂ and increasing the share of CO₂. The following table shows the time of storage for certain types of fruit in their chambers.

Table 3: Time of storage of fruits in CA chamber

Name	Time of storage
Apple	3 – 8 months
Pear	2 – 6 months
Peach	2 – 4 weeks
Sweet cherry	2 – 3 weeks
Cherry	3 – 7 days
Plum	2 – 5 weeks

In order to store fruit after the harvest, it is necessary to build four warehouses. The price of building a warehouse is 21.000.000 dinars. The following table presents the costs associated with operation of the warehouse.

Table 4: Costs associated with operation of the warehouse

Cost	The amount of the cost (din / month)
Warehouse maintenance	40000
Insurance	16000
Worker's salary	200000
Electricity and water	60000
Other	30000
Total	346000

To cover the cost of storing the goods and ensuring the normal functions of the warehouse and cooperative, the plan is to increase the price of products by 1%. Farmers will be paid for their products by previously determined price and the agricultural cooperative will retain the difference in price (1%).

Option 2: Transporting the goods

When it comes to transportation and sales of grains, farmers already have established procedures, so young, hard working and ambitious graduates did not want to interfere. Therefore, it is envisioned that transportation will be managed through agricultural cooperative.

In previous years, plums were grown on 8.6 ha, cherries on 5.7 ha, sweet cherries on 18.5 ha, peaches on 1.2 ha, with apples and pears on 2 ha and 14 ha, respectively. Based on the yield that was mentioned before, it is possible to calculate the predicted amount of fruit for the following year, expressed in tons. Certainly, it is necessary to include these amounts in the total transport, including products of new orchards.

It is known that certain fruits have been harvested at different times of the year, mostly in the summer and autumn months. Therefore, Marijana and Vasa, prepared the following table, which shows when certain fruits are harvested and transported.

Only apples and pears can be preserved during winter, so they are transported throughout the entire year.

Cherries and sweet cherries are very sensitive, so these fruits must be transported as soon as they are harvested. Harvesting and transportation are done every third day throughout the month.

Because there are large quantities of plums and they are easy to harvest, plums are harvested and transported three times per day, during September and October.

Peaches are present during summer, and their transport is performed 10 times per month.

Table 5: Period of harvesting and transportation of fruit

	January	February	March	April	May	June	July	August	September	October	November	December
Plum												
Cherry												
Sweet cherry												
Peach												
Apple												

The farmers usually deliver their fruit, after harvest, to one of five large farms, which are owned by the most famous and the wealthiest families in the village, Matijević, Mihailović, Teofilović, Mišić and Todorović. The same amount of fruit can be placed on every farm. Picked fruit is going to be sold to the most famous producers of fruit juices, Fruvita, Nectar, Coca-Cola Hellenic and Rauch. If agricultural cooperative takes responsibility of transportation, it will have to provide trucks, drivers and perform transportation from farms to factories, which produce juice. After hard work, Marijana and Vasa succeeded in defining the transportation costs per ton of transported fruits. These costs are calculated taking into account the distance from factories to farms, the price of fuel and driver's wages and are valid for any time of year.

Table 6: Transportation costs from farms to factory

	Fruvita	Nectar	Coca - Cola Hellenic	Rauch
Matijević farm	350 din./t	500 din./t	200 din./t	400 din./t
Mihailović farm	200 din./t	250 din./t	200 din./t	300 din./t
Teofilović farm	100 din./t	150 din./t	350 din./t	200 din./t
Mišić farm	300 din./t	400 din./t	100 din./t	450 din./t
Todorović farm	150 din./t	200 din./t	300 din./t	250 din./t

Considering different types of fruit that will be harvested, transported and sold at different times of the year, Marijana and Vasa divided the year into three periods:

1. November-May

2. June-August
3. September-October

In agreement with the producers of fruit juices, young graduates have obtained the following data on the overall demand for the upcoming year, according to the periods.

Table 7: Juice factory demand per year

Demand	Fruvita	Nectar	Coca-Cola Hellenic	Rauch
November – May	10000 t	7500 t	12000 t	18000 t
June – August	12000 t	8500 t	15000 t	22350 t
September - October	140000 t	115000 t	150000 t	258600 t

It is essential to determine the number of trucks necessary to realize the transportation needs of products. Funds raised from the Fund for development of the Republic of Serbia will be used for this purpose. The need for trucks will vary during the year and that has to be considered when deciding on the number of trucks needed. There are two options – buying new trucks and cooperation with Sa&Qu Sped, a transportation company.

Regarding purchase of new trucks, the ones in consideration are those of 30 t and 50 t capacity and their prices are 4.500.000 din and 7.500.000 din, respectively. If the company chooses to do business with Sa&Qu Sped, their service cost will be 9.000 dinar per tour.

To cover the cost of transportation products, truck maintenance costs and to ensure the normal functioning of the agricultural cooperative, the plan is to increase the price of products by 1.2%. Farmers will be paid for their products by previously determined price and agricultural cooperative will retain the difference in price (1.2%).

3. PREPARING FOR THE MEETING

The meeting with representatives of Ramnice was approaching and it was necessary to prepare the results of the analysis in the form of reports that are understandable to everyone. After "putting all the numbers on paper", Marijana started compiling the required analysis and reports.

The first thing that needs to be done is to make optimal distribution of agricultural cultures on arable land using software for linear programming (recommended software is Lindo). After implementing that distribution of cultures, yield and profit per culture should be calculated.

Once the yield is known, it is necessary to decide on the method of utilization of funds received from the Development Fund of the Republic of Serbia.

Regarding warehouse, total costs of construction and maintenance of the warehouse should be calculated. It is also necessary to determine whether the increase in sale price by 1% is enough to cover the costs of maintaining the warehouse.

Funds may also be used for the purchase of trucks. In this option total costs of transporting products and the number of trucks you need to buy or engage via Sa&Qu Sped company should be calculated. Determine if a better option is to buy a certain number of trucks, and engage the rest when needed. It is also necessary to determine whether the increase in sale price by 1.2% is enough to cover transportation costs.

(Values of fruit quantities should be rounded up to the next whole number; closed transport model is used in analysis. Usage of Vogel method (method of least differences) and MoDi method (potential method) is recommended for the determination of the initial solution for verification of optimality)

Once you get the costs for both options, it is necessary to compare them and choose the one that is more productive and profitable.

Consider different ways of investing generated profit in the further development of village and community. Give some suggestions and explain why it is important to invest that way.

AM.PM. – OVERCOMING CONSERVATIVE PURCHASING BEHAVIOR IN FOREIGN MARKET

Marko Krsmanović

1. INTRODUCTION

Established in 1873 in France, La Redoute is today the leading company in mail order and online shopping, as well as in the women ready-to-wear market. For a long time, La Redoute has been successfully operating in many countries worldwide. Their specialized furniture catalogue AM.PM. has been introduced in several countries and continues operating in a same line of success as La Redoute. However, Spain wasn't in a list of countries in which AM.PM. operates, so Spanish subsidiary of La Redoute decided to launch AM.PM. brand in Spain.

Based on in-depth analysis of internal and external factors, the opportunity gap in the market was found in which AM.PM. can be positioned. Further marketing research conducted on customers that are found in this gap revealed that there is a tremendous difference between purchasing behavior of French and Spanish customers. In order to move closer to Spanish customers, the company had to adjust its current distribution channels.

This study is based on authors research and strategic marketing plan prepared for the company La Redoute for the purpose of entering the Spanish market with their furniture brand AM.PM.

2. THE COMPANY

The company was founded by Joseph Pollet in 1873 under the name of "Les Filatures La Redoute". The first catalogue, consisting of only 16 pages, was printed in 1928. It took almost 30 years until the first exclusive furniture catalogue was printed in 1956. Ten years later, the company opened the first La Redoute store in France. With the gradual increase of the popularity and prevalence of the Internet, the company established its website in 1998. As of 2005, La Redoute serves more than 12 million customers worldwide.

La Redoute is not only the leading mail order trade company in France, but also the leader in the woman ready-to-wear market and in the e-commerce. La Redoute is the flagship brand inside the PPR Group, Pinault Printemps Redoute, which generated a turnover of €4.377 billion in 2005. The company is a part of the Redcats (Redoute Catalogue), which is the retail division of PPR.

Operating all over the world, including France, United Kingdom, Switzerland, Sweden, Portugal, Germany in Europe, United States and Russia (the latest entry in July 2006), La Redoute is offering its customers a service of proximity through catalogues and Internet: Clothes collection for women, men, babies and children, interior decoration, linen and furniture (depending on the country). They publish two catalogues per year, autumn/winter and spring/summer seasons, with 7.3 million copies globally sent to the customers. La Redoute served 12 million customers in 2006 worldwide.

In its home country, France, La Redoute enjoys massive brand awareness. With an existence of over a hundred years, La Redoute succeeded in integrating its business model perfectly in the minds of the customers. La Redoute has opened the office in Spain in 1992.

3. AM.PM. BRAND

AM.PM. is one of the specialized catalogues, which are sent to the customers under the brand La Redoute. The AM.PM. catalogue offers a collection of furniture for home under different themes: Campagne, Rustique and Modern.

The catalogue aims to offer the kind of furniture corresponding to the needs and expectations of La Redoute customers, and to the potential customers which are not La Redoute customers yet, a wide range of furniture, trendy and with different styles, appealing to different kinds of taste and preference.

This catalog emphasizes the company's wish to reach different customers by offering a complete collection of items with different styles, corresponding to different kind of interiors.

4. SPECIFIC PROBLEM

The greatest challenge in the Spanish market for any company that is doing distance selling, based on marketing research, is a conservative purchasing behavior of Spanish customers. This conservatism of Spanish customers is seen in their resistance toward distance shopping, because they are ready to buy only products that they can see and touch before purchasing. In order to overcome this challenge, the company had to find the new model of distribution that will allow customers to see and touch a product before they decide to buy it. Based on surveys conducted in Barcelona metropolitan area, 85% of potential customers have never bought furniture via distance shopping distance shopping distribution channel, but in the same time, 80% of them would consider buying furniture over catalogue and/or internet if they have a chance of seeing it in a store before making a purchasing decision.

5. WHY IS DISTANCE SHOPPING UNPOPULAR AMONG SPANISH CUSTOMERS?

The distance shopping business is not popular in Spain due to historic reasons. The Kingdom of Spain preferred to remain neutral to both World War I and II and this choice excluded the country of the massive damages of the post-war periods and kept it apart from the misery, through which all the countries involved in the war had to go for a long time. The post-war period is the time when all mail order companies became so popular in whole Europe, since the rest of the trade was suffering. _Since countries like Germany and France were highly destructed in terms of economy, only the mail order companies were available to offer goods to customers. During the 20th century, although all these countries already recovered their economies, mail order shopping remained popular and it still is, although all kinds of goods were available in the market by now. Therefore, mail order shopping is already included in their shopping culture and is a part of their shopping attitude.

Nevertheless, this is not the case in Spain. In spite of all the efforts to improve e-commerce in Spain, Spanish people are gradually getting used to shopping from catalogues or mail order companies by now. (Euroresidentes, 2007)

Although online shopping is improving recently in the last years, Spaniards still have complaints and concerns about it. Most of them complain of the low availability of articles and state that they want to go out and buy these personally. They also find the quality of Internet service in Spain annoying, due to low connection speed. In addition to these, Spaniards are still not very comfortable with providing their credit card numbers when shopping online. Due to such drawbacks, the increased public investments in the e-commerce can only improve the sector very slowly.

6. CONSUMER ANALYSIS

Primary consumer analysis was based on the marketing research done in December 2001 and September 2003 in Barcelona by Instituto DYM and on the analysis of statistical data provided by Ajuntament de Barcelona and Generalitat de Catalunya. The aim of this consumer analysis was to discover possible target customers for further marketing research that will narrow AM.PM.'s product offer to one core target group. (Instituto DYM, 2001, 2003)

Second stage of consumer analysis was based on the results of the marketing research conducted in Barcelona metropolitan area by the author of this case study in a period from January to April 2007. The second stage contained three survey researches, each on a sample of 1000 potential customers. The results of the first survey led to the definition of AM.PM.'s core target group. Results have shown that women are decision makers most of the time. They choose the products for the whole family or for themselves. 80% of women respondents mentioned that they are the ones who choose what to buy. On the other hand, 70% of the men respondents mentioned that they choose which product to buy with their wives. So, the results

showed that women are more involved in decision-making process for furniture, which resulted in the decision to focus on women as the target group. Other characteristics of core target group based on marketing research are:

Age:	25-45
Gender:	Female
Income:	1500 EUR – 4000 EUR
Occupation:	White-collar, Office worker involved with internet usage
Choice Criteria:	Design & Quality for a fair price with ease of purchase
Lifestyle:	Hard-working, economically independent, limited time for shopping, high internet usage, visiting gym in a free time
Purchasing Structure:	Open to new models that make her save on time such as Internet
Purchasing Process:	Decision maker for herself and her family Buyer-herself User- herself or the family if married or has children

Second and third surveys have revealed that the Spanish customers are very conservative when it comes to the usage of distance shopping and that they do not feel comfortable if they cannot see and touch the product before making purchasing decision.

7. CURRENT DISTRIBUTION MODEL

AM.PM. has two sales channels; the first one is the catalogue, which the customers receive to their homes, and they have the possibility to order through telephone, Internet or by mail with the paper forms they receive with the catalogue.

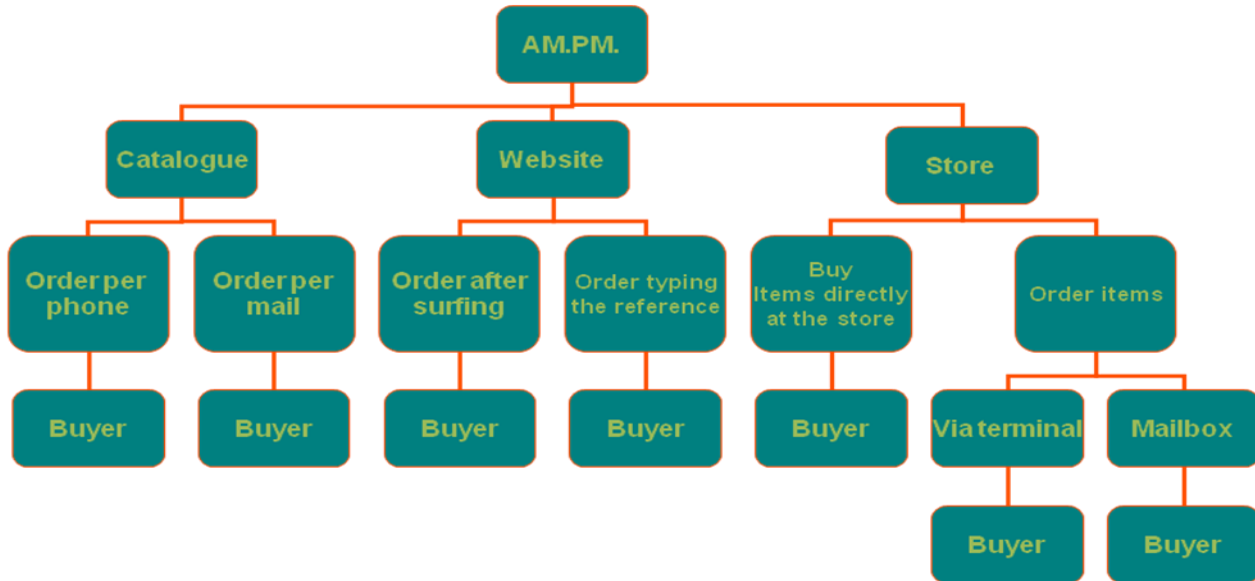

The second channel is the Internet. Through the web site of La Redoute, where customers can find all the articles classified according to their segment and function (women, men, children, interior decoration, brands).

8. THE NEW CHANNEL: AM.PM. FLAGSHIP STORE

Results of the research conducted for the Spanish market has showed that the Spanish consumer wants to see and touch the product before buying it. Based on this information, the decision to open the flagship store as a new distribution model was made. The objectives to reach with the AM.PM flagship store are to:

- Give the customers the opportunity to see the products of the company
- Create brand awareness
- Support the existing channels such as e-mail, phone and internet

9. MODEL OF DISTRIBUTION CHANNELS OF AM.PM. WITH THE FLAGSHIP STORE CONCEPT:

10. ISSUES WITH FLAGSHIP STORE OPENING

As stated before, the concept of flagship store will help company to overcome the challenge imposed by conservative purchasing behavior of Spanish customers. However, when costs of opening and running a flagship store are added to profit and loss account, we get the situation in which AM.PM. will have operational loss in the first two years of almost 700.000 and 250.000 Euros respectively, while without the flagship store concept it is profitable from year one in the amount of approximately 150.000 Euros. Should company continue with opening of flagship store and plan operational loss for next two years or go without the flagship store and be profitable from year one but with the risk of losing potential customers who are too conservative to buy furniture through catalog or over the internet?

11. CONCLUSION

After a detailed analysis of both alternatives, the management has decided to go with the flagship store concept because even though the company would run operational loss for two years, during the third, fourth and first half of the fifth year, it will be able to generate enough profit to cover the loss from the initial two years. From the second half of year five and during year six, it will increase its profit to the amount much larger than it would be able to generate cumulatively for six years without flagship store. The reason for this is the fact that only with the flagship store, the company would be able to get closer to its potential customers and to offer them a unique shopping experience by combining traditional and modern way of furniture shopping.

ANALYSIS OF E-GOVERNMENT IMPLEMENTATION IN SERBIA AND COMPARISON WITH SUCCESSFUL PRACTICES IN FORMER YUGOSLAVIAN COUNTRIES

Žarko Čolović

Abstract: This case study deals with the concept, types and characteristics of E-Government and describes the way in which this modern form of public administration is applied in Serbia, as well as in surrounding countries. The paper contains a theoretical framework that explains the concept, characteristics, and types of E-Government. Also it defines the criteria for monitoring the level of development and summarizes the most important services of the E-Government. The research part provides access to the legal basis on which and through which E-Government functions. It describes the international law, documents and acts of the European Union. The third part of the paper defines the purpose and methodology for the research and establishes a working hypothesis, which is being further researched. In the following sections this paper deals with the study of E-Government in Serbia, as well as countries in the region, and through analysis of its most important service for citizens, businesses and public administration itself. The paper, apart from Serbia described e-government in Slovenia, Croatia, Macedonia, and Bosnia and Herzegovina. Based on the available & collected secondary data it has been made direct comparison between the levels of development of these countries. Also it examines the survey and analysis of available information and summarized the results in order to successfully respond to the previously established working hypothesis.

1. INTRODUCTION

Field of research of this case was the level of successfulness in implementation of electronic government in Serbia and benchmarking with the former Yugoslavian countries (ex-Yu). Before analyzing the subject, the author set theoretical ground in this subject by defining the E-Government, its definition, characteristics, development, and legal framework. Further on with comparative analysis of practices in Serbia and the countries in the region, author provided, from secondary available data, quantitative performance indicators E-government in ex-Yu countries to reflect the true picture of progress in implementation.

2. E-GOVERNMENT IN GENERAL

E-Government is changing the way that the public service is functioning. The model of communication which has previously been a clerk intermediary between the state and the citizen shall be replaced by direct communication. To bring a service offered over the Internet it is necessary to integrate all municipalities, databases, organizational units – a rather complex project whose implementation must be done from a clearly developed strategic approach. Only with successful implementation, E-Government can coordinate the work of public services, improving their organization and providing overall higher quality of services. This technology, in its all, has the potential to redefine and revitalize the relationship between citizens and government.

It is hard to determine the crucial dates when the breakthrough in development was made. In December of 1999, EU Commission started the e-Europe initiative called "Information Society for all" with main goal to connect all the advantages of IT Society with all European citizens. The initiative has set the three main goals:

1. *To establish the online connection for all citizens, households, schools, businesses and governments;*
2. *To create IT educated Europe, supported with entrepreneur spirit, ready for financing and developing new ideas and technologies;*
3. *To enable that the whole process be transparent and social-inclusive, to establish the trust of users and empower social cohesion.*

First official step in Europe was made in March of 2001. in Naples, on the Third Global Forum under name "Fostering Democracy and Development Through e-Government" when the project of creation, implementation and development of e-Government was created.

There are numerous definitions of e-Government nowadays. But, one of the most practical probably is that e-Government presents online exchange of information and service between citizens, business and public municipalities. Also, for the need of this case, author use definition that the e-Government is a most efficient way on which Governments are using information technologies in order to provide its information and services to their citizens. Common thing to these two definitions probably is that e-Government involves the optimization and computerization of existing procedures which will requires in the future new ways of managing, negotiating, strategic decision-making, new ways of businesses and new ways in communications (Rogers, 2002). At the end, e-Government has as its goal to improve access and delivery of government services & benefits to the citizens. In his research Bretschneider (2003) has highlighted the creation of Internet as a best technological breakthrough which is affecting the telecommunications, technologies and overall progress of computer technologies, resulting with the more efficient support for development of e-Government.

Implementation process

Briefly, successful implementation of e-Government, proved by best practice experience is done systematic with strategic approach. From real life practice, it means that Country that is aiming to implement such model of governance needs to arrange:

1. Legal framework that will support and protect to functioning of e-Government
2. Adequate ICT infrastructure, implemented in all parts of governmental bodies (institutions, municipalities, ministries) from the lowest to the highest level of hierarchy
3. Important strategic documents and plans:
 - *National strategy for development of Information society (for next five years at least)*
 - *National plan for development of Information society*
 - *National plan for implementation of e-Government, with coordination on local authorities and municipalities and the highest governing bodies in the country*

European Union with EU Commission provides help to all of its countries in implementation processes. But all these are only the ground documents and plans. If the process of implementation of e-Government is started without clear strategy, it can lead to a numerous problems. For example, in Serbia in the first years of development (2001-2003), instead of having the national strategy in development of e-Government supported from the highest governmental levels, local municipalities were the initiators of implementation process, focused on local level only, with out clear vision for the future and any possibilities for integration on regional and national level.

Hiller and Belanger (2001) identified five stages in implementation of electronic government: (1) information, (2) two way communication, (3) transaction, (4) integration and (5) participation. Modernizing the Hiller and Belanger's model, Moon developed (2002) similar model (despite some minor differences in phrasing): (1) Simple information dissemination (one way communication), (2) Two-way communication (request and response), (3) Service and financial transaction, (4) Vertical and horizontal integration, (5) Political participation.

United Nation Public Administration Online network (UNPAN) presents five stages of e-Government as (1) emerging web presence, (2) enhanced web presence, (3) interactive web presence, (4) transactional web presence and (5) fully integrated web presence.

Importance of the legal framework

Government activities are heavily regulated and initiated in legal frameworks including national legislation and other related laws and regulations and international legislation which deals with this area. Thus, the E-Government should first be supported by local laws and regulations for its legitimacy and legality. Then, when the E-government launch the passive provision of information in an interactive phase (where the electronic services is provided, or State begins to provide services and / or goods on the Internet), e-government is the equivalent form of electronic commerce. Successful e-government is sustainable in an environment free of legal barriers and, therefore, legal reforms are made to support, not interference to electronic administration.

When it comes to international models and laws governing the E-Government, faced with a broad list of subjects treated with such laws and regulations, such as e-contracts, delivery terms and guarantee the provision of online services, data protection and privacy, security and reliability, electronic signatures, electronic payments, consumer protection, intellectual property rights, cyber crime, taxes, and so adopted a legal infrastructure to enable e-Government to achieve its objectives, with no legal barriers and obstacles, and will essentially focus on the following:

1. *Legitimacy*
2. *The recognition of electronic documents and transactions*
3. *Authorization*
4. *Privacy Policy*
5. *Freedom of information*
6. *Cyber Crime (Mohamed, 2009)*

A very important part of information society as a whole, and especially E-Government is the legislation. The EU countries have harmonized legislation in the E-Government, and it is mainly divided into two groups:

- *primary legislation (E-Government in the strictest sense, freedom of information, data protection and privacy) and*
- *Legislation for services and infrastructure*

Most European countries, according to e-Government initiatives that are mainly related to the improvement of governance are at the national level. Significant activities of e-Government take place at the European Commission (EC). In addition to the many laws, the Commission adopted an action plan the "eEurope 2005" that has brought many changes and progresses in the field of e-Government. One of the key action points for achieving goals-convergence of public administration to citizens and businesses by providing modern public services via the Internet (e-Government). Also, EC adopted the document entitled "i2010 - A European Information Society for Growth and Employment", as well as the Ministerial Declaration and guidance from the Ministerial Conference "Transforming Public Services, 24 November 2005, Manchester, UK." At the EU level are defined by common goals and principles and the provision of resources by the financial support programs and professional development of information society, especially in the candidate countries for membership.

3. METHODOLOGICAL FRAMEWORK OF THE RESEARCH

Purpose of research

The purpose of the research results to the quantitative indicators E-government in ex-Yu countries is to reflect the true picture of progress in implementation of the e-Government. The ranking of countries according to any basis, including the results of the E-Government is established on the secondary data of the United Nations on the basis of indicators: e-readiness, Web index and index of infrastructure. The aforementioned indices will serve as a tool for understanding the strengths and weaknesses of implementation. Evaluation of the public sector is tracking a set of technical characteristics: accessibility, adaptability and reliability of service, or organization, such as efficiency, productivity, motivation, and the like. Such data may be particularly challenged when it comes to ranking countries in certain areas, and the ranking results can be inaccurate.

Research Hypotheses

H1: Serbia does not lag behind in developing E - government in the countries ex-YU;

H2: Compared to 2005, Serbia has made progress in the development of E-Government;

Methods of research

The study will use a method of comparative analysis of quantitative indicators of development of electronic government in the period 2005-2010. Based on comparative analysis will be drawn concluding observations and to check the truth of the hypothesis. Indicators should be a balance of influence and contribution of E-Government. Reports and rankings are viewed as tools with which you can access the current status of certain areas and further development of electronic services. As one of such tools can also serve as a UN report, which provides quantitative data on the willingness of member countries for e-government. Generally, the ranking of countries in relation to e-readiness is performed by Economist Intelligence Unit. However, their data do not apply to all countries, and will, in this paper, data will be used for UN.

4. RESEARCH

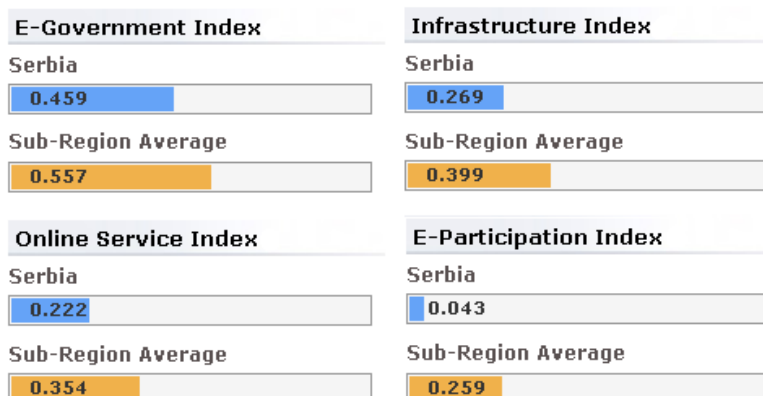

E-Government analysis in Serbia

The total level of sophistication of e-Government in the Republic of Serbia in 2009. amounted to 51% (in 2008. amounted to 47%). Comparing to that it is relevant to mention that according to recent data (RZS, 2011¹) 52,1% of households poses computer and 41,2% of households have the installed internet connection. Rapid sophistication of modernizing the internet connection in households was noted in 2009. (RZS, 2009) when for the first time percentage of households having the ADSL connection was higher then the percentage of the households with dial-up connection.

The sophistication of the basic set of 20 services according to Capgemini², the EU set of 27 + countries for 2007-2009 amounts to - 76% in year 2007. and 83% in year 2009. The overall sophistication of e-Government in the Serbia, when the same group of services is compared (Capgemini, 2011), is 38% in 2007. and 46% in 2009. These data clearly show that Serbia is significantly behind the EU and the countries in the region (Croatia, Slovenia) in the overall level of sophistication of electronic services. While the results of the UN Public Administration program³, Serbia has a variable index of E-Government services (Picture 1).

Picture 1: E-Government index development in Serbia (UNPAN, 2011)

Picture 2: Comparison of E-Government indexes (UNPAN, 2011) compared with region averages

Also, according to a UN E-Government database, compared to countries in the region, all measurable indexes (Picture 2): E-Government index, Infrastructure index, E-Participation index and Online index, are below region averages (UNPAN, 2011).

E-Government analysis in Bosnia

Public administration in Bosnia and Herzegovina (BiH) provides public services in 146 municipalities, 10 cantons, two entities, Brčko District and the level of Bosnia and Herzegovina. Obstacles and barriers to the introduction of e-government in BiH are classified into three categories: people, technology and organization. Objective problems are serious, and above all lack of funds and human resources, social pressures, lack of coordination and a common systematic approach with external parties, etc. BiH was for the first time included in the World Economic Forum (WEF) report from 2004/2005⁴, where it was ranked as 89. from 104 countries, sorted according to level of successfulness of compared web, infrastructure and e-readiness

⁴ World Economic Forum, Global Information Technology Report 2004-2005.

indexes. From the series of these WEF reports in period from 2004. to 2009. Bosnia and Herzegovina had rather slow progress in implantation and development of e-Government, according to measured indexes. According to measured data taken from portal UN E-Government portal database⁵, although the index of e-government services in the BiH has a growing trend (Picture 3), it is still below the level below the average for that region (Picture 4).

Picture 3: E-Government index development in BiH (UNPAN, 2011)

Picture 4: Comparison of E-Government indexes (UNPAN, 2011) for BiH, compared with region averages

E-Government analysis in Croatia

The Croatian Parliament adopted the Strategy for Development of Information and Communication Technology – Croatia for the 21th century and introduced general measures of information society development in Croatia in January 2002. At the end of 2003. Croatian government adopted a program of e-Croatia 2007, which was the policy of the action plan e-Europe 2005, to improve and modernize the electronic government, improved with the "E-Government beyond 2005" and eventually incorporated into the plan "i2010 Initiative". Program e-Croatia has gone over the years through major changes and expansion in all segments through support programs such as "Operation plan implementation of e-Croatia 2007 Program" and the "e-Croatia program for 2006." They have extended the project e-Croatia 2007, particularly in the areas of IT education e-Learning, training information then e-Judiciary and Judicial IT training program through the Health e-Health.

The current situation in Croatia, according to data that can be downloaded from the United Nations E-Government Data base⁶ shows that the E-Government Index is a slow upward trend which is certainly good sign (Picture 5).

⁵ UN Public administration program, UN E-Government database <http://www2.unpan.org/>

⁶ UNPAN Database - <http://www2.unpan.org/>

Picture 5: E-Government index development in Croatia (UNPAN, 2011)

Picture 6: Comparison of E-Government indexes (UNPAN, 2011) for Croatia, compared with region averages

The progress made so far in the availability of public services online, as measured with the EU standards, shows that Croatia has made significant strides in implementing E-Government systems and is one of the leading countries in the region. What data and prove the condition index of E-Government in comparison with the countries of the region (Picture 6).

E-Government analysis in Slovenia

In Slovenia, as well as anywhere in the European Union, E-Government is one of the benefits of modern designed in public administration. Other amenities include a reduction of administrative barriers, improvement of services by public administration (a time of growth and customer satisfaction), the introduction of tools for quality management and human resource management. Public administration in Slovenia has implemented several organizational changes in the range since 2001. to 2006. Development of E-Government is implemented in parallel with these structural and organizational changes.

Picture 7: Comparison of E-Government indexes (UNPAN, 2011⁷) for Slovenia, compared with world averages

⁷ UN Public administration program, UN eGovernment database - <http://www2.unpan.org>

Picture 8: E-Government index development in Slovenia (UNPAN, 2011¹¹)

Current situation in Slovenia, according to data that can be downloaded from the United Nations E-Government Data Base show that E-Government index is having strong growing positive trend (Picture 8). Compared with the average e-Government index of growth at the global level (Picture 7) Slovenia has achieved remarkable results. General Growth Index E-Government services is higher than average, as other segments of the development of E-Government (infrastructure indices, the index of the equity index of online service availability).

E-Government analysis in Macedonia

The project to develop e-government in Macedonia began with the development in 2004. under the help of USAID⁸. The projected period for the development and implementation of the project was in Macedonia since 2004. by 2011. year. The main aim of the project's objective was to implement a modern solution that delivers e-Government in Public Administration of Macedonia, which are aimed at increasing efficiency and greater transparency in the management and operation of the public sector. Project E-government in Macedonia received the recognition by the New York Times magazine which characterized it as very successful in the article titled: *"The fight against corruption with the help of E-Government"*⁹.

Picture 9: Comparison of E-Government indexes (UNPAN, 2011) for Slovenia, compared with region averages

Picture 10: E-Government index development in Macedonia (UNPAN, 2011)

Based on progress shown on UN Public administration network survey, that monitors E-Government development¹⁰, author can clearly confirm that Macedonia successfully implemented the introduction of E-Government System and the National Strategy for Information Society development well designed.

5. COMPARATIVE ANALYSIS OF SUMMARIZED DATA

Research preparedness for electronic government (e-readiness)

United Nations e-Government report for year 2010, presents a comparative review of 192 responses to requests from Member States of their citizens and businesses. It is also the attempt of the UN member states to provide quantitative indicators, to be able to see areas show weakness, and good results. Assessing readiness for e-government is focused on services that are primarily related to citizens' needs.

Graph 1: E-Readiness for 2010 of Former Yugoslavian Countries¹¹

E-readiness index is a measure of the quality of information and communication infrastructure of the country and the ability of citizens, businesses and authorities to use its advantages. The concept of measuring this indicator is based on an overall examination of the development, including human resources, infrastructure development and access to information.

Table 1: E-Readiness indexes for 2010, of Former Yugoslavian Countries¹²

Country	E-Readiness	
	2005	2010
Slovenia	0,6762	0,6243
Croatia	0,548	0,5858
Macedonia	0,4633	0,5261
Montenegro	0,4282	0,5101
BiH	0,4019	0,4698
Serbia	0,196	0,4585

¹¹ Based on data: United Nations E-Government Survey Leveraging e-government at a time of financial and economic crisis 2010

¹² Based on data: United Nations E-Government Survey Leveraging e-government at a time of financial and economic crisis 2010 and OECD: e-Government for Better Government, 2005.

Graph 2: Compare of E-Readiness indexes results during 2005-2010, for of Former Yugoslavian Countries

E-readiness index results show a trend of stagnation in our first graphics Some of the indexes are repaired, but many at a lower level than in previous years (Table 1 and Graph 2). Slovenia is the leading with the observed countries with 0.6762, followed by Croatia Macedonia. Although the region above the world average, it should be noted that the lagging behind developed countries significantly. The region ahead of a lot, mostly on infrastructure and development of new services, closer to European standards in e-government.

Research Web Index (Web measure index)

Web Index is based on five phases of the E-Government development (the presence in its infancy, increased presence, interaction, transaction, integration) and reflects the sophistication of online presence management. Depending on how does the management of a country reaches a certain stage, so it gets on the scale of this index. On line presence of government of each country is measured by the availability of services and web sites of ministries of health, education, social welfare, labor and finance, as it is considered that the administrative bodies to which citizens often pay. Each of the sites mentioned ministries were contacted several times with the same set of questions. Therefore, web index gives countries a comparative analysis of their ability to deliver public services to citizens.

Table 2: Web index results for of Former Yugoslavian Countries¹³

Country	Web index	
	2005	2010
Slovenia	0,5923	0,4
Croatia	0,4423	0,4222
Macedonia	0,3926	0,3206
Montenegro	0,3712	0,3143
BiH	0,2731	0,2762
Serbia	0,4462	0,2222

Graph 3: Compare of Web index results during 2005-2010, for of Former Yugoslavian Countries

Web index (Table 2) from all the study countries is declining, except in Bosnia where stagnant. It talks about significantly weaker investment in software solutions and inadequate maintenance of existing web sites. Very few services in the transaction and integration phase. The Board communicates with the public mainly through the information and statements on websites and e-mail.

A closer look at the web index, respectively, from which the data was performed (Graph 3) shows that Serbia does not have any application in transactional and integration phase of E-Government. The main reason is

¹³ Based on data: United Nations E-Government Survey Leveraging e-government at a time of financial and economic crisis 2010 and OECD: e-Government for Better Government, 2005.

probably the lack of services for electronic payment. This cause must be removed as soon as possible and start developing applications that would facilitate the daily life of citizens.

Research Infrastructure Index (Telco infrastructure index)

Telecommunication infrastructure index is a composite index, consisting of five primary indicators related to the E-Government Services:

- The number of Internet users per 100 inhabitants;
- The number of PCs per 100 inhabitants;
- The number of telephone lines per 100 inhabitants;
- The number of mobile phones per 100 inhabitants;
- The number of broadband connections per 100 inhabitants.

Each of these five indicators is one fifth of the infrastructure index. Source of data in this area is the International Telecommunication Union (ITU).

Table 3: Infrastructure index results for Former Yugoslavian countries¹⁴

Country	Infrastructure index	
	2005	2010
Slovenia	0,4762	0,5025
Croatia	0,3018	0,422
Macedonia	0,1237	0,3804
Montenegro	0,024	0,331
BiH	0,0926	0,2504
Serbia	0,1417	0,2694

Graph 4: Compare of Infrastructure index results during 2005-2010, for of ExYugoslavian Countries

Infrastructure Index (Table 3) indicates an increase in investment in telecommunications infrastructure. All Ex-Yu countries have improved this index compared to 2005. Further development should be based on building a solid broadband infrastructure and the liberalization of telecommunications and computer equipment.

UN data show that Serbia is far behind in the development of telecommunications infrastructure and electronic services in developed countries. With Bosnia and Herzegovina and Montenegro is located at the far end of Europe, by almost all indicators.

Further liberalization of telecommunications (increased competition from providers) would help reduce the cost of services, build more broadband connections and, thus, increase the use of the Internet and its services.

¹⁴ Based on data: United Nations E-Government Survey Leveraging e-government at a time of financial and economic crisis 2010 and OECD: e-Government for Better Government, 2005.

6. CONCLUSIONS & RECOMMENDATIONS

Pressure created from the citizens and businesses leading to launch an initiative to build a modern, efficient and affordable administration. Resistance to these changes is strong and comes mainly from the government, the ossified, legacy systems, which tend to retain their existing status. This resistance must be overcome, but with a big dose of caution, because the administration can not transformed quickly and efficiently as a profitable business organization.

Quantitative performance indicators E-government can be used as a tool for understanding the strengths and weaknesses of implementation. Currently there is no standardized method for monitoring and measuring indicators E-government, and therefore these results have their limitations. Often show only the relationship between input and output parameters, regardless of the processes within the administration. For this purpose, they must be carefully selected or composed (if composite), to reflect the true picture of progress in these areas. The ranking of countries according to any basis, including the results of the E-Government is a very thankless job. Results of the United Nations, however, for several years, provide a picture of e-government in the world, based on two composite indicators: e-readiness and e-participation.

The first hypothesis (H1) is rejected. Based on comparative analyzes have shown that at the moment Serbian delays in the development of E-Government for Ex-Yu, and Europe.. The priority task in overcoming the delays would be expected to develop and liberalize the telecommunications infrastructure. Only implemented with advanced telecommunications services E-Government can have a proper meaning. The second hypothesis (H2) adopts a partially compared with 2005 there has been a growth index, E readiness, with 0.196 to 0.4585. There was also an increase in the infrastructure index "from 0.1417 to 0.2694. But there was a drop Web index of 0.2222 to 0.4462

This comparative study clearly shows how countries that had clear strategy and vision from the start of implementation process, have constant growing positive trend in development of eGov services. It additionally highlights the necessity of having national strategy for development of IT Society and E-Government on all levels.

Define or adapt existing standards (domestic or foreign) is an absolute necessity when introducing E-Government. The mutual interoperability of the administrative authority can only be achieved by applying them. Standards, however, we must first develop and legally defined. Some of them already exist, but must be adapted to electronic data processing (Archive, Documentation), while others have been introduced recently and require further elaboration (for example: electronic signature.). Mutual exchange of information between administrative authorities, as well as exchange of information between administrative authorities and users, is also subject to standardization. Standards must be set so that users are in the foreground, to the evolutionary character, simple and uniform, to support multi-channel access and delivery of services and to indirectly support the rapid development of applications.

Orientation toward new technologies should not be just one idea for networking in the public administration, and also the basis for further development of electronic government. Potential opportunities to be recognized and utilized, there is now a large number of successful practices. Today's information together with knowledge of one of the most important resources that guarantees success and led to changes in management in the public sector or to new public management.
