As to the competitiveness of the Macedonian economy, observed from the aspect of its potential to create, absorb and diffuse knowledge, it could be stated that for the period from 1995 to 2009/10, the economy shows unsatisfactory results in comparison with both the innovation-based and the remaining efficiency-based economies. Thus, for the period from 1995 to 2009/10, the Macedonian economy managed to increase the knowledge index (KI) by 0.1 index point, which is significantly below the average of the innovation-based economies, but also below the remaining efficiency-based economies (0.21 and 0.19 index points, respectively). At the same time, considering the structure of KI, the economy lags behind most in the 'innovation' variable, which results from the small number of registered patents by both firms and individuals. The 'education' variable shows a growing tendency, whereas, regarding the declining tendency of the 'information technologies and communications' variable, no logical explanation can be provided, especially if we take into consideration the continuous growth in the number of users of computer, the Internet and mobile telephones in the analyzed period.

GCI trend for the Macedonian economy, for the period from 2005/06 to 2011/12, indicates a slight tendency of convergence towards the efficiency-based economies, and its growth reaches 0.79 index points (which is by 0.77 index points more compared to the growth in the average GCI of the innovation-based economies, and 0.65 index points more than the growth in the average GCI of the efficiency-based economies, for the same period).

Taking into consideration the structure (pillars) of GCI, it could be stated that in comparison with the efficiency-based economies, the Macedonian economy displays deficiencies in the following determinants of competitiveness: infrastructure, high education and training, technological readiness, market size, business sophistication and innovations.

In that context, the following conclusions regarding Macedonia can be drawn: 1) The capacity for absorption of new technologies on the part of the firms is lower than the firms' capacity for absorption of new knowledge on the part of their employees; 2) Firms' capacity for absorption of new technologies exhibits a significant negative deviation from the average of the efficiency-based economies; 3) The ability for knowledge absorption on the part of the employees in the firms is greater than the average of the efficiency-based economies; 4) Firms and employees' capacity for absorption of new technologies and knowledge is significantly lower than the average of the innovation-based economies.

CORRELATION BETWEEN MANAGEMENT KNOWLEDGE AND EXPORT PERFORMANCE IN SERBIA AS A TRANSITION ECONOMY

Jana Subotić¹, Ana S Trbovich².

¹Faculty of Economics, Finance and Administration, Singidunum University, jsubotic@fefa.edu.rs

²Faculty of Economics, Finance and Administration, Singidunum University, atrbovic@fefa.edu.rs

Abstract: *The authors of this article have demonstrated that a firm's intangible assets in forming knowledge and management skills significantly influence the level of export performance in a transition economy such as that of Serbia, concluding that firms that invest in management knowledge development will more easily adapt to new environments and take better advantage of opportunities that new markets present than firms that primarily rely on tangible assets. The conclusions of the two conducted exporter surveys in Serbia particularly indicate the growth constraint posed by low levels of marketing knowledge and investment in marketing activities, which is in part explained by limited access to finance and in part by low awareness of the range and application of marketing tools. The underlying recommendation is for exporting firms to consider investments in management knowledge, most specifically in market research and other marketing activities, to enhance their growth opportunities.*

Key words: *Serbia, exporters, strategic positioning, knowledge, marketing*

1. INTRODUCTION

Management knowledge and skills play a significant role in improving firm-level exporting performance and export readiness. This hypothesis is here tested based on the context of Serbia as a transition economy. Serbia's market reforms ensued after the change of democratic regime in 2000, ending a period of conflicts and economic sanctions that had rendered Serbia practically an autarchy in 1990s. Therefore, export experience, specific to Serbia as export base, here relates to the period 2001-2011, marked by development of new enterprises and attraction of foreign investment principally through privatization process and business climate reforms.

Two different research studies are presented in the article. The first research study analyzes Serbian exporters needs and it is relatively wide in scope, including 106 company representatives, where 96 completed the survey in entirety. The foremost goal of this study was to determine the preconditions for future development of exports. The second research study focused on exporters' strategic positioning and included 30 select company representatives, as a follow-up to the first study.

While the first study enables us to gain a broad understanding of the needs of Serbian exporters, the subsequent research provides a deeper insight in challenges experienced by exporters in strategic positioning. Both studies pay special attention to the issue of institutional support and examine the impact of knowledge in specific areas of management, marketing and legal matters. The presentation of research results is validated against theoretical findings about the importance of the knowledge factor in firms' export performance.

2. LINKING KNOWLEDGE TO EXPORT PERFORMANCE

To provide theoretical background and facilitate better understanding of the correlation between knowledge and firm's exporting performance, the authors have undertaken a relevant literature review. The review demonstrates several important findings.

For example, Mariola Ciszewska-Mlinarič and Franjo Mlinarič (2010) point out that: „Manager's knowledge and skills constitute firm specific intangible resources and [that] managers play a crucial role in influencing firm internationalization regardless of its size. Yet in smaller and younger firms the skills and knowledge of the management team, are likely to be even more important and influential on the firm's internationalization and performance than in larger firms” (p.242). They claim that knowledge based resources and capabilities exert an influence on the internationalization process of the firm. Similarly, Autio, Sapienza and Almeida

have discovered that knowledge intensity is associated with faster international growth (Autio E, Sapienza H.J, Almeida J.G., 2000, p.909). Finally, Hadley and Wilson confirmed that knowledge relating to international trade is closely related to the firm's actual practice in internationalization (Hadley, Wilson, 2003, p. 697).

Mariola Ciszewska-Mlinarič and Franjo Mlinarič conducted research in Slovenia on the sample of 241 small and medium sized enterprises from five industries. The main goal of this particular research was to prove that knowledge is linked to the level of firm's internationalization. They analyzed the impact of the management team's internationalization knowledge, including: the management team's ability to promptly identify business opportunities, the management team's experience in international marketing planning and implementation, the management team's ability to easily modify marketing mix elements for foreign markets, the management team's ability to easily modify marketing mix elements for foreign markets the management team's level of export procedure knowledge, the management's team's ability to develop international strategy and its general experience in internationalization. The study proved the hypothesis that managerial attitude and trade knowledge are related to the level of the firm's internationalization (Mariola Ciszewska-Mlinarič, Franjo Mlinarič, 2010, p.250).

Authors Autio, Sapienza and Almeida in 2000 conducted a study whose premise was that knowledge about international markets and operations and the efficacy by which such knowledge is acquired, represents an important determinant of international sales growth for entrepreneurial firms. Knowledge and learning can be expected to have an impact on international growth in that internationalizing firms must acquire, share and apply new knowledge in order to compete and grow in markets in which they have had little or no previous experience. The adoption of new knowledge involves not merely the learning of the new body of knowledge, but unlearning of the old ways of doing business. When a firm internationalizes it must acquire completely new knowledge, including experiential knowledge of specific foreign business practices and institutional norms as well as general experiential knowledge of how to deal with foreign competition. Cohen and Levinthal explained that the greater the effort put into absorbing new knowledge the more effective later retrieval will be (Cohen, Levinthal, 1990, p.131). Firms focusing on knowledge creation and exploitation as a source of competitive advantage are more likely to develop the learning skills useful for adaption and successful growth in new environments than firms that are more dependent on tangible resources. Knowledge-intensive firms can exploit international growth opportunities more flexibly through combination of knowledge and fixed assets than can firms dependent on fixed assets alone. Thus, knowledge-intensive firms are less constrained by distance or national boundaries. The more knowledge-intensive an international firm is, the more likely it is to develop the learning capacities necessary for rapid adaptation to a foreign environment and to identify opportunities for continued or accelerated foreign expansion. A dynamic environment may render such capacities particularly salient. Autio et al tested the importance of knowledge in Finnish electronics industry on the sample of 77 firms. The respondents were presidents and vice presidents of companies. The results confirmed the hypothesis that knowledge-related factors positively impact international sales growth of high-technology firms (Autio E, Sapienza H.J, Almeida J.G., 2000, p.911, 913, 918).

Raluca Mogos Descotes and Bjorn Walliser also studied how knowledge affects a firm's performance and its readiness to respond to changes in external environment. The main goal of their research was to examine firm's absorptive capacity, defined as firm's capacity to exploit knowledge for commercial ends. The absorptive capacity may also be defined as dynamic capability that influences the firm's ability to create and deploy the knowledge necessary to build, modify or renew organizational capabilities, in line with shifting market conditions. Absorptive capacity suggests that market knowledge must be converted into action for firms to respond to their environments and learn. Firm's knowledge base guides its effective action. The impact of knowledge acquisition on small and medium size enterprises (SME) responsiveness capacity has also been empirically confirmed. Descotes and Walliser propose that SMEs' export knowledge acquisition has a positive impact on their export responsiveness capacity. The absorptive capacity theory (AC theory) suggests that after knowledge has been acquired, it must be assimilated if it is to enhance future use (Raluca Mogos Descotes, Bjorn Walliser, 2011, p.5; Cohen, Levinthal, 1990, p.128). The efficiency of firm's response to the environment is a well-established determinant of organizational success. SMEs are generally likely to be more innovative, more customer-oriented and more flexible than larger firms, which enables them to achieve quicker response time and be more responsive overall. However, responsive actions designed to address foreign market shifts require continuous adjustments of the export strategy to foreign clients' demands as well as to foreign market-related constraints. In this sense, responsiveness can be behavioral change that translates learning into action. (Raluca Mogos Descotes, Bjorn Walliser, 2011, p. 2,4,5,6). In a dynamic, ever changing and turbulent environment, knowledge-based assets and especially tacit knowledge-based assets as competences are perceived as the most significant factor affecting the

firm's performance level. Organizational competences increase organizational flexibility and reactivity through better resource allocation and the development and sharing of knowledge. Firms with superior international competences likely enjoy more success in export markets. For manufacturing SMEs, international marketing competences should have strong effects on performance. To obtain empirical confirmation for this proposition, Descotes and Walliser surveyed 107 French SMEs that operated in the steel industry. In those firms, export accounted for an average of 40.49% of total turnover. Regarding the level of export knowledge acquisition, SMEs generally were above average and their export responsiveness levels were slightly above average. Firms' export sales increased by 19.2% over the previous three years and companies registered an average increase of 17.24% of export sales profits in that period. Research showed that 40.5% firms' international performance is explained by their positional advantage in terms of international marketing competences. If firms have this positional advantage in form of foreign market-related marketing competences, it drives SMEs to be more successful in international arena. (Raluca Mogos Descotes, Bjorn Walliser, 2011, p.7, 13).

While the literature review confirmed a strong correlation between management knowledge and export performance, the authors of this article wanted to test the level of correlation in a different setting - Serbia as transition economy with just over ten years of exporting experience, following a long period of socialist economy and then a decade of conflicts and economic sanctions.

3. ANALYSIS OF SERBIAN EXPORTERS' NEEDS AND STRATEGIC POSITIONING

Analysis of Serbian exporters' needs

A survey of Serbian exporters and potential exporters was conducted in March and April 2011, primarily by using an online survey tool, SurveyMonkey. A total of 106 company representatives participated and 96 completed the survey in entirety. The survey results were checked against direct interviews with several company and cluster representatives, all of who remain unanimous to ensure impartiality. This analysis thus pertains to over 100 relevant opinions of current and future exporters and it focuses on exporters' needs and the prospective role of a new exporters' association in Serbia.¹³

Companies participating in the survey had the following features:

88.5% were already exporting; they come from a variety of sectors, with agribusiness and ICT being most represented, followed by metals, electronics and wood processing industry (Figure 1). More than 90% had an annual turnover of less than 10 million Euros, were small and medium size companies, and they were about evenly represented by micro, small and medium size companies.

Figure 1: Type of business sector

When asked about exporting services and assistance they would like to receive, the majority of companies considered almost all the listed services to be useful and of interest, although business linkages and market research stood out with over 70% demanding these services to improve their performance.

¹³ The survey results have been analyzed in wider scope, with the aim of identifying measures to improve Serbian export results; see Ana S. Trbović, "Serbian Exporters Needs Analysis to Support Competitiveness and Export Growth," *Ekonomika preduzeća*, 2011. This article uses select survey results to investigate the impact of knowledge factor in exporting performance.

Figure 2: Exporting services demanded by exporters

Similar private sector interest is expressed with regards to training topics; the majority wants to learn about creating linkages while other topics receive less but significant interest i.e. about 30-40% would attend almost all trainings, with only 8.6% declaring no interest in trainings (Figure 3). In individual comments, companies acknowledged a need for trainings in logistics/customs procedures, product certification and marketing. This result demonstrates not only that companies are fully aware of the importance of knowledge but also that they are yearning to obtain that knowledge and improve their skills.

Figure 3: Exporters' interest in training topics

Just about half of the respondents outsource professional services, mainly legal, accounting and ICT followed by marketing and payroll, with several companies also noting design and logistics. This finding confirms that outsourcing represents an area where more awareness is required to enhance economic efficiency, including efficiency gain that is based on enlarging the base of knowledge required to build a more competitive exporting product. The second follow-up study additionally focused on the level of management knowledge in exporting firms.

Analysis of Serbian exporters' strategic positioning

The main goal of the secondary research was to identify the principle obstacles endured by Serbian exporters during strategic international positioning. The questionnaire was distributed to 80 exporting firms, and 30 completed this new survey. While this is a moderately sized sample, the responses correlate with the first

survey and represent a focus research study. In this study, it was crucial to obtain answers to the following questions: How do you establish contacts with potential buyers? How do you conduct market research? What was the biggest problem when you started exporting? How much money do you spend on international marketing? Do you have an export office? These questions aimed to determine the way human resources were used by exporters without directly asking that question, which would have resulted in a socially acceptable response that would not be useful in research.

The goal of first two questions was to determine firm representativeness by type of sector and number of employees.

Figure 4: Type of business sector

The responses showed a diversity of exporting products and services. A total of 11 of 30 surveyed firms export products such as: tires, cables and conductors for industrial production, electric boilers, metal and plastic packaging, furniture, buses and energy equipment. Agriculture sector is represented by 5 firms from this sample, exporting frozen fruit and honey. Firms from the food processing branch produce and export juice, jam and marmalade. In the services sector, 10 firms export IT, construction and other type of services. This research question allowed us to determine which exporting products found a way to foreign markets and customers. Additional qualitative analysis showed firms with finished products to be more successful in entering and expanding in foreign markets. Firms with more primary agriculture products are successful at the moment, but if they do not develop more diversified products, their success may not be maintained.

In this particular sample, the small firms are dominant with 47% sample share, followed by medium sized firms with 23%, and jointly 70% of total number of surveyed firms. Statistical analysis of Serbian exports confirms dominance of small and medium size companies, but this prevalence is less significant when analyzing the volume of exports where several large companies still have an important lead in some sectors.

Data collected in the two presented research studies data show that small and medium sized firms have potential for improved export strategic positioning and export growth. These firms require additional support in the following priority areas: access to finance, export insurance, market research, and business linkages.

Figure5: Obstacles to starting exporting business

As illustrated by figure 5, exporters consider that establishing contacts with buyers and access to finance present greatest challenges when starting an exporting business. Establishing contacts with buyers is complicated because exporters do not know where to find potential buyers. Notably, the first research study also clearly identifies business linkages as an area where exporters demand most support.

It is not certain whether exporters are fully aware of the significance of marketing in foreign markets, including more effective fair participation and brand creation, in forming relationships with potential buyers. Only investments in these activities can render a firm and its product or service more visible in the international arena and ensure new contacts with buyers. However, 23% surveyed Serbian firms reported financing constraints, which, together with other featured problems regarding logistics or difficulty in conducting market research, implies limited funding availability for marketing and related education despite obvious need. From this we can conclude that starting an export business is a multifaceted, exigent activity.

Questions: "Who conducted the market research?" and "How much money does your firm spend on international marketing?" were crucial for our analysis. Responses led us to conclude that Serbian exporters need more training and expert advice in area of market research and more awareness as to how targeted marketing activities can have positive impact on firm's export results.

Figure 6: Responses to "Who conducted the market research?"

Our research revealed that firms in most cases conducted market research on their own (14 firms), 13 firms engaged additional marketing experts, 2 firms hired a marketing firm to perform market research and 1 firm did not perform any market research. Internet and various databases and sector publications are generally a good first source of information about foreign markets. Exporters can also obtain valuable information through personal contacts. Figure 6 shows that 13 firms decided to hire an expert for market research to

ensure quality of information. Firms that are positioning themselves for exports should be made better aware of importance and value of market research. It is important for firms to be well informed about perspectives on foreign markets, entry options, market trends, competition, potential customers and distributors. Firms that already export should continue to research potential markets and thereby identify new export opportunities. Market information allows exporting firms to better organize their activities on international markets. Again, although the samples were different in two conducted researches, in both of the studies exporters indicate market research as the sphere where they need help and more knowledge.

Another important issue in exporting lies in the complex relationship between exporters and intermediaries. Our research showed that exporters considered making contacts with potential intermediaries and concluding an agreement on doing business to be the biggest hurdles in exporting, once an export product is developed. From figure 7 we also see that firms consider definition of payment method as another source of potential problems.

Figure 7: Problems in relations with intermediaries

Exporters need support and assistance in making contacts with potential intermediaries. Firstly, however, they need to be aware of the business linkages process, types of intermediaries, and how various foreign markets distribute imported products in a certain market and product segment. This requires specialized management knowledge that is partially acquired in academic studies and honed in practice.

Figure8: Expenditure on international marketing on annual basis (in Euros)

In Figure 8 we can see that almost half of interviewed firms do not spend any money on international marketing activities (market research is here excluded). Ten firms spend from 5 to 10,000 Euros and only 6 firms spend over 10,000 Euros annually. It is very important for firms to understand that well-organized marketing activities can have a positive influence on recognition of firms and products in new markets and consequently positive effect on attraction of new customers and investors. Firms should be informed about marketing costs and best ways that they can be managed within available budgets. Again, this knowledge is obtained in part in academic studies and in part it is learning by doing – and most certainly, by outsourcing some of the marketing activities to specialized experts.

Figure 9: Number of companies with export office

It is of even greater concern that 63.3% or almost two thirds of surveyed exporters do not have an export office (unit). They probably consider an export office unnecessary or too expensive. Interestingly, firms that have an export office are both small and large-sized, which means that size of firm is not crucial for forming an export office. It is necessary for firms to understand that if they organize export office, they will have a unit, which will be dedicated to export business only. Another advantage is that the company would have a manager whose main role would be to organize export operations. Exporting business is complex and exporters will sooner or later have to dedicate time to understand the functions of a separate export office (unit) and how it can be helpful to their business. Export managers who would be responsible for marketing, sales and logistics, would help the company to better organize its operations, which could have a very positive effect on firms' exporting performance.

4. CONCLUSION

The authors of this article have demonstrated that firm's intangible assets in form of knowledge and management skills significantly influence the level of export performance in a transition economy such as that of Serbia, concluding that firms that invest in management knowledge development will more easily adapt to new environments and take better advantage of opportunities that new markets present than firms that primarily rely on tangible assets. The conclusions of the two conducted exporter surveys in Serbia particularly indicate the growth constraint posed by low levels of marketing knowledge and investment in marketing activities, which is in part explained by limited access to finance and in part by low awareness of range and application of marketing tools. The underlying recommendation is for exporting firms to consider investments in management knowledge, and most specifically in market research and other marketing activities, to enhance their growth opportunities.

USING WIKIS AS KNOWLEDGE MANAGEMENT TOOLS FOR KNOWLEDGE SHARING AND INNOVATION IN THE TIMES OF ECONOMIC CRISIS

Opačić Mladen ¹, Veinović Mladen ²

¹Singidunum University, mladja@mladja.com

²Singidunum University, mveinovic@singidunum.ac.rs

Abstract: *This paper deals with wikis and how they are used in the process of knowledge management in organizations. We explain what wikis are, their major features, advantages and disadvantages. Then we describe how wikis are used in an enterprise and which knowledge management instruments they can support. Paper is a literary research of the current state of practice of using wikis as knowledge management systems interesting for anyone who wants to know more about the use of wikis as knowledge management tools.*

Keywords: *wiki, semantic wikis, knowledge management, knowledge management systems, semantic web, collaboration, innovation*

1. INTRODUCTION

In the times of economic crisis, when companies strive to minimize their expenses, one of the common saving strategies is cutting all unnecessary costs (Papaoikonomou, et al., 2012). Proprietary enterprise knowledge management systems from renowned software vendors usually come with a very high price so it is no surprise that investments in expensive software tools are usually postponed for better times. This is especially true for east European region. According to (Kattel, 2006) Eastern Europe will have to wait quite a few years before recovering from 2008 global financial crisis.

On the other hand neglecting strategic goals such as knowledge management initiatives can lead to severe consequences later on as many organizations are forced to downsize. Downsizing is not the only problem in some companies there is a large employee turnover. (Poole, & Grudin, 2010) doing research in a large software company were surprised to find out that 14%, 619 out of 4444 people whom they identified as wiki users and attempted to survey, have already left the company. With knowledge workers leaving the company there is a real threat of losing valuable knowledge.

In larger firms knowledge managers are faced with what seems to be impossible task maximizing knowledge retention and minimizing the knowledge management budget. In smaller firms according to (Papaoikonomou, et al., 2012) to survive crisis entrepreneurs have to make strategic alliances for sharing resources, knowledge and innovation. A study of Web 2.0 use in 245 manufacturing SMEs found that two most important challenges that these firms will be facing in the near term are total product cost cutting and knowledge as a success factor (Voigt, Fuchs-Kittowski, Hüttemann, Klafft, & Gohr, 2011).

Solution to these problems may be in use of the free open source alternatives instead of expensive proprietary software. One of the most popular knowledge management tools for knowledge sharing and collaboration are wikis.

2. WIKIS

According to (Hester, 2011) wiki technology can be best described as a concept of websites maintained by users who have system access. (Zaidan, & Bax, 2011) describe wikis as Web 2.0 information systems which can be used for:

- maintenance of knowledge networks
- construction of knowledge communities
- cooperation in construction of knowledge
- knowledge management

(Meenan, King, Toland, Daly, & Nagy, 2010) note that wikis are tool for knowledge management that requires no detailed technical knowledge of complex Web programming techniques for users who wish to post information to the Web site.(Bhatti, Baile, & Yasin, 2011) see wikis as a tool deployed for collaboration among employees and capturing their knowledge.

Major difference between wikis and standard content management systems is that in wikis everyone can add, edit and modify any page on the website(Cress,& Kimmerle, 2008). In standard content management system (CMS) only small number of users has the ability to publish articles while others can only read content they make.

Furthermore advanced CMS systems have inbuilt workflow capabilities to automatize process of content approval. In wikis there is no formal article approval system everyone who visits the wiki website can write new articles, edit or modify old ones. To prevent vandalism wikis track all changes made to the article and have recovery and roll-back functions to bring things to original state in the case of mistakes or vandalism(Hester, 2011). Wikis track the history of changes so it is easy to find out who made each change. It can be said that every user who makes some kind of change in the wiki leaves some kind of an “informational footprint” and can be held responsible for his actions (Glassman, & Kang, 2011).

Largest and most popular wiki is Wikipedia. Wikipedia is wiki encyclopedia completely open for anyone to add, edit or modify its contents. Although there are no guarantees for reliability or accuracy that doesn't stop Wikipedia to be most popular encyclopedia and to completely outshine all competition as(Albors, et al.,2008) noted with Wikipedia “who is going to use the authoritative encyclopedias” (p.197).

Wikis are not only for internet they can also be implemented in intranets (Cress, et al., 2008) when used in enterprise intranets they are called enterprise wikis. (Hester, 2011) notes that use of wikis in organizations is growing at a dramatic rate and claims that they are best suited for knowledge that is dynamic, ad-hoc and decentralized.

(Wang, & Wei, 2011) name community participation as most important factor that influences knowledge sharing in virtual wiki communities. They define community participation as voluntary participation in social activities, held or enabled by virtual community, because of shared interests and needs.

According to (Zaidan, et al., 2011)(Meenan, et al., 2010) term wiki is originally from Hawaiian language and means quick.First wiki was created by Ward Cunningham in 1995 and was called WikiWikiWeb. Currently most popular wiki software is MediaWiki the software that is used by Wikipedia (Zaidan, et al., 2011).MediaWiki is free open source software released under GPL license.

According to (Nakanishi, Zettsu, Kidawara, & Kiyoki, 2009) wikis come in many forms often specialized for a particular use or having a specialfeature. QwikWebis WikiWikiWeb extension that integrates wikis with mailing lists, LBWiki is a location based wiki that allows users to create wiki pages via GPS co-ordinates, DistriWiki is a P2P wiki for distributed environment, AniAniWeb is personal home page wiki software,SmallWiki is an object-oriented wiki and ThinkSpace wiki is a specific educational tool. WikiTrails or PmWiki how it is now called provides tracking and trail generation for easy navigation. ShyWiki is a spatial text wiki consisting of notes and graphically represented links used for brainstorming and idea exchange.

According to (Grace, 2009) main advantages of wikis are ease of use, centralized repository, mechanisms for preventing vandalism, collaboration between organizations, solving information overload caused by emailing numerous drafts and building a trusting culture.

Major challenges in running wiki sites are security, categorization of information, data migration, training, navigation and risk of leaving some content unreachable(Grace, 2009)(Alquier, McCormick, & Jaeger, 2009).

Semantic wikis extend traditional wikis semantically so that they can be more readable for the machines (Zaidan, & Bax, 2011). Semantic wikis allow:

- classification and annotation for the links
- dynamic presentation of contents
- richer navigation, metadata
- data in triplets
- semantic searching

- embedded queries

One of the most popular semantic wikis is Semantic MediaWiki an extension to MediaWiki. Semantic MediaWiki is free software published under GPL license. SemanticMediaWiki adds capability of structuring data to the MediaWiki (Alquier, et al., 2009). There are other semantic wikis like SMW+, Platypus Wiki, Semper Wiki, IkeWiki, SAVVY wiki, Sweet Wiki that supports social tagging, Ace wiki and many more (Nakanishi, et al., 2009).

3. WIKIS INKNOWLEDGE MANAGEMENT AND INNOVATION

Organizations use wikis for many different purposes, from using Wikipedia and other public wikis through external wikis for interaction with partners and customers to intranet wikis that support group communication and collaboration (Grudin, & Poole, 2010).

Wikis used in organizations can be divided in three types (Poole, & Grudin, 2010):

- single-contributor wikis
- group or project wikis
- company-wide wikis

Single contributor wikis are those that have only one contributor they are used for personal information management or as easily edited web pages. Group or project wikis are used as a team or project collaboration tool. Company-wide wikis so called "pedias" are used as company encyclopedias.

Peinl (2011) compiles a list of eleven knowledge management instruments:

- market monitoring
- knowledge discovery in databases
- personal experience management
- idea and proposal management
- skill and competence management
- communities management
- collaboration support
- semantic content management
- technology-enhanced learning
- team experience management
- knowledge-based process reengineering

Each of these instruments consists of number of measures. It can be said that each of this eleven instruments is in fact a category of knowledge management measures.

Instrument of market monitoring is the systematic gathering and analysis of knowledge gathered about market, customers, competition, partners and suppliers. This instrument can be also called competitive intelligence instrument. Wikis can be used to create repositories for storing and maintaining gathered knowledge and also collaboration in creating reports.

Instrument of knowledge discovery is the systematic processing of relational data like sales numbers, market data etc. Measures include various market analyses, hiring of data analysts and the use of data analysis software. So far there are no wikis that can do such analyses.

Instrument of personal experience management is about documenting personal experience and new ideas. It includes measures like weblogs, note taking etc. Wikis can be used for personal weblogs and note taking. (Poole, & Grudin, 2010) report single contributor wikis to be very common in organizations they surveyed.

Idea and proposal management involves measures like establishing processes for evaluating and rewarding ideas, supporting idea generation with software etc. Semantic wikis can be customized to support innovation process and idea exchange. One wiki that has such capabilities is Wiki-I (Monticolo, Morel, Boly, & Iahoud, 2012). Wiki-I has a knowledge layer that is based on Idea ontology (Monticolo, et al., 2012) that provides an integrated conceptual model for sharing information related to an innovative idea and a query processor for

building queries with SPARQL language. For example same term “Hood” can be annotated to have type “technology”, “organization” or “process”.

Skill and competence management instrument is about recording employees' competences, planning of their advancement, assessing the target achievement etc. Measures include job descriptions, planning and executing training, creating employee profiles that show skills and experiences and many more. Wikis can be used to support competence management. Creation of all documents can be done using wikis and also wikis can be used to create employee profiles. Semantic wikis can be used to create ontologies for easier navigation, finding experts and for making aggregate automatically updated lists of experts using semantic queries. For example in semantic wiki it is possible to display results of a semantic query as the contents of a page. If that query is something like “show me all experts in software engineering” this page will contain a list of software engineering experts that changes automatically whenever someone anywhere in the wiki is tagged or untagged as a software engineering expert.

Community management is aimed at supporting informal associations between employees to foster exchange of experience, ideas and knowledge. Measures include virtual discussion rooms, communities of practice, organizing informal meetings and similar activities. Both semantic wikis and ordinary wikis can be used for making and managing communities. (Hutchison, & Colwell, 2012) explain how wikis are used to make an online professional learning community for mentoring new teachers. Sheehy in (Sheehy, 2008) describes how wikis are used to facilitate community of practice for school teachers.

Collaboration support consists of support of knowledge work in teams, groups or whole departments by supporting communication, coordination and cooperation. Measures include meetings for knowledge exchange, templates and guidelines for project planning as well as usage of groupware, social software and collaboration software like wikis. Wikis are initially created as collaboration software so supporting collaboration is what they are best at. Collaboration in wikis is not limited to simple tasks, they can also be used for very specific tasks requiring high level of expertise such as knowledge engineering (Baumeister, Reutelshoefer, & F. Puppe., 2011).

Instrument of semantic content management consists of measures like providing pre-structured templates, semi-automatic annotation of documents, text retrieval, training employees in technical writing etc. Wikis with semantic extensions can be used for most of these tasks. (Alquier, et al., 2009) describe use of Simple MediaWiki extension called Semantic Forms which is used to provide pre-structured template for editing wiki pages. Wikis can also be used to annotate documents semantically.

Technology-enhanced learning is aimed at supplying frequently used knowledge, didactically prepared, so that it can be reusable and to maximize learning effects. Measures include collaborative learning management systems, deployment of learning material on demand or in the workplace and similar activities. Although wikis are not able to fully replace LMS they are good enough substitution for many of the knowledge management applications. (Kimmerle, Moskaliuk, & Cress, 2009) describe five main characteristics of learning in wikis. They are:

- community of learners
- use of a shared digital artifact
- learning processes are self-regulated
- emphasis on a jointly created artifact
- community builds new knowledge

Team experience management instrument is comprised of systematic collection, assessment and application of experiences gained on projects or process cycles. Measures include debriefings, lessons learned, good or best practices, process reviews etc. Wikis can be used to store specific knowledge related to projects and processes. This is actually one of the most common uses of wikis 71% of people who responded to (Poole, & Grudin, 2010) survey indicated they used wikis for discussion of special interests, documentation of product features and orientation of new workers.

Knowledge-based process reengineering is comprised of continuous analysis of processes, their redesign and implementation from knowledge perspective. Measures include business process modeling and management and also creating handbooks that describe processes and structures, exceptions, experiences and reasons for decisions. Wikis can be used for creating such handbooks and sharing experiences.

4. CONCLUSION

Wikis have come a long way since 1995 and WikiWikiWeb simple collaboration software. Analysis in this paper has shown that wikis can, to some extent, help with ten out of eleven knowledge management instruments. Only instrument that semantic wikis can't cover is knowledge discovery in databases.

This makes free wiki software ideal software for knowledge management in the times of financial crisis. It is easy to use, easy to install, easy to administrate and completely free. Initial investment is very small especially if organization already has a server. For organizations with more specific needs there are specialized free semantic wikis that offer much more but are also much harder to learn.

Abstract: *The paper points out the key market changes in the first decades of the twenty-first century and their implications on business philosophy, concepts, principles and techniques of relationship marketing from the point of making strategic marketing decisions. In that context points are made to the important role of developing customer relationship management (CRM), highlighting the effectiveness of a combination of the CRM and the customer experience management (CEM) models. One of the important aspects of that relationship is reflected in the fact that CRM tells us what the customer has done, whereas CEM can tell us why he/she has done it. Consequently, CEM can vastly improve the power of CRM to predict future customer behaviour. Successful implementation of CRM concepts implies: excellent understanding of the field of activity and competition; knowledge of customers; market-oriented thinking; an integrated approach to managing channels of communication and sales; and finally, a database development. In this paper we have also presented the CRM value chain as a model which businesses can follow when developing and implementing their CRM strategies and the related CRM diamond model, based on strong theoretical principles and practical requirements of business.*

Keywords: *marketing, customer, relationship, management, CRM, organization, profit*

1. INTRODUCTION

In the last decades of past and the first years of this century there have been dramatic changes in the relevant (micro and macro - local, national and international) market environment of organizations (enterprise/company/corporation), which imposed the need to review existing business practices, business management philosophy, concepts, principles and techniques of marketing management.

Instead of organizing as per product and/or sales territories, successful organizations are organized in compliance with market segments. Successful organizations have adopted the maxim that they should retain the basic activities that constitute their core business, while some minor activities, which other individuals/organizations can perform better and cheaper, shall be procured from third parties (outsourcing). Successful organizations have also learned a valuable message by David Packard from Hewlett-Packard, who once said that marketing is too important to be left to the organizational unit for marketing. Consequently, these organizations have accepted the thesis that creating, communicating and delivering value to consumers, is not the responsibility of the personnel of the marketing organizational unit only, but of all other employees as well (organizational units of production, R&D, Accounting, Finance, HR Human Resource, IT Information Technologies, etc.). In particular, those from other organizational units who have more intense contact with customers /consumers/users.

Instead of an exclusive or excessive reliance on just one channel of communication/promotion - advertising in branding projects (product/service and/or corporate brand), advanced organizations use a combination of integrated marketing communications - a combination of communication channels (advertising, personal selling, sales promotion, etc.) in order to convey a consistent message to existing and potential customers and thus more effectively position brand image of product/corporation. Being aware of the fact that gaining a new customer can cost five times more than retaining existing customer on average, advanced organizations are not only calculating the profit from each transaction, but taking into account the expected lifetime customer value and, consequently, their market offer is shaped in order to achieve the maximum possible profit from the amount of repeated customers' purchases.

Instead of relying solely on financial results such as total revenue, expenses and profits, successful organizations are increasingly taking into account all other indicators of marketing/business performance - the amount and the change of market share, the level and change of the index of customer satisfaction, the rate of customer loyalty, lost rate and the rate of new customers and so forth - which significantly affect the present and expected financial results.

In organizations that have truly understood that the philosophy of marketing is so important in terms of hyper-competitive economy, the top management is not on top of the pyramid, and the clients are not on its bottom, rather than vice versa - at the highest hierarchical level – on top of the pyramid are the customers, in the central part are the employees who are in "contact" with clients, behind and below them are the middle managers to support employees' on the front line, while at the bottom of the pyramid are "the generals" or "top managers", who provide support to managers of intermediate level. Such a modified approach to management has caused the development of a new concept based on the customer, and managing of long-term relationships with customers.

2. RELATIONSHIP MARKETING AND CRM

In the first row of the first page of the paper, below the space reserved for header, you should type the paper title. Names of the authors, names of the institutions and the addresses should be typed below the paper title, as shown at this page of the instruction. In the first empty row below the address of the first author, apply style "Line" or copy/keep the line from this template. Below the paper title and names of the authors, you should write a short abstract. Below the abstract, you should write key words.

Philip Kotler in his recent work in the field of marketing management emphasizes that the art of marketing management and the ability of acquiring new and retaining existing customers. Organizations that start from the postulates of classical/traditional marketing theories focus on art for attracting new rather than to retain existing customers. Such organizations, which operate on the principle of "drills buckets" or "adding water to the bucket drills," assume that they will always be able to provide a sufficient number of new customers who will be able to replace outflow of the lost customers. Such organizations put more emphasis on the exercise of the transaction rather than on creating, nurturing and developing stronger relationships with the (profitable) customers. Consequently, these organizations focus their efforts placed on the resale and sales activities, neglecting the importance of after-sales activities focused on fostering relationships with customers.

Being aware of the empirical facts that "to get new customers can cost on average five times more than retaining existing customers" and "to reduce the rate of outflow of customers by 5% can increase profits by 25 - 85%, depending on the branches of activity," smart organizations recognize the importance of delivering superior value of satisfaction and retention of existing (profitable) customers.

In every organization there is abundance of customer data. Frequently, however, those data are scattered throughout the organization and deeply buried in the "partial" databases, documents "stored" in various organizational units of the company and retined within "minds" of employees who are, in different ways, in touch with customers. When, however, information about customers integrate properly, then they become a real "mine" from which then, the information "worth in gold" could be drawn to build strong relationships with customers and their loyalty makismiziranje.

CRM is a marketing concept/model/system/process that helps the organization to manage detailed information about individual customers and therefore carefully manage with all organization's "touch points" with customers (such as the consumer purchases, contact with vendors, visit the website, etc..) in order to maximize their loyalty. The financial services sector, including banks, insurance companies etc., has developed the concept of KAM (Key Account Management) to manage relationships with key (most valuable) customers of banks, insurance and other financial institutions.

By combining the right software and analytical tools, CRM helps organizations to integrate customers data from various sources, to conduct "deep" analysis and gain a comprehensive view of the organization's relationships with consumers. Using sophisticated analytical techniques of data mining (DM - Data Mining) from data organized in the form of so-called data warehouse (DW - Data Warehouse) CRM helps the organization to discover "real jewels" - the knowledge hidden in the raw data about customers and discover the most valuable/profitable customers to more effectively target and "cut out" offer "tailored" for customer special requirements. The basic structure of CRM, in fact, consists of three parts:

- Operational CRM - refers to supporting the business processes of "the first-line business operation of the company", such as marketing, sales, order management. The basic characteristic of operational CRM is the existence of a single, integrated database that contains information about each client.
- Analytical CRM - refers to supporting the analysis of customer data, including the activities of collection, storage, selection, processing, analysis and interpretation of that data. Goals may be different: modelling the behaviour of the client, design and implementation of specific campaigns (customer acquisition, retention of clients, cross-selling, up-selling, etc.) analysis of service quality, assessment of clients, the

division into segments and making customer profile, risk analysis, demand analysis, sales analysis, analysis of clients' departure and the like.

- Collaborative CRM - enables complete communication, coordination and cooperation with clients via phone, fax, Internet, mail, in person and so on.

Organizations that have experience in this system aplyement understood that CRM is not only the (or primarily) technology and software solution but also an integral part of the overall customer relationship strategy. CRM is all about the relationship and therefore, as pointed out by experts in this area, and focus then should on R (Relationship).

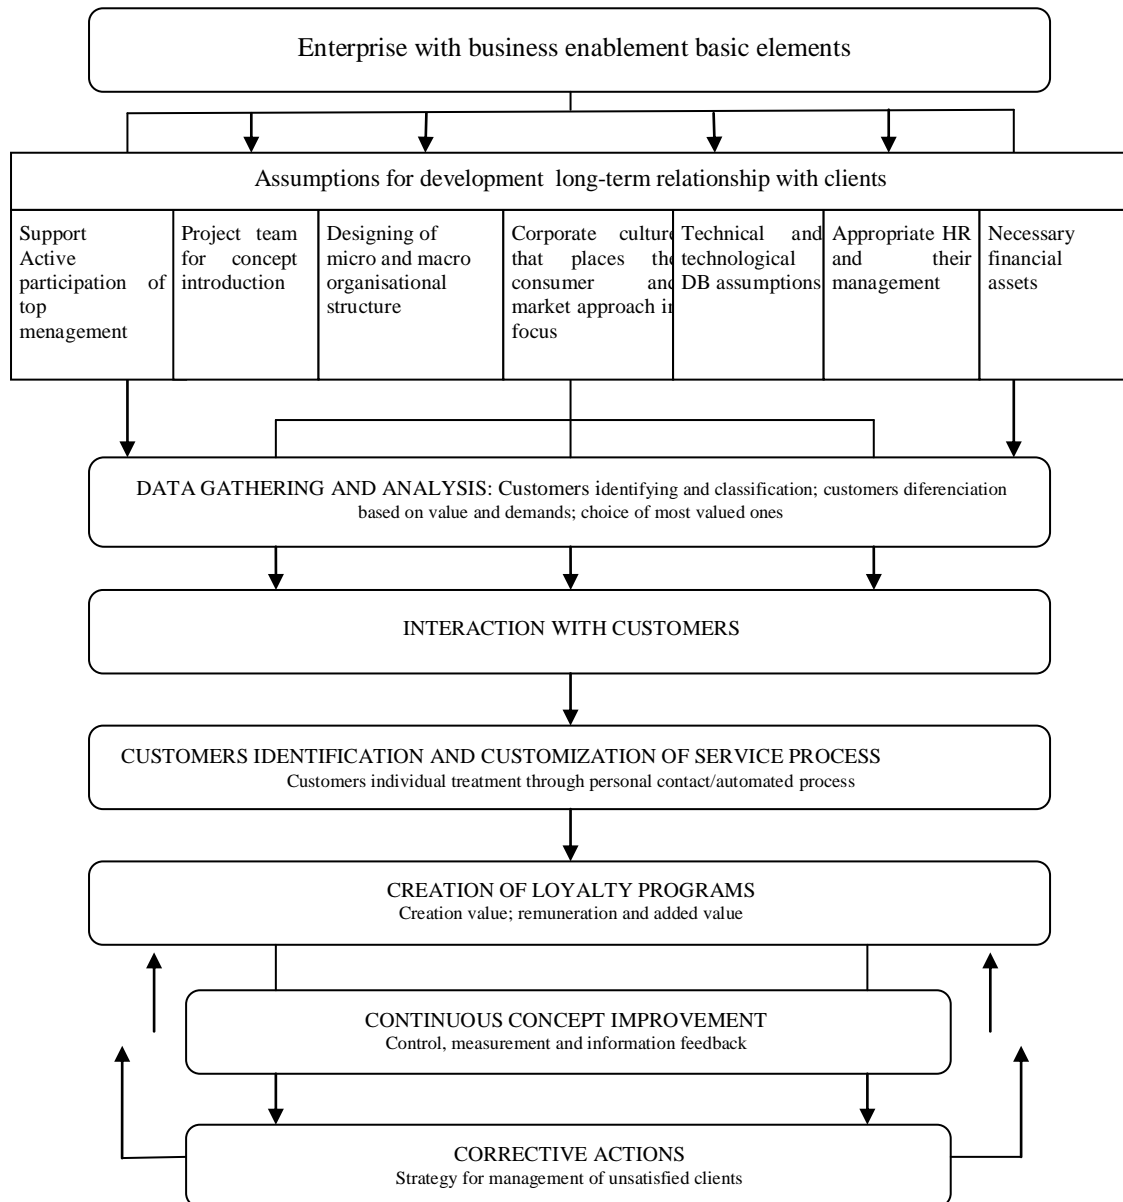

Figure 1: The conceptual framework of CRM

The key factor for success of company CRM concept is the anticipation of client's needs and expectations. It is therefore necessary to build a platform for communication with clients and analytics of relevant information collected from them. In the web site specialized statistical software packages allow monitoring and collecting responses to various questions, which may be stored in the appropriate database. In this way we can keep records of client habits and clients special interest.

Strategic Framework for CRM is the interaction of four inter-related functional business processes that are related to:

- Framing the company strategy (a development strategy is to be analyzed from two aspects: business strategy and customer);
- Creation of value/supply through customer perception and awareness of the value;
- Integration through multiple channels (so called multi-channel management, which includes sales force, output information, telephone, direct marketing, e-commerce, mobile commerce, etc.);
- Evaluating the success of the campaign with the analysis of the results after performed monitoring.

Prerequisites of successful implementation of CRM concepts are: excellent understanding of field of activity and competition; knowledge of customers, market way of thinking, operation of the company as a whole - an integrated approach to managing the channels of communication and sales, as well as database development. These assumptions form the basis of a conceptual framework for developing CRM strategy shown in Figure 1.

3. CRM VALUE CHAIN AND CRM DIAMOND MODEL

The main effects of introducing the concept of CRM are: more effective segmentation of target groups, faster response to market changes, longer customer retention. Other effect could be:

- Analytical forecast of market trends
- Analysis of the profitability of individual customers
- Ability to direct offer to highly profitable customers
- Improving the quality of service and sales opportunities
- Shorter sales cycle and higher profitability of the sale process
- Synchronization and analytical processing of information gathered from various sources
- More intensive development of competitive advantage and company reputation as a strong business partner.

Customer relationships management as a process includes: defining bid value, segmentation, targeting and positioning, operations and delivery systems, measurement and feedback, external and internal market which is shown in figure 2.

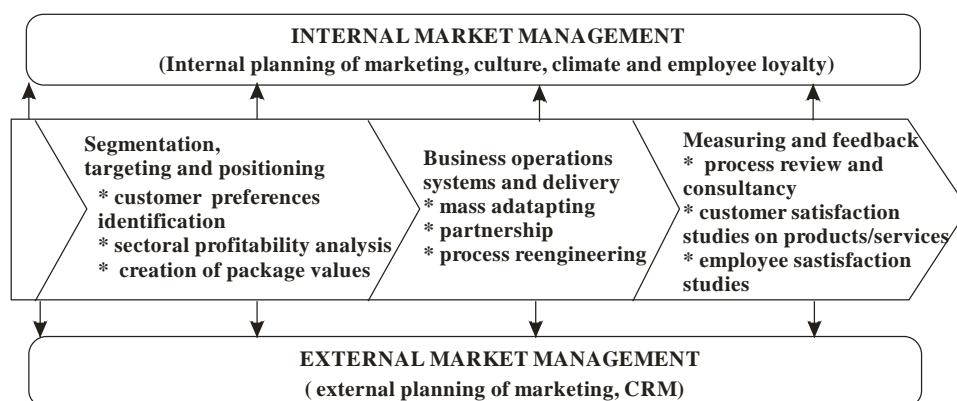

Figure 2: CRM chain (Adapted on Lovreta *et al.*, 2010).

Such a process requires strategic approach in its implementation. One of the most adequate strategic approach to organizational design is given into a Diamond framework, presented on figure 3, in which are organized the basic elements of a successful CRM strategy. It focuses on vision, activities and basic business activities as key factors of successful implementation of CRM in a business environment.

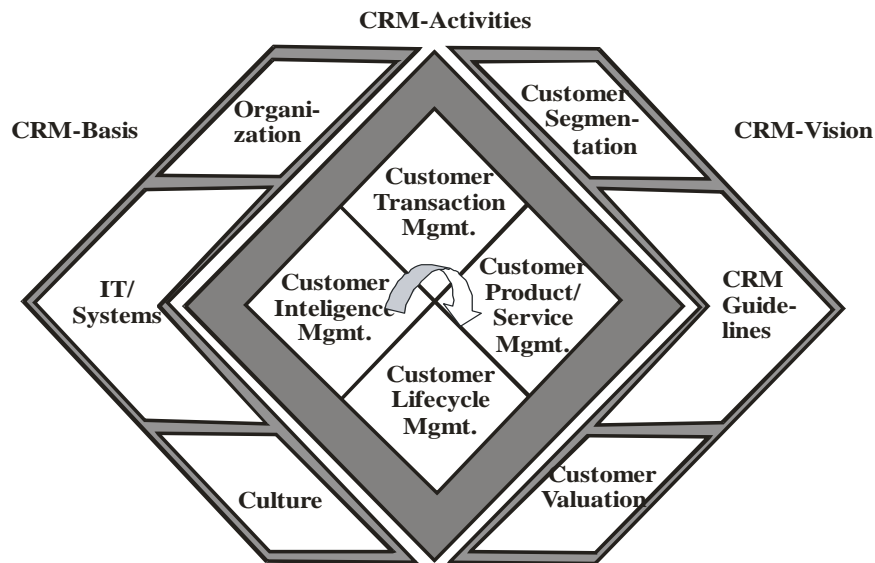

Figure 3: CRM diamond (Mack et al., 2005).

The CRM value chain as a model which businesses can follow when developing and implementing their CRM strategies and related CRM diamond model are grounded on strong theoretical principles and the practical requirements of business.

The main purpose of the CRM value chain process is to ensure that the company builds long-term mutually-beneficial relationships with its strategically-significant customers. Not all customers are strategically significant. Indeed some customers are simply too expensive to acquire and service: they buy little and infrequently; they pay late or default; they make extraordinary demands on customer service and sales resources; they demand expensive, short-run, customized output.

CRM value chain indicates to primary and secondary activities in building long term relationships with customers, in order to achieve higher level of their satisfaction as the basis for long-term loyalty.

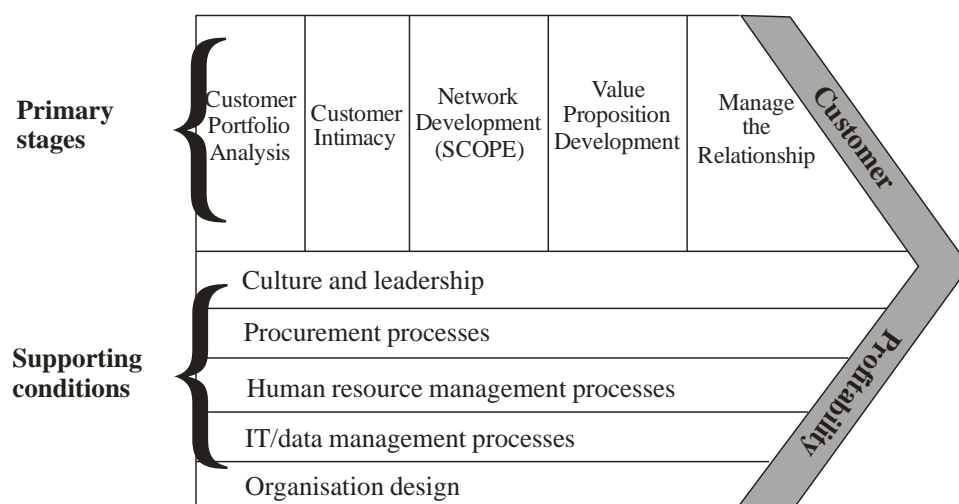

Figure 4: CRM value chain

CRM value chain includes five primary activities:

1. Consumer Portfolio analysis: an analysis of the customer database aiming to offer different products to them.

2. Understanding the consumer: activities on understanding individual or groups of consumers and building database accessible to all stakeholders whose decisions and activities may affect the attitudes and behaviour of consumers.
3. Networking: building a strong network of relationships with employees, suppliers, partners and investors who understand the requirements of target consumers. Central role in the model is given to consumers, which is surrounded by other elements: suppliers, owners, investors, employees, and other partners. Management and coordination, according to these elements, can ensure the structuring, communication and delivery of preferred products to consumers.
4. Development of products/services value: development of proposals which create value for both consumers and the company.
5. Managing relationships with customers: with a focus on structures and processes.

Supporting activities are aiming at: culture and leadership, procurement processes, Human Resources, data management process and company organizational design.

4. CUSTOMER CRM TO CEM

To overcome the perceived problems managing relationships with customers, a growing number of companies employ managers who follow the experience and customer satisfaction. Therefore, some authors suggest that instead of "relation" the usage of the term "experience". They identified three levels of customer experience: experience of the brand, the experience related to transaction and experience of the relationship. The more represented opinion in the recent years is that the understanding of the broader concept of customer experience becomes crucial for understanding the reasons why are customers withdrawing from certain relationships.

Several authors underscored the importance of personality brands that will allow customers to "live the brand" and to "experience the brand." Therefore, interpersonal relationships and relating to brands contribute to the experience of customer-related product. Hypothetically, these two elements can be mutually complemented by deficiencies of interpersonal relationships and for that reason to be offset by benefits from for the use of attitude towards the brand. Customer experience can be an intellectual integrator within which you can find compromises (trade-off). One consequence of focusing on experience rather than on relationships is that a good experience can strengthen the emotional aspects of relationships that are traditionally associated with the brand personality, but can reduce the need for interpersonal relationships that are associated with customer relationship management.

An explicit connection between brands and relationships has been recognized only recently. In the initial stages of theory of customer relationship management, proponents of this theory have often argued that brands and relationships (relationship) are separated by two conceptual domains. Since then, many authors have conceived brands such relationships, where the brand infused personality, which allows it to form a relationship with the customer. This relationship can be developed from the similarity between the brand value and customer's image about itself, and takes place when there is a good balance between physical and psychological needs and the functional and symbolic brand value. The link between emotions related to interpersonal relations and brand is strongest in the context of service brands. In this case, customers have the opportunity to experience the brand through interaction with him and the services of employees in direct contact.

Initially, managers who dealt with the customer experience have emerged in sectors with high levels of emotional involvement of the customer. However, this concept was later expanded massively and to sectors with low levels of customer involvement. Managers who follow the experience and customer satisfaction should have developed skills mediation function and authority, to bring value to customers in the form of experience that meets their needs and expectations.

One comprising CRM and CEM discover following. Centre? In contrast, CEM deals with customer attitudes. How satisfied was the customer? How likely would he or she be to buy again? How willing would he be to recommend us to a friend or colleague? Consequently, CRM's focus is the past and the present. CEM's focus is the present and the future.

Gathering CRM data is relatively easy. We get it by monitoring and recording customer behaviour. Gathering CEM data is much harder because we have to elicit opinions, perceptions and other attitudes consistently across customers, which not all customers will provide. That usually implies conducting surveys. Many

researchers in this area pointed out that the combination of CRM and CEM can be extremely powerful. CRM tells us what the customer did. On the other hand, CEM can tell us why. If a customer switches to a competitor, only attitudinal feedback will tell us that it was because of dissatisfaction with product features, or speed of service, or ease-of-use, or courtesy. In particular, CEM can vastly improve the power of CRM to predict future customer behaviour.

As American author John Chisholm says, in large organizations, CEM systems act as corporate eyes and ears. They:

- Gather timely feedback from key stakeholders – including customers, prospects, partners, and employees on their satisfaction, intentions, and other attitudes towards, and about their experiences with, an enterprise;
- Make actionable that feedback through powerful analytics and reports, and instantly accessible to the right people at all levels of the enterprise through interactive dashboards, pushed reports, emailed alerts, and other means; and
- Enable enterprises to efficiently manage actions responding to feedback.

Optimal design of CEM systems involves considerations not just of IT and corporate strategy, but also of statistics, sampling, market research, and human behaviour. Well-designed CEM systems are especially important to large organizations, where the many divisions and departments could easily inundate customers with survey requests.

The benefits of such CEM systems have been firmly established. They inform the right individuals and teams when customers are dissatisfied and why, enabling those individuals and teams to respond immediately. CEM enables more effective rewards and recognition, thereby enhancing employee satisfaction and commitment. As a consequence of all of the above, CEM systems put organizations on paths of faster learning, faster process improvements, and faster gains in competitive advantage.

5. CONCLUSION

CRM is a set of activities which provide company growth through: more effective segmentation of target groups, analytical forecasting of market trends, faster response to market changes, profitability analysis of individual customers, ability to direct sales to highly profitable customers, improved quality of services and sales opportunities, longer customer retention, shorter sales cycles and higher profitability of the sale process, synchronization and analysis of information gathered from various sources, improved efficiency and flexibility of operations, intensive development of competitive advantage and company reputation as a strong business partner.

Requirements for creation of high quality CRM models are: customers satisfaction and loyalty; data protection, business intelligence tools, enterprise resource planning and creation of integrated business systems. CRM's focus is the past and the present. CEM's focus is the present and the future. CRM tells us what the customer did. CEM can tell us why. But, combination of CRM and CEM can be extremely powerful.

Abstract: *In democratic systems the administration is constantly meet with different challenges. Processes of administration transformation in line with the principles of the new public management bring a higher degree of orientation towards citizen as one of the most important stakeholder group, primarily in local governments work. It became evident that the administration should adopt the operation manner of the business systems on the market, expressed primarily through the application of marketing orientation. The paper describes the application of marketing in public administration and presents the tools for assessment of business performance in this area. The results of the research implemented in Serbia are shown and they identify the local government's commitment to customers and ways to measure their satisfaction.*

Keywords: *marketing, public administration, business performance, customer satisfaction*

1. INTRODUCTION

There are several key reasons for the existence of public sector in every society (Kotler & Lee, 2007): it defines the principles according to which the society functions; it delivers public services of general interest (e.g. police, education, health sector etc.); it performs public services that profit and non-profit organizations do not wish or cannot perform with the existing resources, which is, for example, the case with social assistance to those population groups that are in need.

Considering the fact that the citizens participate in financing public sector services, their expectations are justifiably high and this is why the organizations should continually invest in improvement of their performance in order to raise the level of citizens' trust and satisfaction and obtain their support.

Public administration is faced with a huge number of challenges in democratic societies. The public administration transformation process in line with the principles of the New Public Management resulted in its higher decentralization and active citizen participation (Livingstone et al., 2007; Vigoda-Gadot, 2004), especially in the area of local government. According to the New Public Management principles, citizens are the customers of public administration services, hence the terms are used as synonyms,

Academic research has already studied to great extent the necessity of adopting the market way of doing business in non-profit organizations (Andreasen & Kotler, 2003; Alexander & Weiner, 1998) regardless of the complexity of political and economic characteristics of the public sector and it was confirmed in practice. Special emphasis is put on adoption of marketing concept and understanding of customer/citizen (Day, 1994). The accustomed understanding of organization-oriented marketing in non-profit sector is identified as the main limitation to adoption of marketing concept of doing business that is entirely customer-oriented. This means that the non-profit organizations function under the assumption that their products and services are needed by their customers and that they would consume them regardless of whether or not they were created and delivered according to the customers' needs since the products/services had been predefined and cannot change according to market needs (Dolnicar & Lazarevski, 2009). However, the authors confirmed by their research that market orientation and marketing strategies and tools, especially in the area of communication, are also necessary for non-profit organizations (that include public sector organizations) and that they affect the efficiency and effectiveness of operation.

2. MARKETING ORIENTATION OF PUBLIC ADMINISTRATION

The importance of applying a marketing concept in the non-profit sector was studied by Kotler, Levy, Zaltman, Shapiro and others (Dolnicar & Lazarevski 2009) who managed to confirm and prove that in their research. However, in the beginning, the use of marketing mostly referred exclusively to promotion. Gradual and systematic adoption of the concept resulted in adoption of the philosophy according to which marketing begins and ends with the customer - it is customer-oriented (Gonzalez et al., 2002). Much research was done in order to investigate the degree of marketing application in the non-profit sector. A study by Dolnikara

and Lazarevska (2009) combines the literature and results achieved so far. Besides theoretical analysis, the authors conducted research that was supposed to examine the current situation of the application of marketing principles, methodologies and techniques in the non-profit sector organizations. However, practice in Great Britain, United States and Australia where the research was conducted still shows that marketing in the non-profit sector is primarily focused on sales and promotion and there is insufficient strategic approach to marketing. One of the important identified reasons for that is that most employees dealing with marketing activities lack education and training in this area. Thus, the general conclusion would be that there is a huge potential for improving the efficiency and effectiveness of operation in the non-profit sector by full application of marketing philosophy and concept.

Besides specific political and economic features of the public sector, observation of customers is not quite identical to that in the profit sector which makes the application of marketing concept all the harder. Namely, the principle "the customer is always right" and "his wishes should be complied with" cannot be unconditionally accepted in the public sector organizations. It could happen that customer or in this case, the citizen, is not right, and it is up to the organization to perform the best professional practice regardless of whether the citizen agrees to that or not at that moment (e.g. removal of illegally parked vehicles).

Majority of public sector organizations deliver services that are for the general wellbeing of society and are often of restrictive and limiting nature. In this case, the citizen is far from being satisfied with the service. Unlike private sector, organizations in the public sector do not depend on individual customer (Proctor, 2007). However, this does not mean that they should use their position and function of the organization while neglecting citizens' needs. The simple application of marketing principles is hindered by specific nature of services provided by certain organizations: services that are delivered regardless of whether they meet the needs of the citizens or not – social services, then free-of-charge services which the citizens better accept as they are, than not have them at all – primary education services, as well as the services that citizens actually do not want at all – customs and tax services.

In accordance with the specific nature of public sector services, one might say that the goal of marketing is to educate and inform the citizens and other stakeholders about things available or unavailable, about factors determining/limiting the manner of delivery of certain services, about best interests of general public etc. By establishing relations with the stakeholders and adequate communications, public sector organizations may gain understanding and satisfaction of their customers (Cicvarić Kostić, 2011). Of course, accomplishing this goal includes continuous efforts in improving the services and manner of their delivery while considering the opinions, proposals and suggestions of the stakeholders.

As for the public sector, it is increasingly taking over and applying best practice of the private sector (Kotler & Lee, 2007): total quality management; customer-oriented strategy; reengineering; business performance measurement; cost benefit analysis; engaging external resources and consultants; e-government etc. Apart from that, the marketing philosophy of public sector organizations' operation is evident in their every day activity, especially: service improvement, doing business in compliance with the law, improvement of citizens' living conditions, increasing the citizen satisfaction, provision of citizen support etc.

Management approach and marketing orientation stress the importance of establishing relations between the administration institutions and the citizens. The emphasis is on "understanding the perception of citizens/customers concerning the public administration work and level of organizations' awareness of public needs" (Vigoda, 2000).. Vigoda developed a model of public administration responsiveness to citizens' requests in which he identified the factors affecting the responsiveness and citizen satisfaction: quality of governance and management of organization; quality of employees; general impression from the contact with the employees; business and social orientation of the institution; eagerness and readiness for change; ethics; organization policy.

Flynn (1995) studied the request of the citizens for higher level of service quality and realized that the competition generally raised the citizens' expectation concerning any kind of service, including the public service. That emphasizes the importance of "client research that helps understand in which way they would like to deal with the administration organizations, their potential remarks, suggestions, proposals for service improvement etc..."

At the beginning of 1990-ies, public sector in most European countries adopted the new public management business philosophy that is client-focused and includes the application of marketing tools and strategic planning (Cousins, 1990), in order for organizations to successfully "sell" their "policies" to the citizens

(Proctor, 2007). Proctor (2007) identified four types of marketing that can be recognized in public sector organizations that differ according to their basic goals (table 1).

Table 1. Types of Marketing in Public Sector (Proctor, 2007)

Marketing Type	Characteristics	Goal
"Marketization"	Looking at public sector products and services in terms of commercial market competitiveness	Set the price and adjust the quality according to client demand
Promotion of organization's interest	Marketing is used only to promote organization's interest	Provide support of the market and society
"Local" marketing	Local self-government is using marketing to promote the areas under its competence	Provide support of the market and local community
Marketing as an instrument	An organization is using marketing only as an instrument to promote its political goals	Promote basic political goals

In any case, only complete adoption of marketing philosophy enables the public sector organizations to provide a whole range of services in education, health, recreation, utility services etc. that are addressing citizens' needs and to do that efficiently. If we consider the basic role of local authority, for example, it exists as the "voice of the citizens" it serves. Thus, the citizens expect the municipality to advocate their rights and protect them from possible adverse situations, like construction of a factory in an inhabited area of the municipality.

For marketing application in administration, it is important to emphasize the inclusion of all instruments of the mix, especially those relating to services:

- Participants in the service delivery process – they must be professional in the work they do; they have to be informed about the whole service delivery process in order to provide information to citizens; they have to be aware of their role in providing value to the citizens, to be kind and have developed communication skills;
- The process of service delivery – the procedures are customer-oriented so that the beneficiaries can finish the task that brought them to that organization in an efficient manner; the way they are treated; the manner of resolving complaints and
- Physical evidence in which service is provided – how the premises are arranged and marked, info material in the premises (leaflets, brochures, notice boards), web site.

From the aspect of relationship marketing the functioning of an organization is viewed as interaction of different stakeholders and organization, and that applies to public sector as well. Thus, the adoption of marketing concept is a good way to manage the relationship with stakeholders and meet their expectations, which is one of the key goals of doing business. The importance of communication, interaction, quality and value for the stakeholders are emphasized in the context of modern marketing theory and practice that introduce the concept of relationship marketing, stakeholders engagement etc. (Proctor, 2007).

Communications refer to full application, integration and management of all communications in the organization. Interactions in this context include the delivery of values to customers and other stakeholders by the employees of an organization. The authors of the paper have grouped the internal communications and relationship management under the term of internal marketing that aims to provide service quality and satisfaction of both external and internal customers. The importance of communications in internal marketing is considerable, to the extent that success of the internal marketing application depends on that since, in order for the employees to deliver the value, they must understand the value they are delivering, the way they are supposed to deliver it and how the value delivery would benefit them. Understanding of the stated factors includes the development of (internal) communications system. Development and application of internal marketing are important for all organizations of the non-profit and public sector (Cahill, 1995).

Local government exists in order to serve the society and it has to find the ways and means to meet the needs of citizens as customers and all stakeholders. Since administration institutions are traditionally bureaucratic, the changes executed in transition and their transformation open room for application of the internal marketing tools. Internal marketing aims to ensure that everything is customer-oriented through the manner in which the employees are performing their work, and building and maintaining the relationships

with citizens and stakeholders. Furthermore, the internal marketing's task is to achieve satisfaction, trust, dedication and loyalty of the employees in an organization. So, within the internal marketing concept, employees and customers are the most important stakeholders. In order to emphasize the importance of internal marketing, the literature refers to the employees as "internal customers" which leads to a conclusion that their needs and wishes should be observed as well and programs should be created to satisfy them (Proctor, 2007). Since internal marketing primarily includes informing the employees about the organization's mission and their role in achieving that mission, the basis of internal marketing consists of internal communications (formal and informal, written and oral). Besides communications, programs of internal marketing include trainings, acknowledgments, motivation of the employees etc.

3. BUSINESS PERFORMANCE ASSESSMENT IN PUBLIC ADMINISTRATION

Balanced Scorecard technique defined by Kaplan and Norton (1996) has been widely accepted and suitable for use in the corporate sector. Although its successful application in the public sector can be identified (Radnor & Lovell, 2003), Proctor (2007) underlines that its application in the public sector demands certain modifications, since all these organizations are above all responsible to state administration and then the other stakeholders, as well as that financial aspect of business is of primary importance in the private sector while that is not the case in the public sector. Modified technique for the application of business performance assessment for the public sector organizations (Figure 1) was presented by Moullin (2007).

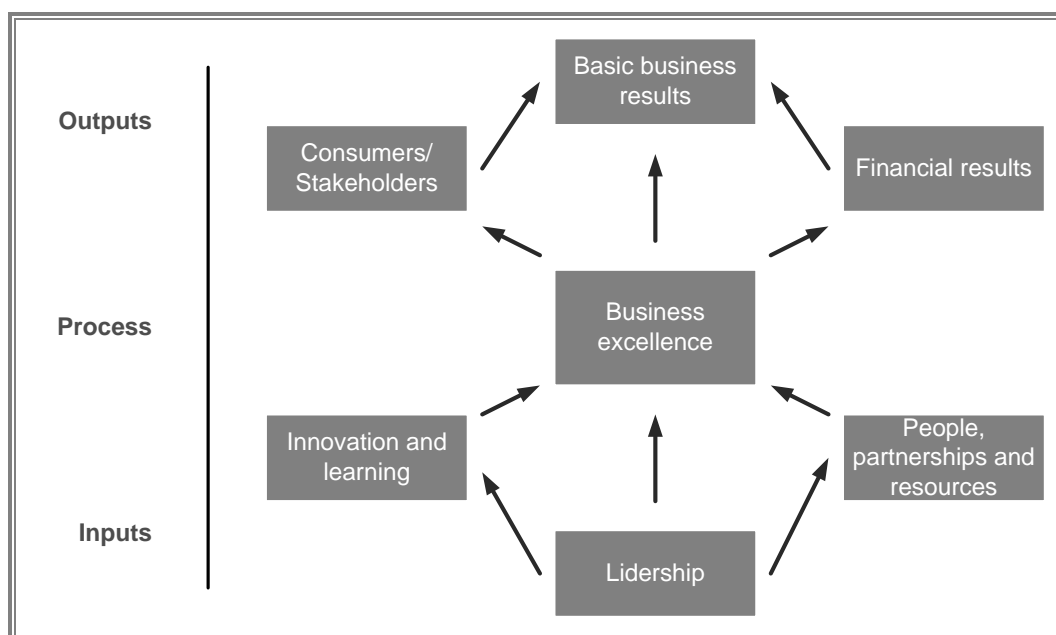

Figure 1. Business performance assessment for the public sector organizations (Moullin, 2007)

It should be stressed that communications pervade every phase and every degree of assessment shown in the Figure. Therefore, they have an extremely big role and importance in the entire model. Integrated communications concept also represents one of the key elements in creating and delivering the value to the stakeholders. All messages sent by organizations, all channels and places of communication, are united under the term integrated communications and they are directed to establishment of a dialogue with stakeholders. Often, in designing the communication program, choice of instruments, defining the message, choice of communication channel etc., the models describing the phases undergone by customers in the process of deciding about purchase, are used as the basis (AIDA, DAGMAR, hierarchy of effect model etc). As for the public sector services, they are characterized by low citizen participation in their creation, so that communication programs in this case need to include all phases of customer buying behaviour from cognitive degree, through affective degree to behaviour.

Service quality measurement is one of the basic indicators that should be included in the measurement of public sector business performance. Other indicators are speed of service delivery, speed of resolution of complaints, how well-informed and kind the employees providing services to end users are, how well-equipped the premises of the organization are etc. One of the most frequently used instruments for measuring service quality is the so called SERVQUAL that includes measuring the difference between the

expectation and perception of users in the area of communication, both employees communication and the whole set of external communications. A technique often used in practice is the so called “mystery shopper”. Also the portfolio models for assessment of service value for the stakeholders are used, like BCG matrix, then matrix of competitive advantage and market attractiveness etc.

Faculty of Administration of the University of Ljubljana developed a model including the system of budgetary indicators for measuring the local government success. The model includes 75 indicators for measuring successfulness that can be classified in four groups: synthetic indicators, indicators related to municipal revenue, indicators related to municipal expenditures and time series of the main indicators. The developed model indicates successfulness of the public sector (planning, goals, and results). The system of budgetary indicators within the model is available at <http://www.fu.uni-lj.si/SIB/vhod-ang.htm> and it offers methodology for the development of similar models.

The model of balanced scorecard for the local government and state bodies includes planning and monitoring of all areas in which public administration organizations function. The model is a complete framework for establishment of the indicator system, and the indicators for measuring marketing success may be integrated in a comprehensive structure of organization's work.

The research conducted in Serbia and presented in chapter 4 showed that local governments most frequently use questionnaires and comment boxes in order to measure their success in the customer satisfaction segment.

3.1. CUSTOMER SATISFACTION

Customer satisfaction, as one of the most fundamental marketing concepts, may be defined as the overall performance assessment of various attributes constituting a product/service (Johnston, 1995). Customer satisfaction may be used as an instrument for measuring the improvement of quality and overall business (Filipović et al, 2010).

Customer satisfaction concept has been studied in literature to great extent and research showed that the attributes assessed by the customers based on which they achieve their satisfaction are as follows: expectations, perceived quality of product/service, confirmation of expected quality level (Anderson & Sullivan, 1993), then image, expected quality of equipment and people providing the service, as well as the expected value (Kristensen et al, 1999).

In order to accomplish customer satisfaction, the organizations develop customer satisfaction programs. It would be wrong to assume that satisfaction programs are solely data collection from the customers. The programs include creation and implementation of action plans based on the information obtained from the customer. Satisfaction programs are formed in several stages. Their successful implementation (Douglas, 2003) requires the following:

- Support from the top management;
- Making the satisfaction concept the focus of business;
- Integrating the work of business functions and forming of multi-functional teams;
- Accountability of employees that are in direct contact with the beneficiaries for the customer satisfaction program implementation;
- Measuring the satisfaction of customers which includes both qualitative and quantitative methods;
- Evaluating customer satisfaction with competitive products/services;
- Well-elaborated communication plan;
- Good implementation plan in line with organization's goals.

The results of a research conducted among the managers of the state-owned health institutions in Serbia in 2006 showed that positive attitude of managers towards communication activities of the institution have positive effect on the patient satisfaction (Filipović et al, 2010). In the study, the attitude towards communication activities was examined through the approach the managers have to external stakeholders, primarily the media (proactive/reactive) and through institutionalization of the position/sector in charge of the communication activities (marketing, public relations). The study concludes that managers who understand and support marketing and public relation activities are also committed to managing the patient satisfaction programs, which leads to a positive image of the institution, loyalty of patients and increase of profit.

4. LOCAL GOVERNMENT'S ORIENTATION TOWARDS CUSTOMERS AND SATISFACTION MEASUREMENT

In order to determine the orientation of local government in Serbia toward customers and other stakeholders, as well as the tools used for customer satisfaction measurement, the research was carried out in 2010. The research was conducted in cooperation with: The Ministry of Economy and Regional Development of the Republic of Serbia, Statistical Office of the Republic of Serbia, and Standing Conference of Towns and Municipalities. The tool used for the research was questionnaire. The questionnaire was sent to respondents by Standing Conference of Towns and Municipalities representatives, through the network of people in charge, electronically with a cover letter in which the subject and goals of the research were explained. The questionnaire was sent to addresses of 167 municipalities in Serbia. After four iterations, the total number of gathered valid questionnaires was 109.

In identifying local government goals, employees have ranked them as it is shown in table 2 (they marked primary and secondary goal of their municipality in the proposed list of goals).

Table 2. The goals of local government

	Primary goal	(%)	Primary goal	(%)
I	Contribution to the development of local community	41.7	Informing the public about programs and activities	20
II	Increasing work efficiency through servicing a greater number of customers	17.7	Complying with work procedures and scrupulous performance of activities by the employees	14.7
III	Achieving customers' satisfaction	15.6	Achieving customers' satisfaction	14.7

Analysis of obtained results brings to conclusion that the local government is still more oriented towards its productivity and efficiency and one-way communication. Increasing the customer satisfaction is recognized as a less important goal compared to the previously stated, while building good relationships with individuals and groups from the surrounding is not even included in work objectives. This indicates an extremely low level of understanding and application of the concept of relationship marketing and stakeholder relations management which can be an important area for improvement of administration practice in Serbia.

The survey of citizen satisfaction with municipal services is most frequently done through questionnaires (34.3%) and comment boxes (32.1%). In 50.5% of cases, the municipalities do not conduct any kind of citizen satisfaction survey but in 92.7% of the cases they believe that citizens are satisfied with their service. This information shows that the employees are quite optimistic with regard to citizen satisfaction with their work. According to the results of the municipalities that emphasized they conduct satisfaction surveys, the citizens are mainly satisfied with municipal work (Figure 2) which should be compared to the citizen survey on the satisfaction with the local government work.

Figure 2. Citizens satisfaction according to research municipalities conduct

5. CONCLUSION

All organizations, including the public sector, are faced with new challenges, complex and turbulent environment, increased competition, development of Information and Communication Technologies, development of society in general etc. and they must respond to those challenges through the application of strategic management, innovation, business performance measurement and above all, value delivery to citizens and meeting their needs. Management approach and marketing orientation emphasize the importance of establishment of relationship between the management and the citizens. At the beginning of 1990-ies, administration in most European countries adopted the business philosophy based on the new public management principles. They put the focus on service beneficiaries and include the application of marketing tools and strategic planning. From the aspect of relationship marketing the functioning of organizations is viewed as interaction of different stakeholders and organization, and that applies to administration as well. Thus, the adoption of marketing concept is a good way to manage the relationship with stakeholders and meet their expectations, which is actually one of the key goals of doing business.

APPLICATION OF NEUROSCIENTIFIC CONCEPT IN DEFINING AN EFFECTIVE MARKETING COMMUNICATION STRATEGY

Marija Babic¹, Vesna Damnjanovic²

¹Faculty of Organizational Sciences, bwmarija@gmail.com

²Faculty of Organizational Sciences, damvesna@fon.bg.ac.rs

Abstract: *New trends that recognize the neuroscientific approach in marketing research are encouraging academic experts and specialists from practice to better understand consumer behavior, as well as the response to adequate marketing communication strategies towards a target group. The paper reviews the methods and techniques used in neuromarketing: Functional magnetic resonance imaging (fMRI), the method of Electroencephalography (EEG) and the Steady State Topography (SST) method. The majority of devices that are used in the field of neuroscience during exposure to different sensory stimuli measure brain activity, and based on standardized patterns of brain region activation, a general conclusion is derived regarding the reaction to the stimuli. The advantage of these measurements as compared to traditional marketing research methods, focus groups, surveys and observations, is that they provide direct information on attitudes which, in many cases for subjective reasons, a person is incapable of reproducing on their own. The paper focuses on the systematization of literature in the field of neuromarketing, as well as the application of results of neuroscientific research in the defining of a marketing communication strategy.*

Keywords: *Neuroscientific concept, Neuromarketing, Consumer behavior, Methods and techniques of human brain scanning, Marketing communications, Strategy.*

1. INTRODUCTION

Technological advance of society has significantly changed the individual and social profile of modern man, who is today faced with a great number of communication instruments that influence his attitudes and opinions on a daily basis. While the marketing strategists had for decades been focusing on positive reactions of potential customers and the creation of a positive brand image by advertising a product's comparative advantages against the competition, a new science was simultaneously developing, one that would relocate the field marketing and communications to a whole new level: the hidden level of the subconscious and emotions, which can be manipulated to achieve what was once unachievable. Traces of emotional manipulation can be found as far back as the war propaganda of Nazi Germany during World War II, when the public awareness of the then war-torn nations was systematically and in a planned fashion influenced using anti-Semitic messages. The fact that awakening of the senses and emotional reactions represents an instrument whose power to this day remains cognitively unlimited was known as early as last century by all subjects creating public opinion, but the scientific merit of the principle of subliminal influence was questioned given the level of development of neuroscience at the time. Great technical inventions in the field of neuroscience took place in the 21st century, when the door opened giving access to the processes occurring in the human brain, and information that may be of crucial importance in the process of forming an opinion about products, services, personalities, events, as well as other instances that depend directly on their image with the audience. Most of the devices used in the field of neuroscience operate on a simple principle: they measure brain activity during exposure to different sensory stimuli (visual, auditory, olfactory and tactile), and based on standardized patterns of brain region activation, a general conclusion is derived regarding the reaction to the stimuli. The advantage of these measurements in relation to standard methods such as focus groups, surveys and observations, is that they allow for direct insight into information regarding attitudes, which, in many cases for subjective reasons, a person is incapable of reproducing on their own.

The focus of the paper will be on the potential applications of these research results in the creation of an effective marketing communication strategy. The aim of this study was to identify the intersecting and (or) contact points of two scientific disciplines, and to discuss the possibilities for cooperation between two scientific disciplines: medical sciences (neurology, psychology and psychiatry) and marketing communications.

The creation process of a marketing communications strategy relies on numerous tools and concepts, of which the neuroscientific concept is only one of the possible approaches whose application is to this day considered a *new-age* approach. The concept of *effective* marketing strategy has changed in parallel with the intervals of current consumer generations, where the baby-boomer generation and generations X (eXcel) and Y had defined the principles of marketing strategies of their time, with their life attitudes, experiences, reactions and values. With years the marketing paradigm of targeting generations according to their characteristics and current age has matured, so in accordance with generalizations about the target groups, marketing communication strategies were created adaptively.

The neuroscientific approach, unlike the previously mentioned, strives to reach the hidden and hard to reach data that is sometimes recorded as nothing more than an impulse of brain activity, never to emerge to the conscious part of the mind, thus it cannot be cognitively reproduced. These data appear in the form of waves of brain activity that are measured by a variety of neurological devices (electroencephalogram, magnetic resonance imaging, eye movement tracker, etc.), and as such they represent a more objective insight into human cognition and thinking as compared to a reproduced verbalized word.

2. THE NEUROSCIENTIFIC CONCEPT. FIELD OF RESEARCH AND DEVELOPMENT

“Men ought to know that from nothing else but the brain come joys, delights, laughter and sports, and sorrows, griefs, despondency, and lamentations. And by this, in an especial manner, we acquire wisdom and knowledge, and see and hear, and know what are foul and what are fair, what are bad and what are good, what are sweet, and what unsavory... And by the same organ we become mad and delirious, and fears and terrors assail us... All these things we endure from the brain, when it is not healthy... In these ways I am of the opinion that the brain exercises the greatest power in the man.” (Hippocrates, On the Sacred Disease, 4th century BC)

It is human nature to strive for self-knowledge, thus it is not surprising that for thousands of years so many have dealt with the issues of human feelings, reactions, behaviors, as well as many other questions that to this day remain in the field of study of the scientific discipline called neuroscience. The job of neuroscience is to “explain behavior through the framework of activities of the human brain. In which manner does the brain control millions of individual nerve cells to produce behavior, and how are these cells influenced by the environment...? The final boundary of biological sciences - their ultimate challenge - is to understand the biological basis of consciousness and the mental processes which we perceive, behave, learn and remember” (Eric, 2000). The main object of study in neuroscience is the nervous system, and seeing as how this science is based on multidisciplinary research even though it is traditionally classified as a branch of biological science, its domain also reaches many modern scientific fields such as computer science, microbiology, neuropsychology, statistics, physics, psychology and medicine.

The roots of the idea of studying the human nervous system are tied to the period as far back as 7000 years ago: remains of human (hominid) skulls have been found with traces of cranial damage assumed to be the result of trephination, a process of drilling of the human skull (Bear, 2007). Trephination was performed in order to treat headaches and mental disorders.

The scientists of the 17th and 18th century were more devoted to the study of brain tissue structure, and they had noted a difference between the gray and white matter. Noticing the nerve connections in the white matter, they had properly concluded that these connections served to send information to the gray matter and receive its feedback. By the end of the 18th century, all parts of the human nervous system had been dissected, and its anatomy had been described in detail. With the discovery of the microscope the research had become far more precise, and during the 1890s Santiago Ramón y Cajal had established the doctrine of the neuron, as the cell that represents the basic unit of the nervous system. In the late 19th century, DuBois-Reymond, Müller and von Helmholtz discovered that neurons possess electric activity, while Paul Broca came to the conclusion by working with patients with different brain disorders, that different brain centers are responsible for different functions.

The 20th century brought about new scientific achievements in the field of neuroscience, and divided it according to the level of analysis into the following fields: Molecular neuroscience, Cellular neuroscience, Systems neuroscience, Behavioral neuroscience and Cognitive neuroscience.

The research that will be discussed in this paper was performed at the level of behavioral and cognitive neuroscience, with focus on the application of the results in the field of marketing communications. The

development of neurological diagnosis and a multidisciplinary approach to neuroscientific research have opened the knowledge from this field to many other fields that can benefit from it greatly. Due to this reason, the approach to marketing research has changed its course and direction, while a new branch of marketing has been created - neuromarketing.

3. NEUROMARKETING

Neuromarketing represents a new direction of marketing that relies on neuroscientific research, which through the use of neuroscientific methods reaches conclusions regarding primal desires, opinions, attitudes, tastes and preferences. While traditional marketing relies on traditional methods of gathering data, neuromarketing relies on the results of so-called “mechanical devices”, spoken about by Kotler. As far back as 1957, Vance Oakley Packard had published a book titled “The Hidden Persuaders”, in which he spoke about how companies are using motivational research and other psychological tactics in order to manipulate expectations and awaken the consumers’ desire for the consumption of their products.

However, it was not before the year 2002 that the term “neuromarketing” was first used by Ale Smidts (Erasmus University), while the first studies using the fMRI method were conducted by Gerry Zaltman at Harvard in 1999.

Neuromarketing is with certainty the only field of marketing that has in recent years experienced its greatest expansion, since it has radically changed the direction of research. It studies the “sensory-motor, cognitive, and affective responses to marketing stimulation. Researchers use technologies such as magnetic resonance imaging to measure changes in the activity of certain sections of the brain, electroencephalography (EEG) to measure activity in specific regional spectra of the brain’s responses and/or sensors to measure changes in physiological states (heart rate, respiration, galvanic skin resistance), all with an aim of finding out why customers make the decisions they do, as well as which part of the brain is telling them to do so. Neuromarketing is a marketing direction developed in America in the late eighties, which creates and sends out messages based on an analysis of how the brain reacts, and then tests them by applying functional magnetic resonance imaging and recording the brain’s reactions, contrary to the polygraph and the moment of truth.

The Australian company “Neuro Insight”, which deals with numerous marketing researches with application of the neuroscientific method, has outlined three key novelties of the neuroscientific concept as compared to other conventional methods of data collection for marketing purposes (NeuroInsight, 2009):

- Identification of the factors that people are not consciously aware of
- Collection of reactions and responses that people cannot or do not wish to describe in words
- Identification of particular moments during the communication process that represent a “trigger
- Simultaneous measuring and testing of multiple indicators
- Re-examination of the same respondents
- Overcoming cultural differences

As can be seen from the advantages stated by Neuro Insight, the basic characteristic of the application of neuroscientific methods in the process of creating an effective marketing communication is that they provide an insight into information that has until now been unattainable. It is information on the attitudes, preferences, appeals and reactions of consumers, which has not been obtained directly - through verbalization of the experience, but it has instead been collected at the place of its origin: in the very brain of the respondent. This is the reason why such information is considered to be more objective than the one obtained through classical research methods.

4. TECHNIQUES AND METHODS OF THE NEUROSCIENTIFIC APPROACH IN THE GATHERING OF REACTIONS, OPINIONS AND ATTITUDES OF CONSUMERS

Modern neurological diagnosis uses a number of technologically advanced instruments to research and record brain activity, in order to determine whether the nervous system of a person is functioning properly. While modern neurology and neurosurgery use neurodiagnostics to establish a diagnosis and contribute to the patients’ treatment, many researchers throughout the world have recognized the possibility for applying neurodiagnostics in another field as well: the field of marketing research. Neurodiagnostics are used in marketing research during various stages of creation of a marketing communication strategy: during the preparation phase, implementation phase and phase of evaluation.

In the preparation phase of the creation of a strategy, neuroscientific studies are used to gain an insight into consumer desires. Based on the desired effects that the marketing communication aims to achieve, in cooperation with neurologists, marketing experts map the brain centers in which an “emotion” occurs as a result of the received message. When we know the effect that we wish to achieve, a tactic for evoking activity of a specific brain region is developed, and a stimulus is created that is meant to initiate the reaction. The process of creating messages (stimuli) is a complex process that requires the engagement of a multidisciplinary team, which usually consists of a neurologist, a psychologist, a communicologist and a marketing expert.

The creation of a “pilot” version of the stimulus is followed by the testing phase: through the use of neurodiagnostics the effectiveness of the stimulus is measured, and any necessary corrections of the content of the message are made depending on the level of success of brain region activation. In other words, it is measured whether the message has brought about the desired effect in the respondents. In this phase, neurodiagnostics replaces the traditional methods of measuring the effectiveness of a marketing message. The evaluation phase is most often conducted in cases when the neuroscientific approach is not used during the preparation phase of a marketing communications strategy: companies then implement this type of research in order to identify their mistake and find out where the “noise” occurred in the receiving process of the message by the target consumer. In this phase, neurodiagnostics can provide an insight into the manner in which the consumers have actually received the message, which is often in contradiction with the goals defined by the sender. In all of the given phases of marketing research, many modern neurodiagnostics technologies are used that are aimed to provide insight into the manner in which the human brain reacts to marketing stimuli.

4.1. Functional magnetic resonance imaging

Functional magnetic resonance imaging (fMRI)¹ is one of the most modern medical methods of brain activity diagnosis, which measures the magnetic oscillations of hemoglobin, the component of red blood cells that carries oxygen via the blood to the cells. In other words, fMRI measures the flow of oxygen in the brain and identifies increased and decreased activity of brain regions, because depending on their activation, the flow of blood (and therefore oxygen) in them increases or decreases. FMRI, unlike a CT and PET scan, is not an invasive method because it involves no radiation, while the advantage is that it is highly detailed and can show very small changes in regions the size of only one millimeter. As opposed to EEG and MEG, fMRI registers activity inside the brain, while the two other techniques record activity on the cortical surface.

Martin Lindstrom conducted the largest systematic study in the field of neuromarketing by using precisely the fMRI technique. This multi-year study involved thousands of respondents throughout the world, two hundred experts, ten professors and doctors, an ethical committee, and a cost of \$ 7 million.

FMRI is a technology that only seemingly resembles classic magnetic resonance: it is a large-scale scanner in which a respondent is placed in the lying position over the entire length of their body. The respondent must lie completely still during the test, without any movements, because even the slightest movement of the body can make the results completely unreadable: the reason is because the scanner monitors millimeter changes in the flow of hemoglobin through the human brain, so a movement of the head of even a few millimeters can have an effect on the results.

The scanning procedure continues after the respondent is set into the initial position. The respondent can be stimulated by all kinds of stimuli (visual, auditory, tactile, and olfactory), but most of the studies are based on a combination of visual and auditory stimuli: photographs, sound recordings and video recordings. While a respondent is watching a video, for instance, a reaction occurs in his brain in the form of increased blood (hemoglobin) flow through the brain centers in which the activity is occurring. In other words, fMRI monitors which brain centers are affected by the stimulus (the video), while the data is then interpreted by a neurologist who gives an explanation of the changes in brain activity.

The interpretation of fMRI results and their proper use represent the most important step in the application process of the neuroscientific concept in the creation of a marketing strategy. Neuromarketing is a young

¹Hereinafter fMRI

scientific discipline, thus it is expected that collisions will occur during the defining and laying of foundations for future directions of development, because there is no unanimous agreement concerning the adoption of postulates on which the further science could be developed.

4.2. Electroencephalography (EEG)

Electroencephalography represents a special neurophysiological method that registers brain activity through electrodes placed on the surface of the human head (which is the most common form of use) or inside the brain tissue (which is used in preoperative preparation). The resulting diagram is known as an electroencephalogram (EEG)², which was earlier written out on paper by special pens sensitive to voltage changes, while today it can be more frequently found in the form of a digital drawing made by a computer. EEG records brain waves, which are according to their frequency divided into delta waves (activity up to 4 Hz), theta waves (4 to 8 Hz), alpha waves (8 to 12 Hz) and beta waves (over 12 Hz).

When it comes to EEG in marketing, its great advantage over the previously mentioned fMRI is its portability. A modern EEG device is very compact and can easily be transferred to the location of measurement, which means that the respondent does not have to be confined to a testing room and that the research can also be conducted at the point of sale. One of the first scientists who initiated the entire process of the portable EEG in neuromarketing was Dr. David Lewis, who has recently, with the company Neuroco from Great Britain, conducted a study in a local shopping center in the town Lakeside.

“Generally, every shopping center would like to know how its visitors react to the entire ambient - how they react to the orientation signalization, whether they feel rushed or that they can stand in front of a shop window and look all they want, without standing in anybody’s way. To be precise, they wish to know how a store window should look in order to capture the attention of the customer, and if we look at it from the perspective of each individual store, how do the customers respond to their arrangement”). (BelfastRound, 2007).

The use of neuroscientific methods in the creation of a marketing communications strategy no longer represents a secret. The method was mystified up until the year 2000, studies were conducted “under the radar”, and no company wanted to admit that it had resorted to a method whose ethics had been questioned on a daily basis, because information on the application of these methods at the beginning of this century had represented a threat to the long-built image of a company. Today’s situation is completely different: use of the neuroscientific approach in the product development process, creation of a campaign and positioning strategy is today only considered as a competitive advantage: a company that resorts to such methods is “modern, progressive, futuristic and values the opinions of its consumers”. This year is certain to bring change in terms of understanding of the neuroscientific approach in a marketing framework:

Forbes magazine published an article in November of 2009 called “Neuromarketing: Companies Use Neuroscience for Consumer Insights” (Forbes Org., 2008). In this article, the author Laurie Burkitt lists several examples of the use of EEG and fMRI methods among prestigious international companies:

Hyundai, one of the world’s major automobile manufacturers, speaks publicly about the use of EEG for reading the brain activity of potential consumers and buyers of the new models coming out in the year 2011. “We want to know what consumers think about a car before we start manufacturing thousands of them”, said Dean Macko, the brand manager at Hyundai Motor America. This study was conducted on 30 respondents (15 female and 15 male) who were equipped with an EEG device and had the task to only observe parts of the car, even the windshield, tires and the bumper. Their brain activity will show what brings them closer, and what it is that pushes them away from a decision on a potential purchase. This testing is performed by the company NeuroFocus, whose clients in addition to Hyundai are also Google and Walt Disney.

E-Bay has, based on tests conducted using neuroscientific methods, come to a conclusion that the users of their services place the security of their payments in second place: they are far more concerned with the speed of transactions, which has led E-Bay to change its approach to the consumer through a repositioning campaign.

² A diagram known as an electroencephalogram (EEG), which is obtained through application of the electroencephalography method, hereinafter referred to as EEG

All of the given examples clearly show an increasing trend of use of the neuroscientific concept in the planning of a marketing communication strategy, as an unavoidable method that provides insight into until now unobtainable data, which may be of crucial importance for the development of a new product, repositioning of an existing product, as well as any other activity on which the future success of a company directly depends.

4.3. The Steady State Topography Method (SST)

Another neuroscientific method, whose primary purpose of development and application was in the field of medical research of neurological disorders such as the attention deficit disorder and the hyperactivity disorder, is Steady State Topography, or SST for short.³ Professor Richard Silberstein from the Institute for Brain Science at the University of Melbourne has since the 1980s been working on the development of this method, while in early 2000, in cooperation with NeuroInsight, he introduced this technology into the domain of marketing.

SST recording is performed by placing a compact device in the form of a helmet on the head of the respondent, which contains a device for monitoring brain activity and eyeglasses showing the image, thus creating a stimulus in the form of a visually evoked potential of the brain of the respondent. This device is easily portable, while its advantage is that with the help of 64 electrodes it is able to register up to 13 brain responses in a second, making it sensitive to rapid changes in brain activity. For this reason, it is more suitable for dynamic stimuli. In addition, the setting up of this device does not require the application of gel, or sticking on electrodes, thus the studies are carried out much faster considering the short preparation time of the participants.

5. CONCLUSION

As can be seen from the review of relevant researches and neurodiagnostic methods, the neuroscientific concept has experienced major progress during the last decade, both in development as well as in the fields of its application. Until recently used only for medical research purposes, neuroscience opens the door to knowledge and information that can be of great benefits to other scientific fields as well: psychology, evolutionary history, genetics, biochemistry, pharmacology, informatics, computer neuroscience, statistics and many others, and among them of course marketing. Although marketing is viewed solely as a science whose ultimate goal is profit maximization, this perceptual illusion of the purpose of marketing is incorrect. Marketing Science has a wide area of applications, and marketing services do not exclusively focus on manufacturing and service-oriented companies. Marketing communications also find their application in projects such as philanthropic humanitarian activities such as “Live Aid”, an event for raising people’s awareness on diseases (such as cancer, HIV, diabetes), UNICEF’s humanitarian activities for helping children in threatened areas, as well as many other noble programs.

On the other hand, the lack of transparency of marketing research with application of the neuroscientific concept, as a result of the competitive advantage that companies gain through application of this approach, represents a major problem for the future development of this approach. The reason is the lack of sharing of information and conclusions that have been reached, because they represent amorphous competitive advantages based on which market dominance is achieved.

By reviewing the given studies and examples from practice, it can be concluded that the application of the neuroscientific concept in the creation of an effective marketing communication strategy requires the engagement of a multidisciplinary team. Each member of the team should make a contribution to the drawing of a correct conclusion on the basis of their expertise in the fields of neurology, psychology and marketing. Neuroscientific research results remain completely inapplicable and worthless if a systematic and careful analysis is not conducted, and if a conclusion on the indications is not drawn in the correct and logical manner.

The conclusions of neuroscientific research must then be properly implemented in the very strategy and tactics of an effective marketing communication. The process of research-conclusion-implementation is very complex and its final outcome depends on many factors of the process itself, as well as the success

³Hereinafter referred to as SST, which represents an abbreviation of the description of the technology

in maintaining continuity, which leads to the conclusion that small errors in the conclusion and implementation during any stage of the process itself can completely undermine its usefulness.

Although this paper declaratively highlights a number of advantages of the neuroscientific approach over the traditional methods in marketing research and the creation process of a marketing communications strategy, the application of these two different concepts is not mutually exclusive. Precisely due to the fact that the traditional and neuroscientific concepts each have their numerous advantages and disadvantages, a collaboration of these two concepts is suggested. The neuroscientific concept in the study of consumers adequately compensates for the problem of "subjectivity" that cannot be overcome by traditional methods, while the traditional focus groups compensate for the problem of materialization and verbalization of opinions which, at the present stage of science, the neuroscientific methods cannot achieve. The key of collaboration of these two concepts can be found in the synergy of their power.

Ethics, as an indispensable guide in all scientific development, raises many ethical questions regarding the application of the neuroscientific concept in marketing. However, the quote of Martin Lindstrom greatly contributes to the understanding of the issue: "I believe that it (the neuroscientific concept) is a simple tool, like a hammer. Yes - in the wrong hands a hammer can be used to hit someone on the head, but that is not its purpose nor does it mean that it should be banned, that we should stop its use, or sanction it."

That which is certain is that the development of the neuroscientific concept has changed the understanding of how the human mind works, and thus it has changed the direction of focus of many scientific disciplines, including marketing. Neuroscience is the science of the future, and anyone who recognizes the value of pro-action and innovation in their field of expertise will recognize the importance and potential of application of the neuroscientific concept. Development of neuromarketing requires the engagement of academics and experts in the fields of marketing, psychology and medicine, allowing for a multidisciplinary approach as a response to a better understanding of the needs and desires of consumers, as well as the guidelines for an effective marketing communications strategy.

Abstract: *The public sector is undergoing technological and organizational reforms. Following the market development and application of electronic commerce in the private sector, the public sector has started to introduce the application of information/communication technologies. In countries around the world, governments have introduced modern operating methods presented through the concept of eGovernment. This paper presents basics of eGovernment in terms of marketing, as well as challenges of eGovernment in Serbia. The results of empirical research on the level of implementation of eGovernment in municipalities in Serbia are presented at the end of the paper.*

Keywords: eGovernment, marketing, local government

1. INTRODUCTION

eGovernment is a new concept of government accepted in many, especially developed, countries. It became a global phenomenon and it represents a field in which governments of almost all the countries throughout the world invest a lot (Grant & Chau, 2005). Intensive application of Information and Communication Technologies (ICT) in government includes new management approaches that should provide better service to citizens and economy based on full cooperation between all entities and all levels. That is why there is an assumption that application of marketing activities in the development of electronic services may contribute to the accomplishment of this goal (Cicvarić Kostić, 2011).

The objective of this paper is to present the foundations and role of marketing in eGovernment as well as the application of eGovernment in Serbian local governments. The first part of the paper provides theoretical definition of eGovernment and indicates the necessity of applying marketing approach in its development. The second part presents the results of the survey on application of eGovernment in municipalities of Serbia, conducted in 2010.

2. MARKETING APPROACH IN E-GOVERNMENT

Apart from technological transformation of the state apparatus, another thing that stimulated changes is the understanding that there is a need for marketing in public sector as well (Walsh, 1994). Although the essence of marketing concept implies profitability, in terms of eGovernment the primary goal is meeting the customers'/citizens' (the terms will be used as synonyms, as the citizens are the consumer of governmental services) needs. Introduction of eGovernment created the opportunity to change the traditional understanding of the state apparatus as a slow and inefficient one. eGovernment offered a modern, efficient service and transparency as well as the change of paradigm in the process of communication between the government and the citizens (Vintar, 2002). According to the same author, the basic characteristics of communication in the earlier period were as follows: it was one-sided and the citizens had a subordinate role, i.e. communication was mostly oriented towards the needs of the government itself. eGovernment is a contemporary way of government operation according to the following principles (Vintar, 1999):

- Citizens and organizations are seen as new information systems' entities that require information (role of a partner);
- Two-way communication is necessary in order to build relations between partners;
- Citizens and organizations are seen as customers of government services (marketing approach).

Understanding of these principles and the fundamental change in government operation in line with the stated principles actually represent the biggest challenges for modern government.

However, experience shows that the application of eGovernment is not always successful. United Nations (2008) stated that one of the reasons for eGovernment failure was insufficient application of marketing. Although not a central starting-point of eGovernment, marketing orientation contributed to development

and improvement of eGovernment from techno-centrism to orientation to customers' needs. Furthermore, the basic goals stated in the European strategic choice of eGovernment system also testify of the need and necessity of applying the marketing concept in eGovernment here. They are, among other (document „Improving, development and standardization of Internet presentations of state bodies“):

- Putting the citizen in the foreground i.e. creating electronic services and ensuring the access to online services to all citizen categories;
- Services adapted to customers' needs;
- Provision of access to public information and services through innovative usage of ICT;
- Increase of public trust;
- Raising awareness of the benefits provided by eGovernment;
- Improvement of skills necessary for using the eGovernment services.

In the last years the development of eGovernment and its importance for the future government operation became a topic of discussion among theorists and practitioners from different fields. The phenomenon is still insufficiently studied and that is why it is frequently misunderstood and misinterpreted. First of all, it should be noted that eGovernment is not just a phase in automatization and computerization of government but it implies the usage of ICT for improvement of government activity and it addresses a complex problem demanding a holistic approach and study from different aspects – technological, legal, socio-political, organizational, functional etc. One of the aspects that may have a strategic role in eGovernment development includes examining the role of marketing.

eGovernment most often refers to provision of public services through the Internet. Wider definition of the term eGovernment is presented in Schwabe (2005) where it is defined as the “use of information and communication technologies aimed at improvement of range and quality of public services used by the citizens and business entities, making the public administration more efficient, reliable and transparent”. eGovernment is attempting to ensure easier access to public services by providing better conditions for the beneficiaries. Moreover, in that way it aspires to more efficient public administration and greater transparency in management of social and economic resources of the state.

Development of electronic services enables government functioning in a completely new way: without paper, without direct contact with customers and face-to-face communication etc. This involves specific environment for defining marketing goals and activities. In order to analyze the marketing aspects of eGovernment, it is necessary to define basic marketing instruments:

- Product – good online service adjusted to customers' needs.
- Distribution – service accessible to the customer, at the right time and at the expected location of access.
- Price – minimizing the time and effort necessary for getting the online service.
- Promotion – communication activities directed at providing information to potential and current customers on the availability of a service and stimulation of its usage.

The application of marketing in eGovernment may contribute to development of service focused on customers' needs.

Development of eGovernment includes three main areas (Heeks, 1999):

- Improvement of the administration process (eAdministration) – relates to improvement of the internal operation of the public sector;
- Connecting and building relationships with citizens and service customers (eCitizen and eServices) - encompasses the relationship between the government and the citizens as the target group on which the legitimacy of national and local government depends and as public sector customers;
- Connecting and building relationships with other target groups (eSociety) – organizations from other sectors.

Having in mind this definition of eGovernment development, the basic role of communication and marketing approach in the area of building and maintaining relationships with all target groups is obvious. Primarily, this means raising the level of awareness and knowledge about the existence of eGovernment, building trust in this type of government functioning, building partnership relations with all target groups and the like.

eGovernment is focused on five target groups: citizens, enterprises, public administration employees, other public institutions or departments and non-governmental organizations. In accordance with that, there are eight types of relationships in eGovernment (Fang, 2002):

1. G2C – Government to Citizen - provision of services and information to the citizens, online services, digital democracy;
2. C2G – Citizen to Government - exchange of information and communication of citizens with the government;
3. G2B – Government to Business - provision of services and information to companies, electronic procurement;
4. B2G – Business to Government - exchange of information and communication of companies with the government;
5. G2E – Government to Employees - intranet, internal communication with employees and provision of information, notice board, education;
6. G2G - Government to Government - intranet, communication subsystem, cooperation and internal exchange of information with other state institutions or between different departments of a single administration;
7. G2N - Government to Nonprofit - provision of services and information to non-governmental organizations;
8. N2G - Nonprofit to Government - exchange of information and communication of non-governmental organizations with the government.

3. E-GOVERNMENT IN SERBIA

eGovernment is still developing in Serbia and it has still not reached the level of development and sophistication of the EU member states (Marković et al, 2002; Marković et al, 2008). Based on the inspection of eGovernment portal of the Republic of Serbia, it could be concluded that two-sided communication with the state bodies is not fully developed and that eGovernment in Serbia includes providing information on public administration services, possibility to download the forms from websites, in some cases to order the forms to be delivered by mail, scheduling appointments for application submission in some government institutions, but also delivery of certain services electronically. By joining the public discussion processes and through the forum (eParticipation) the citizens may take part in discussions on topics of importance for improvement of government's work (www.euprava.gov.rs). Application of social media is necessary for the development of eParticipation. eGovernment intended for business entities is somewhat more developed which means that the companies may download most of the required documentation from the Internet.

More serious approach to development of eGovernment in Serbia is confirmed by acceptance of the EU's i2010 initiative and adoption of Strategy for the Development of eGovernment in the Republic of Serbia for 2009-2013 (document „Strategy for the eGovernment Development in Serbia“). The Government of Serbia accepted the i2010 initiative as a general framework for development of Information Society through signing of the eSEE Agenda +3 for the development of information society in South East Europe (document „Handbook for ICT in local government“). The Strategy does not explicitly state the application of marketing concept in eGovernment development in Serbia but it defines basic goals, mission and vision of eGovernment oriented towards customers' needs. The Strategy does not indicate the necessity of promoting eGovernment in Serbia but that conclusion is inevitable since commercial electronic business also needs to be promoted.

Usage of eGovernment services in Serbia is in its initial phase. According to a study of Statistical Office of the Republic of Serbia from 2010 (document „Usage of ICT in Republic of Serbia, 2010), 13.2% of the respondents among the Internet population and 70.6% of enterprises use eGovernment services. The number of customers in both segments (citizens and enterprises) has a tendency of growth. The number of customers, as well as the number of services used is expected to increase with the development of eGovernment.

eGovernment portal of the Republic of Serbia (www.euprava.gov.rs) was posted in March 2007. The portal enables eParticipation through public discussions where all interested persons may send comments, suggestions and attach documents pertaining to the topic of public discussion. Apart from that, at portal's forum page each registered user may take part in discussions on all topics of importance for improvement and advancement of contacts between state bodies and citizens and they may also start a new topic on the forum. Introduction of the portal will facilitate citizens' communication with state bodies and overall

public administration in terms of easier way to find information and appropriate forms, as well as simpler submission of requests and receipt of decisions and other documents.

Further introduction and development of service is planned in the Strategy for the eGovernment Development in Serbia while special attention will be given to improvement of service accessibility to citizens at local levels of government.

Since eGovernment development level in Serbia is still low, a survey was conducted among local governments to identify the electronic services being delivered, as well as attitudes of the employees regarding the challenges for the introduction of eGovernment, in order to find potential ways for its faster application.

The survey was conducted with assistance from: Ministry of Economy and Regional Development of the Republic of Serbia, Statistical Office of the Republic of Serbia and Standing Conference of Towns and Municipalities (SCTM). SCTM is a national association of local governments in Serbia, founded in Belgrade in 1953. Today the association has 167 members (towns and municipalities) that come together on a voluntary basis in order to achieve cooperation, joint action and accomplish common objectives at the local and international level. At the beginning of 2007 SCTM launched an initiative saying that every town and municipality in Serbia should appoint a person as a local commissioner. Namely, local commissioner is a person employed in the local self-government unit whose role is to coordinate and be in charge of communication between the association and the local self-government unit. The network consists of 167 members i.e. all towns and all municipalities have appointed a person as a local commissioner.

The survey involved collection of primary data by method of examination i.e. poll and it was intended as a census. The survey instrument was a questionnaire sent electronically to respondents by the SCTM representative, via the commissioner network, along with the letter explaining the subject and goals of the survey. The questionnaire was sent to the addresses of 167 municipalities in Serbia. Through four iterations the total number of collected valid answers was 109 which is a 65% response.

The main condition for ICT application in government and development of electronic government services is for the institution to have its Internet presentation. It is encouraging to know that only three of the surveyed municipalities in Serbia do not have a website and do not fulfil this basic condition for electronic services development.

A great number of municipalities that have Internet presentations (70.9%) regularly post information and documents pertaining to municipal institutions' work on their website. In conclusion, the first level of eGovernment development is reached, but it still involves only one-way communication between government-citizens/organizations, i.e. it is a static application of ICT.

Posting of applications and forms for submission of requests in a municipality was considered as the next level of eGovernment development. In 46.5% of municipalities this is constantly applied (regularly or occasionally), in 25.7% only occasionally while 27.7% does not conduct this activity.

Possibility to order documents via website is provided (regularly or occasionally) by 52% of surveyed municipalities while 47% of municipalities do not provide that service.

According to replies of the employees in surveyed municipalities, a great number of municipal departments are available (regularly or occasionally) to citizens and other customers through electronic mail (around 80%), while in one fifth of the cases there is no such possibility. As for electronic communication with other institutions of public administration, 97.1% of the surveyed municipalities in Serbia do not exercise this communication (regularly or occasionally). Aggregate results are shown in Figure 1.

Figure 1. Electronic services development in Serbian municipalities

Among the most frequent dilemmas and challenges faced by the employees in municipality concerning the introduction of electronic business there are the following (the order does not represent the importance of the problem):

- Insufficient training of the staff for computer work;
- Employees' fear from introduction of innovation (especially with older population);
- Insufficient knowledge of the importance and advantages of eGovernment;
- Lack of financial means for introduction of eGovernment system;
- Lack of necessary equipment and software;
- Problem regarding protection of data and lack of adequate legal framework;
- Insufficiently developed procedures and standards;
- Fear from potential job loss etc.

By identifying potential challenges and problems i.e. barriers that might appear during the introduction of eGovernment, directions and priorities of action for the institutions in the process of eGovernment introduction may be clearly identified.

4. CONCLUSION

There is an evident need for government in modern society to adopt the manner of operation of the market-oriented business systems. Many studies have examined the altered role of citizens in society, new relationships among government and citizens, improvement of quality and ways to deliver public services through the introduction of eGovernment. As a contemporary way of government operation, eGovernment involves the application of new technologies for achievement of "better government practice". One of the important aspects of study and improvement of eGovernment is the application of marketing approach. Understanding of marketing principles and changing the government operation in accordance with them represents the biggest challenges of modern government.

Abstract: *Provision of resources is very important for the survival, development and operation of nonprofit organizations. In addition, there are different approaches that non-profit organizations use. This paper investigates if the marketing concept is generally applicable when it comes to non-profit organizations, and how to create a marketing strategy for the provision of resources by non-profit organizations. Marketing desk research was conducted and secondary data from the literature dealing with this topic were used. The basic implication of the paper is to show the feasibility of the marketing concept in the non-profit sector. Besides, implications may relate to the need for the application of the marketing concept in non-profit organizations and can indicate important elements in the structuring of marketing strategies for the provision of resources by non-profit organizations that operate in the domestic environment.*

Keywords: *marketing concept, marketing strategies, a nonprofit organization, resources*

1. INTRODUCTION

Marketing concept is usually associated with business enterprises that operate profitably by providing long-term customer satisfaction. So, the question arises whether it is possible to use the marketing concept by non-profit organizations. The question in this paper can be seen at two levels. Firstly, we look at a general level, afterwards there is given analysis of possible application of the marketing concept in the provision of resources by non-profit organization.

The provision of resources is essential for survival, development and operation of nonprofit organizations. It can be identified with the provision of financial resources, human resources, and as well as the provision of resources to non-profit organizations in cooperation with the private sector. At all these levels, arguments may be identified that are in favour of the application of marketing concepts in the process of the provision of resources by non-profit organizations.

2. POSSIBILITIES OF APPLYING THE MARKETING CONCEPT IN NON-PROFIT ORGANIZATIONS

In the standard case, the application of marketing concepts is in the connection with business enterprises that seek to operate profitably by providing long-term customer satisfaction. However, marketing is characterized by ambiguity, so it can be seen as an economic process, a business function, a business concept and as a scientific discipline (Vasiljev, 2005). The above mentioned can suggest that the marketing observation upon the relation of company and the market does not illustrate all the meanings that can be added to marketing. Especially, if one takes into account the fact that goods, services, events, experiences, personalities, places, property, organization, information and ideas are placed on the market nowadays (Kotler & Keller, 2006).

Historically, the marketing concept is one of the ways in which the companies undertook marketing activities in their orientation to the market. Specifically, analyzing the various ways in which the companies undertook marketing activities in their orientation to the market, several competing concepts can be identified: production concept, product concept, sale concept, marketing concept and the concept of holistic marketing (Kotler & Keller, 2006). By using the marketing concept instead of previous philosophy "produce and sell" companies have passed to the motto "feel and react" aimed at the consumer. This motto is arising from the assessment that the essence of achieving company's goals is in greater efficiency in comparison with the competition, when it comes to the creation, delivery and communication of value for consumers in targeted markets. This approach is followed by the concept of holistic marketing, which stems from the need for a more complete, cohesive approach, and which is transcending the traditional application of marketing concepts and trying to accept and reconcile the scope and complexity of marketing activities.

Gašović (2009) points out that if marketing is seen as a mechanism that brings together those who have a need with those who meet the need, it should be noted that such a mechanism exists for non-profit organizations when they make the exchange with participants in program, donors, volunteers, recommended persons, the media and other non-profit and profit organizations etc. (p.112). The differences in marketing of profit and non-profit organizations can be recognized in the key goals of their marketing activities (profit or benefit to the community). The significant adjustment of certain postulates to specificities of non-profit organizations and feasible marketing strategies allow non-profit organizations to fulfil their mission, to research customer needs, to realize program goals and to raise the necessary funds.

Development of non-profit marketing is largely determined by the same factors that have influenced on the creation and operation of nonprofit organizations in society: the growth of privatization, reduction of financial support from traditional sources (government, companies, private donations), and increased volunteerism (Kancir & Đurica, 2011, p. 314). The increase in privatization in the non-profit sector is determined by the need to increase efficiency in resource use and effectiveness of non-profit organizations. The trend of reducing state support and assistance, as well as reducing private donations for financing the non-profit organizations, influenced the development of marketing in the market of donors / financiers. As a result of the need to compensate insufficient funds for financing the activities of non-profit organizations, it comes to increasing volunteerism i.e. involvement of people on a voluntary basis in order to achieve social interests. According to the results of extensive empirical research, non-profit organizations operate more effectively when they apply marketing concept. This is evident when such non-profit organizations are compared to non-profit organizations that do not do business in accordance with the philosophy of marketing (Kancir & Đurica, 2011, p. 316).

3. MARKETING STRATEGY OF NON-PROFIT ORGANIZATION

Marketing activities of non-profit organizations should be aligned with the overall strategy of non-profit organizations, primarily, in terms of coordination of all marketing activities, in order to form a single unit with clearly defined cause-effect relationships. This means that it is necessary to create a marketing strategy for non-profit organizations (Gašović, 2009, p. 112).

Establishing and implementing marketing strategy involves taking a series of activities related to marketing research and factual realizations of marketing. In this sense, it is necessary to conduct marketing research. In the marketing research, situation analysis and perspectives of non-profit organizations are particularly important. The next step is analyzing donors or funders of non-profit organization. Analysis of the employees and / or volunteers is also essential to a nonprofit organization. Competitive analysis is the next step in the process of marketing research. The analysis of the external public is related to all those factors which may not be sorted into any other category important for non-profit organization. Analysis of results may be related to the totality of achieving the mission, but it also relates to less specific goals. It is also necessary to determine (to review) mission in order to answer what task of non-profit organizations is, who are its customers, what is provided to them and what organization's tasks should be in the future. Establishing goals is in most cases related to the general quality level of activities, specific goals of the marketing mix instruments, quantified objectives, offer differentiation and positioning in the minds of the target groups, diversification of the activity into new segments and the like. SWOT analysis is, in fact, an analysis of non-profit organization and its environment by identifying strengths and weaknesses that are typical for a non-profit organization and that can be influenced by non-profit organization. SWOT analysis also includes the analysis of external opportunities and threats that non-profit organization faces in its activities. When it comes to the realization of marketing strategies, non-profit organizations use marketing mix technique, known as "4P". The instruments of marketing mix of non-profit organizations include product, price, place (distribution) and promotion.

4. THE PROVISION OF RESOURCES BY NON-PROFIT ORGANIZATIONS

When it comes to the provision of resources by non-profit organizations, Pavičić (2003), as sources, lists: all citizens, sales and special events, membership fees, regular contributions, large donations and planned grants (p. 282). He emphasizes that for each of the sources listed from the beginning to the end, the collection becomes more demanding and lasts longer.

Andreasen and Kotler (2008) identify three levels of the question.⁴ Firstly, the question is how to secure financial resources. The question of human resources is next. And finally, it can be concluded that a part of resources comes from the private sector to non-profit organizations.

The provision of financial resources by non-profit organization

In connection with the financial resources of non-profit organizations, their two sources can be identified: the collection of funds and generating of their own income. It should be noted that although the non-profit organizations consider fundraising as extremely important, at the same time they should pay attention to the fact that not all sources of financing are equally desirable. On the one hand, they may jeopardize the mission of the organization. It can be caused by external influences, for example, if any funder requires that the results of certain studies should not be published for some years. It can be caused from the side of organization itself, for example, when sources of funding for employee's benefits are being sought although it is inconsistent with the mission of the organization. In addition, some sources are not cost effective: for example, a charity concert that seems it will make a substantial income, actually makes significant costs or sometimes when non-profit organizations sell products that are not related to their basic business.

Fundraising in 21st century is significantly changing: the donor base is being diversified, the collection of funds is being transformed from periodic to the annual cycle, the specialists are being hired to gather funds, databases are being developed in order to track future donors or potential donors, more creative ways to help those in need are being sought. Throughout this process, the Internet plays a special role.

There are four sources of fundraising. These are the foundations, corporations, governments and individuals. When it comes to foundation, there can be identified independent foundations, corporate foundations and communities foundations. Corporations can also directly donate some funds to non-profit organizations, mostly within its own "strategic philanthropy" while attempting to the change of the image of the organization, to create an alliance that would give support to corporations in the period of crisis, to create awareness and interest for the corporation by future customers and future employees, to strengthen the link between employees and distributors, to lead to increased sales. Governments are also donors to non-profit organizations. However, the main source of funds is individuals who donate funds to non-profit organizations. With them, one can see the corresponding relationship between age and patterns of giving. Up to 50, they are mainly engaged in arranging their family life or caring about their careers. They do not have great resources available, but they are regular donors of money, less often of property especially to their churches and synagogues. When people are between 50 and 70, most of them have regulated life issues, most of the obligations in this regard or for children's education are paid, so they are still regular donors, and they become candidates for larger donations, such as, for example, a specific vehicle for non-profit organization, scholarships for students at local colleges or they support larger programs donations. After 70, they reduce the frequency of regular giving's, but they become candidates for giving "the last gift."

When it comes to individual providers, three types of giving can be identified: annual giving, major giving and planned giving. Great benefits allow that 80% of funds available to non-profit organizations are provided by 20% of effort. Planned giving is related to gifts to non-profit organizations that remain after the death of the donor.

Revenues from sales and services are caused, on the one hand, by intensified competition among non-profit organizations, while on the other hand it is a consequence of the efforts of these organizations to make their programs self-sufficient. These revenues are usually realized on the basis of marketing skills, retail operations and additional unique skills of non-profit organizations.

The provision of human resources by non-profit organization

When human resources of non-profit organization are concerned, they involve permanent staff, volunteers, and members of the board of directors.

In connection with employees the need to resolve the issue of human resources at two levels has to be emphasized. Firstly, it is necessary to ignore the frequent and unjustified assumption that the work in a

⁴ This paper is structured according to the classification given by Andreasen and Kotler (2008, p. 349-435).

non-profit organization means that employees need to live on the edge of poverty by receiving the minimum wage. Some examples tell us a different story and show that certain employees of such organizations have salaries and not only that they can be measured, but also they sometimes exceed the amount of money of those who work in similar positions in the profit sector. On the other hand, it is extremely important to make certain aspects of conducting business activities in non-profit organizations closer to those of profit organization in order to move easier from one sector to another.

When it comes to volunteers, firstly it is noted that a large source of volunteers are members of the younger population. However, in certain parts of the world there is a different approach to volunteering, particularly, bearing in mind, and the needs that are caused by certain characteristics of society. In Scandinavia, for example, there are fewer volunteers because the state takes a number of charitable activities and in the U.S., UK or Australia; all of them are undertaken by non-profit organizations.

Finally, members of the board of directors are involved in human resources. They have a role to oversee the operations of nonprofit organizations, make decisions, provide appropriate technical analysis and connect organization with the environment.

The provision of resources by non-profit organization in cooperation with the private sector

When it comes to cooperation of non-profit organizations with private sector, firstly it should be point out that this is one of the important ways in which it is possible to obtain resources. The cooperation between nonprofit organizations and advertising agencies has been significant and successful.

Cause related marketing should be specially mentioned within the cooperation of non-profit organizations and the private sector.

5. APPLICATION OF MARKETING CONCEPT IN PROVIDING RESOURCES BY THE NON-PROFIT ORGANIZATION

For each of these areas in which non-profit organizations are providing resources there can be found out connection with the application of marketing concept. In the literature, there can be found a view that activities in connection with the provision of resources, even though being a part of the overall marketing strategy, can be regarded as a separate strategic and tactical issues because of a significant number of people who specializes in these activities and because this issue is widely treated in literature (Pavičić, 2003, p. 281). However, possibilities and advantages of the use of marketing concept in the process of providing of resources by non-profit organizations will be primarily in the focus of this paper.⁵

It should be noted that when all these resources are concerned, it is extremely important to find an appropriate way to "sell" your offer to various actors who are relevant for non-profit organization. It is also important to emphasize the role of personal contact in such situations and to know the personal sales process (Gašović, 2010). This process is, of course, understood in a way customized with a variety of possible situations in which a non-profit organization may be while in the process of providing resources. Firstly, there is the need to find potential "customers" and to determine their characteristics which contribute to avoid the unnecessary loss of time or misallocation of sales efforts. Then, it is important to be prepared for "sales performance" by collecting additional information and planning the visit, which includes establishing goals, developing strategies and ultimately the scheduling of the meeting. The presentation refers salesman performance, start of presentation and convincing potential customers using different techniques of presentation. It is important to know how to behave when there are potential objections of customers. The following stage is the stage of closing. The process does not have to end up here. Post sale activities that follow are not less important for building long term relationships with customers.

The application of marketing concepts in the provision of financial resources

When it comes to fundraising, three different concepts can be identified as a possible source of financial resources. The first is the product concept with a slogan "We have a good goal, people need to support us." This concept is used by churches and colleges, most of them are supported by a small number of major donors for who are organized glamorous events. The second concept is sale concept characterized

⁵According to Andreassen and Kotler (2008, p. 349-435).

by: "There is strong competition for resources, and people generally are reluctant to give, so if we want to grow, we must be more aggressive." Sales efforts are accompanied by dramatic emotional appeals and propaganda that are characteristics of this approach. The last approach refers to consumer orientation (marketing concept) where there is characteristic attitude: "Like all the other marketers, our challenge is to understand needs and desires of our targeted market and then to find a way to fulfil them." Most of the time is spent in an effort to understand donors and potential donors and to answer what they seek.

An example of successful application of the latest concept is the organization of United Way of America. In fact, they realized that they are not successful in getting donations from increasingly important group of young business people - professionals. They dedicated themselves to this problem and they found out that the main difference of this segment in comparison to other donors was that they were significantly committed to investment in shares of various companies in the market. This characteristic considered a choice among purchasing shares of different companies in order to diversify risk in portfolio so the segment of young people was used to having a choice and a lot of information on possible alternative courses of action. Considering donating to non-profit organization, the problem was that they didn't have a clear attitude towards what amount of money that should invest, and what their options were. The classic appearance of non-profit organizations that did not offer them alternative investments and did not provide a lot of information but not lack of will, was the reason for the lack of humanitarian activities in this segment. By changing the United Way of America to "Charity Investment Chancellor" that allowed to mentioned category of donors to "invest" in the charity and offered a wide range of possible directions of money, the great success was accomplished and organization started receiving significant funding.

When it comes to fundraising sources (foundations, corporations, governments and individuals) there should be emphasized several elements related to the implementation of the marketing concept. Firstly, in connection with foundations, it is necessary to find a connection between the interests of foundations and non-profit organizations offer. In addition, it is important to estimate the expected level of interest of foundations to invest adequate resources. In this regard it is important to write a proper proposal for which is necessary to study the needs and interests of the foundation. When searching for the appropriate corporation that could donate to certain funds, non-profit organizations should seek corporation with similar features: it has to be local, to be engaged in activities in similar occupations, to have personal ties or contacts and to have adequate structural similarity as well.

Individuals as sources of funding non-profit organizations often provide that 80% of the funds are available to non-profit organizations with 20% of effort. So, the application of marketing concept in this context is extremely important. Namely, in order to organize effective annual giving campaign, a company needs to fulfil several requirements: to provide strong leadership to volunteers and support of staff, to determine a clear organizational structure, to have ambitious but realistic goals, to make a careful segmentation of donors and prospects, to make the preliminary research, to conduct training of volunteers in area of legal consultation, to make a detailed schedule of activities, to have reporting, to give recognition to donors and volunteers, to provide the option of online donating and to build donors for their whole life. The ways in which donating events can be organized are: auction, charity dinner, dinners with invitations, balls, fairs, fashion events, small gatherings at home of sponsors, meeting of the famous and the like.

The application of marketing concepts in the provision of human resources

Marketing is essential for reaching the appropriate human resources. There are two major issues when it comes to volunteers in non-profit organizations: their recruitment and management. When it comes to recruiting volunteers, it should start from the existing data to identify the segments from which is the most appropriate to recruit volunteers. Then you have to target specific segments and to take position in their minds by presenting them volunteering and the organization. Attention should be paid to the competition, but in a broader sense. There are four levels of competition. It may be in terms of competing the inertia that exists when the attitude to the activities of non-profit organization is concerned. The second level is the level of different contributions that an individual could give (donations, free services or just volunteering). Then it comes to a decision among various broad categories in which it is possible to work with the non-profit sector. And finally, it refers to the question about the choice of the specific organization.

Certain benefits need to be presented to potential volunteers (career advancement, self-satisfaction, strengthening social ties, understanding the environment, value expression), as well as the sacrifices that volunteering brings. It is surprising that researches show that as the required level of volunteer involvement increases, the motivation of people to embrace volunteerism increases as well. It is also

important to think about ways to make it possible to concretize one's desire to volunteer, and provide a test of experience and internal marketing activities to volunteers that would be tied to the organization.

Considering the management of volunteers, there has to be noticed that there is a space for possible conflicts especially in the relationship between full-time employees in certain non-profit organization and volunteers. On the one hand, the volunteers often assume that since they donate their services to the organization, they shouldn't be told what to do, but they should be asked to do something, that one should respect the schedule of their other activities when entrusting them the tasks and that they deserve a pronounced appreciation for their commitment. On the other hand a volunteer is, very often, regarded as a dilettante in the non-profit organization. They are regarded as people who receive training casually, and very often cannot execute the orders of others since they are the heads of their organizations. They are also regarded as people avoiding any demanding job in a non-profit organization.

In order to narrow the available space for conflict, the model of relationships with volunteers is proposed. It includes:

1. Identification of appropriate skills of volunteers and giving them tasks for which these skills are most appropriate.
2. Assignment of responsibility for certain tasks in detail and in advance.
3. Providing appropriate objectives and measures of performance,
4. Informing volunteers about the goals and expectations.
5. Informing that if the goals are not met, volunteers will be asked to leave or will be assigned to the harder task.
6. Insistence on respect of these standards and rules in order to make it clear that the management is firm considering their observance and implementation.

When recruiting members of the Board of Directors the application of marketing concepts plays an important role. Namely, it is necessary to start from their needs and desires, and they can be offered financial incentives and incentives in terms of achieving social responsibility, development and ideology.

The application of marketing concepts in providing resources in cooperation with the private sector

The most common motives for advertising agencies to cooperate with non-profit organizations are business contacts, increasing the "goodwill", the personal psychological satisfaction of its own employees, possibilities to express personal and organizational creativity and opportunity for young staff to gain valuable experience without fear to undermine their own important business partner. Non-profit organizations, like in the case of managing volunteers, should in the same manner contact with the staff of the private sector: treating them as paid professionals, instead as someone who works for charity. Also, it is necessary to take into account that such cooperation avoids endangering the realization of the objectives of non-profit organizations.

When it comes to cause related marketing, firstly it is necessary to distinguish it of corporate social responsibility and corporate philanthropy. Corporate social responsibility refers to the entire company's responsibility towards society, including the relationship with employees and the environment, corporate ethics and accounting practices and the like. Corporate philanthropy refers to help of companies to non-profit sector. But its goal is not to promote these companies. Because related marketing is an arrangement under which a corporation seeks to increase its own sales by contributing to the achievement of the objectives of one or more non-profit organizations. As the beginning of this practice is American Express decision in 1982 to donate a few pence to artists every time when someone uses American Express credit card, or a few dollars when they get a new member.

Generally, there are several forms in which the private sector has contributed to certain socially responsible goals. The first is promoting of socially responsible behaviour without connection to a particular non-profit organization. Another form is when a private company, in cooperation with the non-profit organization, promotes certain socially responsible behaviour, without expecting a refund in a direct manner. The third form of promotions aims to increase the sales of private companies. The following is a form of licensing and co-branding when, for example, a non-profit organization provides a license for a private company logo and expect material compensation. In addition to these, we should mention the internet support, volunteering or helping the expert knowledge.

Relations between private companies and non-profit organizations may go through three stages. The first is 'philanthropic' where non-profit organization looks for donations of private companies in a traditional way. The second is 'transaction' where the particular partnership is formed. Cause related marketing is part of this category. The third is the 'integration' stage where the mission, employees and partners' activities start to connect more closely.

Multiple benefits can be attached to using because related marketing. On the one hand, the company increases its sales, while non-profit organizations receive direct financial payments or donations of goods, services and volunteers. In the long run corporations can positively contribute to the morale of their own employees, the investor's attractiveness and the establishment of new forms of cooperation. For non-profit organization, in the long term benefits can be identified in terms of increased revenue, the impact on the mission, the increased visibility of the messages, the access to new audiences, the access to corporate networks, employees, suppliers, distributors and, as well as, expertise in marketing, strategy development, and other experiences.

On the other hand, one should not forget the risks that are possible consequences of such cooperation. When it comes to the private sector, it is usually the allegations that the engagement in such activities is a way to blur a clear picture of the basic unethical business. For non-profit organizations, there is a risk that other sources of fundraising decline and non-profit organization can be accused that it has "sold its soul" to corporations. The blurred image can be a special danger for both.

All these points show the need for the careful development of marketing strategies in the use of cause related marketing. First of all, in fact, it is necessary to identify potential partners, and then to choose the one with which there is mutual interest and to exclude those with which can occur conflict of interest. It is necessary to consider how the proposed cooperation can contribute to the goals of private companies, to design proposal of joint cooperation well and to describe in detail the role in that cooperation. In addition, it is important to involve the public, make long-term cooperation, ask for respect of certain flexibility of non-profit organization, and look at the results of cooperation in the honest way and clearly point out what a private company gets with its cooperation.

6. CONCLUSION

The application of marketing concept is, in the standard case, in connection with business enterprises that seek to operate profitably by providing long-term customer satisfaction. However, if marketing is seen as a mechanism that brings together those who have a need with those who meet the need, it should be noted that such a mechanism exists in non-profit organizations when they make the exchange with participants in program, donors, volunteers, recommended persons, the media, other nonprofit organizations, profit organizations, etc.

Marketing activities of nonprofit organizations should be aligned with the overall strategy of non-profit organizations, primarily in terms of coordination of all marketing activities in order to form a single unit with clearly defined cause-effect relationships. This means that it is necessary to create a marketing strategy for non-profit organizations. In the marketing strategy the issue of securing funds by nonprofit organizations is important. In addition, three levels of this set of questions are identified. First, the question is how to provide financial resources, then human resources and ultimately question is the provision of resources for non-profit organizations in cooperation with the private sector.

To each of these areas in which non-profit organizations provide the resources can be linked the application of marketing concept. When it comes to financial resources, non-profit organizations may apply a consumer oriented approach, where all marketers try to understand the needs and desires of targeted markets and then to find ways to fulfil them. Most of the time is spent in an effort to understand donors and potential donors and to answer what they seek.

When organization provides human resources, application of the marketing concept is expressed both in terms of volunteers and the members of the board of directors. Elements of the marketing concept should be applied in recruitment for both of these functions in a non-profit organization. When it comes to volunteers, it is important to identify the segments from which it is the best to recruit volunteers, target them and position among the members of these segments, taking into account the whole process and competition. When recruiting members of the board of directors it should proceed from their needs and desires, and they can offer financial incentives, and incentives in terms of achieving social responsibility,

development, and ideology. After recruitment, while managing volunteers, it is extremely important to rely on principles of internal marketing.

In cooperation with the private sector the application of cause related marketing is particularly important. Because related marketing is an arrangement under which a corporation seeks to increase its own sales by contributing to the achievement of the objectives of one or more non-profit organizations. Multiple benefits can be attached to using because related marketing, both for the private company and for non-profit organization. In doing so, it is necessary to develop marketing strategies carefully: from the identification and selection of potential partners, thinking about how the proposed cooperation could contribute to the objectives of private companies, creating proposals of cooperation with detailed description of the role in it, all to the engaging the public, making cooperation to be long-term, requiring compliance with certain flexibility of non-profit organizations and considering fairly the results of cooperation with stating in a clear way what private companies get from that cooperation.

Basic implications of the paper may relate to the necessity of application of marketing strategies in order to provide resources by non-profit organizations as well as to indication to the important elements in the structuring of marketing strategies in order to provide resources by non-profit organizations. The mentioned solutions are applicable when it comes to non-profit organizations that operate in the domestic environment as well and in authors' opinion necessary in such an environment.

Abstract: *In the today's highly competitive business environment, identifying unique market segments is both a reality and a necessity for every company. Essentially, there are two basic approaches to market segmentation: a-priori and post-hoc. A priori segmentation requires the researcher to first choose variables of interest and then classify customers according to that feature, while in a priori segmentation, the number of segments, their relative size, and their description are known in advance. This paper deals with the applicability of a technique known as conjoint analysis to both segmentation approaches. Conjoint analysis is one of the best methods of measuring benefits sought by customers, where measuring actual or perceived benefits lies at the heart of most market segmentation approaches. Understanding what people value most in products or services allows to tailor marketing programs so as to communicate those benefits and redesign the existing products or create new products with those benefits in mind.*

Keywords: market segmentation, conjoint analysis, part-worth utility, preference-based segmentation.

1. INTRODUCTION

In today's highly competitive marketplace, locating and specifically targeting unique market segments is both a reality and a necessity for most companies. Creative market segmentation strategies often afford the company a strategic advantage over its competitors.

Market segmentation was first defined as a condition of growth when core markets have already been developed on a generalized basis to the point where additional promotional expenditures are yielding diminishing returns (Smith, 1956). There was later widespread agreement that they form an important foundation for successful marketing strategies and activities (Wind, 1978; Hooley & Saunders, 1993). And now, market segmentation aims to divide markets comprised of individuals into groups whose characteristics are relatively homogeneous within each set or segment and heterogeneous between segments, based on an identified set of variables (Kara & Kaynak, 1997).

Along with product positioning, market segmentation is one of the most talked about and acted upon concepts in marketing. The basic ideas are (Green & Krieger, 1991):

- Market segmentation presupposes heterogeneity in customers' preferences for products/services.
- Preference heterogeneity for products/services can be related to either person variables (e.g. demographic and psychographic characteristics, product usage, brand loyalties, etc.) or situational variables (e.g., type of meal in which beverage is consumed, buying for oneself versus a gift for someone else, etc.), and their interactions.
- Companies can react to preference heterogeneity by modifications of their current product/service attributes including price, distribution, and advertising/promotion.
- Companies are motivated to do so if the net payoff from modifying their offerings exceeds what the payoff would be without such modification.
- A company's modification of its product/marketing mix includes product line addition/deletion decisions as well the repositioning of current offerings.

Market segmentation and product positioning are indivisible related. This is due to the fact that customers and sellers seek mutual accommodation in product/service offerings that best satisfy customers preference and sellers profit objectives. This process takes place in a competitive milieu of other brands/suppliers in the same product category or even other categories of goods competing for the customer's budget.

The benefits of market segmentation have been seen to include an ability to gain a fuller understanding of a particular market, improved techniques to predict consumer behaviour, and an improved ability to identify and exploit new market opportunities for commercial benefit (Hoek et al., 1996). Where the company can create a more fine-tuned product or service offering and price it suitably for the target segment (Kotler, 2000) for which the company can more easily select the best distribution and communications channels, and also have a clearer picture of its competitor. The information of the

segments also helps the decision makers to deploy resources more effectively and efficiently and determine the particular competitive strategies (i.e. differentiation, low cost, or focus strategy) (Aaker, 2001).

In order to be a true market segment, the customers in each segment must respond differently to variations in the marketing mix compared with those in other segments. This implies that for any classification scheme to qualify as market segmentation, the segments must exhibit these behavioural response differences (Neal, 2005).

Green and Tull (1978) set four basic criteria for market segmentation:

1. The segments must exist in the environment (and not be a figment of the researcher's imagination),
2. The segments must be identifiable (repeatedly and consistently),
3. The segments must be reasonably stable over time, and
4. One must be able to efficiently reach segments (through specifically targeted distribution and communication initiatives).

This paper will explore various methods for market segmentation with emphasis on two approaches: *a priori* and *post hoc* segmentation. Special attention will be paid on applicability of technique known as conjoint analysis to both segmentation approaches.

Conjoint methods of analysis were first developed in the 1960s by mathematical psychologists and statisticians Luce and Tukey (1964). Because people tend to be better at giving well-ordered preferences when evaluating options together ("conjointly") rather than in isolation, the method relieves a respondent from the difficult task of accurately introspecting about the relative importance of individual attributes for a particular decision (Green & Rao, 1971).

Conjoint is one of the best methods of measuring benefits sought by customers. Actually, measuring actual or perceived benefits lies at the heart of most market segmentation approaches. Understanding what people most value in products or services allows to tailor marketing programs to communicate those benefits and redesign existing products or create new products with those benefits in mind.

2. MARKET SEGMENTATION METHODS

A market segmentation strategy requires a major commitment by the company. A company adopts either a mass-market strategy or a market segmentation strategy. There is no in-between. Market segmentation has several benefits over mass marketing as it provides the opportunity to expand a market after satisfying the specific needs of particular consumers

When a decision is made to explore a market segmentation policy, two immediate questions must be addressed: What method is to be used to segment the market, and on what basis will the market be segmented? (Neal, 2005)

The literature discusses two main approaches to segmentation. They are *a-priori* and *post-hoc* or data driven (Dolnicar, 2004; Kara & Kaynak, 1997; Wind, 1978). In *a priori* segmentation, the number of segments, their relative size, and their description are known in advance while in *post hoc* segmentation, these three characteristics are found after the fact.

A priori segmentation is a procedure whereby a company chooses to break out customer groups by a generally accepted classification procedure related to variations in customer purchase or usage of the product category. This grouping may be the result of company tradition, recognized industrial groups, or some other external or internal criteria. *A priori* segmentation requires the researcher to first choose variables of interest and then classify buyers according to that designation (Wind, 1978).

While an *a priori* approach may guarantee within segment similarity by ensuring, for example, that all segment members come from similar geographic regions and income ranges, this does not necessarily mean that all segment members will respond in the same way to marketing stimuli (Hoek et al., 1996). Therefore, the second approach is to segment markets on a *post-hoc* basis where the researcher chooses a range of interrelated variables and then clusters buyers into groups whose average within-group similarity is high and whose between group similarity is low (Wind, 1978). This approach may result in

segments that are not necessarily internally consistent. Even if researchers can identify groups with similar attitudes or usage habits, members often possess different demographic characteristics making marketing decisions such as media buying, difficult to action (Hoek et al., 1996).

Traditional a-priori and post hoc methods differ with respect to the selection of an appropriate base. A-priori methods require the analyst to select of a base for segmentation prior to analysis while post-hoc methods from a base for segmentation after analysis (Hoek, et al., 1996; Tynan & Drayton, 1987; Wind, 1978).

The bases available for *a priori* segmenting a market are nearly unlimited and can include (Neal, 2005):

- Standard Industrial Classification groups,
- Geographic regions or sales territories,
- Basic demographic groups (e.g., sex, age, household composition),
- Purchase or usage groups (e.g., heavy users, light users, nonusers),
- VALS (SRI's Values and Life Styles classification system), and
- PRIZM, or similar geo-demographic classification systems.

Post hoc segmentation is empirically derived based on the results of a research study undertaken for the specific purpose of segmenting a market. Segments generated from such a study are formed by aggregating customers who respond similarly to a set, or sets, of basis questions. The most critical question facing the researcher in conducting a post hoc segmentation study is selecting the basis variables for the segmentation. It takes an astute and product-experienced researcher to choose the relevant set. Examples include: product attribute preferences, values, product purchase patterns, product usage patterns, benefits sought, brand preferences, price sensitivity, brand loyalty, deal proneness, lifestyles, attitudes and opinions toward one's environment (Neal, 2005).

In general, there are four major classes of traditional algorithms for conducting post hoc segmentation studies. They are:

1. Cluster analysis,
2. Correspondence analysis,
3. Search procedures, and
4. Q-type factor analysis.

Among clustering methods, the K-means method is the most frequently used (Anil et al., 1997). Correspondence analysis procedures are gaining some popularity in the applied marketing research arena. Search procedures are also widely used, especially for segmenting large databases, while Q-type factor analysis has been mostly discredited and is seldom used (Neal, 2005).

3. SEGMENTATION IN THE CONJOINT ANALYSIS FRAMEWORK

3.1. Conjoint analysis concept

Conjoint analysis is a methodological tool that allows studying consumer preferences among multiattribute alternatives in a wide variety of product and service contexts (Green & Srinivasan, 1978). This technique has its origin in psychological research (Luce & Tukey, 1964). The term "conjoint" derives from the idea that buyers evaluate an overall product or service based on its multiple conjoint attributes – also called features (Orme, 2006). As opposed to traditional expectancy-value models, conjoint methodology is characterized by a decompositional approach (Green & Srinivasan, 1978, 1990; Jaeger et al., 2000). In other terms, products or services are thought as possessing specific levels of defined attributes, and respondents' liking for a product is modelled as the sum of the partial utilities for each of its attribute levels. Therefore the purpose of the research is to determine the contributed portion of each attribute level to the dependent variable (Moore, 1980).

Conjoint analysis assumes that a consumer assigns a utility value to each level of each attribute and makes his or her final decision based on the total utility values across attributes for a given choice set (Green & Srinivasan, 1978, 1990; Jaeger et al., 2000; Marshall & Bradlow, 2002). Assuming that a product can be defined as a vector in a multidimensional attribute space, and that the evaluation of the product is based on its attribute levels, it becomes theoretically possible to relate preference to attributes (Janssen et al., 1991).

In contrast to direct questioning methods that simply ask how important each attribute is or the desirability of each level, conjoint analysis forces respondents to make tradeoffs like the ones they encounter in the real world.

A conjoint analysis study includes the following key steps:

1. *Attribute list formulation.* A business problem is defined and an attribute (features) list as well as their performance levels is developed to study the problem.
2. *Experimental design construction.* The attribute levels are combined to create different alternatives called profiles or concepts. It should be decided which profiles to present to respondents
3. *Data collection.* Respondents are asked to express the trade-offs they are willing to make among product features by rating, sorting or choosing among hypothetical product profiles.
4. *Utility calculation.* A set of preference values (also called part worth utilities or part-worths) is derived from the interview data; they reflect the trade-offs each respondent made.
5. *Market Simulation.*

Conjoint analysis is based on the assumption that each product (service, idea) is composed of an almost infinite number of attributes. However, not all attributes are relevant to different customers. Therefore an important step in conjoint measurement is to define which attributes and levels do influence the most customers' preferences. To be included in the analysis, attributes should meet the following criteria:

- Relevance (they need to be relevant in the company's decision making)
- Influence (they can be influenced by company)
- Independence (attributes and levels should not interact)
- Compensatory (can be substituted one with the other in company's perceptions)
- Understandable (not misleading)

The attribute levels are combined to create different alternatives called profiles (see Figure 1).

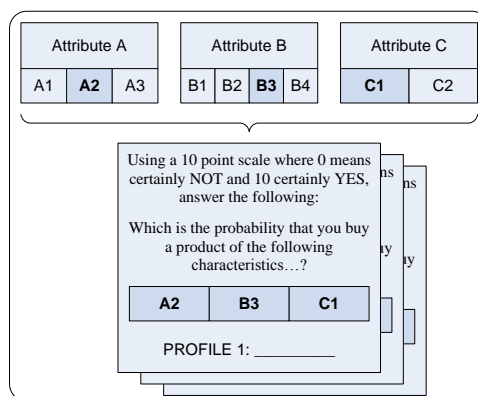

Figure 1: Creating profiles in conjoint analysis

The experimental procedure involves profiles being presented to respondents who are invited to express their preference by rating or ranking these profiles. Preference functions are estimated from this data, using ordinary least squares regression for rating the data, and ordinal techniques when the rankings are obtained. These functions assume preference, or utility, to be a linear-in-parameters function of the attributes that are included in the profiles.

It would be time consuming and difficult for respondents to evaluate all possible product combinations in order to provide information on their values for the various product features. Conjoint analysis offers the researcher a more efficient way to obtain such information: only a carefully chosen set of hypothetical product profiles is presented to respondents for evaluation. For that purpose, an orthogonal matrix should be developed, which allowed to screen and reduce the number of attributes and levels in order to keep the number of product profiles to a manageable size.

By analysing the answers conjoint analysis can estimate the weights and preferences respondents may have placed on the various features in order to result in the observed product preferences. The simplest

and most commonly used model is the linear additive model. This model assumes that the overall utility derived from any combination of attributes of a given good or service is obtained from the sum of the separate part-worths of the attributes. Thus, respondent i 's predicted conjoint utility for profile j can be specified as follows:

$$U_{ij} = \sum_{k=1}^K \sum_{l=1}^{L_k} \beta_{ikl} x_{jkl} + \varepsilon_{ij}, \quad i=1, \dots, I, \quad j=1, \dots, J, \quad (1)$$

where I is the number of respondents; J is the number of profiles; K is the number of attributes; L_k is the number of levels of attribute k . β_{ikl} is respondent i 's utility with respect to level l of attribute k . x_{jkl} is a (0,1) variable that it equals 1 if profile j has attribute k at level l , otherwise it equals 0. ε_{ij} is a stochastic error term.

Part-worth utilities (β_{ikl}) are estimated by a regression analysis. These parameters can be used to establish a number of things. Firstly, the value of these coefficients indicates the amount of any effect that an attribute has on overall utility – the larger the coefficient, the greater the impact. Secondly, part-worths can be used to calculate the relative importance of each of K attributes, which is known as an *importance score* or value. These values are calculated by taking the utility range for each attribute separately, and then dividing it by the sum of the utility ranges for all of the attributes. Thus the relative importance that i th respondent assigned to the attribute k is given by

$$F_{ik} = \frac{\max\{\beta_{ik1}, \beta_{ik2}, \dots, \beta_{ikL_k}\} - \min\{\beta_{ik1}, \beta_{ik2}, \dots, \beta_{ikL_k}\}}{\sum_{k=1}^K (\max\{\beta_{ik1}, \beta_{ik2}, \dots, \beta_{ikL_k}\} - \min\{\beta_{ik1}, \beta_{ik2}, \dots, \beta_{ikL_k}\})}, \quad i=1, \dots, I, \quad k=1, \dots, K \quad (2)$$

The results are then averaged to include either all the respondents belonging to a priori identified segments or respondents with similar preferences.

Using above presented model (1), every respondent's needs are modeled by an individual utility function - the functional form of the model is the same for all subjects, but the parameters of the function (betas) will differ. An aggregate model (using one model for all subjects) is also possible. However an aggregate model is likely to mask differences in preferences for different market segments. Individual models or models for separate market segments are likely to have greater predictive validity than aggregate models (Green & Srinivasan, 1990).

Overall utility scores (U_{ij}) for each of the possible concepts (profiles) can be estimated for different combinations of attributes by inserting the appropriate part-worths into Eq. 1. These utility scores can be further used to predict the market shares for each of the defined combinations. There are three most common choice rules to transform part-worths into the product choices that customers are most likely to make. They are maximum utility, share of utility, and logit rules, while the logit is one of the most common used rules. A logit model represents the probability that customer i will choose the j th profile from a set of m exiting profiles on the market, and can be expressed as:

$$P_{ij} = \frac{e^{bU_{ij}}}{\sum_{j=1}^m e^{bU_{ij}}}, \quad i=1, \dots, I, \quad j=1, \dots, J. \quad (3)$$

The exponent b is used to fine-tune the results so that they reflect the current customer behaviour on the market more accurately. However, the real power of conjoint analysis is the ability to both predict preferences for profiles that weren't rated by the respondents, and to perform a *what-if analysis*. This can be done using *conjoint simulation models*. Market simulations make it possible to find out all hidden effects that could have influence on products' market share.

3.2. Segmentation based on conjoint data

As mentioned above, conjoint analysis is well suited for the implementation of both types of market segmentation: *a priori* and *post hoc* (see Figure 2.). It is possible for several reasons. First, the focus of conjoint analysis is squarely on the measurement of customer preferences for product attribute levels (including price) and customer benefits that may flow from the product attributes. Second, conjoint

analysis is a micro-based measurement technique. Part-worth functions (i.e. preference for attribute levels) are measured at the individual level. Hence, if preference heterogeneity is present, the researcher can find it. Third, conjoint studies typically entail the collection of respondent background information (e.g., demographic data, psychographic data). One should bear in mind, however, that customer background variables, particularly demographic ones, do not necessarily correlate well with attribute preferences (Moore, 1980). Increasingly, background data include information collected on respondents' perceived importance of purchase/use occasions. Fourth, even rudimentary conjoint studies usually include a buyer choice simulation stage in which the researcher can enter new or modified product profiles and find out who chooses them versus those of competitors. Wind (1978) calls this approach flexible segmentation.

It should be noted that there are two types of conjoint data which can be used as variables for market segmentation: importance values of attributes and part-worth utilities of attribute levels. Consequently there are two types of conjoint-based post hoc segmentation, also known as *preference-based segmentation*:

- importance-value-focused post hoc segmentation
- part-worth-focused post hoc segmentation

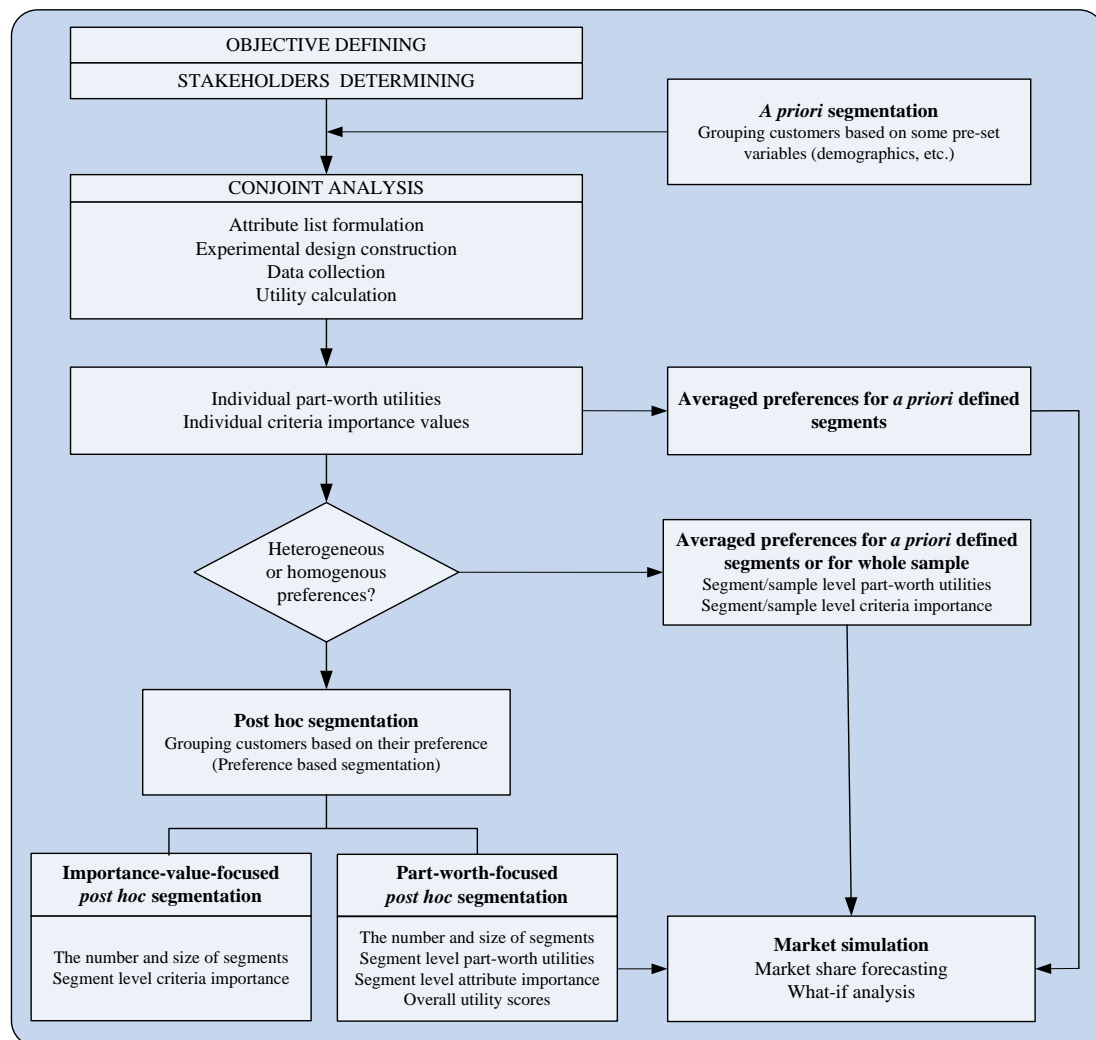

Figure 2: Conjoint analysis implementation procedure and its application for market segmentation

At first glance it seems that the *importance-value-focused post hoc segmentation* is enough simple and suitable. Although in many cases this approach gives good results, it is not always adequate. The reason is that it lacks the ability to identify heterogeneity within the attribute. For example, importance-value-focused segmentation may indicate that a brand is a very important attribute in segment 1 (let us assume that its significance for segment 2 is negligible), but it could not indicate whether the members of segment 1 prefer different brands differently.

Disadvantages of this approach to post-hoc segmentation can be overcome by using part-worth-focused segmentation. Segmentation of conjoint part-worths produces true "benefit segments", i.e. respondents who place similar value to the various attribute levels will be grouped together into a segment.

Widely used method for preference-based segmentation across industries is K-means cluster procedure (Kuzmanovic et al., 2012; Mankila, 2004).

Another procedure is *Latent class segmentation*, tool for discovering segments of respondents who tend to have similar preferences manifest within CBC (choice-based conjoint) data. This approach requires larger sample sizes than traditional cluster analysis, but it is the most useful when researcher does not know (or cannot make a good guess about) the number of segments.

One more procedure is *Hierarchical Bayes procedure*. Let us assume that customers come from one or more populations (i.e., from a finite mixture of populations), but that customers in each population have different part-worth functions determined according to a specified distribution (e.g., multivariate normal). It can be then estimate the "posterior point estimates" of each respondent's part-worth function, conditional on that respondent belonging to a given population (segment). These part-worth estimates may be used in simulations to determine the expected market share for any specified product in any segment, and across the overall population. Hierarchical Bayes methods are computer-intensive, but software packages are now available to simplify their practical applications.

4. CONCLUSION

Market segmentation is a powerful and well-developed marketing tool. A properly segmented market can improve marketing, distribution, and manufacturing efficiency and generate additional profits and/or market share. It is crucial to choose those variables that form the appropriate basis for market segmentation. Therefore, market segmentation research, especially baseline segmentation research, must be carefully planned and executed, using the highest professional research standards.

The purpose of this paper was to point out the applicability of conjoint analysis for both a priori and post hoc market segmentation. Conjoint analysis defines precisely the performance levels of studied product attributes, whereby ensuring that respondents and researchers understand the research question more clearly. Conjoint analysis allows measuring and analysis of consumer preferences even for individual respondents, thereby enabling the segmentation and clustering of customers. An additional advantage is that a conjoint analysis can be conducted on small samples, which is particular useful in business-to-business settings that are characterized by a relatively small sample size.

Abstract: *The beginning of the 21st century is marked by an increasing number of media and marketers. This new trend is caused by increasing use of the Internet, which began in 1990s. Advertising through the web is becoming the most popular medium, connecting customers directly to advertisers by clicking on ads. The focus of this paper is on exploring different ad types, formats and revenue models. Furthermore, successful promotional campaigns using digital advertising are presented. The final part of this paper focuses on analysing pros and cons of this new form of advertising, and how companies and customers can benefit from the use of innovative technologies in promotional activities. Finally, projections of future trends and concepts are given in the form of suggestions for all parties included.*

Keywords: *digital marketing, digital advertising, Internet, ad formats*

1. INTRODUCTION

With growing use of Internet and online media, new trends are emerging in both marketing and advertising. Jared Reitzin (2007) point out that "Digital Marketing is the practice of promoting products and services using database-driven online distribution channels to reach consumers in a timely, relevant, personal and cost-effective manner". Digital media, or new media, refers to any video or audio content that exists in digital formats and are distributed via the internet (Ming, Kumar & Whniston, 2008), or more generally to any media that publish or diffuse information goods in digital formats (Shapiro & Varian, 1999). A digital campaign can easily be tracked and measured, along with many following parameters, including frequency of views and details about purchases. All of the previously stated points out the new direction in advertising, the switch from traditional to new and innovative form of advertising. Companies are becoming aware of this, and the funds from the promotional budget for digital advertising are increasing every year. Other main reasons for this switch include: the improvement of technologies, focusing on two-way communication with customer, easier communication with target groups and "behavioural targeting" that enables companies to focus on sending personalized message to customers.

Online advertising or online ad is a "form of promotion that uses the Internet and World Wide Web for the expressed purpose of delivering marketing messages to attract customers". Harker (2008) defines online or Internet advertising as, "any form of commercial content available on the internet, delivered by any channel, in any form, designed to inform customers about a product or service at any degree of depth". Jensen (2008) states that internet advertising consists of three primary constituents: display advertising – which includes banners, pop-ups and interstitials; search engine optimization (SEO) and search engine marketing (SEM) – including paid and unpaid SEO and SEM (e.g. Google Adwords); and, affiliate programs, where a marketer's link (e.g. Amazon) is provided on a host's website.

Search engine optimization (SEO) and marketing can be organic or paid for. Organic SEO represents the achievement of high listings on a search engine without payment. Paid for SEO, also referred to as search engine advertising (SEA) is commonly identified as Google Adwords. Under this approach, marketers use keywords to indicate what the ad is about – subsequently paying not for the appearance of the ad, just when someone clicks on it. In effect, consumers are affirming that the ad is relevant and not intrusive to their interests at the time (Clarke, 2008).

2. THE LOGIC BEHIND ONLINE ADVERTISING

When it comes to traditional marketing promotion techniques (TVC, radio, print) the supplier of media space is evident – it is the TV/radio station or a newspaper company. But when it comes to online advertising, who should an advertiser call when he want to place his ad? That's what Ad Servers are for. An Ad server is a technology that places advertisements on web sites, and delivers most of these types of ads. Ad serving companies provide software (to web sites and advertisers) that is able to serve ads, count them, choose the ads that are best fitted for the content of the website, and monitor the success and progress of advertising campaigns. An ad server also helps the publisher monitor and manage the

available advertising space on a website. One of the fastest growing ad server companies in the world is *DoubleClick* - a subsidiary of Google that develops and provides Internet as server services. Its clients include publishers who serve customers like Microsoft, General Motors, Coca-Cola, Motorola, L'Oreal, Palm. Inc, Apple Inc., Visa USA, Nike, Carlsberg etc. Since 2008 Google controls estimated 69% of the online advertising market (Browser Media, 2008)

So, what the ad server does is store advertisement and deliver them to website visitor, with the purpose of delivering targeted ads that match their interest.

It can be said that the most common and most important ad server functionalities are:

1. Uploading advertisements
2. Trafficking ads according to differing business rules.
3. Targeting ads to different users, or content.
4. Tuning and optimization based on results.
5. Reporting impressions, clicks, post-click & post impression activities, and interaction metrics⁶.

Ad targeting and optimization

One of the most important characteristics of ad serving technology is the ability of targeting – optimization of bid prices and placement of the ads. There are more ways in which targeting can be done, and the most important methods include:

- Behavioural Targeting - Using a profile of prior behaviour of the viewer to determine which ad to show during a given visit. For example, targeting computer ads on a portal to a viewer that was known to have visited the computer section of a general media site. That means that ads that are shown to you depend on your web browsing history and previous interest shown online.
- Contextual Targeting (also known as Semantic targeting) – The process accurately interprets the meaning and classifies the main subject of the page and then infers the optimum ad placement from information contained on the page. A contextual advertising system scans the text of a website for keywords and returns advertisements to the webpage based on what the user is viewing (PC Magazine, 2008). A good example is placing kitchen wear ads automatically on a web site with cooking recipes. By closely linking content to advertising, it is assumed that the viewer will be more interested in the advertised product or service.
- Geographical targeting – When ads are served based on a user's geographical location, it is known as geo-targeting. The audience will be shown only the advertisements that are relevant to their geographical position. For example, if you are living in Belgrade, Serbia and looking for a hair salon, you won't be shown ads for hair salons in any other country, or city for that matter, than the one you are actually in.

3. REVENUE MODELS

While highly efficient investing is one of the main advantages of online advertising, the choice of revenue models for ads is one of the most confusing aspects. Each has its advantages and disadvantages, so the choice should be made taking in consideration the site's audience and the product being advertised. The most common revenue models are the Cost per Impression, Cost per Click, and the Cost per Action.

3.1. Cost per Impression (CPM)

One of the simplest types of ad revenue, and the first to emerge when Web sites started advertising, is the CPM ad (Monocur, 2004). The term CPM means *cost per miles* or *cost per thousand impressions* and refers to the amount the publisher (website) is paid for showing 1000 ads. That means that advertisers pay for exposure of their message to a specific audience. However, some impressions may not be counted, such as a reload or internal user actions.

3.2. Cost per Click (CPC)

Some advertisers want to pay for immediate results rather than views. A cost per click ad pays a publisher a certain amount, typically between one and fifty cents, each time a user clicks on an ad. As with a CPM ad, usually only the unique clicks are paid. Unlike the CPM method, running a CPC ad presents an element of risk for the publisher - if no users click the ad the publisher doesn't earn anything. But on the

⁶ http://en.wikipedia.org/wiki/Ad_serving

other, if an ad's target audience matches the audience of the site, the publisher can often earn more than low-end CPM ads.

3.3. Cost per Action (CPA) or PPF (Pay Per Performance)

While a publisher earns money instantly when a user clicks on a CPC ad, CPA (cost per action) ads require more of a commitment from the user. The publisher is paid each time a user completes a particular action—for example, completing a survey, signing up for a subscription, or buying a product. CPA ads are typically used with affiliate programs, and there are two basic types of CPA ad campaign⁷:

- **Cost per lead:** You are paid each time a user signs up or provides contact information. This usually doesn't require a payment from the user. These programs typically pay somewhere between 50 cents and \$3.00 per signup.
- **Cost per sale:** You are paid each time a user buys one or more products. The commission is usually a percentage of the sale price, so the amount you earn for a sale depends on how much the user spends.

Like CPC ads, In this payment scheme, the publisher takes all the risk of running the ad, and the advertiser pays only for the amount of users who complete a transaction, such as a purchase or sign-up. Some webmasters make more money from affiliate programs than any other source, because they have found affiliate programs that closely match their audience. If a program does not fit your audience, the publisher may find himself running thousands of ads without a commission.

3.4. Cost per Pixel - Million Dollar Homepage

As seen above, the large majority of online advertising has a cost that is brought about by usage or interaction of an ad; there are a few other methods of advertising online that only require a one-time payment. The Million Dollar Homepage⁸ is a very successful example of this. The home page consists of a million pixels arranged in a 1000 × 1000 pixel grid - the image-based links on it were sold for \$1 per pixel in 10 × 10 blocks. Visitors were able to pay \$1 per pixel of advertising space and their advert would remain on the homepage for as long as the website exists with no extra costs. The purchasers of these pixel blocks provided tiny images to be displayed on them, a URL to which the images were linked, and a slogan to be displayed when hovering a cursor over the link. The aim of the website was to sell all of the pixels in the image, thus generating a million dollars of income for the creator (and it did). The Wall Street Journal has commented that the site inspired other websites that sell pixels, marking a trend called pixel advertising (Bounds, 2005). Today it is defined as a form of display advertising on the web, in which the cost of each advertisement is calculated dependent on the number of pixels it occupies (Bounds, 2006).

4. AD FORMATS

One of the many advantages of online advertising is a wide variety of online ad formats and targeting methods to ensure the most effective and cost-efficient media buys for your campaign goals. Depending on the particular format, online advertisements can be categorized into following types:

4.1. Text ads

Text-based ads, as their name applies, are simple text-based hyperlinks that do not include graphic images. They are usually related to the content of the website they are published on, and can be set up with a program like AdSense or manually added by the publisher of the site. Text ads can be website-wide and located in the sidebar, footer or any other area in the advertising site or Internet search engine (Google, yahoo, etc). Sometimes they are even incorporated within the content of the website itself. One of the most effective types of text ads are *Search engine driven text ads* that are used in Search engine advertising. This type of online advertising involves purchasing text ads and having those ads show as sponsored results with a link to a publishers website when certain keywords or phrases are searched for.

⁷ Retrieved from <http://www.whyaffiliatemarketing.com/>

⁸ Retrieved from www.milliondollarhomepage.com

4.2. Display Ads

Graphical advertisements featured on websites are known as Display Ads or Banners. These banners can consist of static or animated images, as well as interactive media that may include audio and video elements. Display ads use eye-catching visuals to quickly grab catch the attention of website visitors. It is intended to attract traffic to a website by linking to the website of the advertiser. The advertisement known as a "click through". Display ads are often available in many standard shapes and sizes, that have been standardized by the Interactive advertising Bureau (IAB). These standards include: banners, leader boards, skyscrapers, large boxes, and other sized graphical ads (see graph below).

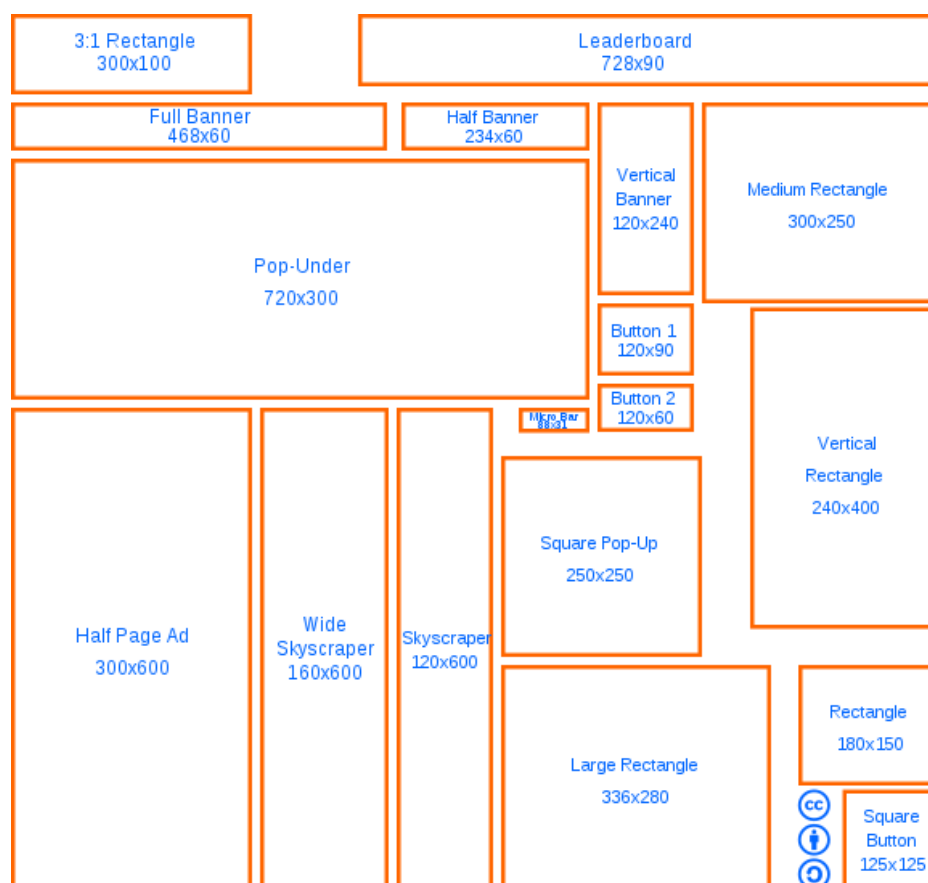

Figure 1. [Graph – Standard dimensions of banner according to the IAB⁹]

4.3. Pop-Up Ads

A sub type of display ads are Pop-ups - Advertisements that appear to "pop up" in a new window as users browse a website. Hoover ads, floating ads, expanding ads and slide-in ads are also considered pop-up ads. Sometimes these ads are also known as Pop-Under Ads, depending on whether they are displayed over or underneath the current web content being browsed. Because they tend to distract a person browsing the web, the use of Flash and DHTML ads has risen in recent years in an effort to counter the increased usage of pop-up blockers.

4.4. Social media ads

Social media ads are a type of online advertisement that is placed on social networking sites like facebook, MySpace, Google+ and so on. One of the major benefits of advertising on a social networking site is that advertisers can take advantage of the users demographic information and target their ads appropriately. Two most common forms of social advertising are:

⁹ Retrieved from <http://www.iab.net/>

- **Direct Advertising on social networking sites** - the same as banner ads on other sites, except the social network itself strictly regulates their dimensions. Here networks can take advantage of demographic data on a person's profile and hence target the ad directly to them.
- **Indirect Advertising by creating 'groups' or 'pages'** - This is an innovative marketing technique in which a company will create a 'page' or 'group' that users can choose to join. They will use this to build up 'subscribers' or 'fans' and use this to market a contest, a new product, or simply just to increase brand awareness.

4.5. Interstitial ads

Interstitial ads appear before or after an expected content page, that is between web pages that the user requests, often to display advertisements or confirm the user's age (prior to showing age-restricted material). For example, an interstitial ad may appear after you click on a link in an excerpt to view the full content of news story. Because interstitial ads load in the background and do not interrupt the users immediate browsing experience, they are a preferred method of delivering ads with rich media, streaming video, and/or large graphics. Some people take issue with the use of such pages to present online advertising before allowing users to see the content they were trying to access (Brown, 2007).

4.6. Rich media ads (interactive ads)

Interactive ads normally refers to products and services on digital computer-based systems which respond to the user's actions by presenting content such as text, graphics, animation, video, audio, etc.

4.7. Video Ads

With the popularity of online video watching, video ads have become a viable means of distributing rich advertising content. Google (via YouTube), MSN, Yahoo and AOL offer advertising on their video websites. There are two types of video ads:

- **Website commercials** - A video that is entirely created by the advertiser, and has an entertainment value attached to it and has the potential of going "viral" (being passed around through referrals or word-of-mouth).
- **"In video" ads** - Ads that will show your ad within a video. "In video" advertising is done in the same manner as banner advertising by using different video screen sizes or it can have blatant advertising and presented as Website commercials.

4.8. Email Ads

Ads that are distributed by a publisher through email audiences are known as email ads. Email ads have emerged as a popular tool that marketing managers use to raise product and service awareness among customers. Advertisers can individually sponsor a publisher's email newsletter or they can purchase classified ad space. Legitimate Email advertising or E-mail marketing is often known as "opt-in e-mail advertising" to distinguish it from spam. Though email spam is a menace, 'opt-in' e-mail delivers some of the best results for online advertising along with contextual advertising.

5. EXAMPLES OF INNOVATIVE ONLINE ADVERTISING

5.1. Tipp-ex "A Hunter Shoots a Bear" campaign – Example of rich media ads

Online video ads have much more potential than static video content that is available on TV, and the following example proves how a successful campaign through online media can be created (). Tipp-ex is a European company that makes correction fluid, and in 2010 it wanted to promote its whiteout called "Pocket Mouse". Target groups included mainly students and other existing customers of Tipp-ex. Even though the product is not exactly web-related product, the campaign relied on using online advertising, and it proved to be very effective.

The strategy used in this campaign was to create a unique user experience through an interactive production, and therefore "The Tipp experience" was created on Youtube. "Share" and "like" buttons were integrated, so that the viral experience of the video is complete.

The ad represents a new type of interactive video in which viewers can create their own storyline. The video's original title is "A Hunter Shoots a Bear", but in the end of the video a user can replace the word "shoots" with any other word. A hunter suddenly faces a bear in the woods, and the viewers can decide what happens next. Video content for 42 different scenarios has been created, and if the chosen word scenario is not available, line "Error 404" or "On strike! Won't work!" appears. By inputting words such as: eats, sleeps, dances etc., a user can get interesting video content. Whatever the viewer chooses, the hunter reaches outside of Youtube video and grabs the Tipp-Ex Pocket Mouse from the banner placed on the side of the video. A hunter whites the word "shoots" and the viewer can input any word in the blank field provided.

The campaign provided excellent results both short and long-term. In first 100 days the Tippex Youtube channel received more than 35.5 million views. The campaign started by sending videos to bloggers in Italy and UK, but later expanded to 217 countries around the world. The video was shared over 380.000 times on social media, and the virility rate of 500%. In long term, the campaign had a total of almost 50 million views, 1 million shares, 220.000 tweets and 60.000 online articles. It earned international TV coverage, 3.2 million euros, and the sales increased by 30% in Europe during the campaign. Total sell-in increased by 35% in 2011 vs. 2010. The success of this campaign proves how online advertising has much more potential than traditional form of advertising, and how it enables much more creative approach in attracting new customers.

5.2. The Google Job Experiment – Example of text ads

The next example shows how Google AdWords can be used in a creative and practical way, resulting in getting the wanted job. The story focuses on Alec Brownstein, a young advertising executive looking for a job in one of the leading New York advertising agencies. Among hundreds of other candidates, Alec was unable to attract attention and get himself hired. However, he used Google AdWords and by spending only 6 US Dollars, he was able to get his dream job.

As Alec didn't manage to get an interview with creative directors from agencies where he wanted to work, he appealed to their ego and the habit to Google themselves. Alec knew their names and he used Google AdWords to say "Hey, Ian Reichenthal (the co-executive creative director at advertising giant Young & Rubicam in New York), Googling yourself is a lot of fun. Hiring me is fun, too." This was the first link that appeared in sponsored search results. Alec created personalized AdWords for four more directors. When clicked on a link provided in an ad, creative director would be able to see Alec's portfolio. Out of five creative directors, four invited Alec for an interview and he got two job offers. Finally, he got a job at Y&R New York.

6. GOOGLE ADSENSE AND ADWORDS

When talking about online advertising when cannot go by without mentioning platforms like Google AdWords and AdSense. The main difference between the two is that AdWords is used by *advertisers* and AdSense is used by *publishers*.

AdWords is Google's main advertising product and main source of revenue¹⁰. It lets people advertise on Google.com, the Google Search Network (including sites like AOL search and Ask.com), and the Google Display Network (content sites that are not search engines). AdWords allows advertisers to reach new customers at the precise moment they're searching for their type of products and services. For example, when users search on Google, they're demonstrating which products they're interested in. With AdWords ads, users will see advertisers ad next to relevant search results they've requested. In addition, the ads could also appear on relevant search and content sites within the Google Network. And with Google's precise targeting and the advertisers ability to control how much they're willing to pay per click, the end result is a higher return on investment (ROI) for their advertising budget¹¹.

AdSense lets publishers in the Google Network to monetize their websites or blogs by earning money from relevant AdWords ads displayed next to their content. The publishers receive a small payment each time one of these ads is clicked on. These adverts are administered, sorted, and maintained by Google, and they can generate revenue on either a per-click or per-impression basis. If a publisher's site has

¹⁰ Retrived from <http://investor.google.com/financial/tables.html>

¹¹ Retrieved from <http://www.netthing.net/pdf/AdWordsOverview.pdf>

enough readers, this can be a simple way to generating a revenue stream from its content. In Q1 2011, Google earned US\$2.43 billion (\$9.71 billion annualized), or 28% of total revenue, through Google AdSense¹²

AdWords/AdSense important phrases:

- **Keywords:** The words or phrases you select – when users search for those words on Google, your ad may appear next to or above the search results.
- **Clicks:** The number of times users clicked your ad. **Impressions:** The number of times your ad appeared.
- **Click-through Rate (CTR):** The number of clicks divided by the number of impressions, shown as a percentage. A good CTR can improve your average position.
- **Average Position:** The average position that an ad appears in when it's triggered. An average position of 1-8 generally means that the ad is appearing on the first page of search results.
- **Cost:** The total amount you spend with AdWords.
- **Conversion:** The action that your advertising results in, such as a phone call, lead, or sale. This is usually a good metric to use to measure the success of your advertising.

7. CHARACTERISTICS OF DIGITAL ADVERTISING – Pros and cons

Online advertisements function the same way as traditional advertisements are intended to function: notifying consumers of the product or service and presenting reasons why the consumer should choose the product in question (Briggs, R., Hollis, N., 1997). Online advertisements differ in that the results for advertisement campaigns may be monitored real-time and may be targeted to the viewer's interests. That is why advertiser's investments are more efficient in online advertising. For example, AdWords, Yahoo!Search Marketing and Google AdSense enable ads to be shown on relevant web pages or alongside search result. Another benefit is the fact that online marketing is not limited by geography or time. The cost of digital advertising is minimal, compared to other traditional forms of advertising. Moreover, banners are much more effective. For the price of five hundred Euros in Serbia, a banner can be seen by 200.000 people in one month, which is much larger reach than the reach of traditional media forms for the same price. A company can also control and adjust ads to the characteristics and interests of its target groups. Finally, the success of the campaign can easily be measured. Unlike traditional advertising forms, where it is impossible to measure how many people have seen a billboard and how many have chosen to buy the produce, in online advertising the effects of a campaign are being analyzed by simple tools, such as Google Analytics. It enables anyone to get information about number of people that have seen the content, visits per web site or number of purchases made. By implementing received data into everyday operations, the company is able to decide about further marketing strategies and ways of adjusting marketing campaigns to target audiences.

Digital advertising is a growing form of advertising, as previously mentioned. However, it still leaves space for improvement, especially in the area of frauds and manipulations. One of the main disadvantages of digital advertising is Click fraud (Knight, 2005), a form of fraud caused by clicking on ads without an intention of buying a product or any interest in it. It appears in pay per click advertising, and is caused by either a person or a computer. Digital advertisements can also be irritating for a user, with ads randomly popping up and distracting from an actual content (Edwards, Li & Lee, 2002). In spite of irregularities and problems that occur, future of advertising lies in digital advertising. Everyday improvements are being made in order to improve online advertising process and help companies develop better connection with target group. The biggest advantage for a company is gathering information about its customers, and using new forms of advertising enables complete data collection. Further research in this area must be made in order to help develop technologies and methods that can help create benefits for both company and its customers.

8. FUTURE IMPLICATIONS

The future predictions for digital media are mainly related to mobilization of the content. It is projected that in by 2014 mobile internet will take over desktop internet in number of users¹³. This means that advertisers must adjust content for accessing via mobile device. It is also expected that in future customers will be more able to pull content they are interested in, rather than having it pushed to them by companies. Digital

¹² Retrieved from http://investor.google.com/earnings/2011/Q1_google_earnings.html

¹³ Retrieved from <http://www.digitalbuzzblog.com/2011-mobile-statistics-stats-facts-marketing-infographic/>

advertising in future will be much about an individual being able to create content for himself, and the advertisers must focus on discovering new and creative ways of getting consumers interested in their business.

The authors of this paper advise advertisers of the 21st century to embrace the marketing innovation and to become more acquainted with online advertising. Some are still sceptical about its efficiency, but it is evident that is becoming an integrated part of marketing promotion, and can lead to a viable source of income. Society as a whole is becoming more globalized and connected, and the way we advertise must follow that path.

Further studies on the subject matter should be done, in order to fully grasp how online advertising affects brand loyalty and brand recognition, and to create the basis for an innovative marketing approach.

²University of Strathclyde, Glasgow, United Kingdom, stevo.pavicevic@strath.ac.uk

³Faculty of Organizational Sciences, jovana@elab.rs

Abstract: *In today's business, companies are trying to lower everyday costs and labour expenses. The increasing numbers of educated and ambitious people who are willing to participate in various projects by using modern online technologies have forced companies to switch from outsourcing their business activities to other countries to the new approach known as crowd sourcing. This term is used to describe outsourcing tasks to the online community that is able to complete it in a better way or for less money than the company's employees. The aim of this paper is to define the term crowd sourcing and distinguish it from similar theoretical and practical concepts, such as open innovation, user innovation and open source. The authors tend to describe crowd sourcing in light of new product and service development. Furthermore, this paper will show examples of applying crowd sourcing in various companies and organizations, both profit and non-profit. Finally, the conclusions regarding the future of this concept will be presented by analysing its advantages and limitations.*

Keywords: *crowd sourcing, outsourcing, marketing, innovative business concept*

1. INTRODUCTION

The switch from traditional Internet to Web 2.0. has marked the beginning of new concept that most companies tend to take advantage from. Le Deuff, (2007) and O'Reilly (2005) describe Web 2.0 as "the utilisation dimension and not to the physical network that supports it". This concept tends to encourage collaboration and sharing between users, which leads to numerous options for application in everyday business. By using Web 2.0, a company can switch from outsourcing activities to other countries or firms specialised in certain field to engaging individuals in its everyday activities. This way, the company can collect fresh ideas from individuals all around the world, and save and allocate resources to other business activities. Crowd sourcing presents one way of using the power of crowds in solving everyday tasks and challenges.

Even though crowd sourcing platforms and concept itself appeared much earlier, the term crowd sourcing was firstly introduced by Jeff Howe and Mark Robinson in an article published in wired magazine in June 2006. Since, the concept of crowd sourcing has appeared in many blogs, magazines and books. Dahlander and Magnusson, (2008), and Agerfalk and Fitzgerald, (2008) discuss the term crowd sourcing, while others only mention it as an example of Web 2.0 (Tapscott and William (2007), Albors et al. (2008)). Due to the fact that this concept is still developing and growing, it is important to distinguish it from other similar concepts, such as open source, open innovation and user innovation.

2. CROWDSOURCING

2.1. Definition

The word crowd sourcing consists of words crowd and outsourcing. Its basic meaning is outsourcing to the crowd. At first it was mentioned on an Internet forum, it was not popularised until Howe and Robinson explored this subject in an article published in an online journal Wired. Howe gave this definition of crowd sourcing: "Simply defined, Crowdsourcing represents the act of a company or institution taking a function once performed by employees and outsourcing it to an undefined (and generally large) network of people in the form of an open call." Howe adds that "the crucial prerequisite is the use of the open call format and the wide network of potential labourers". In his recent book and posts on his blog¹⁴ (2008 and 2009), Howe gives two more precise definitions of crowdsourcing – The White Paper Version, and The Soundbyte Version. *The White Paper Version* describes crowdsourcing as "the act of taking a job traditionally performed by a designated agent (usually an employee) and outsourcing it to an undefined,

¹⁴ <http://www.crowdsourcing.com/>

generally large group of people in the form of an open call”, while *The Soundbyte Version* states that crowdsourcing is “the application of Open Source principles to fields outside of software”.

The most typical use of crowdsourcing tracks the following pattern: The company recognizes processes and activities that are suitable for outsourcing. Instead of forwarding these actions to another company or performing them within a company, they are “released to a crowd of outsiders who are invited to perform the task on the firm’s behalf for a stipulated fee”. There are two options to conduct this action: an open call to everybody who is interested to participate in completing the task, or by limiting the crowd to certain individuals who have previous experience in this field and therefore are more suitable to complete the task. It is also possible to combine these two methods by limiting an open call to a group of people most likely to complete the task. Whitla (2009) also notices that “sometimes a single task can be completed by many different users and each can be paid if they successfully complete the task”. This illustrates why crowdsourcing is becoming more and more popular among both companies and individuals – while companies are enabled to significantly lower fees that they are paying, individuals get the chance to earn money in easy way, by using resources available to them. In many cases, individuals are not familiar with the company itself, but only with the task given to them. A widely known Amazon’s Mechanical Turk is a perfect example of this type of platform. Named after Hungarian nobleman Wolfgang von Kempelen who invented “the Turk”, the first machine capable of beating human at a chess game, Mechanical Turk is a platform that enables individuals to solve simple tasks that computers are not able to do. These tasks are called HIT’s (human intelligence tasks), and require very little time and effort to complete. The amount of money rewarded to those who complete the task usually varies from couple of cents to less than a US dollar. Whitla (2009) illustrates the crowdsourcing process in the following figure:

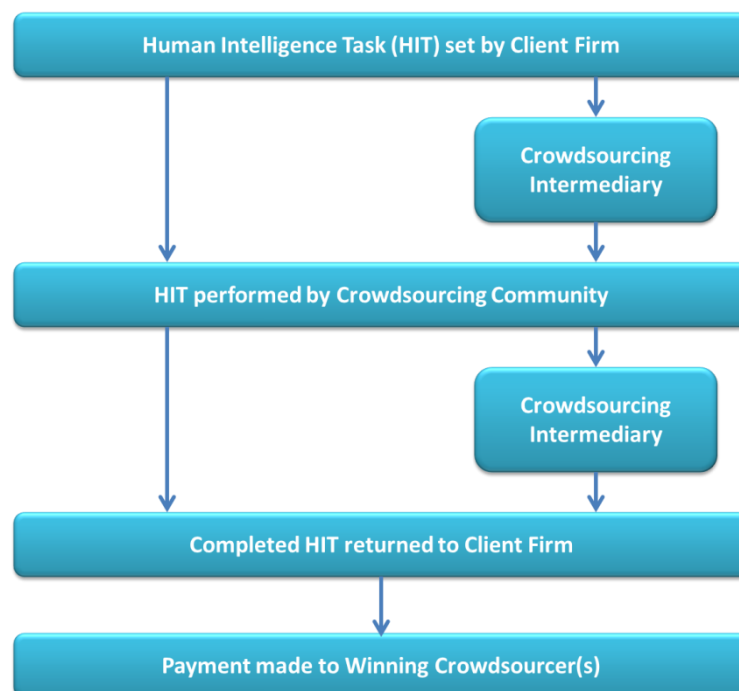

Figure 1: Crowdsourcing process

Even though there are modifications depending on the purpose of crowdsourcing, the basic principle of outsourcing specific activities from a company to individuals remains the same.

2.2. Similar concepts

Since crowdsourcing is yet to be further explored and analysed, it is sometimes difficult to distinguish this new concept from other similar concepts that rely on the power of crowd.

First of all, there is a difference between crowdsourcing and outsourcing. Basic process of both activities is very similar, with both having a client company that seeks help from outside, but the main difference is

the fact that, while outsourcing means seeking help from other companies, crowdsourcing company focuses on getting ideas from individuals.

Open Innovation and user innovation have the same central idea as crowdsourcing, that “in a world of distributed knowledge, companies should not rely on their own research and development”, but to “outsource some R&D functions through Intellectual Property Rights (IPR) purchases from other companies.” Open innovation, like outsourcing, focuses on cooperation between firms, while user innovation describes connection between specific product users who focus on solving issues with final products. In both open and user innovation processes, the focus is on innovative and original solutions to the problem, and crowdsourcing is not restricted only to innovations and innovative processes.

The term “Open Source” is used by Howe (2008) to describe crowdsourcing as “an application of the open source principles to other industries”. Schenk and Guittard (2009) notice that Open Source Software relies on the concept of sharing and altering free access codes, and “thus Open Source Software can be copied and freely distributed on a large scale”. Brabham (2008) states that “it is obvious that crowdsourcing is not restricted to software development”. With all this in mind, we can conclude that open source is a practical approach to theoretical concept of crowdsourcing. It is one of the fields where crowdsourcing model can be applied.

3. APPLICATION OF CROWDSOURCING

3.1. Types of tasks

As previously mentioned, a call for crowdsourcing can be in form of an open call, or limited to a certain group of individuals. The question is, what types of tasks can be crowdsourced? According to Schenk and Guittard (2009), there are three types of tasks that can be outsourced to a crowd: routine tasks, complex tasks and creative tasks.

Routine tasks refer to the tasks that can be completed quickly and easily, such as collecting data or mark text and images. Micropayments are usually a reward for this kind of effort. Examples of solving routine tasks include ReCaptcha¹⁵, Open Street Map (OSM)¹⁶ and TxtEagle. ReCaptcha window is used for text recognition on websites where it is necessary to distinguish virtual robots from human beings. OSM collects geographic data in order to create a world map. TxtEagle¹⁷ enables mobile phone users to complete simple tasks by sending a text message. Routine tasks are usually issued in form of an open call, due to the fact that almost anyone can participate in solving them.

Solving complex tasks requires more skills and knowledge than solving routine tasks, and therefore it is limited to a smaller group of people. This makes it a limited or selective type of crowdsourcing. This type of tasks can be solved in profit and non-profit sectors, and it usually involves larger compensation from a firm, due to the effort required to successfully complete the task.

Finally, the third types of tasks that can be solved are creative tasks. This type of tasks was crowdsourced even before Internet, in form of design contests and competitions. Companies usually issue creative tasks with limitations only in the form required from a solution. This way the crowd can provide original ideas and solutions. Monetary compensation for these type of tasks is couple of hundred dollars, but varies depending on the task.

3.2. Crowdsourcing marketing activities

To explore practical use of crowdsourcing, this paper will focus on its application in marketing. Whitla (2009) explored the nature of Human Intelligence Tasks (HIT's) and identified the fields of marketing that are most suitable for their use. By surveying literature and published HIT's, he recognizes product development, advertising and promotion and marketing research as three fields where crowdsourcing is widely used by firms.

¹⁵ <http://recaptcha.net>

¹⁶ <http://www.openstreetmap.org>

¹⁷ <http://txteagle.com/>

In the area of advertising and promotion, it is possible to use crowdsourcers in basic activities that a firm has no resources to complete, or in getting fresh ideas for promotional and advertising campaigns. Sometimes people are hired to post comments and reviews on social networks, which can lead to getting false impression about the company. On the other hand, smaller firms often hire crowds to help them get fresh and innovative ideas that can be implemented in the campaign.

Crowdsourcing in market research usually focuses on collecting data in form of a paid survey. However, it is questionable wheatear the research is objective, due to the fact that the payment may have effect on the responses, resulting in unrealistic image of the company.

3.3. Use of Crowdsourcing in product development

Third and final area where crowdsourcing is most present in marketing aspect of new product development. This is the area which we will be mostly focusing on, mainly due to its wider use than in other aspects. Von Hippel (1998, 2006) notices that firms have been using consumer inputs for its purposes for a long time. Manufacturers have been collecting feedback and implementing results in new product development for years. But the crowdsourcing process is expanding this approach in three basic ways. First of all, getting feedback is not limited only to customers, but also to potential customers or anyone interested in suggesting improvements. Crowdsourcing allows companies to directly contact customers and gather information, unlike getting feedback in a classic way where distributors are involved. Finally, while crowdsourcing an activity, the company is able to select specific fields of product development where they require help. Having this in mind, many firms are now turning to this innovative approach, looking for fresh ideas and suggestions regarding improvement of their products and services. In this paper we will further focus on successful examples of using crowdsourcing in developing new products and services in profit and non-profit sector.

3.4. Successful crowdsourcing profit projects

Even though crowdsourcing is a relatively new concept, many companies have already successfully implemented it in their businesses. A crowdsourcing firm InnoCentive¹⁸ specialises in offering scientific solutions to firms. Howe (2006) points out that InnoCentive “enables companies to tap into the talents of a global scientific community for innovative solutions to tough R&D problems”. Companies offering tasks include Proctor and Gamble, Boeing, DuPont, which offer up to 100.000 US dollars for a winning solution. Other examples include Netflix and Google, and they offered up to a million and ten million USD respectively for those who developed innovative and successful solutions to their problems. A perfect example of a company looking for new ideas on how to improve everyday business is Nokia with its project “Calling All Innovators”. This project was launched in May 2009. and it was Nokia’s answer to Apple’s “App Store” by creating “Ovi Store”. “Calling All Innovators” was divided into three areas and interested parties were called to submit a solution in one of these categories, which included internet innovation, flash applications and innovative applications created by using mobile technologies. Three best projects were rewarded with 30.000, 15.000 and 10.000 USD, but even non-winning projects could earn money depending on number of downloads from the Ovi Store. Even before the launch of the project, there were over 1.700 pending requests from developers from 85 countries, which only confirm that crowdsourcing proved to be very successful in gathering ideas from professionals and enthusiasts all over the world.

Not only large companies offer monetary compensation to those who helped those finding solutions for new business challenges. Smaller businesses are able to provide more exciting and creative tasks to their crowdsourcers. They are able to either submit their designs and create products of their own, or to offer information and experiences which help the firm in developing new products. Threadless is a web based company that organizes online competition for t-shirt designs. Users vote and the winning designs are rewarded with up to 1.500 USD prize and the satisfaction of having their design available for sale through the web site. Online portal Cafepress.com has a similar concept where crowdsourcers provide designs for various items and get a percentage of each sale. Crowdspirit.org enables members to select ideas and jointly finance product development in the field of electronic items (Hempel, 2007). Furthermore, iStockphoto.com is one of the most popular crowdsourcing site. On this website users can post stock

¹⁸ www.innocentive.com

photography, video clips and animations. Photographers are paid 20 per cent of the purchase price for the photo each time the photo is downloaded, and this platform gathers both amateurs and professionals.

In order to remain competitive in both local and global market, companies must search for new, innovative business models. Crowdsourcing is one of the platforms that enable companies to implement these concepts. The examples we have shown confirm that application of crowdsourcing is justified.

3.5. Successful crowdsourcing non-profit projects

One of the newfound potentials of collective knowledge is certainly the use of crowdsourcing in emergency management. Disasters and catastrophes happen in various natural and social contexts. In these situations, disaster relief teams need certain information in order to make proper plans to resolve the critical issues. This information is habitually generated by various individuals on the site, but it is usually unstructured and disorganized. Vivacqua and Borges (2012) identified the information needs for emergency management, as well as the various types of information needed in different phases. The mitigation phase (pre-disaster) demands information needed for risk assessment. The preparedness (pre-disaster) phase requests information needed for composing plans and procedures to deal with the possible emergency. The most information intensive phase is the response (disaster) phase. In this phase a large amount of time sensitive information is required. The following phase is the recovery phase. Crowdsourcing has found its great use particularly in the response phase. Best-known initiatives for crowdsourcing in the response phase are Ushahidi¹⁹ and Sahana²⁰.

Ushahidi is a crowdsourcing platform, which can be freely downloaded and used for various projects. Ushahidi allows anyone to collect and visualize information on a given set of information. The platform enables individuals to send in information (by Web or sms), and aggregates this information. This open source platform was first used in Kenya, as a violence-mapping tool after the post-election fallout in 2008. Its most known and successful usage was in the Ushahidi Haiti Project when the platform was used to quickly map the needs after the Haiti earthquake (Morrow et al., 2011). In the words of David Kobia, a Kenyan software developer and founder of Ushahidi, the reliability of the crowd-sourced information can represent a problem in certain situations. On the other hand, crowdsourcing is based on Internet, as a liberating technology, and people's willingness to help in common issues (Vericat, 2010).

Crowdsourcing has found its use in many other non-profit areas. One popular example includes Hult Global Case Challenge. It is a competition for students all around the world, with the goal of financing the best project for a non-profit organization. Each year an organization provides a task in form of a case study, and students are required to give a realistic and sustainable solution for a given challenge. The best solution receives 1 million USD for implementation and the students are involved in the process of further development of the solution and its implementation. Some of the best known non-profit organizations, such as Water.org, One Laptop per Child and Habitat for Humanity are among those who have successfully participated in this event and are currently in process of completing implementation of their projects with the help of students

During the last several years, some non-profit crowdsourcing projects have been started in Serbia, one of them being imamproblem.rs²¹. This project proposes crowd-sourcing knowledge about communal issues in Belgrade and promotes voluntary engagement in solving recognized issues.

4. CONCLUSION

The above discussion showed that ranges of application which may be handled by means of crowdsourcing exist. Even though the concept is in its development stage, there is no doubt that many businesses in the future will find many tasks which can be accomplished by using this innovative approach. The evolution of technology and the increase of the competition on a global level are only few of the major crowdsourcing drivers. By showing some of the most successful examples, it has been presented that crowdsourcing as one the modern approaches can provide many benefits for the organisation. However, some disadvantages can also be identified.

¹⁹ www.ushahidi.com

²⁰ <http://sahanafoundation.org/>

²¹ www.imamproblem.rs

Despite the fact that the bigger sample should generally give more accurate and higher-quality results, sometimes an uncontrolled crowd can turn into a vast amount of noise source, which can provide irrelevant information and thus cause harm to the goals or the intended purpose of the system. That is why mechanisms for filtering ideas have to be developed in parallel with the crowdsourcing platform. Furthermore, additional issues may arise in the legal aspect, where it can be hard to deal with ownership of ideas etc. Finally, there are some limitations in the use of crowdsourcing, for example in cases where the success of the business relies of information or tasks' secrecy. Ethical issues may arise as well.

We need to learn much more about the possibilities and limitations of crowdsourcing. One important area of research, for example may be understanding the motivational and reward structure of crowd workers and how they generalize across different kinds of markets. The concept itself includes variety of disciplines such as: psychology, sociology, management science, technology, information technologies etc which is why the improvements of the concept should be searched for from different perspectives. However, the development of ICTs gives the biggest support for the development of crowdsourcing platform. Therefore, taking into account their rapid development, we can expect similar in the crowdsourcing area.

Further research should focus on possibilities of using a wide range of social networking platforms for both profit and non profit crowdsourcing initiatives. Social networks attract millions of users, whereby attracting only a small percentage of them could give significant contribution to the increase of innovation capacities and capabilities all over the world.

Abstract: *The trend of increasing prices and shortages is predicted for food and other agricultural products in the future. Brands among agricultural products are found more often and have increased importance for products sales on the market and building relationships with customers. This trend will certainly continue, given that consumers are looking for something they can trust and something that will give them security in terms of the quality and origin of agricultural products. The essence of this paper is to define and determine the most important factors affecting the formation of the brand of agricultural products which includes labeling of unprocessed agricultural products, geographical indications, as well as the relationship between agricultural products brands and country brand. This paper also presents the results of research on the possibilities and directions for branding of agricultural products in Serbia.*

Keywords: *branding, agricultural products, geographic origin, country brand*

1. INTRODUCTION

Aaker and Joachimsthaler(2000) stated that the development of brands was the only way to remove oneself from commodity status and price competition. Brand is a name, term, sign, symbol, or design or a combination of them intended to identify the goods and services of one seller or group of sellers and to differentiate them from those of competition. Brand equity consists of awareness, recognition, and tom of the mind awareness of the product among consumers; positive brand association; perceived quality and brand loyalty. Brand equity will result in price premiums, consumer and trade loyalty, trade co-operation and joint marketing efforts and pride of ownership among the company.

Traditionally producers of fresh produce have seen their responsibility for the product end when their produce leaves the farm gate (Crocombe, Enright & Porter, 1991). Agricultural producers focused on large volume throughput to a large number of independent buyers who purchased unbranded, undifferentiated produce on an *ad hoc* transactional basis from the supplier who offered the best price and quality at the same time (White, 2000).

Marketing for agricultural products has often been left up to single desk producer boards that have focused on increasing product quality in order to develop a competitive advantage (Crocombe, et al., 1991). Lichentathal and Long(1998) stated that it was no longer sufficient for agribusiness to produce a technically superior product. Agribusiness would need to adopt strategic planning models if they are to be successful in the future. These models will need to address the development of strong brands, a unique selling proposition, the formation of close relationships throughout the supply chain, and the development of market orientation (Miles, White & Munilla, 1997).

This research provide the initial point towards building a theory of branding agricultural products which aims at understanding which information can differentiate a brand from its competitors and so make a company gain a benefit advantage.

2. COMMODITY BRANDING IN CASE OF UNPROCESSED AGRICULTURAL PRODUCTS

Branding strategies have become widely accepted part of marketing activities and as a rule processed food products are offered to consumers as branded products. However, we can easily see that there is a wide range of food products that are not branded. This is usually the case with agricultural products such as meat, fruits and vegetables that are sold relatively unprocessed and without any label either of manufacturer or a seller. In attempt to explain the reasons for the lack of brand among these products, it is often assumed that the lack of activity of branding is a result of many small producers who have the same products or lack of knowledge among these producers about the need for brand development.

There has been little consideration of agricultural products in the branding literature. However, one author who has attempted to bridge the gap between agricultural products and main stream marketing

theory is Bowbrick. Within agricultural products branding seems to include identifying a product with various types of labels (e.g. region of origin, variety) to differentiate products. Bowbrick(1992) acknowledges this characteristic and suggests that a “brand is a label attached to products from a specific manufacturer, distributor, country of origin, or retailer with the aim being to convey information on, or persuade the consumer about; the quality, reliability, social status, value for money or safety of a purchase“(p.29).

A product provides an array of cues that a consumer uses as the basis for making judgments about which product they will purchase. Consumers form a composite judgment about which product to purchase by going through a process in which the consumer identifies, evaluates, and integrates some or all of the various items of information (i.e. cues) associated with the product. The cues that consumers use when making purchase decisions have been classified as intrinsic or extrinsic cues (Jacoby, Olsen & Haddock, 1971). Intrinsic cues are those cues which if changed would change the physical product itself (e.g. taste, nutrition content, size, shape, and color of a product). Extrinsic cues refer not to the physical product itself, but to other cues provided (e.g. price, store image, label, advertising). The important distinction to note is that cues of an extrinsic nature can be supplied by either the producer or the seller, whilst the intrinsic cues are determined by the product itself. Intrinsic cues pose further problems for consumers as they can be classified as either hidden intrinsic cues or revealed intrinsic cues. Hidden intrinsic cues are those product attributes which cannot easily be physically identified by the consumer before purchase, (e.g. the flavor or taste of the product, or the durability and reliability of a product). Revealed intrinsic cues include those product attributes which the consumer can identify and assess visually or physically, (e.g. the shape, size and color of a product).

Whether these important attributes (i.e. cues) are hidden or revealed becomes important to the consumer during this search. To aid consumers in their search for the desired bundle of attributes, the seller can make an extrinsic cue available (e.g. a label) to act as a proxy for the important hidden cues. For example, as an indicator of the different taste characteristics different varieties of apples possess, retailers provide an extrinsic cue in the form of a variety label. Consumers subsequently use this cue to select the variety of apple that has the taste characteristics which correspond to their preference (Pay, White & Zwart, 1996).

It has been suggested that consumers would be prepared to pay a price premium for those products which are difficult to inspect and too expensive to sample (Png & Reitman, 1995). Although many agricultural products cannot be considered too expensive to sample, many are difficult to inspect. Where inspection is difficult consumer search costs are high. Labeling can reduce these search costs. Where producers have extra costs of labeling to retrieve, and consumers have high search costs, it would seem likely that labeled products would attract price premiums. This framework can be illustrated with a simple model (Pay et al., 1996, p.8).

PRODUCERS ABILITY TO CONTROL
BIOLOGICAL VARIABILITY
WITHIN IMPORTANT PRODUCT ATTRIBUTES

	HIGH	LOW
IMPORTANT PRODUCT ATTRIBUTE IS CHARACTERISED BY:	• SUPPLIER LABEL	• NO LABEL
	• CONSUMER BRANDS	• COUNTRY OF ORIGIN
	• RETAIL BRANDS	• VARIETY LABEL

Figure 1 : Model of brand development

The model is a combination of the ability of consumers to assess this important product attributes given that the attributes can either be hidden or revealed and the producer's ability to manage biological variability within important product attributes. Depending whether the important cue is revealed or hidden, and to what extent producers can control variability within product attributes, the model can be used to predict the type of labeling observed on a particular product

In cases where the important intrinsic cues are revealed and a single producer has little or no ability to control biological variability of the important product attributes, we would expect to see no labeling. For those products which have important hidden intrinsic cues and where producers have little ability to control biological variability, country of origin or variety labels may be used. Country of origin labels may be used for those products where the region of production consistently affects product attributes, or variety labels may be used for those products which consistently differ due to the genetic make up of the product.

In those cases where the important attributes are revealed and the important product characteristics are controllable by the producer, a label will not be offered to consumers. However, as the producer is able to control the biological variability of important product attributes, or can use management practices to consistently differentiate products, a supplier label may be provided which is important to buyers within trade channels. Finally, where the important attribute is a hidden intrinsic cue and producers have a high level of ability to control the biological variability within important product attributes or use management practices to consistently differentiate their product from others, it is expected that these products will be labeled with consumer brands. In the case where the important intrinsic cue is hidden, and the seller is providing the management practice to consistently differentiate a product, it is expected that these products will be labeled as retailer brands. We now have a basis for formulating three testable hypotheses.

3. GEOGRAPHIC ORIGIN AS A FACTOR OF BRANDING AGRICULTURAL PRODUCTS

Origin indication has been used as a basis for differentiating agricultural products for a long time. Over the course of decades, and in some cases centuries, some of the most successful and internationally renowned agricultural products have had their quality reputations built with reference to their geographic origin (e.g. Champagne, Parma ham, Roquefort cheese, Czech beer, Scotch whisky). As agricultural markets become increasingly liberalised, it is likely that many more producers will consider using origin within their marketing strategies - not only is the market for origin-labelled food products growing, a range of policy instruments now exists at national and European Union levels to encourage the development of such products (Tregear & Gorton, 2006).

It is important to bear in mind that many origin products are not traded on markets under a geographical indication, and consumers and other economic participants may well be unaware they are dealing with an origin product. The use of a geographical indication to indicate product origin is a step in the value-enhancement process and a result of the behaviour of local and non-local actors. As a consequence of their ties with a specific territory, origin products are characterized by one or more key factors, albeit to different degrees: (i) material characteristics making the product 'particular' (virtually no other products exhibit exactly the same characteristics); (ii) specific character of the resources used in the production process; (iii) product history and tradition, and connections with the history and tradition (know-how, traditional know ledge) of the inhabitants of the territory; and (iv) collective dimension (many actors involved) with shared local knowledge of production (Barham & Sylvander, 2011, p xiii). Long before the geographical origin has been recognized in the legal framework, the names of different parts of the world had an important place in the trade. Certain products are recognized for being in possession of specific characteristics and they are often, but not systematically, determined by geographical name when they were found on market. These cases are dating long before the period of industrialization and continue to the modern world where the food is almost completely commercialized. Recognition of products based on place of origin by consumers and retailers because of its specific quality is nothing new. Generally speaking, the origin of the product is viewed as the expression of specific local resources and knowledge shaped in the form of different products.

Indicating the geographical origin may imply different types of informative elements. Some geographic indications are constituted only by a geographical name (Bordeaux wine, Roquefort and L'Étivaz cheeses), whereas other geographic indications are constituted only by a non-geographical name referring to a geographical origin (as in the cheeses Fontina, Tête de Moine, Feta) (Barham & Sylvander, 2011). Products with geographical origin are established with a link between the product and its special

characteristics, no matter what are those characteristics or how they are determined. Products with geographical indications are those products that have a known origin, which is credited for a given quality, reputation or characteristics. Specific quality of products with geographical indications are primarily identified and maintained in local community. Even if their reputation is maintained at that level, the preservation of local knowledge and resources such as indigenous varieties still gives enough reason for public recognition and protection on national and international level. But the real market value of such products occurs by creating a reputation in the competitive market with similar products that may be protected or generic.

As product with geographic indication strengthens its reputation and recognition as special product in different markets around the world, may over time be perceived by consumers more as a type than as the concrete result of origin-specific assets that consumers are not aware of. In this case, the name becomes generic and product features are no longer controlled by the original manufacturer. This creates opportunities for producers who are not located in the region of origin to use the geographical name for products of a similar type to the original one, even if their production cannot have exactly the same characteristics as that coming from the region of origin. In this case, the name becomes generic and the properties and the characteristics of the product escape control by the original producers (Bérard & Marchenay, 2008). Protection against this practice is at the source of rules which aims to protect the identity of origin products by associating them with an intellectual property right represented by the geographical name. Know-how and tradition are determining factors for maintaining stable quality in GI products, given that these products pre-suppose a continuity of production practices and product appreciation over generations.

Taking into account that geographical indication transmits information to consumers, we can say that it is the same role as the brand. In other words geographical indications have the potential to change the perception that the consumer has towards the product attributes which can be very similar to products coming from other geographical areas. Geographical origin may be determined by other indications than words, pictures, emblems or design of packaging can be interpreted as an indication of geographical origin as well.

Numerous studies have demonstrated that consumers are interested in the origin of products of both ordinary and specialized use. For example, the origin of a spice (e.g. paprika) counts for more when it is used as an ingredient in cooking than when it is just one among other condiments found in already prepared dish. Loureiro and McCluskey(2000) calculated consumers' willingness to pay for 'Galician Veal' which is known to 48% of Spanish shoppers. They found that the geographic indication label generates a high premium for only certain cuts of meat occupying the mid-range of the quality spectrum (specifically, for 'high'-quality cuts), but it has no effect at the poles of the spectrum (both for high-end 'deluxe' cuts and 'low'-quality cuts) (Loureiro & McCluskey, 2000). These results suggest that geographic indication labels attract effective value – which is the main goal of collective quality control – only in combination with other aspects of the product.

4. IMPORTANCE OF COUNTRY BRAND FOR BRANDING AGRICULTURAL PRODUCTS

Historically, there has been considerable public sector involvement in agriculture, where most farms are too small to garner the economics of scale associated with marketing activities. Individual farmers face direct competition from other farmers producing near perfect substitutes, the production of any individual farm is not sufficiently large to satisfy retailers' demands for consistency of supply and quality, and costs of organization are high. Governments become involved to assist agricultural producers in overcoming these hurdles. Product differentiation comes in many forms. For example, the European Union has been in the forefront of developing product differentiation strategies based on geographic indicators. Countries as New Zealand, Scotland, Kyrgyzstan and Ecuador have implemented or investigated country branding strategies.

Defining the difference between a label and a brand is key to understanding how a country brand for agricultural products differs from a country-of-origin label. Both can signal information about a food's origin and bring to mind past experiences with the country and its products, while a brand is not limited to describing the product itself (Van Riel & Van den Ban, 2001). For example, a "Product of Canada" label is only informing consumers that the product was produced in Canada. A Canada brand, in contrast, would by its design represent all past brand marketing and a heightened awareness of what the consumer associates with Canada, in addition to identifying the product's origin. A brand's use of a consistent image

or logo rather than just words means that the associative effect of linking all past experiences to the current product is much stronger than for a label.

Applying a symbol indicative of a particular country to a range of food products can be viewed as an origin brand or country brand that links a product with its place of origin. Van Gelder(2003) states that this type of brand seeks to leverage the reputation of a geographic location to contribute to the consumer's positive perception of a product. Using a country brand that builds on the collective reputation of a country, its citizens, and other products using the brand makes managing it considerably more challenging than managing a traditional private brand. There are two challenges inherent in a country brand for food products: the complexity of managing a brand that is used on multiple products; and the effect on brand equity of the country's image in general (Innes, 2007).

Effective management of a brand requires appropriate linkages and information transfers along the supply chain to ensure that consumers receive a consistent message about the brand. When the owner of a brand manages all stages of the supply chain, the task of ensuring the product lives up to the brand's proposition is simplified. Vertical integration by agribusiness companies is one way to facilitate information transfer and product consistency. Alternative approaches exist, for example the cooperative model. As outlined by Hobbs(1998), 97% of Danish pork is channeled through cooperatives that participate in an umbrella organization which acts to ensure that consumer preferences are communicated to producers who then deliver consistent products.

A country brand will only assist in expanding exports if foreign consumers have a positive image of the country. We cannot assume that a country's brand equity will always be positive, especially as it is impacted by factors beyond the control of the licensor or its users. Many of the factors influencing country brand are beyond the control of either the brand users or managers. With the reputation of the brand resting in part on the reputation of the country, to fully manage the brand's image one would in theory need to control political, environmental, human rights and food safety systems in the country. If a country brand can credibly signal a positive product attribute about its brand equity, complementing the exporter's own private brand then it could be a valuable tool for a government to promote their agribusiness industry. From an individual firm's perspective geographic labels have been shown to add value to private labels by providing complementary quality signals (Hobbs, Kerr, and Klein, 1998).

A country brand on a food or agricultural product is intended to signal specific quality characteristics to consumers, which have been promoted as embodied in the country's products, in addition to consumers' preconceptions of what the country represents. A country brand therefore queues consumers to recall an image of the quality attributes that they associate with the country, its citizens, and the brand itself.

According to Caswell(2002) brand equity results from past experiences with the product, marketing efforts, and individual factors relating to a consumer's perception of the country and its citizens. Brand equity, in-turn, influences the strength of an extrinsic search indicator by providing a recognizable mark or logo that can signal a specific quality to the consumer. The intrinsic attributes of the product, like taste, appearance or the way it was produced, influence the perceived quality of the product following consumption. Past consumer experiences with the intrinsic attributes of products carrying the country brand can affect the total level of brand equity inherent in the country brand.

5. RESEARCH RESULTS IN SERBIA

The main objective of this study is determining of the most important factors that influence branding of agricultural products in Serbia and assessment of the importance of different participants in agriculture in creating branding strategy. The study included 125 respondents of which 65 were male and other 60 were female. Respondents in most cases were employed in different types of organizations involved in agriculture. Respondents in a given sample were aged 22 years and up to 66 years, and the average age of respondents was 38.46 years. The questionnaire also measured the number of years of experience in agriculture, which ranged from respondents with no work experience in agriculture to those with 60 years of experience, and the average number of years of experience in agriculture in this sample was 10:38 years.

Evaluation of factors affecting the formation of brand for agricultural products in Serbia, the following results are presented for unprocessed and processed agricultural products:

Figure 2: Significance of different factors for branding of agricultural product

Research results shows that the taste and quality are recognized as the most important factor in branding for unprocessed agricultural products while the geographical origin and organic origin acquired lower, but roughly the same ratings. In processed products taste and quality are also best evaluated while the technology of production and geographical origin scored somewhat lower grades. On the basis of these results it can be concluded that the taste and quality is the most important prerequisites for developing brand among agrarian products while other factors may significantly contribute to a successful brand and better communication with consumers.

Respondents were asked which sector of agricultural production in Serbia has the greatest potential for creating a brand, the following results were obtained:

Figure 3: Rank of branding potential for different sectors of agricultural production

When asked which is most important level for development of agricultural products brands, respondents said that the agricultural products should be branded on product level (38%) as well as on national level (33%) in that way products from Serbia would have better chance to be accepted in foreign markets.

6. CONCLUSION

Looking at present trends both in the field of branding as well as in agriculture and food industry, it suggests that the branding of agricultural products will become increasingly important for their placement and sales, especially given the predictions of an increase in food prices in the future.

Brands in agriculture have the most important function to create an association to the product in the mind of consumers and provide a guarantee of quality and safety of marketed products. They can transmit the information about the product that will make consumers choose particular manufacturer or product. Geographical origin also indicates the specific product characteristics, quality assurance, a specification of production and place of origin, but does not include emotional relationship between customer and the product itself. One can therefore say that the geographical origin of products is a good basis for brand development, but it takes certain effort to create successful brand.

For branding agricultural products, it is necessary to take into account the natural characteristics that affect the brand that we want to create. Some products, especially unprocessed, are difficult to brand as there aren't characteristics which would make connection with consumers. When a manufacturer can produce unique high quality product then starts process of branding by putting a label that will effectively communicate with consumers.

Bearing in mind that agriculture is of great importance to the economy of most countries and this applies particularly to Serbia, branding is becoming one of the ways in which different countries can improve the competitiveness of their products on the global market. The activities of the country are reflected primarily in the creation of conditions for the successful production and product branding, and the can be, as well, implemented through the creation of the country brand that would serve as a support and a guarantee of quality products from certain countries.

Research on branding agricultural products was conducted on a sample of 125 respondents who were mainly employed in organizations from agribusiness. Results show that the greatest potential for creating brand in agricultural production has fruits and processed fruit products which clearly shows the strategic direction in creation of agricultural brands in Serbia. According to the survey branding of agricultural products in Serbia should be performed both on the product level and at national level in order to achieve more significant effects, and manufacturers should play a major role in this process

UTILIZATION OF CONSUMER RESEARCH IN STRATEGIC DECISION MAKING

Marko Djordjic
Scires, marko.djordjic@gmail.com

Abstract: *The purpose of this methodological article is to explore the utilization of consumer research in the building of informational surrounding for strategic decision making. The article exposes methodologies of longitudinal research and segmentation research as two key methodologies which possess the required analytical and employment potential for successful utilization in strategic decision making. Practical implications of the article imply guidelines for managers and consultants which ensure that strategic research provides positive contribution in the process of strategic decision making. Theoretical implications imply guidelines for further scientific research which can enhance practical application and the overall quality of strategic research efforts.*

Keywords: *research methodology, strategic research, longitudinal research, segmentation research, strategic decision making.*

1. INTRODUCTION

Strategic decision making has always been one of the greatest challenges managers face throughout their carriers. First decades of long awaited second millennium have brought unprecedented macroeconomic uncertainty and volatility, and thus made strategic decision making even harder and riskier. Managers extensively rely on Business Intelligence (BI) in order to reduce the inherent risks of decision making, and subsequently base their decisions upon the learning acquired through various instruments of BI. Due to the fact that the majority of strategic decisions directly influence market performance, Consumer²² Intelligence (CI) as an integral component of BI, fulfils a particularly important role in strategic decision making.

Previous scholarship has thoroughly investigated the field of strategic decision making in marketing (West, Ford, & Ibrahim, 2010) and the field of consumer research (Aaker, Kumar, & Day, 2004). However, further research is necessary in order to explore (a) utilization of consumer research in strategic decision making, and (b) specific methodologies of consumer research which can deliver findings with strategic employment potential. Therefore, the purpose of this methodological article is to expose two methodologies of consumer research which have the required employment potential to be successfully utilized in strategic decision making. The article summarizes author's professional experience in project management of strategic research and management consulting, with previous scholarship in the field of consumer research.

2. CONSUMER RESEARCH AND STRATEGIC DECISION MAKING

Main instrument for acquisition of data for CI are various types of consumer researches. However not all consumer researches are of equal importance from the standpoint of CI. Therefore, the question is which type of consumer research possesses required analytic and employment potential to be utilized for the acquisition of findings which can be subsequently converted into inputs for strategic decision making?

Easwaran and Singh (2006) have introduced a very valuable classification which recognizes two distinct types of research regarding their role in decision making:

- *tactical* research which is utilized to objectively evaluate decisions made in the past in relation to their contribution in achieving corporate objectives; and
- *strategic* research which is utilized in setting and assessing long term corporate objectives.

When it comes to tactical research it is useful in providing answers on some of the following questions:

²² Author suggests distinguishing the term *consumer* which designates final recipient of goods or services, from the term *customer* which designates a person who has purchased a good or service but may or may not be the final recipient of a good and service.

- How effective is our advertising?
- To what extent are we successful in satisfying our customers?

Consumer satisfaction surveys (CSS), mystery shopping, advertisement tracking surveys (ATS), and so forth are excellent examples of such types of consumer researches. Even though they provide valuable findings, their contribution in the process of strategic decision making is not significant.

On the other hand strategic research recognizes how volatile business environment is, and the fact that successful policies and strategies of yesterday may not be equally successful in the years to come. Therefore, the key property of strategic research is its orientation towards future. Strategic research provides answers on some of the following questions:

- Are we going to experience growth or decline of our market share in next 12 months?
- What limits further growth of consumption of particular products or services?
- Is the introduction of new product going to decrease the demand for other products from our portfolio?
- Which consumer segments exist, how large they are, and what is their growth forecast in two years time?

3. PURPOSE AND OBJECTIVE OF STRATEGIC RESEARCH

Even though strategic research is the most important type of research from the standpoint of CI, it is very important to recognize that strategic research is not the *only* instrument for acquisition of data for CI. Conducting strategic research alone is not enough to build quality surrounding for strategic decision making. Furthermore, strategic research can yield its true potential *only* in synergy with other instruments of CI. Secondary researches, such as macroeconomic studies, can be particularly valuable for strategic decision making.

Therefore, the *purpose* of strategic research is to provide positive contribution in the building of informational surrounding for strategic decision making. Even though generic *objectives* of strategic research are related to the acquisition of various types of data for CI, particular objectives of strategic research projects can significantly vary. (Further argument reveals more details about specific objectives.)

4. METHODOLOGIES OF STRATEGIC RESEARCH

Subsequent sections expose two research methodologies which have the required employment potential to be utilized in strategic decision making. These researches belong to the group of strategic researches because of their orientation towards the future. The objective is to provide an overview of their main methodological properties, rather than detailed methodological specifications.

Longitudinal Research

Methodology of longitudinal research can be utilized to deliver forecasts²³ of consumption on the basis of continuous, comprehensive, and systematic acquisition of data in reference with consumers' behaviour, usage of goods or services, preferences, satisfaction, loyalty, needs, lifestyle, demographics, and other subjects of observational interest. Even though this type of data is primarily available for acquisition through survey research—which mainly offers insights into consumer attitudes—it can be also obtained through other sources such as: retail audit, customer relationship management (CRM), panels, audience measurement, and so forth. These accompanying sources complement survey researches because they reduce the bias which may surface when surveying consumer attitudes. However, having in mind the inherent rigidity of their methodology, they cannot substitute customized longitudinal survey research.

What are the main properties of longitudinal researches which determine their analytic and employment potential in strategic decision making?

²³ Easwaran and Singh (2006, p. 576) indicate the distinction between the term *predicting* which denotes the announcing the likelihood of occurrence of an event derived from examination of cause and effect relationship between two variables, and the term *forecasting* which denotes measurement of the exact probability of the occurrence of an event.

Firstly, longitudinal research requires *continuous* acquisition of data in a *systematic* and *unified* manner in regular frequency, preferably in longer time periods (more than two years). Discontinuous acquisition of data, without sequence and coherence, combined with frequent changes in research methodology, or changes of research contractor will significantly degrade analytical and employment potential of the research. If nothing else it will make the aggregation of data from various sources even more difficult.

Secondly, the reach of longitudinal studies is not limited to the examination of current consumption. Its reach also covers future consumption by examining intended future consumption of *present* consumers and intended future consumption of *prospecting* consumers. This data is vital for subsequent consumption forecasting.

In terms of strategy of data analysis longitudinal researches favour *integral* over *isolated* observation. In contrast to the other types of researches which limit the reach of research subject to a *single* topic—such as consumer satisfaction or corporate image—longitudinal studies intend to explore a *multitude* of topics. Integral observation delivers superior findings because it is possible to study cause and effect relationships between various topics of observational interest (e.g., the effects of consumer satisfaction on loyalty, or the effects on communications on brand equity, etc.).

In the case of research methodology of longitudinal surveys, it is especially important to use medium size or large samples ($N \geq 1,000$ respondents)²⁴. When possible, utilization of stratified random sampling (SRS) method is highly recommended, due to its superior reliability and representativeness. Non-probability based methods, such as quota sampling, should be used *only* under circumstances when application of SRS proves to be unfeasible or impractical. Otherwise it should be avoided. As mentioned earlier, longitudinal research must be conducted in a pre set constant frequency (e.g., bimonthly, quarterly, etc.). This is very important because otherwise research will fail to maintain its integrity and ultimately be of no value for decision makers. Computer Assisted Telephone Interviewing (CATI) is the survey method of choice for longitudinal surveys, because it provides affordability and rigorous supervision and control of data acquisition. However, due to the fact that longitudinal surveys can require lengthy questionnaires Face-to-Face (F2F) survey method can be utilized when necessary.

The main objective of data analysis strategy of longitudinal research is to deliver forecasts. Therefore, the process of data analysis consists of following phases.

- Phase 1: Synthesis of data in reference with present consumption with the data about intended future consumption.
- Phase 2: Analysis of probability for various future outcomes.
- Phase 3: Development of forecasts for most probable outcomes.

Data analysis in the longitudinal studies requires the usage of various forecasting methods such as: moving averages, exponential smoothing, time series, and so forth. These methods are important for subsequent development of various marketing strategies as strategic response for each of possible outcomes.

Even though the importance of longitudinal research is immense there are some inherent deficiencies and limitations of this research methodology. Firstly, conducting any type of research on a large sample in a continuous manner demands significant amount of financial resources, thus making these types of surveys particularly expensive. Therefore, this type of researches might be out of reach for majority of companies. Secondly, forecasting method have deficiencies of its own. They require expert knowledge, advanced technology, and adequate experience in order to deliver reliable outputs. This further limits their range of application only to those companies which have required resources.

Segmentation Research

While the longitudinal research focuses its efforts to track and forecast consumption, segmentation research offers insights into the future from entirely different angle. Methodology of segmentation research can be utilized in strategic decision making to reveal consumers' segments, and subsequently provide insights on how to develop customized marketing strategies for each specific segment. Segmentation research achieves this by examination of strong habits (Ji & Wood, 2007) of target population which mold

²⁴ This and other recommended sample sizes refer to surveys conducted on a single geographical domain, which may contain 4–6 smaller geographical units, regardless the size of the target population in question.

entire consumer behaviour, drive their needs, colour their preferences, and so forth. Furthermore, these insights into specific properties of target population are prerequisite for consumer segmentation and analyses of consumers' segments from the standpoint of strategic decision making (e.g., whether particular segment will adopt changes in packing or new taste of beverage). Therefore, segmentation research wonderfully complements longitudinal research because it provides in-depth insights and compensates the informational deficit which may arise due to the focus of longitudinal research on describing consumption.

What are the main properties of segmentation research?

Firstly, segmentation research explores strong habits of target population which tend to be deeply embedded into personality of each respondent. These habits are very resilient and usually change very little or very slowly over time. Strong habits are representation of constitution of personality, beliefs, ethnic, social and cultural background of elements of target population. Therefore, segmentation research is primarily *explorative*.

Secondly, segmentation research employs a unique strategy of data analysis. The data in segmentation research is acquired with intention to reveal consumers' segments, on the basis of the acquired data about strong habits of target population. This requires the usage of advanced methods of data analysis such as cluster analysis. The ability to observe and analyze particular consumer segments from the standpoint of specific research objectives provides the necessary employment potential of segmentation research for its utilization in strategic decision making. Without segmentation research managers would not be able to develop marketing strategies customized according to the specificities of each consumer's segment.

Finally, segmentation research is by default related to the exploration of consumption of certain products or services. But, in contrast to the longitudinal research which tracks and forecasts consumption, segmentation research aims to reveal *why* consumers purchase certain goods or services, what drives their choice of brands, how consumption differs across various consumers' segments, and so forth. This makes them an indispensable instrument for decision making in product management. Decision making about products based upon findings acquired through various smaller studies, conducted quickly on small scale samples, can be dangerously misleading or impartial. Development of new products or major changes in product portfolio deserve serious research efforts and that is exactly what segmentation research provides.

The methodology of segmentation research is quite different than the methodology of longitudinal research, even though both of them belong to the group of strategic researches. Segmentation research requires extensive preparation through a series of exploratory researches which precede the main survey. Preparations commence by conducting prevalence research, which is utilized to determine whether elements of target population are particularly hard to reach or reluctant to participate in the survey. It is also necessary to obtain description of target population which is further utilized for sampling.

If the main survey proves to be feasible, it is necessary to conduct qualitative research through focus groups, in-depth interviews, or other methods of qualitative research in order to aid the development of methodology of main survey. Insights acquired through qualitative research are mainly utilized for questionnaire development and formulation of initial research hypothesis. After completion of research methodology, pilot survey needs to be conducted in order to confirm soundness of finalized research methodology.

In terms of research frequency it is recommended to conduct segmentation research once in two to three years in the times of relative macroeconomic stability. There is no need to conduct them more often due to the fact that changes of strong habits of target population require more time to develop.

Regardless of the sampling method recommended sample size is $N \geq 2,000$ respondents. Such large samples are necessary for subsequent analyses of consumers' segments. Unfortunately, due to the complexity of target population, it is not always possible to obtain sampling frame for sample development. Therefore, research contractors are usually forced to conduct these researches by utilizing some of the non-probability based sampling methods, such as quota sampling. Due to the inherent deficiencies of non-probability based sampling methods, rigorous quality control needs to be enforced throughout the phase of data acquisition. Otherwise, the representativeness of the sample may be compromised. The

segmentation research is usually conducted through Face-to-Face (F2F) survey method, due to the fact that questionnaires for segmentation research can be particularly lengthy. Usage of F2F is a reason more to enforce rigorous quality control and strive for flawless execution of data acquisition.

Defining target population is of crucial importance for the success of segmentation research. In general target population can be either *present* or *prospective* consumers. Exploration of prospective consumers (e.g., customers interested in taking car loan in next 12 months) can be particularly useful because it provides insights how prospective consumers make their first choices, which drivers influence their choice of brands, and so forth. These findings can be utilized to create strategic advantage over competitors. Another direction for defining target population is related to the usage of products or services. Target population can be consumers of some *general* type (i.e., category) of products or services (e.g., non-alcoholic beverages, or banking services) or *particular* type of products or services (e.g., carbonated non-alcoholic beverages, or holders of savings account). Either way, definition of the target population must integrate the requirement for information research ordered intends to acquire. In order to avoid unsatisfactory research outcome, definition of target population must be perfected until the mentioned criterion is met.

The reach of research subject in segmentation research is determined by the need to retrieve data which can be utilized for subsequent consumer segmentation. Therefore, the subject of segmentation research covers a multitude of topics including consumption but with emphasis on consumers' strong habits, needs, preferences, perception, and so forth. If needed, more attention can be paid to the communication topics such as brand or corporate image. These findings can be utilized to develop customized strategies of communications.

The data analysis in segmentation research is a complex and nonlinear process consisting of various phases and individual steps, some of which need to be repeated multiple times. The objective of data analysis in segmentation research is to develop consumer segments and reveal how strong habits influence consumption. Therefore, it is necessary to apply advanced methods of statistical analyses such as cluster analysis and various accompanying methods (e.g., factor analysis, discriminate analysis, analysis of variance [ANOVA], regression analysis, conjoint, correspondence analysis, etc.). In general the entire process of data analysis starts with development of segments and continues with analysis of segments, from the stand point of various topics which research subject covers.

Segmentation research is to an extent limited by inherent deficiency of cluster analysis. So far there has not been developed a completely objective procedure for statistical significance testing of cluster analysis (Aaker et al., 2004), so it is hard to assess the quality of developed consumers' segments. Also, the usage of quota sampling can turn to be a problem if instruments of quality control are not enforced, or if the response rate turns to be significantly lower than predicted by prevalence research (Biemer & Lyberg, 2003).

5. RECOMMENDATIONS

Recommendations for practical application of longitudinal and segmentation research are very specific depending on particular industry, company, requirement for information, and other circumstances. However, some general recommendations can be made.

Firstly, it is recommended to develop corporate resources for conducting strategic researches *prior* to the engagement in such types of research projects. Without adequate operational and human resources, especially among middle management who is in charge of carrying out these research projects, it is much better to postpone them until adequate resources are developed. Relaying *only* on the expertise of research contractor may be counterproductive and effectively undermine subsequent strategic decision making. Also, it is very important to ensure benevolence and involvement of senior management. Ultimately senior managers are the ones who will be making strategic decisions, and they need to believe in the power of strategic researches.

Secondly, it is recommended to optimize annual research program around strategic researches. This usually requires sacrificing smaller research projects in order to have enough financial resources to carry out strategic researches. If planned out properly, it is possible to organize strategic researches in such

manner that they fulfil the majority of requirements for information and effectively substitute majority of smaller research projects. Also, from the standpoint of research management it is certainly easier to manage two or three large projects annually than a significant number of small studies. Furthermore, conducting a large number of unplanned small studies can actually create confusion, if findings acquired through these studies are conflicting and overlapping. Therefore, in terms of overall involvement of financial, operational, and human resources, properly planned strategic researches are actually more efficient than smaller studies.

Finally, whenever possible it is recommended to choose the methodology of strategic research which is developed specifically for the application in a particular industry, rather than a generic methodology developed for application in various industries. Generic methodologies may neglect some important aspects of a particular industry and therefore may not deliver required information.

In practice here are some guidelines for development of methodology of strategic researches.

Longitudinal researches should be conducted in steady frequency once every three to four months on medium sized samples ($N = 1,000 - 1,500$ respondents). These researches should cover a multitude of topics such as: present and future consumption, needs, preferences, satisfaction, loyalty, image, and demographics. They can be complemented with some topics of special interest from time to time, depending on the particular requirements for information. By conducting them in such manner they will effectively assume the role of CSS, provide information about competitors' consumers, and fulfil their main objective to forecast consumption.

Segmentation research should be conducted once in every two to three years on large samples sized ($N \geq 2,000$ respondents) especially when there is a need to setup or revise market offer or strategy of communications, or gain in-depth insights into consumers' segments. If found necessary segmentation research can be conducted more often through a sequence of research projects. The sequence starts with a research project which objective is to gain in-depth insights into all consumers' segments, and continues with a research project which is focused to further explore one consumer segment of particular interest. This is particularly useful when there is a need to gain more insights into consumers of particular brand of goods or services. Insights into the profile of consumers' segments, their size, and growth potential will steer further development of customized marketing strategies according to the specific needs of particular segments.

6. CONCLUSIONS

Previous argument displayed two methodologies of consumer research which possess required analytic and employment potential for application in strategic decision making. Longitudinal research and segmentation research provide different but complementary insights into the future. While longitudinal research forecasts consumption, segmentation research reveals strong habits of consumers' segments and allows development of marketing strategies customized to the specific properties of consumers' segments. Optimized annual research program allows efficient deployment of operational, human, and financial resources even with such expensive research projects.

Further efforts in terms of scientific research of methodologies of strategic research should be invested into improvement of their reliability and overall survey quality. Also, the applicability of strategic researches deserves particular attention of scientific community. It is especially important to explore how inherent deficiencies and limitations of these research methodologies influence strategic decision making, what are practical challenges managers face when using these research methodologies, and so forth. All of these efforts can increase analytic and employment potential of strategic researches.

Nevertheless, strategic researches will remain a valuable instrument of strategic decision making. Its findings and insights highly enhance effectiveness of strategic decision making and bring certainty to a rather complex and demanding process.

GROUP BUYING IN SERBIA: NECESSITY OR JUST MARKETING?

Abstract: *The concept of group buying services in Serbia is spreading very fast. With a simple business model, many new entrepreneurs are turning to this type of business, expecting low costs and quick profit. There are three types of participants in this business process: customers, web sites offering group discounts and clients who are giving discounts on their own products or services. The main idea of this study is to show that clients do not need to give their products and services at a lower price for the purpose of advertising, but they need to give the discounts because it became a necessity today, as the Serbian market is saturated with sites for group purchases.*

Keywords: *group buying, discounts, consumers, clients, services, survey*

1. CONSUMERS VS. CUSTOMERS

A consumer is a person or group of people that are the final users of products and or services generated within a social system. A consumer may be a person or group, such as a household.

The consumer is the one who consumes the goods and services produced. As such, consumers play a vital role in the economic system of a nation because in the absence of the effective demand that emanates from them, the economy literally collapses.

A consumer and customer are commonly used in the same context at times in business literature. However, they are not the same. Consumers are just one sub group of customers. What does this mean? It means that if you buy a product for any commercial purposes, you are not a consumer. If you buy a product purely for your own consumption, you are a consumer.

2. INTERNET SHOPPING

Online shopping is a form of electronic commerce whereby consumers directly buy goods or services from a seller over the Internet without an intermediary service. An online shop, eshop, e-store, Internet shop, webshop, webstore, online store, or virtual store evokes the physical analogy of buying products or services at a bricks-and-mortar retailer or shopping centre.

Internet shopping represents the launch of a new industry with corresponding levels of praise and concern. It is both the golden child for innovative net users, and the evil empire for anxious brick-and-mortar retailers. That on-line purchasing is growing at a dramatic rate, but, yet the expected explosion of Internet shopping has not occurred; its market share is small, at under 2 % of total retail spending (Retail Forward, 2003a). Most consumers have been slow to adopt on-line shopping.

3. GROUP BUYING

Group buying, also known as collective buying offers products and services at significantly reduced prices on the condition that a minimum number of buyers would make the purchase. Origins of group buying can be traced to China where *tuangou* or team buying was executed to get discount prices from retailer when a large group of people were willing to buy the same item. In recent time, group buying websites have emerged as a major player in online shopping business. Typically, these websites feature a "deal of the day", with the deal kicking in once a set number of people agree to buy the product or service. Buyers then print off a voucher to claim their discount at the retailer. Group buying strategy is quickly gaining traction as a truly effective marketing medium.

Group buying websites leverage the power of collective bargaining to provide attractive local deals that offer significant savings for consumers while also promising lucrative sales numbers to participating merchants.

A business promotes their product or service on the group buying website, typically marking down the cost of the item by 50 %, sometimes more and sometimes less. For consumers to take advantage of this deal, a minimum number of buyers must also buy in. The business advertising their product pays nothing upfront and if the deal does not attract the minimum requirement of sign ups, then the business pays nothing at all. Once the deal is valid and the product or service is paid, the group buying site keeps a percentage of the sales as their commission, cuts a check to the business that advertised their product and sends a voucher to the consumer.

We defined three key groups in this business model: consumers, group buying services and companies that provide discounts on their products or services. (in further text: clients, because they are actually clients of the group buying services).

4. SITUATION IN SERBIA

Population in Serbia in 2011. is 7.310.555 people, country area is 77.474 square kilometres. Capital city is Belgrade with population of 1.764.650 people in 2007. There are 4.107.000 Internet users in June, 2010., and 3.173.440 Facebook users in December, 2011.

The concept of collective buying in Serbia is becoming very popular in recent years, and has a tendency to increase. On the Serbian market, there are currently 44 companies operating as a service for group buying. 75 % of these companies are operating as Limited liability companies. During the time period between 2009. and 2011., there were 35 group buying companies opened, and 9 companies were registered before 2009., but did not deal with this type of business. 59 % of these companies were opened in 2011. The question is how many of them will survive. Some of the companies are already in liquidation process, and some companies, with their unattractive and outdated offers, clearly show small chance of survival.

Services that offer discounts cover all areas of your life. Hairdressers, salons, gyms, cafes, restaurants, travel, doctors, dentists... And the fun is the fact that you suddenly need all of that, and everything is waiting just for you. These services force you to buy goods and services you would not need otherwise. But they are here to create the need, perhaps even to cause addiction. They offer luxury at a reduced price. We are familiar with the fact that customers do not buy products/services, but they buy the value. Therefore, service providers offer additional value for customers, such as „head massage" which is free when you buy voucher for hair washing. Everyone tries to make an attractive title for its offer.

Putting ourselves in the role of a group purchasing service, we recognized two main target groups:

1. Clients, who are actually service companies (rarely manufacturing companies) who offer services at a discounted rate.

These are the companies where business is not going so well and the companies that look on these services as an exceptional opportunity for good marketing move. Market conditions are creating the necessity to provide the goods and services with discounts, because that is the way to stay concurrent. If our competition offers discounts, we must also offer discounts.

2. Consumers who buy vouchers

Our market is very big. It includes part of the Serbian population that uses the Internet. The focus is placed on the larger cities, such as Belgrade, Novi Sad, Kragujevac, Niš,... Main characteristic of our target group is that they are people with less purchasing power, who want to afford a bit of everyday luxury. And there will be more and more such people.

In order to obtain a real market situation in Serbia, we researched all of three aspects of this business model: consumers, group buying services and clients of the group buying services.

5. CONSUMERS' POINT OF VIEW

In order to obtain information about group buying websites' customers, we conducted a survey. Our survey was completed by 250 persons, 130 of them are male, and 120 are female. 9 persons are ages

between 16 and 20, 234 persons are ages between 21 and 30, 6 of them are between 31 and 40, and one person is older than 40. Their payment ability is shown on the chart below:

Table 1: *Payment ability of survey participants*

97,38 % of our survey participant are using Internet every day. 47,55 % have never bought something over the Internet. Only 73 people have used group buying services. 36 people found out about these services via social networks, while 31 found out through recommendations. 59 of them are sharing interesting offers with their friends. We asked our survey participants which service do they use the most. There was possibility to choose multiple answers. The results are showing:

Chart 2: *Choice of group buying services*

85 % are paying offers via invoice, which will later be proven by managers of these sites. The value of bought voucher is usually not bigger than 1.000 RSD (54 say so). The most sold services are beauty and health vouchers, also as concert and theatre tickets. 60 % participants who used these services were completely satisfied by service, 37 % were sometimes satisfied and 3 % were not satisfied at all. 90 % will repeat the shopping again.

We also asked people who do not use these services why are they not using them. There was possibility to choose multiple answers.

Table 3: *Why people do not shop online?*

6. GROUP BUYING SERVICES' POINT OF VIEW

We interviewed few managers of this type of companies, and some of their answers were very similar, while the others were very different.

The first thing to know was their opinion about current market situation of group buying services in Serbia. The fact is the market is saturated and overcrowded with sites and offers. There are many players, which makes the market chaotic and establishes the basis for destroying the loyalty. It is very hard to differentiate among the concurents and create a new value for customers. People generally think that this business model is easy to copy and follow, keeping the costs low and gaining profit easy. They are not aware it is easy to build a model, but it is hard to stay on the market. As we already said, it is extremely hard to differentiate among concurents, to inovate your strategy and think up of something new. Since the number of these services is rapidly growing, it will lead us to burst of the bubble dot com system.

Bubble dot com is a company that embraces the internet as the key component in its business. Dotcoms are so named because of the URL customers visit to do business with the company, e.g. www.Amazon.com. The "com" stands for "commercial."

The biggest and the most persistent will survive.

We looked a little bit closer to operations of these companies (group buying sites). Bestsellers services are in domain of health and beauty. They are followed by concert and theatre tickets. Analysing active and previous offers of one group buying site, purchasing preferences for 2011. are:

- 5.507 vouchers for dentists services were sold,
- 10.000.000 RSD was spent on weight loss treatments,
- 8.147 vouchers for massages were sold,
- 14.780 vouchers for hair treatments were sold

Some services are very committed to seeking clients, so they could prepare a single and unique offer, while on the other side, there are services where clients rather come by themselves. Of course, in some companies, this relation is balanced. Most of the clients are coming back to make a new arrangement, because they are satisfied with the previous results.

Managers of the group buying services think some branches are sentenced to fail if they do not provide discounts, like beauty and hairdressers industry. They are forced to give discounts on their services, because the competition is providing the same service at a lower price. But, it depends from industry to industry.

Some of the clients are convinced that their offer on a site is a perfect type of commercial. But, the biggest benefit of their offers is surely amount of sold vouchers. Group buying services pay their clients in different

periods of time. Some are paid in three to five days, some are paid fifteen days after the offer is ended. Services take a fee, which is between 20% and 50% of sales vouchers. We were also interested to find out which is the most common form of customers' payment. Most of the managers said it is invoice, about 70 % users are paying via this way. We wondered what happens when great amount of vouchers is sold and people do not have enough time to use it. Usually, services in agreement with clients, extend the time limit of possibility using vouchers.

7. CLIENTS' POINT OF VIEW

Since we wanted to get the other side of the story, we contacted the salons that are offering their services via these sites. Namely, on the basis of their answers, we came to certain conclusions.

The questions they asked were the following:

- What led you to offer your services through the websites for group discounts, whether it is marketing or necessity?
- Have you repeatedly been bidding?
- Did you use more than one site?
- What percentage of your salary was their?
- Do you think that you can remain competitive in the market with your real prices, while those sites exist?
- Do you have a website?
- Do you advertise in any other way?
- What do you expect in the future related to these sites?

Although we tested different types of salons, from hairdressers to beauty salons, which offered different types of services, their responses were very similar. The conclusion to which we came is the following:

With the advent of the sites for group discounts in Serbia, there was a loss of work for salons that offered their services in the traditional way. Therefore, in order to stay competitive, they were joined by other, smaller salons, and hence the spread of clients, which necessarily leads to the space for new group discount sites. Over time it became a necessity, and the marketing completely lost the sense here, but it is a necessity to remain present in the market. They consider that this way of doing business is to serve the people for small price to see how the professionals do, but very few of these people return, because these clients will always go to a new place. Only 1% of satisfied customers return to the same salon and pay full price for the service.

Salons often collaborate with multiple sites, but works with better, more popular site, and other associates are usually small or new sites which offer better business conditions. Our respondents made offer via these websites average five to six times. With the advent of this type of business, the percentage taken by the sites for group discounts was 50, but as the competition among them is increasing, now it is an average of 30%. Sites like Kolektiva.rs or Popusti.rs are currently the most popular and have a maximum of conditions for cooperation, they require 40% of its clients. But, new and lesser-known sites, sometimes ask not for even 10%.

Some of these salons have their own sites, some of them plan to have them in the near future, but the current form of marketing they are using is the Internet, precisely cooperation with specific portals that specialize in this type of service.

What do they expect in the future, is that the market will saturate of these sites and the traditional way of doing business will be restored. They also hope that the way these sites are operating is going to change, because the current situation does not make enough profit neither one or the other.

8. CONCLUSION

Summing up the impressions of consumers, sites and clients, we came to the conclusion that the offers on group purchasing sites are not really for marketing purposes, but they are necessary part of survival strategy. In the beginning, it was really all about marketing, but the market became saturated and many new group purchasing sites were born. In the context of service industries, those companies must give discounts to keep pace with the competition. Otherwise, they are threatened of disappearance from the

market. These companies hope that this system will not last for long, that „the bubble is going to burst", and that one day, they will make greater profit with decreased volume of services.

Abstract: *The subject of this paper is the application of marketing in the prevention of obesity. Health Marketing aims to influence the public by a range of actions with the aim of achieving changes in behaviour, attitudes or habits of each individual for the benefit of the overall community.*

Marketing is a necessary and useful tool that can be applied to improve the function of communication aimed to prevent obesity. Based on previous studies of the obesity problem in Serbia, it can be concluded that there is a considerable scope for the application of marketing approaches to improve population health by reducing obesity and excessive body mass. Although marketing strategy in profit-oriented organizations - whose ultimate goal is their own profit - is used in the prevention of obesity and excessive body mass, it would be wrong to measure the effects only through direct financial impact. Health as a capital asset has no cost, and profit in health, quality of life, reducing the years of lost life, as well as the prevention of negative consequences of obesity as an epidemic in the population, is above any direct financial gain. Much more developed economies than ours have recognized the importance of this problem and developed a national strategies to define actions and multi-activities that are aimed at reducing the incidence of obesity, and are primarily aimed at children as a target group.

Keywords: *obesity, marketing, prevention, children, population*

1. INTRODUCTION

Research on the application of marketing in the prevention of obesity analyzes the possibilities of using scientific achievements through which both the individuals and population in general can be influenced in order to promote and maintain health (Berkowitz E.N., 2006).

The main purpose of applying marketing in the prevention of obesity is to satisfy the needs of users more efficiently; to raise the level of health care and life quality; to connect the participants of health care system both vertically and horizontally in order to provide preventive measures of protection; to determine the priorities within the prevention activities; to rationalize business activities and use available resources in prevention more economically and to include all factors outside the health sector that can give their contribution to health (Kotler F., 2007, Filipović V., 2009).

The way to introduce marketing concept in the health sector should be gradual, in the following order: identification of needs for adopting marketing concept and orientation towards the user; determination of strategic directions of marketing activities; definition of the marketing vision, mission and objectives; determination of strengths, weaknesses, opportunities and threats (SWOT), concretization of strategic objectives; development of marketing strategies; determination of marketing mix instruments; control and analysis of the effects achieved.

Marketing in health services, being a segment of social marketing, is directed towards the collective benefit. Its objective is to exert influence over the public by a series of actions in order to make some changes in behaviour, attitudes and habits of each individual to the benefit of collective. However, marketing actions directed towards the collective benefit cannot be implemented if the decision-makers are not willing to solve the problem recognized by the professional circles (Marks L, Cave S, Hunter DJ, 2010).

It has been known for decades that mass non-infectious diseases are the leading cause of morbidity and mortality in non-developed and developing countries. And while one part of our planet is struggling with malnutrition as a widely spread problem, the other part of the planet and general population come face to face with obesity and overweight and their consequences (Atlas of Health in Europe 2008).

The phenomena underlying these negative developments and problems are unhealthy life-style, obesity and physical inactivity, to which their contribution is given by industry and fast-food market, way of living and cheap high calorie foods as well as lack of facilities and motivation to go in for any sports or physical

activity. Insufficient strength and cohesion of the society to tackle these problems and to try to stop these negative trends by appropriate decisions and in a systematic way lead to even more negative trends in the population health condition (Fleming F, Zgodzinski E, 2005).

Global increase in overweight and obesity depends on numerous factors, including:

- Global change in diet in favour of increased intake of energy rich foods with high content of fats and sugars and low content of vitamins, minerals and other micro-nutrients
- Trends regarding diminished physical activity resulting, first of all, from other forms of transport and increased urbanization

Overweight and obesity and diet-induced diseases represent big problems of public health for the World Health Organization (WHO) in Europe and forthcoming growing epidemics and leading causes of mortality and morbidity in Europe. Overweight or obesity is recorded in more than 50% of adult population in Europe. Overweight is found in 30-80% of adults and 20% of children in the countries of European region of the WHO, whereas one third of children are obese. The annual rate of increase in children obesity prevalence is constantly on the rise, and today it is 10 times higher than in 1970s (Closing the Health Gap in EU 2007).

An increased body mass index (BMI) is the main risk factor in development of the following diseases:

- Diabetes – became a global epidemics very fast. The WHO predicts that the rate of death caused by diabetes will rise by more than 50% worldwide in the next 10 years
- Arterial hypertension
- Cardiovascular diseases (predominantly cardiac diseases and insults) – already takes the first place as the cause of death of 17 million people every year in the world
- Some forms of cancer (endometrial, lung and colon cancer)
- Bone and muscle disorders – particularly osteoarthritis.

Obesity is associated with very high expenses in public health care and losses in productivity. Obesity prevention programs can reduce expenses in public health care for a short time; however, their effects on long-term expenses are still insufficiently determined. According to some studies, obesity directly increases total expenses in public health care services for more than 7% (The European Health Report 2009).

Implementation of current recommendations requires the permanent cooperation of a great number of participants, both public and private ones. Governments, international partners, associations and non-government organizations and private sector have a vital role in the formation of healthy environment and creation of healthier eating habits which are acceptable and easily available (Health in All Policies, 2006).

Special attention should be paid to the most vulnerable categories in the society – the poor and children – who have limited choices regarding food and surrounding in which they live (WHO European Action Plan for Food and Nutrition Policy 2007-2012, 2008).

The starting point of marketing concept in problem solving is the necessity and wish of potential patients, including the knowledge at various levels, from obesity as a disease to social and economic politics which result in different models of exposing the individuals and population to risk factors. The emphasis in this approach is put on the importance of economic, behavioural and social factors whether they are manifested at the level of an individual or a greater part of population (Witkowski TH 2007).

Body mass above normal affects metabolism, blood pressure and increases cholesterol, triglycerides and insulin resistance. In addition, many other discomforts and symptoms are associated with obesity: difficulties in breathing, skin problems, infertility, etc. Cardiovascular diseases, endocrine disorders, some cancers (breast, colon, prostate, endometrial, renal cancer, etc) and insulin dependent diabetes represent serious health consequences which are greatly enhanced by obesity.

One of possible ways to achieve satisfactory effects and results is to:

- Create conditions which will provide proper choice of fiber rich foods with low content of fats
- Provide appropriate sports facilities to individuals and all different population categories
- Promote healthy life-styles; higher consumption of vegetable and fruit and wholemeal grains; physical activity for at least 30 minutes a day; limited intake of saturated fats and increased intake of unsaturated fats

- Engage all levels of authorities and make decisions on investments into infrastructure, economy, environment which means systemic and planned allocation of appropriate amount of money
- Follow the effects achieved by decisions made at the level of cooperation between food manufactures and consumers
- Engage clinical medicine in giving efficient support in reducing body mass, where necessary; it should be noted that health care services deal with the consequences of inadequate decision-making process and implementation of decision in non-health sector, which give their contribution to health

Bearing in mind all facts influencing the development of problem of overweight and obesity, it is obvious that obesity is not only a health problem of the individuals; it is the problem of wider social surrounding and a diverse range of participants. Such an approach to the problem compels us to think of the importance and role of social marketing (Filipović V, Stanković Kostić, 2008)

2. COMPOSITION

The attempt at getting insight into the knowledge and skills of social marketing in the function of solving the problem of obesity is the topic and challenge of this paper. Marketing in health services can be observed as corporation marketing, wide-sector marketing, brand marketing and social marketing.

The paper is aimed at pointing to the importance of strengthening the capacities of marketing resources while attempting to achieve the positive outcome of the actions undertaken in the prevention of obesity and overweight.

According to the results of measuring BMI within a study performed in the population of Serbia in 2006, there were 38.3% of those normally nourished, every other person was overweight (54.5%), 18.3% of the participants were obese and 36.2% were pre-obese.

One of the strategic objectives of the national healthcare policy is to promote health of the population of Serbia by reducing the incidence of obesity and pre-obesity. The application of marketing in the field of preventive medicine and public healthcare is being done without a systematic approach, clearly defined plan and sufficient knowledge of scientific principles in the implementation of marketing skills.

Marketing approach to this issue starts from the needs and wishes of potential patients, including the knowledge at various levels, from obesity as a disease to the social and economic policy which result in different models of exposure of the individuals and general population to risk factors. The main point in such focusing is the important role of economic, behavioural and social factors which can be manifested either at the level of a person or a greater part of population.

Children obesity has become the biggest healthcare challenge because it affects every third child under the age of 12 years. Marketing of fast food rich in saturated fats and salt is one of the main causes of children obesity. Although the experts agree that children obesity results from several factors, such as insufficient physical exercises, big portions, poor choice, sedentary way of life, genetic predisposition, food marketing is still widely discussed with food manufacturers (Child Obesity Policy Brief, 2010).

If good results are to be expected in the prevention of obesity, multi-sector approach and wide social actions are required, starting from the fact that public health institutes carry the activities as one of the most important links in the chain of all necessary steps to be taken in order to achieve the effects in the prevention of obesity and increased body mass.

The paper also deals with the importance of mass media participation and the possibility of their contribution, which may be even negative in case of inadequate transfer of information. In accordance with the fact that mass media are an important source and a partner in public health, their exposure was analyzed in order to survey the presence of this topic in media and to assess the number of readers who receive the information on the key words: nutrition, obesity, diet, physical activity (Table 1).

Table 1. Number of contributions with the key words (nutrition, obesity, diet, physical activity) compared with the contributions on other subjects in print media

Fields	Number of contributions
Political parties	28402
Banks, leasing	26698
Car industry	10588
Oil companies	8356
Health	8200
Insurance companies	7623
Culture	7264
Sports	6666
Telecommunication	6403
Meat industry	2121
Healthy nutrition, diet, obesity, physical activity	660

Table 2. Participation of media exposure of key words in print media

Key word	Number of contributions
Nutrition (incorrect)	498
Obesity	211
Diet	133
Physical (in)activity	207

The analysis of the participation of media exposure of key words in print media suggests that the key words connected with obesity are minimally present in research results, the most exposed word is nutrition and the least exposed is diet, which practically means eating habits. The accuracy of use of these terms was not analyzed (Table1, Table 2).

The annual analysis is available first of all for print media and it has been performed within the case study research of public health institutes. The greatest number of contributions published by print media in 2010 dealt with political parties and corresponding topics – over 28000. The second place was taken by topics about banking and leasing discussed in 26698 contributions, and 10588 contributions discussed about car industry.

The number of contributions dealing with the key words healthy nutrition, diet, obesity and physical activity was 660, the highest number of which (572) was published in periodicals (the so called lifestyle magazines and magazines for women).

The following has been found by analyzing the source of contributions:

- The greatest number of contributions discussing the topic (un)healthy food was published in Vita, Lepota i Zdravlje (Beauty and Health) and Lisa
- Obesity was written about in the greatest number of contributions published in Lepota i zdravlje (Beauty and Health), Blic and Vita.
- (In)activity was discussed in the greatest number of contributions published in Vita, Lepota i zdravlje (Beauty and Health) and Blic Woman.
- Of 88 contribution published in daily newspapers, 23 were published in Blic, 18 in Politika and 11 in Press.
- Of 572 contributions published in periodicals, 102 were published in Vita, 54 in Lepota i zdravlje (Beauty and Health), and 53 in Blic Woman.

The number of contributions discussing the above topics was as follows: (in) correct nutrition – 498, Obesity – 211, Physical (in) activity – 207, Diet – 133.

The source of information according to which the journalists wrote the articles was not given in the greatest number of contribution (314), medical staff working in Serbia was the source of information in 102

contributions, whereas only 33 contributions mentioned medical magazines, i.e. institutions outside Serbia as their source of information.

The estimated number of readers of all the articles was 14,826,000. According to the results, it is clear that there is a gap between needs/demands and inadequate response of the media to the existing problem and the absence of education of journalist in this field.

This analysis points to the fact that the journalists, having the valuable sources at their disposal, represent an important partner; however, additional education and motivation is necessary, together with more intense cooperation between health professionals and journalists not only in print media but also in all kinds of available media. Although the information transfer and education are not within the primary assignment of journalists, it is possible to make a move and ensure adequate space in media and motivate the journalists to be more cooperative in pursuit of the common goal in the prevention of obesity and overweight.

The very fact that more than 50% of the population are pre-obese and obese corroborates the statement confirming the existence of demand, i.e. need for finding the solution to this problem. Top-down approaches can be used when strategic solutions and actions are expected at the national level, financed from the secured sources. Bottom-up approaches are used when assessing the frequency of obese people and assuming that there will be enough people interested to visit nutrition consultancy services. It should be noted that this part of demand for services has been covered by activities of prevention centres in public health institutes.

Resources in solving the problem of obesity are analyzed by SWOT analysis

Strengths: Network of public health institutes and departments Strategic documents Ministries of Health of the Republic of Serbia Primary health care Interests shown by non-government organizations	Weaknesses: Insufficient engagement of non-health sector Insufficiently developed conditions for physical activity Inadequate implementation of strategic documents Difficulties in changing habits and behavioural patterns
Opportunities: International funds Support in research work Mobilization of non-health sector Greater cohesion and cooperation within various levels of healthcare services Strengthening the role of network of institutes and departments of public health in cooperation with local government	Threats: Strong trade lobby in the field of food consumption Marketing of food, particularly for children Epidemic proportions of the phenomenon of obesity, starting at younger age Financial expenses resulting from not solving the problem of obesity

The gap between the number of users of nutrition consultancy services and potential users is enormous. Marketing and media plan would help to reduce this gap and make space for better work and higher number of patients. In addition to nutrition consultancy services, other activities are necessary to contribute to positive outcome in solving this problem. It is now clear that there is a gap between the need and demand, which is also evident in the population being educated and informed about their responsibility regarding their health.

As for the assignments and activities which are and should be coordinated by the Ministry of Health and National Institute of Public Health, there certainly is a gap, which could be reduced by additional engagement of experts and adequate systemic solutions (activities directed towards reduction of obesity to be planned for longer period and coordinated by the network of institutes and departments).

Users of services rendered by institutes and departments for public health are heterogeneous, which correlates with the diversity of services offered and which are not directed only towards a person but toward the general population, certain target groups or certain institutions. The users of services can be grouped as the patients from the primary health care, patients from the secondary and tertiary health care, local government, economy – e.g. private food producers, importers, non-government sector (partnership

in projects), educators and sector of education, children and student population, persons who interested in services but do not have doctor's recommendation for these services so they have to pay for them, etc.

When it comes to the identification of users regarding the problem of obesity, the situation is similar, i.e. the communication with these groups of users can be direct and indirect through various activities. Possible multi-sector activities in the prevention of obesity by applying marketing approach are as follows:

- Prevention of children obesity in cooperation with the educational sector
- Implementation of school programmes in order to increase physical activity among young people
- Promotion of physical activity to achieve longer life
- Implementation of comprehensive interventions in the local community to increase physical activity (incorporation of cycling into the plan and creation of transport means)
- Education on nutrition and strategies at schools, with local government
- Education of consumers on healthy food choice with target groups
- Programmes of screening and education, monitoring of obesity
- Promotion of foods with positive recommendations and their consumption
- Promotion of healthy nutrition in primary schools (Kotler P 2010, Francesko B, Nikogosian H, Lobstein T, 2007)

On the basis of research, the following strategies for promotion of communication in the prevention of obesity are recommended:

- The strategy of direct marketing in nutrition consultancy services

Direct marketing and promotion can be organized in nutrition consultancy services in cooperation with media, schools, local community, family and all levels of authorities. On the basis of the defined target groups, determined objectives and marketing of the communication plan it is necessary to offer understandable and clear messages in accordance with the target group they are attended to, use direct canals of communication and, along with emphasizing the benefits for the individuals, and adequate evaluation, aspire to a wide inclusion of the selected target group (use mailing lists, telephone conversations, direct communication, interviews and other methods).

- The strategy of promotion of cooperation with media

Relations and cooperation with media is nowadays considered an indispensable link in the marketing strategy. Public health sector may use free forms of forwarding messages on the importance of maintaining desirable body mass, which can be communicated to the public through various media. Experts may convey the information to the widest circle of potentially interested people in an adequate way; therefore, mass media are the most important link in the communication between the institution and the public. They are used to influence both the public and individuals: future users of the services, competition, local and broader community as well as the whole country. The possibility to broadcast educational programmes intended for children, parents, general population is of great importance in boosting awareness, level of informing the public and knowledge, and thus, the motivation to change bad behavioural patterns and accept good eating habits and take up sports activities. Choosing the advantage of advertising desirable foods and limiting advertising of bad food are connected with financing the commercials, which cannot be influenced easily. These are the reasons why it is necessary to provide necessary time in informing the population about correct nutrition and good choice of foods as well as about physical activity. Various media have various capacities and possibilities for conveying the information and this should not be forgotten.

- The strategy of electronic communication (internet and social networks)

Today it is impossible to imagine the communication among young people without using social networks. Therefore, if we want to address children and adolescents, messages and communication must be developed through internet pages, blogs, micro blogs, internet forums and similar ways. Social networks and digital communication are the only ways to cover this very important target group, in spite of all potential risks involved with this forms of communication from the social aspect.

- The strategy of economic publicity (donations to some publications, organizing meetings, etc)

The marketing strategy of economic publicity is indispensable because the activities in the public health sector are usually not profitable and sustainable without sponsorship and support of non-health sector, media, individuals, and other organizations. A good example is finding the sponsors for campaigns promoting correct nutrition who make such activities possible by their products, but on the other hand,

they use the space for their marketing. Various sponsors promote physical activities, for example, and give support to the local community, which has created conditions for the citizens to be physically active by appropriate investments into the infrastructure.

- The strategy of market relations with the public

By recognizing the necessity for services rendered by consultancy for obesity prevention, i.e. for correct nutrition, some organizations opt for developing marketing plan in rendering health services which are in accordance with the existing conditions of financing either by the users of services (individuals or organization) or by donors and sponsors.

- The strategy of cooperation with economy and food producers

Under the present conditions it is possible to develop the marketing strategy bearing in mind the possibility of cooperation with the Chamber of Commerce and appropriate groups that assemble food producers, and thus influence and contribute to creation of adequate labels for food, and recommend production of foods which are not only desirable for the market but are justified from the health aspect. It is necessary to provide the possibility of recognizing and stimulating those producers who do not count on profit only but have the consumers' health in mind as one of the priorities besides their production.

- The strategy of cooperation with the sector of education

The marketing plan of promoting communication in the sector of education is probably of utmost importance because it has the direct influence on the most important target group – children. The communication plan includes conveying messages and collecting feedback information as well as the top-down and bottom-up approach and cooperation with children, parents, teaching staff, and those who prepare food. It is also important to make decision on prohibiting fast food shops nearby schools and to provide adequate budget and conditions for preparing high-quality, desirable and safe meals at schools. In addition, adequate conditions and facilities must be provided for physical activity.

- The strategy of cooperation with the local community

The marketing strategy of promotion of communication in the local community can be developed during the preparation of the local strategy for public health, where it is one of the possible components depending on the priorities which are determined at the level of the local government in relation to nutrition, obesity, physical activity and all the conditions in the surrounding which may contribute to reducing negative consequences of environmental factors in the community.

3. CONCLUSION

Marketing is an indispensable and useful instrument that can be used in the function of promoting communication in obesity prevention. According to the previous studies on the problem of obesity in Serbia it can be concluded that there is considerable space for the application of marketing approaches in the promotion of the population health through reduction of obesity and overweight.

The public health sector should use marketing tools in conquering the market space and achieving its objectives. Constant development of marketing strategies will contribute to better positioning of public health sector and provide better insight into the needs of users.

It is necessary to use marketing strategies and then follow their implementation at all levels, including both national and provincial government, local community and the institution itself, because this is the only way which ensures long-term positive effects in solving the problem of obesity.

Within marketing which is applied in the prevention of obesity and overweight it would be wrong to measure the effects only through the direct financial effect. Health, as the most precious asset of the society, is priceless and benefit in health, life quality, fewer years of lost life, hindered by negative consequences of obesity which seems to be an epidemics in the population, are above the direct financial profit. Economies much more developed than ours have recognized the importance of this problem and developed national strategies, defined multi-sector actions and long-term activities aimed at the reduction in obesity incidence, directed first of all at children as a target group.

RESEARCHING THE ROLE OF SOCIAL MEDIA MARKETING IN CONTEMPORARY BUSINESS PRACTICES

Ivana Bulut¹, Marija Mandarić²

¹ Faculty for Business Studies, Megatrend University, ibulut@megatrend.edu.rs

² Faculty for Hotel Management and Tourism, University of Kragujevac, mmandaric@kg.ac.rs

Abstract:

Purpose – The aim of the paper is to present an overview and assessment of challenges and opportunities for companies emerging from greater diversity and complexity in doing social media marketing. It focuses on social media marketing benefits in business practice.

Design/methodology/approach – The paper adopts a theoretical approach and reviews the current deployment of social media into marketing practice. The paper examines how social media marketing issues have emerged, progressed and diversified with the process of the development of information technologies.

Findings – The paper argues that marketers' perceptions of marketing in a new communication era have changed with the market expansion of companies. The paper concludes that, regardless of the dominant focus of marketing within an organisation, marketing practitioners increasingly have a social media requirement within their marketing practice.

Originality/value – The paper is a reflection on the changing nature of marketing and companies' new priorities in their marketing strategies and tactics in order to achieve a better position on the market. The paper advances that the understanding of social media marketing can improve their relationships with customers and their business process.

Keywords: social media, marketing, web 2.0, blog, social network

1. INTRODUCTION

If we choose to see the Internet as a single invention, it would probably be one of the greatest inventions of all time. It has developed from a small university network into a versatile worldwide communication tool. Today, we can do our shopping, read and listen to the news, pay our bills, socialize with our friends and even stream movies and TV-shows using the web. In the beginning, the Internet was primarily a static place; however, with the introduction of the web 2.0, all has changed. The web has become more flexible and its content increasingly user-generated. We can now interact with one another and therefore, the Internet has become a social medium. As humans, we have always been engaged in social networks. They can be formed around our families, friendships, religious beliefs, social status and more. Social media is any kind of information we share with our social network, using social networking websites or services. Examples of it are blogs, forums, photos, audio, profiles and status updates (Eley & Tilley, 2009).

Social media allows people with no special knowledge to post and share content with the world instantly. In the last few years, social networking has become increasingly popular with hundreds of millions of users worldwide. These new web sites are not only useful for keeping in touch with friends and family, it is a new powerful marketing tool. Web is a place where customers set the rules and the word-of-mouth makes or breaks the product. With social media, marketing is a two-way communication, rather than the one way communication used in traditional marketing. While these social networks may have started up as the typical geek hangout, just like the Internet did in the 1990s, it has now become mainstream. Everyone, from college students to business people has embraced this new channel.

2. THE ROLE OF WEB 2.0 IN CONTEMPORARY MARKETING PRACTICES

While researching and promoting web technologies, the term Web 2.0 refers to the second generation of web-based communities such social sites, wikis (for example Wikipedia), blogs and so on, promoting the creativeness, collaboration between and sharing of information and content amongst users. Although the term itself suggests a new version of WWW, it does not refer to any technical improvements whatsoever; it rather refers to changes in the manner in which software developers and end-users use the web. Web 2.0 enables the user much more than a simple information generation; it enables them to fully personalize the

existing web content of various kinds and to create their own one (e.g. an on-line diary in the form of a blog, a personal presentation on a social network) and a direct exchange of information with other users (e.g. the creation of video contents for www.youtube.com).

Companies have also found a way how to promote their services and products as well as build better relations with existing clients and more easily find new ones using these communication channels (Tepper, 2003). This means that interactivity and collaboration possibilities are the primary advantages of web 2.0. Users can now interact much more easily with each other, and create collaborative documents on the web. For example, a multiple author internal blog can serve a number of purposes; a living document of processes, a knowledge container and shorter decision cycles with comments and discussions. A well-known web 2.0 service, with collaboratively created content, is a free encyclopaedia - Wikipedia.

3. SOCIAL MEDIA AND MARKETING PRACTICES

Social media have been developed through web 2.0. Social media are *consumer-generated media* and represent a diverse source of online information created, driven and used by consumers intending to inform each other about products, brands, services as well as problems they have encountered (Blackshaw & Nazzaro, 2004).

Social media include various types of Internet communications, just to name several types (Mangold & Faulds, 2009):

- Social networking sites (*MySpace, Facebook, Faceparty*)
- Creativity works sharing sites (For instance: photos, videos, music, intellectual property people share on *YouTube, Flickr, Jamendo.com, Piczo.com, Creative Commons, etc.*)
- User-sponsored blogs (*The Unofficial AppleWeblog, Cnet.com*)
- Collaborative sites (*Wikipedia*)
- Virtual worlds (*Second Life*)
- Commercial communities (*eBay, Amazon.com, Craig's List, iStockphoto, Threadless.com*)
- Business networks (*LinkedIn*)

An increasingly important role of social media is reflected in the fact that, through social media, organizations are able to communicate with their consumers and also encourage consumers to communicate with each other. Particularly important is communication between consumers, because consumers have more trust in information regarding the products and services received through social media, rather than through the traditional means of communication through a promotional mix (Foux, 2006). Social media are frequently updated, have a large number of hyperlinks and encourage further social networking on the Internet. Sites such as *Facebook, MySpace, YouTube, Flickr, Trip Advisor, etc.*, allow consumers to share their experiences in different ways by posting their comments, pictures and videos (Xiang & Gretzel, 2010).

As their use increases exponentially, not only the existing social networkers but business firms and government organizations as well are joining and using them as communication tools. Unlike individual social networkers, these entities actively make use of the media for advertising and marketing. While commercial messages and interactions with consumers partner with media, events, entertainment, retailers, and digital services through social media, it is possible to perform integrated marketing activities with much less effort and fewer costs than before. According to Kim and Ko (2010), social media can have a dramatic impact on a brand's reputation. One-third of the surveyed participants posted opinions about products and brands on the brand's blog, and 36% thought more positively about companies that have blogs.

Before accepting the social media practise, companies need to know what they want to achieve, and what they do not want to achieve. Therefore, a strategy is needed on how to produce the social media content. There are a lot of social media tools that can be used, so companies must decide which one suits their goals the best. A blog is often the easiest tool to begin with, and to set a solid strategy on how to use it.

3.1. Inclusion of blogs in a company promotion technique

There are several important reasons why companies use the blog in their promotional presentations on the Internet (Dyrud M. A., et al., 2005):

- the great visibility of blogs on search engines,
- direct communication with the consumers,
- the ability to create market brands and means for differing from competitors and a personal relation with the consumer,
- to provide a better introduction to the market, build on-line reputation, enable the demonstration of personal attitudes and opinions and internal communication in companies.

Everyday reasons multiply for companies to use blogging platforms to their social media channel. Platform like [LinkedIn](#) creates an environment for companies and clients to connect online (Deis et al., 2010). Companies recognizing a need for information, originality and accessibility employ blogs to make their products popular and unique, and ultimately reach out to consumers who are privy to social media (Chiang et al., 2011). Blogs allow a product or company to provide longer descriptions of their respective products or services. A longer description can include reasoning and uses. It can include testimonials and can link to and from *Facebook*, *Twitter* and many other social-network and blog pages. Blogs can be updated frequently and are promotional techniques for keeping customers. Other promotional uses are acquiring followers and subscribers and directing them to your social network pages.

3.2. Social networks as a marketing tool

Social networks are a form of social media. They have become the basis of modern electronic communication and, gradually, they push out the so-far mechanism of information exchange. The time when one-way means were used to sell a product or develop a brand has gone. No longer is it sufficient for a company on the Internet. The consumer wants more and their expectations are greater. Attention is increasingly paid to interactive contents, created by a wider social community, not just a company. In that manner, faster and more easily, companies come to information about the market they are doing business on, creating their campaigns virally widespread, blogging, giving useful pieces of advice. Communication has become the essence of digital technologies and media.

Many researches are indicative of the fact that using social networks is currently one of the most present activities of the user in Internet using. Today, there are around 1.5 billion people worldwide using social networks. Each one of them is inside the system where it has become normal to publicly advertise favourite companies, products and services. The majority of them are ready to reveal their demographical data, which, together with data about their wishes and ways of thinking, make a good basis for collecting pieces of information significant for companies' marketing activities. Some social networks have a user-base bigger than the population of the country is. Thanks to that extremely big user-data- and user-attitude base, companies have found themselves in a situation that they have started to establish direct contact with the precisely determined target group and potential consumers. On the other hand, the consumer has found him/herself in a situation that they have started to receive personally tailored offers with a much greater chance to attract their attention to.

Social networks represent a big potential for companies' business doing and have become extremely interesting for companies in a sense of conducting various marketing activities. Companies should be paying due attention to their presentations on social networks, simultaneously choosing those services and communication channels deemed to be the most appropriate ones when the nature of their business doing is concerned. There are a large number of social networks and they are typical of a certain geographical climate, profession, interest and need. Each of them has its different purpose and requires specific marketing techniques in order to generate the biggest benefit from itself.

4. TRANSPARENCY IN BUSINESS

Conversations in social media are available to everyone to observe or participate in. This leads to both good and bad effects. More openness does not necessarily lead to good feedback and information about a company. However, all available knowledge is valuable within a market analysis (Landslips & Lundgren, 2009). Transparency is one of the most complicated aspects of social media. Precisely, transparency is an

aspect of all communication, and communication is the essential part of social media. It is often discussed as two extremes, total openness or total confidentiality. It is important what company represents be discussed and, then, the level of transparency will grow. It is much more likely that companies see transparency as a threat; however, the truth is that it is more about safeness. Transparency creates the trust and speed required for the social media usage.

Transparency is the future of all business, mostly because it will solve the trust issue. Business increases through good relations, which requires requires trust, and to earn trust, you have to be transparent. It is possible to compare transparency with a unique selling point. Social media and transparency increase and improve dialogues, and dialogues are important especially in times of a crisis.

5. THE NEW COMMUNICATIONS PARADIGM

In the traditional communications paradigm, the elements of the promotional mix are coordinated to develop an IMC strategy, and the content, frequency, timing and medium of communications are dictated by the organization in collaboration with its paid agents (advertising agencies, marketing research firms, and public relations consultants). The flow of information outside the boundaries of the paradigm has generally been confined to the face-to-face and word-of-mouth communications amongst individual consumers, which has had a minimal impact on the dynamics of the marketplace due to its limited dissemination (Mayzlin, 2006). This paradigm has served as the framework for developing IMC strategies (Muniz & Schau, 2007). Its long shelf life appears to be largely due to the high degree of control over the communications process it affords to businesses.

However, in the era of social media, marketing managers' control over the content, timing and frequency of information is severely being eroded. In the new paradigm, information about products and services also originates in the marketplace. This information is based on the experiences of individual consumers and is channelled through the traditional promotion mix. However, various social media platforms, many of which are completely independent of the producing/sponsoring organization or its agents, magnify consumers' ability to communicate with one another. This "groundswell" has profoundly affected all aspects of consumer behaviour, and has bestowed consumers with a power they have not previously experienced in the marketplace (Li & Bernhoff, 2008). In the new communications paradigm (see Figure 1.), marketing managers should recognize the power and critical nature of the discussions being carried out by consumers using social media.

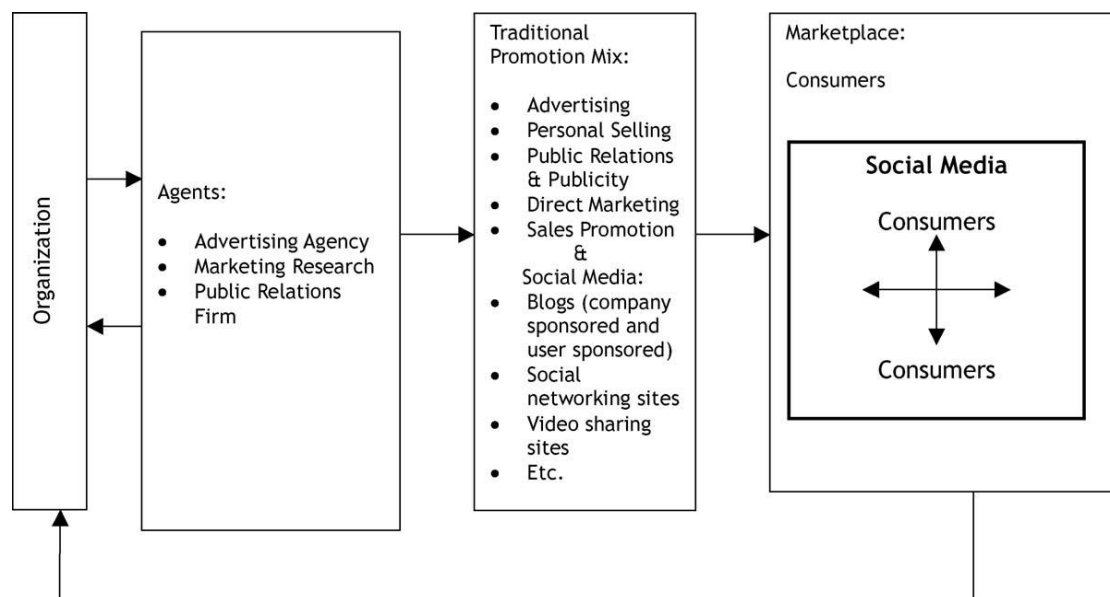

Figure 1. The new communications paradigm
Li, C., Bernhoff, J. (2008). *Groundswell: Winning in a world transformed by social technologies*. Boston: Harvard Business Press.

The impact of the interactions among consumers in the social media space on the development and execution of IMC strategies is illustrated by the following points:

- The Internet has become a mass media vehicle for consumer-sponsored communications. It now represents the number one source of media for consumers at work and the number two source of media at home. The Internet reaches more than 60% of all United States consumers for an average weekly usage rate of more than 100 minutes (Rashtchy, et al., 2007)
- Consumers are turning away from the traditional sources of advertising: the radio, the television, magazines, and newspapers. Consumers also consistently demand more control over their media consumption. They require on-demand and immediate access to information at their own convenience (Vollmer & Precourt, 2008).
- Consumers are turning more frequently to various types of social media to conduct their information searches and make their purchase decisions (Lempert, 2006; Vollmer & Precourt, 2008).

Social media is perceived by consumers as a more trustworthy source of information regarding products and services than corporate-sponsored communications transmitted via the traditional elements of the promotion mix (Foux, 2006)

The above trends have severely diminished the usefulness and practicality of the traditional communications paradigm as a framework for developing IMC strategies. The new communications paradigm, on the other hand, requires several important changes in management's attitudes and assumptions about an IMC strategy formulation. First, marketing managers must accept the reality that a vast amount of information about their products and services is being communicated by individual consumers to other consumers via social media forums. Second, consumers are responding to this information in ways that directly influence all aspects of consumer behaviour, from information acquisition to the post-purchase expressions of satisfaction and dissatisfaction. Third, consumers are turning away from the traditional elements of the promotion mix; in particular, they are reducing their reliance on advertising as a source of information to guide their purchase decision-making. Finally, managers who are accustomed to exerting a high level of control over company-to-consumer messages must learn to talk with their customers, as opposed to talking at them, therefore influencing the discussions taking place in the social media space.

6. CONCLUSION

The web has become social and made communication between companies and customers much easier. The social media marketing is a new way for promoting products and services. Instead of a one-way communication, social media give opportunity for company to talk and discuss with consumers, in order to improve offer. Services often focused on today are blogs, Facebook and Twitter, even though there are a lot more useful services. The underlying aspects of IT and the Internet are of a technical nature; however, the usage is not. Social media is not even about which tools someone uses. Social media is about communication, attitude, honesty, participation and relations. Using social media as a marketing tool, company have an ability to talk with customers. If she talks friendly and generously to customers and consumers, simultaneously is appearing to be more humane than a traditional marketing is. This will improve customer relationship and may give a free marketing, through the word-of-mouth.

²University of Belgrade, Faculty of Organizational Sciences, marija.stosic@estiem.org

Abstract: The paper presents the results of a relative efficiency evaluation, performed on the data collected from 19 insurance companies which operate in Serbia, covering a reference period of two consecutive years – 2009 and 2010. The Data Envelopment Analysis (DEA) method was used to evaluate relative efficiency of each insurance company from its operating and financial aspects. The companies' ranking was made taking into consideration the obtained index of efficiency. In addition, DEA provided information of inputs that need to be reduced in order to improve the efficiency of the analysed companies.

Keywords: Data Envelopment Analysis, insurance companies, operating efficiency, financial efficiency

1. INTRODUCTION

One of the most important principles in every business is the principle of efficiency, which consists in achieving the highest possible output with minimal input or investment. The most obvious example of efficiency is ratio between one output and one input. Data Envelopment Analysis (DEA) allows simultaneous consideration of more than two ratios and calculates the relative efficiency for every observed unit. (Bulajić, Savić and Savić, , DEA is an increasingly popular management tool and is widely applied in solving real business problems. At the beginning, DEA has been used for the efficiency evaluation of the non-profit units. Later on, the area of application has spread to profit sector such as banking and insurance industry.

In this paper, the efficiency of the 28 insurance companies in Serbia is assessed using DEA method. The insurance sector in Serbia is one of the least developed insurance sectors in Europe. However, in past few years, there have been some indicators and signals of improvement in this field. The purpose of this research is to evaluate and compare efficiency from the different aspects of business in the whole industry. The first approach concerns assessing operating efficiency as ability of companies to produce financial income using the available resources. The second approach is developed to assess the financial efficiency as a ratio that combines different types of income and costs. Furthermore, within the approach there is a comparison of the efficiency in the insurance industry in Serbia in 2009 and 2010.

The paper is organized as follows. The first section describes the theoretical background of Data Envelopment Analysis. Afterwards, the problem and data set were described. Results are obtained using EMS software (EMS DEA Software, 2012). Furthermore, the paper presents the ranking of the companies and the comparison of operating and financial efficiency. Conclusion and remarks are given in the last section.

2. BACKGROUND OF DATA ENVELOPMENT ANALYSIS (DEA)

American economists Charnes, Cooper and Rhodes (1978) introduced the CCR DEA model in 1978 with assumption of constant returns to scale. The proposed approach was further developed by Banker, Charnes and Cooper (1984) known as BCC DEA model that includes variable returns to scale.

Data Envelopment Analysis (DEA) is a linear programming methodology, which is used to measure the efficiency of multiple decision-making units (DMUs) using multiple inputs for producing multiple outputs. DEA has been successfully applied in efficiency assessment of hospitals, schools, libraries, banks, insurance companies, university departments and police stations.

The basic CCR DEA model (Savić & Martić, 2012):

$$(Max) h_k = \sum_{r=1}^s \mu_r y_{rk}$$

s.t:

$$\sum_{i=1}^m v_i x_{ik} = 1 \quad (1)$$

$$\sum_{r=1}^s \mu_r y_{rj} - \sum_{i=1}^m v_i x_{ij} \leq 0, \quad j = 1, 2, \dots, n$$

$$\mu_r \geq \varepsilon, \quad r = 1, 2, \dots, s,$$

$$v_i \geq \varepsilon, \quad i = 1, 2, \dots, m$$

The basic BCC DEA model:

$$(Max) h_k = \sum_{r=1}^s \mu_r y_{rk} + v^*$$

s.t:

$$\sum_{i=1}^m v_i x_{ik} = 1 \quad (2)$$

$$\sum_{r=1}^s \mu_r y_{rj} - \sum_{i=1}^m v_i x_{ij} + v^* \leq 0, \quad j = 1, 2, \dots, n$$

$$\mu_r \geq \varepsilon, \quad r = 1, 2, \dots, s,$$

$$v_i \geq \varepsilon, \quad i = 1, 2, \dots, m$$

where:

h_k is the efficiency of unit k ,

x_{ij} is quantity of input i used by observed DMU j ($j = 1, 2, \dots, n$),

y_{rj} is quantity of output r produced by observed DMU j ($j = 1, 2, \dots, n$),

μ_r is the weight given to output r by base DMU k ,

v_i is the weight given to input i by base DMU k ,

n is the number of DMU ($j = 1, 2, \dots, n$), m is the number of inputs ($i = 1, 2, \dots, m$), s is the number of outputs ($r = 1, 2, \dots, s$), and ε is a very small positive number.

The v_i and μ_r are the variables in both problems presented above. They are determined as weights assigned to the inputs and outputs. These variables need to be greater than or equal to some small positive number ε , in order to avoid any input or output being ignored in determining the efficiency. Each DMU is allowed to adopt the most favourable set of weights. The unit is efficient if the efficiency is equal to 1, otherwise if it is less than 1 it is considered inefficient.

The performance of a DMU was evaluated by comparing its performance with the best performing DMUs of the data set. The best performing DMUs form the efficiency frontier. If DMU is enveloped by frontier (e.g. not lay on the frontier), it is considered as inefficient. DEA provides information on what are the changes required in input and output data for inefficient DMU to reach the efficiency frontier. After the evaluation of the relative efficiency of every DMU, the analysis shows how inputs and outputs need to be changed in order to reach the efficiency of the target DMU (Stancheva & Angelova, 2004).

Data Envelopment Analysis (DEA) is becoming an increasingly popular management tool, which is applied in solving of the real business problems.

The advantages of DEA method:

- Proven to be useful in uncovering relationships that remain hidden for other methodologies
- Capable of handling multiple inputs and outputs measured in different units
- Applicable with any input-output measurement
- The sources of inefficiency can be analyzed and quantified for every evaluated unit.

The disadvantages of DEA method:

- Results are sensitive to the selection of inputs and outputs
- The number of efficient DMUs on the efficiency curve tends to increase with the number of inputs and output variables
- DEA is good at estimating "relative" efficiency of a DMU but it converges very slowly to "absolute" efficiency
- Since DEA is a nonparametric technique, statistical hypothesis tests are difficult and are the focus of on-going research
- Since a standard formulation of DEA creates a separate linear program for each DMU, large problems can be computationally intensive.

This paper describes the usage of the Data Envelopment Analysis (DEA) method in estimation and comparison of the efficiency of the insurance industry in Serbia.

Insurance company is a legal entity that is obliged by a contract to repay certain amount of money if the unwanted (risked) circumstances occur. There are different types of insurance companies considering the company size, type and volume of the risk they cover. Generally, there are life and non-life insurance companies. The efficiency has been evaluated by DEA method in the area of life and non-life insurance together.

In the paper (Tone & Biresh, 2005) authors applied a new variant of data envelopment analysis model to examine the performance of Life Insurance Corporation (LIC) in India. For these analyses, they used data for the period of 19 years. Insurance inputs, which they have selected, can be classified into four groups: business services, number of employees, debt capital and equity capital. In this study, they used present value of real losses and the ratio of liquid assets to liabilities as outputs.

Few years later (Wu, Yang, Vela & Liang, 2007), authors analyzed production and investment performance of the life and health insurance companies in Canada. They used data for over 70 companies in 3-years period. Authors of "Compare the Performance of Private and Public Insurance Companies in Using Data Envelopment Analysis" (Saedy & Kazemipour, 2011) used DEA to examine and compare the technical efficiency, allocation and economic public and private insurance companies in Iran.

3. PROBLEM DESCRIPTION

As it was already mentioned above, the insurance sector in Serbia is among the least developed sectors on the insurance map of Europe. Comparison of indicators coming from 2009 until now shows a slow growth and improvement of the insurance sector in Serbia. The most representative measurements show an increased capital by 3,3% and increased technical reserves by 7,9%. Technical reserves cover the whole life insurance sector, and large number of nonlife insurance. The whole amount of premium is increased at the level of 57.300.000.000 RSD, which present the growth rate of 1,4%. The involvement of life insurance in the whole premium is dominant and takes 82,6%. Nonlife insurance premium has a slow growth of 0,3%, while life insurance premium has a growth of 0,9%.

The number of insurance companies in Serbia has increased. Today there are 28 insurance companies operating in Serbia. The main areas where insurance companies should pay attention nowadays are corporate management, which consider adequate management of internal control systems, improvement of risk management and techniques for risk estimation. Furthermore, the companies should improve the techniques of investment evaluation, strengthening good business practices and fair treatment to customers (National Bank of Serbia, 2012).

The aim of this paper is to present one possible way of evaluation of the relative efficiency of insurance companies in Serbia. Furthermore, the paper presents the ranking of the companies and the comparison of operating and financial efficiency. The paper illustrates the changes in ranking companies regarding financial efficiency from 2009 to 2010. Some efficient companies become inefficient because of the economic crises. On the other hand, some inefficient companies become efficient with a tendency to improve their ranking in the future.

Criteria (inputs and outputs) selection was made based on the available data and the data that present the company operations in the best way. For determining the operating efficiency of the companies, the following inputs was used: insurance costs, capital and reserves, number of employees, number of insurance types and number of branches. Total income was used as output. Considering total cost in income statement of

insurance companies, insurance costs have the biggest share, which is why they were chosen as an input. On the second place are costs of employees. The number of employees were chosen as input for this analysis because of the high correlation between number of employees and costs of employees. Numbers of insurance types and branches show the diversity of the company. They are connected with the customer satisfaction and affect the amount of income directly. Capital and reserves were chosen as input because total income as output can present the real condition of the company only if it is compared with capital and reserves.

Moreover, additional analyses were used in order to present changes from 2009 to 2010. Only financial indicators were used for this analysis. There were three inputs: insurance costs, capital and reserves and costs of employees and two outputs: income from insurance and other income.

Two out of 19 companies, Basler and Uniqa present data for life and nonlife insurance separately in their reports. For the sake of the analyses, this data were consolidated, because nonlife insurance has a small impact comparing to life insurance. The same approach was applied for companies Delta Generali and Wiener Stadtische with a small difference of consolidating data for insurance and reinsurance.

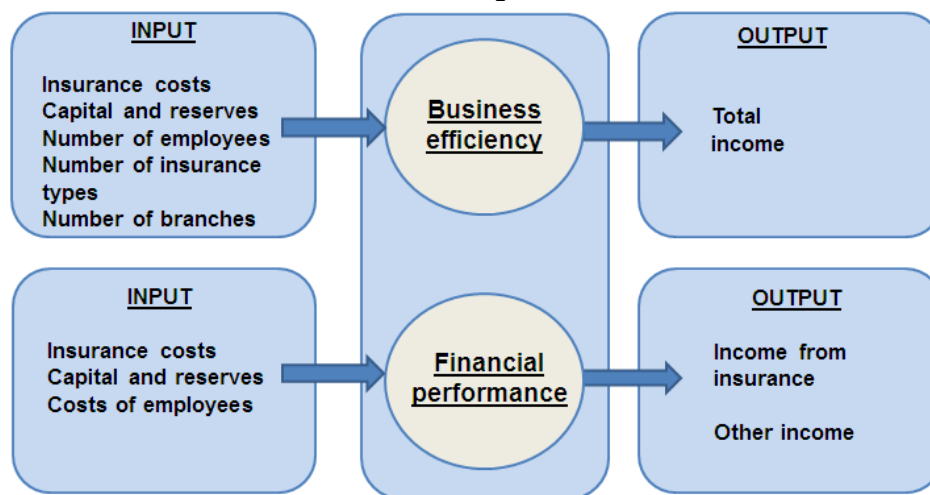

Figure 1: Model for analysis of operating and financial efficiency

4. RESULTS AND DISCUSSION

The ranking of insurance companies was obtained using the output-oriented modification of CCR DEA model. The modification was introduced by Andersen and Petersen (1993). In order to differentiate the observed units and enable their full ranking, Andersen-Petersen model for measuring super-efficiency was used (Andersen & Petersen, 1993). This model excludes the DMU under evaluation from the reference set, which allows efficient DMUs to become super-efficient and to have different super-efficiency score under the 100% for output-oriented model (Lovell & Rouse, 2003).

The output orientation was chosen in accordance with the goal of companies to maximize the outputs by using the existing inputs. Such orientation means that efficiency index (h_k) is reciprocal to input-oriented DEA model presented in section 2. Consequently, DMUs with efficiency index less or equal to one were assessed as efficient. If efficiency index, h_k , is greater than one than the observed DMU is inefficient, and some output increases are needed in order to become efficient.

Results were obtained using EMS software (www.dea.com). Table 1 and Table 2 present ranking of efficient and inefficient companies.

Table1: Results of operating efficiency – Efficient Insurance companies

DMU	Dunav	GRAWE	Merkur	Wiener Stadtische	AMS	Delta Generali	DDOR Novi Sad	Triglav	Takovo
Score	37,68%	47,25%	53,71%	71,59%	85,10%	88,39%	92,20%	92,86%	99,98%

Table 2: Results of operating efficiency – Inefficient Insurance companies

DMU	Energoprojekt Garant	SAVA	UNIQA	Milenijum	AS	AXA	Globos
Score	102,86 %	120,98 %	126,76 %	137,09 %	137,78 %	147,21 %	242,25 %

The efficient companies have score less than 100%. The most efficient is Dunav insurance company. The following companies: GRAWE, Merkur, Wiener Stadtische, AMS, Delta Generali, DDOR Novi Sad, Triglav and Takovo are also efficient. Six from these eight companies (GRAWE, Merkur, Wiener Stadtische, AMS, Delta Generali and DDOR Novi Sad) were used as benchmarks for 8, 4, 3, 4, 1 and 4 times, respectively. Dunav is the biggest insurance company and has never been used as a benchmark, because of high values of inputs and outputs. Looking backward Dunav has the longest presence in insurance sector in Serbia, highest reputation and tradition, and it was expected to be ranked at first place.

Inefficient companies score is greater than 100%. Insurance company Energoprojekt Garant is inefficient. In order to become efficient as Grawe and Merkur, it has to decrease capital and reserves for 685080600 RSD and number of insurance types for 29. Comparing to inputs (capital and reserves are 685080600 and insurance types 30) this recommendation is hardly achievable.

Insurance company SAVA is inefficient and has to decrease insurance costs for 250418900 RSD, number of branches for 2 and number of types of insurance for 28 in order to become as efficient as DDOR Novi Sad and Delta Generali.

Milenijum and AS have to decrease insurance costs for 10 RSD and 178963200 RSD, respectively. In order to become efficient this companies need to decrease number of insurance types for 25 and 11, respectively. Benchmarks for these two companies are DDOR Novi Sad, GRAWE and AMS, with addition for Milenijum that has one more benchmark Wiener Stadtische insurance company.

The last two insurance companies AXA and Globos are also inefficient and need to decrease capital and reserves for 106203200 RSD and 472582500 RSD, number of branches for 1 and 6, number of types of insurance for 11, respectively, in order to become as efficient as GRAWE and Merkur insurance companies. Insurance companies Basler, Alico and Societe Generale are too inefficient, so these companies were excluded from further analysis.

Comparison of 2009 and 2010

Further analyses showed the comparison of financial efficiency in insurance sector in Serbia for 2009 and 2010. Correlation coefficient between number of employees and costs of employees in 2009 and 2010 is close to 1 (0,94 and 0,92 respectively). Because of financial assessment and high correlation only costs of employees were used.

Figure 2: Financial efficient insurance companies in 2009 and 2010

The chart shows the compared results of only efficient insurance companies in 2009 and 2010. The smaller percentages present better result, and efficient insurance companies have scoreless or equal to 100%. GRAWE is more efficient in 2009 (with score 34,51%) compared to 2010 (51,5%). DDOR Novi Sad was in

the second place in 2009, and in the fifth place in 2010, decreasing his score for 18,45%. This is the result of increased costs of insurance, reduced costs of employees and reduced income from insurance and other income. The chart shows that Wiener Stadtische, SAVA, AMS and Delta Generali have improved their scores in 2010, comparing with the results from 2009. The improvement is particularly noticeable for Winner Stadtische and SAVA companies. The data for both companies show the growth of the business, which was presented by increased inputs and outputs. This improvement is probably the result of a minor economy improvement and a slight hint of overcoming the crises. AMS and Delta Generali have almost the same score in 2009 and 2010.

Figure 3: Financial inefficient insurance companies in 2009 and 2010

The chart presents scores of inefficient insurance companies. Milenijum had been efficient in 2009, but due to smaller increase of income compared to increased costs, it became inefficient. On the other hand, Takovo and Triglav become efficient in 2010. Dunav, AXA and Globos have better scores in 2009 compared to 2010. UNIQA and Energoprojekt show better results in 2010 than in 2009 with low rate of improvement in resource usage. Merkur and AS improved their business in 2010 by increasing income much more than costs, but still not enough to become efficient.

Figure 4: Financial and operating efficient insurance companies in 2010

The chart shows the changes in scores for operating and financial efficiency of insurance companies when in the analysis are used only financial indicators and mix of financial and nonfinancial indicators (number of insurance types, number of branches and number of employees). Only Wiener Stadtische has greater financial efficiency than the operating efficiency. Measured by financial indicators, Wiener Stadtische is used as a benchmark 8 times, compared to 5 times when measured with mixed indicators. The differences in scores can be explained by relatively low costs of employees. All other units shown in the chart have greater operating efficiency than financial efficiency. Takovo and Triglav show almost the same scores.

Figure 5: Financial and operating inefficient insurance companies in 2010

Sava is only financially efficient while operating efficiency is greater than 100%. Dunav and Merkur have the opposite tendency and are inefficient considering financial indicators. Dunav has the highest number of employees, but not the highest level of the cost of employees. The value of income from insurance, other income and total income is the largest compared with other companies. Milenijum and Globos have better financial efficiency than the operating efficiency, but they are inefficient in both cases. UNIQA, Energoprojekt, AS and AXA have better operating efficiency than financial efficiency, but they are inefficient in both cases.

5. CONCLUSION

This paper presents the efficiency measurement of insurance companies in Serbia. Leaders in the insurance industry, companies that follow them and those that are inefficient were identified using DEA. In order to survive in the market inefficient companies have to change their business principles. The first analysis includes financial and non-financial aspects and measure operating efficiency of insurance companies in Serbia, and offers suggestions related to the performance improvement. The following analysis includes only financial data, and the financial efficiency was measured using a data available for the years 2009 and 2010. Results shows that GRAWE, Wiener Stadtische, AMS, Delta Generali and DDOR Novi Sad are the only companies that are financial efficient in 2009 and financial and operating efficient in 2010. SAVA is only operating inefficient, while Dunav and Merkur are financial inefficient for both years. Triglav and Takovo are only financial inefficient in 2009.

Future research in this industry can include data for the upcoming years and the recent changes in insurance industry. Moreover, further research can monitor the developing trends and growth of the insurance companies in Serbia. Re-ranking can show which insurance company has survived, has grown and developed, has sustainable business and increased earnings.

Abstract: *Efficiency assessment based on multiple inputs and outputs which are not necessarily financial is considered to be a complex process. Data envelopment analyses (DEA) is firstly introduced in the purpose to evaluate the efficiency of non-profit units. In this paper, an extended DEA – Window analysis is used for the efficiency assessment of banks in Serbia based on panel data for the period from 2005 to 2011. This analysis provides trends of efficiency and rank of each bank evaluated in terms of its profit and operating effectiveness. Furthermore, the obtained results allow an analyses of trends of the overall banking sector efficiency.*

Keywords: *Window analysis, banks efficiency, DEA and panel data, Serbian banking*

1. INTRODUCTION

In this paper, we analyze the performance of twenty-eight commercial banks in Serbia over period 2005 – 2011. Available data before 2005 are not comparable because in Serbian banks' reports were not regulated by the law. In 2005 independent institution "National Bank of Serbia" implemented the regulation for banking system in Serbia.

The evolving process of a banking system started in 2001 along with the transition of the Serbian economy when the country had approximately 90 banks. From that year, until now, some banks were liquidated. Some merged with others, and the remainders were privatized.(SS BOFOS)

Banking system of The Republic of Serbia consists of the Central Bank (National Bank of Serbia) and commercial banks. Banks in Serbia are independent in their pursuit of profit-oriented business activities based on the principles of solvency, profitability and liquidity. At this moment, there are thirty-three banks in Serbia fighting for customers in a market with 7.12 million citizens (except province Kosovo and Metohia). Among banks in Serbia (33 banks), we can find a number of banks that are still (or at least partially) owned by The Republic of Serbia (8 banks). Some of them are foreign banks (21 banks) and there is also domestic-privately owned banks (4 banks) (NBS | Banking Sector, 2012).In our analysis, we excluded five banks because these five banks were not operating during the whole analyzed period. Alternatively they did not enter Serbian market before 2005, either they don't work now (proclaimed the bankruptcy). We excluded Opportunity banka a.d.Novi Sad, Moskovska banka a.d. Beograd, Dunav banka a.d. Zvecan, Jugobanka a.d. Kosovska Mitrovica, Poljoprivredna banka Agrobanka A.D. Beograd. We have used annual panel data for this research.

The extended version of data envelope analysis (DEA) – Window analysis designed for assess the efficiency of decision making units (DMU) based on panel data is used for efficiency evaluation of selected banks operating in Serbia. Reviewing the literature, the authors mainly found studies dealing with a similar principle of approaches in measuring the efficiency of banks over period of time. In mentioned literature, there are several differences in used methods (DEA Windows analysis or Malmquist Index analysis) and several differences in considered models, i.e. considered aspect and goals of analyses.

The main objective of the paper is to evaluate the efficiencies of Serbian banks in order to follow dynamics of efficiency of each banks and the banking sector as whole. Furthermore, banks' management can identify trend of annual efficiency, which can help them to improve their business results.

It would be interesting to see how Global Financial Crisis (GFC) affected Serbian bank sector. Particularly, we tend to determine a difference between the period before, and period after GFC beginning. This could be done by DEA Time series, i.e. Window analysis.

The paper is organized as follows. In the next section, Section 2, we introduce the methodologies which are used, namely DEA analysis with a main focus on Window analysis. Section 3 describes the approach used for this particular study, and discusses the data used, while the Section 4 identifies and discusses results. Finally, in Section 5 the conclusions are given.

2. THEORY AND METHODOLOGY

About Data Envelopment Analysis

Data Envelopment Analysis (DEA) was originally introduced by Charnes, Cooper and Rhodes (1978) and is a non-parametric linear programming approach, capable of handling multiple inputs as well as multiple outputs (Paradi, Asmild, Aggarwall, & Schaffnit, 2004). Precisely, this approach allows handling different type of input and output together.

A DEA model can be constructed either to minimize inputs or to maximize outputs. An input orientation aims at reducing the input amounts as much as possible while keeping at least the present output levels, while an output orientation aims at maximizing output levels without increasing use of inputs. (Cooper, Seiford, & Tone, 2000)

Window analysis

Economists especially insist that the efficiency is changeable category, and that depends on the time! Regarding of previous sentence, we decided to use appropriate technique - Window analysis technique. Window analysis technique works on the principle of moving averages (Cooper et al. 2007) and is useful to detect performance trends of a decision making unit over time. Each DMU in a different period is treated as if it were a „different“ DMU (more accurate independent) but remain comparable in the same window (Cooper, Seiford, & Zhu, 2011). *“Such capability in the case of a small number of DMUs and a large number of inputs and outputs would increase the discriminatory power of the DEA models.”* (Cooper, Seiford, & Zhu, 2011). Formally, it is necessary to observe n DMUs and they represent the number of decisions making units in a given time period t , while P denotes the total number of time periods, and of course the given time period in time range $t=1, \dots, P$. Window size in the label W denotes the number of included time periods, which applies throughout the whole analysis, from where we can calculate the number of analyzed windows(AW) using the simple formula: $AW = P - W + 1$.

It is clear that this procedure implies AW separate analyses, where each analysis examines $n \times W$ DMUs. Using Window analysis we make sample size of $n \times P$ observations where an observation j in particular time period t , (referring to DMU_t^j) has an m -dimensional input vector: $x_t^n = (x_{1t}^n, x_{2t}^n, \dots, x_{mt}^n)^T$ and an s -dimensional output vector: $y_t^n = (y_{1t}^n, y_{2t}^n, \dots, y_{st}^n)^T$. Then a window IW with $n \times W$ observations is denoted starting at time I , $0 \leq I \leq P-1$ with width W , $1 \leq W \leq T-I$. So the matrix of inputs is given as:

$$X_{IW} = (x_1^1, x_1^2, \dots, x_1^n, x_{I+1}^1, x_{I+1}^2, \dots, x_{I+1}^n, x_{I+W}^1, x_{I+W}^2, \dots, x_{I+W}^n)$$

and the matrix of outputs will be:

$$Y_{IW} = (y_1^1, y_1^2, \dots, y_1^n, y_{I+1}^1, y_{I+1}^2, \dots, y_{I+1}^n, y_{I+W}^1, y_{I+W}^2, \dots, y_{I+W}^n).$$

The input oriented DEA window analysis problem with constant returns to scale (CRS) assumption is given by solving the linear program illustrated in Equation 1 below, also similar to the basic DEA models, it is possible to create a DEA window model with output orientation illustrated in Equation 2.

Equation 1: Input oriented DEA Window analysis

$$(Min) Z_{kl_w}^t$$

s.t.

$$Y_{l_w} \lambda \geq y_{kl_w}^t$$

$$Z_{kl_w}^t \times x_{kl_w}^t - X_{l_w} \lambda \geq 0$$

$$\lambda_s \geq 0; s = 1, 2, \dots, n \times W$$

Equation 2: Output oriented DEA Window analysis

$$(Max) Z_{kl_w}^t$$

s.t.

$$X_{l_w} \lambda \leq x_{kl_w}^t$$

$$-Z_{kl_w}^t \times y_{kl_w}^t + Y_{l_w} \lambda \geq 0$$

$$\lambda_s \geq 0; s = 1, 2, \dots, n \times W$$

3. DATA AND METHODOLOGY

There are few approaches which could be used for measuring efficiency in banking sector:

- In bank analyses, **The Production Approach** commonly views banks as producers of services and products using labour and other resources as inputs and providing deposits, loans and others (in value or number of transactions) as outputs. (Cooper, Seiford, & Zhu, 2011)
- Under **The Intermediation Approach**, as the name suggests, the bank's intermediary role is mainly studied to examine how efficient the bank is in collecting deposits and other funds from customers (inputs) and then lending the money in various forms of loans, mortgages, and other assets (i.e., investments, etc.). (Cooper, Seiford, & Zhu, 2011)
- **The Profitability Approach** is designed to examine the process of how well a bank uses its inputs (expenses) to produce revenues. (Paradi, Rouatt, & Zhu, 2010)

We have decided to use the intermediation approach because the idea of intermediation approach is to look more technically at what banks do. *The bank's production process is a black box whose efficiency is simply judged by the amount of output produced from a certain amount of input.*(Jemrić & Vujčić, 2002).

Different sets of input and output data are used for follows two models in estimating efficiency. In this paper, two analyses are carried out. The first is related to banks' profit efficiency and second one is relate to banks' operating efficiency. For the profit efficiency model all available data are taken from banks' income statements. Description of input and output data is shown in Table 1.

Table 1: Profit efficiency model from intermediation aspect

Inputs		Description
1	Interest expenses	Accrued normal and default interest expenses for the reporting period irrespective of the time it falls due.
2	None-interest expenses	Sum of two positions from income statement: fee and commission expenses and other operating expenses.
Outputs		Description
1	Interest income	Accrued normal and default interest income for the reporting period irrespective of the time it falls due.
2	None-interest income	Sum of two positions from income statement: fee and commission income and other operating income.

For the operating efficiency model all available data are taken from banks' balance sheets. Description of input and output data is shown in Table 2.

Table 2: Operating efficiency model from intermediation aspect

Inputs		Description
1	Number of employees	Based on data collected from National Bank of Serbia.
2	Fixed assets and intangible investments	Sum of two positions from balance sheet: intangible assets (investments in identifiable non-monetary assets without physical substance to serve for the production or delivery of goods and services, to be leased out to other parties or used for administrative purposes) and fixed assets and investment property (land, buildings, equipment, other fixed assets, investment property and equipment provided by finance leases, as well as investments in acquiring fixed assets and investment property).(NBS Accounting Regulations, 2012)
3	Capital	Position from balance sheet (consists of equity and other capital, reserves, revaluation reserves, unrealized losses in respect of securities available for sale, accumulated profit / loss).
4	Deposits	Sum of two positions from balance sheet: transaction deposits (banking deposits that have immediate and full liquidity, with no delays or waiting periods) and other deposits.
Outputs		Description
1	Granted loans and deposits	Position from balance sheet.
2	None-interest income	Sum of two positions from income statement: fee and commission income and other operating income.

Descriptive statistics for the performance variables used in the analyses are given below in Table 3 for profit model and in Table 4 for operating model. Data in the following two tables is expressed in thousands of Serbian Dinars (RSD), except number of employees.

Table 3: Overall descriptive statistics for data used in profit efficiency model

Statistic	Inputs		Outputs	
	Interest expenses	None-interest expenses	Interest income	None-interest income
Mean	1,800,499.52	2,075,078.63	4,563,408.30	2,088,448.86
Median	1,140,674.50	1,363,187.00	2,918,808.00	1,226,145.50
S.D.	2,019,229.97	1,725,054.70	4,980,425.77	2,471,197.93
I Quartile	379,256.00	776,947.25	1,283,059.50	558,694.75
III Quartile	2,468,261.25	2,879,555.00	5,953,639.25	2,586,256.75
Minimum	15,786.00	193,041.00	202,239.00	80,715.00
Maximum	11,652,708.00	8,820,418.00	31,090,463.00	16,190,122.00

Regarding of previous table, we could conclude that interest income is much higher than non-interest income. Based on conducted more detailed analyzes we can see that after 2007. only Postanska stedionica had higher none-interest income than interest income, and the difference between this two position is melting every year. Among all banks, the smallest standard deviation is for none-interest expenses input.

At the end of 2011.inSerbian banking sector, half of the banks were operating with less than 679 employees. In general, distribution of used data has positively skewed, which means that extreme scores are larger or in other words there are more low scores than high scores. In Table 4 we can see average number of employees for whole period and more descriptive statistics.

Table 4: Overall descriptive statistics for data used in operating efficiency model

Statistic	Inputs				Outputs	
	Number of employees	Fixed assets and intangible investments	Capital	Deposits	Granted loans and deposits	None-interest income
Mean	992.76	2,218,608.27	12,445,773.77	38,626,804.57	35,858,694.78	2,088,448.86
Median	702.50	1,410,922.00	6,823,957.00	22,650,330.00	20,625,058.00	1,226,145.50
S.D.	803.21	1,966,413.96	13,722,122.87	44,456,351.29	41,607,388.60	2,471,197.93
I Quartile	396.25	773,837.50	3,230,344.50	9,765,784.75	8,266,978.75	558,694.75
III Quartile	1,376.25	2,960,685.75	15,496,964.50	52,113,694.25	46,174,798.50	2,586,256.75
Min	107	250,154.00	895,976.00	1,884,923.00	999,658.00	80,715.00
Max	3,209	9,093,120.00	80,414,325.00	236,510,888.00	249,337,726.00	16,190,122.00

4. FINDING AND ANALYSIS

In order to obtain the following results, we used the software EMS 1.3 (Scheel, 2000)for academic purposes. The banks' performance over a seven-year period of time is considered, and then a three-year window is selected. The window length was determined by experimenting with different length size without using formula given by Sun (1988) according to which window length should be four years. We suggest that our panel with 28 banks is large enough to provide adequate discriminatory power in the process of ranking.

We exclude obtained efficiency for DMUs inside every window and in next summarized tables (Table 5 for Profit model and Table 6 for Operating model) give the super-efficiency scores for each bank within each year. In order to calculate results of overall super-efficiency we used average of super-efficiency in five windows (for each bank separately), and average of annual super-efficiency. We rank the all banks by average annual super-efficiency.

Mentioned super-efficiency in the following tables is calculated in the same way as with Anderson-Peterson model, with the note it's about input orientation and CRS assumption. In the following text efficiency and super-efficiency will be considered as synonyms.

Profit model

Based on the analysis of the average efficiency (by years) only two banks are efficient (Agroindustrijska komercijalna banka and JUBMES banka) while all other banks show some kind of inefficiency. Even 11 banks out of 28 have efficiency score between 60% and 70%.The least efficient bank overall was Privredna banka Beograd. As much as seventh-teen bank have efficiency lower than average. It's interesting that Raiffeisenbanka and Volksbanka, since 2005 until today have constant efficiency increase, from previous 43.26% to 95.42% and from 27.74% to 99.63% respectively. JUBMES banka is the most dynamic in efficiency changes. If we want to determine which banks have the biggest inter-annual increase in efficiency

we can see that those banks are JUMBES banka and Banka Postanska stedionica. Their peaks took place between 2007. and 2008. At the contrary the largest decreases in efficiency belong to KBC banka (between 2005. and 2006.) and Agroindustrijska komercijalna banka (between 2007. and 2008.)

Table 5. Superefficiency according to profit model

Rank	Bank name	Average efficiency per year [%]							Overall super-efficiency	
		2005	2006	2007	2008	2009	2010	2011	by windows	by years
1	Agroindustrijska komercijalna banka	154.70	199.29	223.52	150.56	111.74	86.69	94.63	151.92	145.87
2	JUBMES banka	137.07	105.79	71.59	149.68	100.53	78.61	112.19	105.56	107.92
3	KBC banka	262.82	109.77	38.59	49.34	57.52	56.64	66.51	73.23	91.60
4	Banka Postanska stedionica	40.96	40.99	27.21	84.93	116.96	99.71	101.42	74.07	73.17
5	Čacanska banka	77.79	56.50	56.73	67.66	78.60	84.05	85.45	70.22	72.40
6	Srpska banka	68.45	67.46	59.82	72.55	61.40	77.85	88.75	68.61	70.90

Operating model

Erste banka can be considered as bank on the right path because in the whole analyzed period, except 2006. its efficiency score never fell. The same conclusion is made for Findomestic bank. All the other banks have more dynamic efficiency changes. Five banks that have the biggest amount of efficiency decrease are: ProCredit Bank, Hypo Alpe-Adria-Bank, Univerzal banka, Komercijalna banka and Srpskabanka. In operating model we can see that there is no bank with efficiency lower than 50%, while four banks have efficiency score above 100% (Agroindustrijska komercijalna banka, Banka Postanska stedionica, Volksbank, ProCredit Bank). As mentioned in the previous model, seven banks, in the case of this model, have efficiency between 60% and 70%, which also represents the range with most banks. In the case of operating model the least efficient bank overall was Razvojnabanka Vojvodine. Banks which have the biggest inter-annual increase in efficiency are Banka Postanska stedionica (between 2006. and 2007.) and Agroindustrijska Komercijalna banka (between 2005. and 2006.). It's interesting that these two banks also had the largest decrease in efficiency between 2007. and 2008.

Table 6. Superefficiency according to operating model

Rank	Bank name	Average efficiency per year [%]							Overall super-efficiency	
		2005	2006	2007	2008	2009	2010	2011	by windows	by years

Analysis of the entire banking sector

Based on previous analysis, Table 7 shows banks' participations in different aspects of efficiency within whole banking sector (given in percentages). Separately looking at profit and operating aspects we can conclude that the largest percentage of the banks have efficiency between 60% and 70%. In profit model 92.86% of the banks have efficiency below 100% and the same goes for 88.89% of banks in operating model.

Table 7. Frequency distribution for overall super-efficiency by years separately according to used models

Overall super-efficiency by years						
Statistic	Profit model			Operating model		
	Frequency	Percentage	Cumulative Percentage	Frequency	Percentage	Cumulative Percentage
$E < 0.4$	0	0.00%	0.00%	0	0.00%	0.00%
$0.4 \leq E < 0.5$	7	25.00%	25.00%	0	0.00%	0.00%
$0.5 \leq E < 0.6$	4	14.29%	39.29%	4	14.81%	14.81%
$0.6 \leq E < 0.7$	11	39.29%	78.57%	7	25.93%	40.74%
$0.7 \leq E < 0.8$	3	10.71%	89.29%	5	18.52%	59.26%
$0.8 \leq E < 0.9$	0	0.00%	-	6	22.22%	81.48%
$0.9 \leq E < 1.0$	1	3.57%	92.86%	2	7.41%	88.89%
$1.0 \leq E < 1.1$	1	3.57%	96.43%	2	7.41%	96.30%
$1.1 \leq E < 1.2$	0	0.00%	-	0	0.00%	-
$1.2 \leq E < 1.3$	0	0.00%	-	1	3.70%	100.00%
$1.3 \leq E < 1.4$	0	0.00%	-	0	0.00%	-
$1.4 \leq E < 1.5$	1	3.57%	100.00%	0	0.00%	-

Looking at banks' operating efficiency through their annual operations (Table 8) for the period from 2005. to 2011. we can see that the banking sector had its highest peak in 2005 (88.80%), and after that it oscillated between 74.64% – 88.80%, with average value of 80.75%. If we look at profit model, the average annual efficiency increased every year, so it had its highest peak in 2011. (80.24%). Reason for this may be found in banking sector's situation, which is that the banks are more oriented at income from already given loans. Reasons for banks' orientations at already given loans may be found in the lack of payment capable clients or in the long-term impacts of GFC.

Table 8. Banks efficiency over years separately according to used models

Banks super-efficiency by years [%]							
Models	2005	2006	2007	2008	2009	2010	2011
Profit	61.01	51.43	49.67	68.38	71.65	74.96	80.24*
Operating	88.80*	74.64	86.19	75.87	76.24	85.67	77.88

Note: Asterisk (*) indicates the best average

Efficiency trends for some mentioned banks, are shown on the following figures: (Profit model – Figure 1) and (Operating model – Figure 2).

Figure 1:Efficiency trends for Profit model

Figure 2: Efficiency trends for Operating model

5. CONCLUSIONS

This paper employs a window DEA to evaluate the efficiency from the profit and operating aspects of the bank sector in Serbia during from 2005 to 2011 period. Using panel data and Window analysis we got the opportunity to realize efficiency trends in the banking sector in Serbia, and to perform the same ranking as in the Anderson-Peterson model.

Further analysis revealed that the majority of banks are located in the range of efficiency from 60% to 70%, regardless of whether it is a profit or operating efficiency of the banks. Only one bank (Agroindustrijska komercijalna banka) exceeds efficiency of 100% in both observed aspects, in fact, only five banks exceed the efficiency of 100% in some of the analyzed models. During the period in which banks were analyzed, if we are looking at profit model, it is evident that the banking sector has the annual constant increase in efficiency. In the operational model minor fluctuations are observed, that can't be clearly connected with GFC, we only can assume that there is a potential impact of GFC's long life, but if we want to confirm the impact GFC it would be necessary to conduct additional analyzes. In the case of operating model, the banking sector firstly shows the effects of bank privatization and saturation in the issuance of loans.

Based on this example it's very clear that when the goal of future analysis is set properly, and used inputs and outputs are appropriate, then the Window analysis can be used on panel data.

Summary: By introducing the Bologna Declaration, Serbia has aligned itself among countries with modernized and contemporary higher education system. The old, under-functional and flexible system has been replaced by new one that should facilitate and accelerate education. Therefore, there is a need to analyze that system as well as the effects of its introduction. This paper measures the efficiency of studying at faculties of Belgrade University. As a method for measuring efficiency, DEA (Data Envelopment Analysis) will be used, which is usually used in education and generally in the non-profit sector. For the purposes of further analysis, extensions of a basic model have been applied: bilateral CCR model and CCR model with categorical variables. The obtained results indicate that declaration is not equally well implemented at all faculties, and that there is a lot of space for increasing the studying efficiency. The faculties that represent the benchmarks for inefficient ones are isolated, with the aim to enable more successful and more efficient studying and further adjustments and adoption of Bologna Declaration.

Key words: Data Envelopment Analysis, Faculties, Efficiency, Bilateral model, Categorical variables, Ranking

1. INTRODUCTION

The main question that most of pupils of final years of secondary schools ask themselves is "Which faculty should I enroll", but also "Which faculty is best for me". Along the profession they want to deal with, the factor that can influence on a selection of the future faculty is equipment, method and quality of studies and more. This topic is therefore shown interesting to a number of authors which tried to establish what distinguishes one faculty from the other, but also which are the key factors that influence on their work quality and efficiency. Data envelopment analysis is one of the techniques that is widely used to analyze faculties and universities with the aim of their comparison and efficiency evaluation.

For example, Jill Johnes (2005) writes about efficiency evaluation of the universities in the UK using the DEA method. Her paper deals with efficiency evaluation of universities keeping in mind the most important input – quality of students at the beginning of studying. The factors that are relevant in the efficiency evaluation she observed the gender, school type and number of graduates.

Other authors (Kuah & Wong, 2011) in their paper mentioned two models of which one is refers to evaluation of teaching efficiency, and the other one to research efficiency. As concerns the first model, inputs are: number of academic staffs, number of taught course students, average students' qualifications, University expenditures, and outputs: number of graduates from taught courses, average graduates' results, graduation rate, graduates' employment rate. As for the other model, inputs are: University expenditures, number of research staffs, average research staffs' qualifications, number of research students, research grants, and outputs: number of graduates from research, number of publications, number of awards, number of intellectual properties.

Abbott & Doucouliagos (2001) observe and measure technical efficiency of Australian University system. In this context, technical efficiency is refers to the fact that institution cannot produce more output based on existing input. This means that technical efficiency of university cannot provide more output that refers to teaching and research based on labor, capital and other inputs. Efficiency proportion is a range to which institution has advantage of returns to scale by tampering its size according to the optimum. For inputs and outputs they took: inputs – total number of academic staff, number of non-academic staff, expenditures of all other inputs other but labor inputs, value of non-current assets; outputs: number of equivalent full-time students, number of post-graduate and under-graduate degrees enrolled, number of post-graduate degrees conferred, number of under-graduate degrees conferred.

Breasley (1989) dealt with the same subject matter and he stated the following inputs: general expenditure, equipment expenditure, research income; and outputs: number of undergraduates, number of postgraduates on taught courses, number of postgraduates who are doing research, research income.

Especially interesting paper for this study is paper by Avkiran (1999). Using three models with different combinations of inputs and outputs, he performed the efficiency evaluation of universities (Table 1).

Table 1: Three Avkiran's models

Model 1	Input	Academic staff; Non-academic staff
	Output	Undergraduate enrolments; Postgraduate enrolments; Research quantum
Model 2	Input	Academic staff; Non-academic staff
	Output	Student retention rate; Student progress rate; Graduate full-time employment rate;
Model 3	Input	Academic staff; Non-academic staff
	Output	Overseas fee-paying enrolments; Non-overseas fee-paying enrolments

Based on experiences of these authors, similar analysis was applied on faculties of Belgrade University. The aim of research is the efficiency analysis of studying at faculties. The reason for this type of analysis is lack of data that could be used for determining the scientific and research efficiency, technical efficiency and others. University of Belgrade is made of 31 faculties of which 24 faculties are included in the analysis because of data availability. All these faculties can be divided into two groups, with regard of scientific field to which they belong, thus there are technical-technological, nature and mathematics (14 faculties) and faculties of social sciences and humanities (10 faculties). The second division is by number of years of undergraduate studies: four-years (19 faculties) and three-years (5 faculties). All data were collected from the official web site of the University of Belgrade (University of Belgrade, 2012) and refer to the generation of students enrolled in 2006/2007, four years after enrollment. This is one of the first generations that are enrolled on studies compliance with Bologna Declaration which aims to accelerate schooling and increase student passing. Still, there is not enough the information on whether the Declaration was well carried out, but with this analysis of the studying efficiency will get a little bit more information on this subject.

According the availability of data (University of Belgrade. (2012)) the following input-output factors are selected:

Input	Output
<ul style="list-style-type: none"> Number of academic staff Number of non-academic staff Number of students enrolled for the first time 	<ul style="list-style-type: none"> Number of graduated students Quality of students (average score of generation)

In the first phase of analysis, all faculties are divided into two groups: faculties of technical-technological group and faculties of social sciences and humanities group, with aim of finding the differences in the studying efficiency these two groups. In the second phase, these faculties are divided on four-year and three-year faculties, to avoid the impact of duration of studies at the ultimate outcome.

Paper is conceptualized so the second chapter provides an overview of the methodology which was applied in this paper, and the third chapter gives the analysis of obtained results.

2. METHODOLOGY

Efficiency, as one of the basic assumptions of economy, represents the quotient of output and input of certain entity, and tendency is to make this quotient larger, so the business results of this entity surpass the investment in it. In the case of one entity, that has one input and one output, calculation of the efficiency can be easily performed using the formula:

$$\text{Efficiency} = \text{output} / \text{input} \quad (2.1)$$

However, in reality this is not a case, so usually there are a number of entities or DMUs (Decision Making Unit) which should compare and which has a number of inputs and outputs. In this case, the following formula can be implemented:

$$\text{Efficiency} = \text{sum of weighted outputs} / \text{sum of weighted input} \quad (2.2)$$

In solving these problems is used DEA (Data Envelopment Analysis). DEA is specially designed non-parametric technique for measuring the efficiency of complex entities with diverse inputs and outputs. DEA become for a very short time the leading method for efficiency measurement, which is indicated by a number of papers in this field (Emrouznajed et al, 2008). DEA method is presented in 1978 by Charnes, Cooper and Rodes (Charnes et al, 1978). The basic characteristic of the DEA method is that each DMU is estimated as relative efficient or relative inefficient. By the same authors, DMU can be considered as efficient only if these two conditions are not fulfilled:

- It is possible to increase any output without increasing any input and without decreasing any other output
- It is possible to decrease any input without decreasing any output and without increasing any other input

Beside the fact that for each DMU it can be showed whether it is efficient or not, DEA for inefficient DMUs define benchmarks, i.e. efficient units on which the inefficient should look up to and towards to them to improve its performance so it becomes the efficient.

DEA has proved to be especially useful for application in nonprofit sector (health, education, sports...) that is characterized by their diverse inputs (technical, technological, ecological, social and other). It should be mentioned that DEA is not a tool for prediction and it can just provide the insight into current or past state of efficiency of certain entities.

General advantages and flaws of the DEA method can be represented as follows (Table 2):

Table 2: Advantages and disadvantages of the DEA method

Advantages	Disadvantages
It can operate with diverse inputs and outputs	Even the smallest error in data can disrupt the results
Inputs and outputs can be diverse	DEA measures the relative efficiency, i.e. entities compares to each other, not with the theoretical maximum
Great flexibility	Great sensitivity on changes of input-output data sets
Indicates to inefficient units on which efficient units they should look up to	It doesn't provide concrete solution for increasing the efficiency, but only the exemplary units

There are several different models that are used for solving the problem, and basic factors that affect to which model will be chosen:

- Returns to scale (if it is constant or variable)
- Orientation (input or output)
- Limiting the weights
- Exogenous variables, etc.

CCR (Charnes-Cooper-Rhodes) DEA model assumes constant returns to scale (with increasing/decreasing the input, the outputs proportionally increases/decreases). Suppose that x_{ij} represents input i ($i=1, \dots, m$) and y_{rj} represents output r ($r=1, \dots, s$) of DMU _{j} ($j=1, \dots, n$). The primal form of DEA model for relative efficiency evaluation is as follows:

$$(\text{Max}) h_k = \sum_{r=1}^s \mu_r y_{rk} \quad (2.3)$$

s.t.

$$\sum_{i=1}^m v_i x_{ik} = 1 \quad (2.4)$$

$$\sum_{r=1}^s \mu_r y_{rj} - \sum_{i=1}^m v_i x_{ij} \leq 0, \quad j = 1, 2, \dots, n \quad (2.5)$$

$$\mu_r \geq \varepsilon, \quad r=1, 2, \dots, s, \quad v_i \geq \varepsilon, \quad i=1, 2, \dots, m \quad (2.6)$$

Dual model:

$$(\text{Min}) Z_k - \varepsilon \left(\sum_{r=1}^s s_r + \sum_{i=1}^m s_i \right) \quad (2.7)$$

s.t.

$$\sum_{\substack{j=1 \\ j \neq k}}^n \lambda_j y_{rj} - s_r^+ = y_{rk}, \quad r=1, 2, \dots, s \quad (2.8)$$

$$Z_k x_{ik} - \sum_{j=1}^n \lambda_j x_{ij} - s_i^- = 0, \quad i=1, 2, \dots, m \quad (2.9)$$

$$\lambda_j, s_r^+, s_i^- \geq 0; \quad j=1, 2, \dots, n, \quad r=1, 2, \dots, s, \quad i=1, 2, \dots, m, \quad Z_k - \text{unrestricted} \quad (2.10)$$

where:

h_k, Z_k – relative efficiency of k -th DMU

n – number of DMU

m – number of inputs

s – number of outputs

μ_r – weighting coefficient for the output r

v_i – weighting coefficient for the input i

s_i^- and s_r^+ – show how much is possible that k -th DMU individually reduce the i -th input and increase r -th output to become efficient

λ_j – is the dual weight indicating the importance assigned to DMU $_j$.

Generally, all models can have dual orientation: input and output. In input-oriented model efficiency is improved through a proportional reduction in inputs, and output-oriented model requires proportional increase in outputs. Specifically, the input-oriented model project inefficient DMU to the left (horizontal) side of limit point, and output-oriented model make vertically projection. Solutions that provide output and input oriented models are connected.

One extension of the basic model allows us to compare the efficiency of two groups of entities and it is called bilateral model. This model is suitable in a situation where we have two groups of entities A and B and when it is necessary to analyze the differences between two groups. Each DMU from A (B) group should be compared with respect to all entities from another group and thus to further highlight the differences between groups. Model is shown below (Cooper et al, 2006):

$$\min \theta \quad (2.11)$$

s.t.

$$\sum_{j \in B} x_j \lambda_j \leq \theta x_A \quad (2.12)$$

$$\sum_{j \in B} y_j \lambda_j \geq y_A \quad (2.13)$$

$$\lambda_j \geq 0, (\forall j \in B) \quad (2.14)$$

The null hypothesis of this model is that two groups have the same distribution of efficiency results. The obtained results can be used for further statistical tests.

In real situations we encounter the case that there are certain categories of entities that are mutually more similar than others (they have similar behaviour, circumstances of the business, etc.). In this case, it is not appropriate to compare each DMU with all entities, but only to those entities that belong to the same category or group.

These problems are solved by introducing categorical variables (Banker & Morey, 1986). They introduced L new binary variables d_i^k for each DMU, and $L+1$ is the total number of values which one categorical input can have. The model itself remains the same with the addition of the following limitations:

$$\sum_{j=1}^n \lambda_j d_j^l \leq d_k^l \quad (2.15)$$

$$d_k^l = \{0,1\}, l = 1, 2, \dots, L \quad (2.16)$$

These restrictions ensure that the reference group for each DMU_k consists of only those units that have m -th input in the same or lower category than themselves.

3. RESULTS

Since some faculties don't have publicly available information about inputs and outputs referred to in this paper, these faculties will be excluded from our study. These faculties are missing information of the number of graduates, as well as the quality of students at output (average score), and these faculties are:

- Faculty 15
- Faculty 16
- Faculty 17
- Faculty 18
- Faculty 19
- Faculty 20
- Faculty 21

For the purposes of the first analysis, faculties were divided into two groups:

Table 3: Groups of faculties in bilateral CCR model

Technical, Technological, Natural and Mathematical Faculties - TTNM	Faculties of Social Sciences and Humanities - SSH
<ul style="list-style-type: none"> ▪ Faculty 1 ▪ Faculty 2 ▪ Faculty 3 ▪ Faculty 4 ▪ Faculty 5 ▪ Faculty 6 ▪ Faculty 7 ▪ Faculty 8 ▪ Faculty 9 ▪ Faculty 10 ▪ Faculty 11 ▪ Faculty 12 ▪ Faculty 13 ▪ Faculty 14 	<ul style="list-style-type: none"> ▪ Faculty 22 ▪ Faculty 23 ▪ Faculty 24 ▪ Faculty 25 ▪ Faculty 26 ▪ Faculty 27 ▪ Faculty 28 ▪ Faculty 29 ▪ Faculty 30 ▪ Faculty 31

To solve this problem we used already mentioned bilateral CCR model, which is specialized in comparing two groups of entities. Basic statistics for these two groups of faculties is represented in the following table:

Table 4: Descriptive statistics of bilateral CCR model

	TTNM group	SSH group
Number of DMU	14	10
Maximal efficiency	6.260412918	1.291367127
Minimal efficiency	0.537950189	0.292222496
Average efficiency	2.274124596	0.780333299
Standard deviation	1.701689542	0.253606038

Presented descriptive statistics of efficiency of the two groups shows significant differences between them. The null hypothesis (the two groups have the same distribution of efficiency results) is rejected by Wilcoxon rank-sum test (Cooper et al, 2006). It is shown that the TTNM group came out with much better results than the efficiency of SSH group. This conclusion sharply reduces further possible applications of statistics in order to have more detailed analysis of the two groups.

Considering that studies on certain faculties lasts three and on certain faculties four years, there is a need to point that important factor, because the data relate to a period of four years from the time of enrollment, and thus are favored three-year faculties (students had a year longer to finish faculty). CCR model with categorical variables and with output orientation is thus especially suitable in this case. In order to eliminate the influence of that additional year, a comparison of faculties will be made as follows: four-year faculties will be compared only to themselves while the three-year with all faculties (three-year and four-year).

First group of faculties (three-year) include: Faculty 1, Faculty 5, Faculty 6, Faculty 7 and Faculty 14, while all others belong to other group (four-year). The results are shown in the following table:

Table5: The results of CCR model with categorical variables

Rank	DMU	Score	Cat.
1	Faculty 1	1	2
1	Faculty 8	1	1
1	Faculty 23	1	1
1	Faculty 22	1	1
1	Faculty 28	1	1
1	Faculty 14	1	2
1	Faculty 4	1	1
1	Faculty 2	1	1
9	Faculty 3	0.909402	1
10	Faculty 27	0.900031	1
11	Faculty 25	0.875592	1
12	Faculty 24	0.858403	1
13	Faculty 26	0.81863	1
14	Faculty 31	0.761941	1
15	Faculty 9	0.643958	1
16	Faculty 7	0.636014	2
17	Faculty 29	0.588564	1
18	Faculty 10	0.534048	1
19	Faculty 11	0.475185	1
20	Faculty 13	0.465358	1
21	Faculty 6	0.440676	2
22	Faculty 12	0.417451	1
23	Faculty 30	0.377182	1
24	Faculty 5	0.256675	2

Table6: Descriptive statistics of categorical CCR model

	Four-year faculties	Three-year faculties
Number of DMU	19	5
Maximal efficiency	1	1
Minimal efficiency	0.377182	0.256675
Average efficiency	0.769776	0.666673
Standard deviation	0.222182	0.297431

The results indicate that eight faculties are efficient and 16 are not. Also, efficient faculties appear as benchmarks to inefficient units with following frequencies:

Table7: Number of appearances as benchmark unit

Faculty	Number of appearances as an benchmark unit	Category
Faculty 2	15	1
Faculty 8	4	1
Faculty 22	4	1
Faculty 1	3	2
Faculty 4	3	1
Faculty 23	1	1
Faculty 28	0	1
Faculty 14	0	2

It is particularly important that efficient faculties are among those found in the first and those from second group, so none group is favoured. Faculty 1 is one of efficient faculties. The reason for its good position is the high percentage of students who have finished faculty in four years – 80.52% of enrolled students graduated, which is far better than all others (the first after him by the percentage of graduates is Faculty 7 with 37.21%). In addition, faculty have a relatively small number of employees (especially non-academic staff) which means that with fewer people they achieved results which other faculties achieve with significantly higher number of employees (Faculty 7, Faculty 6 and Faculty 5). Faculty 14 is one more efficient faculty from group of three-year faculties and main reason is his average mark (score) of 9.46. On the other hand, Faculty 23 and Faculty 2 which are also efficient due to the small number of employees. For each DMU, DEA is looking for reasons for its efficiency, and in this case number of academic and non-academic staff is highlighted as most important. Also, Faculty 2 appeared 15 times as benchmark unit to other inefficient units, which puts it on first place regarding that criterion. Faculty 8, Faculty 4 and Faculty 28 deserve their place among efficient units because of large number of students who completed studies for four years.

Faculties that are close to the efficiency frontier are Faculty 27, Faculty 3 and Faculty 25. Benchmark for Faculty 3 is Faculty 2, and it should reduce the number of academic staff for 24.88% and non-academic for 23.62%, while increasing the number of graduates for 179.61% to become efficient. Important factor which influence Faculty 27 to be inefficient is the number of enrolled students. In order to become efficient it should reduce the number of enrolled students for 67.25%, to reduce number of non-academic staff for 13.82% and to increase for 11.11% both, number of graduate students and their average score (benchmarks for this faculty are Faculty 8 and Faculty 22). Faculty 25 has three benchmarks: Faculty 8, Faculty 22 and Faculty 2. In order to become efficient he needs to reduce number of non-academic staff for 9.84%, to increase the number of graduates for 14.21% and to increase average score from 8.49 to 9.69.

Faculties with lowest ranks are Faculty 30 and Faculty 5, one from each category. The reasons are mainly due to the extremely low percentage of graduated students (11.33% and 6.11% respectively), low average score (7.57 and 8.88 respectively) and relatively large number of employees.

4. CONCLUSION

Data Envelopment Analysis, as non-parametric approach for evaluating efficiency of different entities, proved to be very successful in applications in the non-profit sector. Since education belongs to that sector, there is number of methods and applications of DEA in education, especially in high education. State faculties are largely financed from the budget, and therefore a lot of their success depends on the quality of studies and how to attract students. Following the example of the analysis of many foreign authors, in this paper we analyze efficiency of studying at University of Belgrade. Faculties were first grouped into two categories: technical and technological faculties and faculties of social sciences and humanities and it were observed that there is a significant difference in efficiency among these groups. In order to make further analysis and to neutralize impact of number of years (three or four), we divided faculties to those with three-year and four-year studies. There were efficient faculties in both groups, but much more were inefficient.

Implementation of the Bologna Declaration in Serbia was officially started in 2005. Now we have first graduates of that new system, and the effects and results of a new system of high education may be considered more accurate and reliable than previous years. Now we have situation that on the one hand we have faculties who have managed to achieve the primary goal: to reduce the time of studying and increase passing from one year to another. On the other hand, there are faculties which struggle with new system. So we can conclude that high-educational system of University of Belgrade can still improve. The goal of this research was to measure only the efficiency of studying while some other aspects of performance are ignored (scientific research, equipment, etc.). Also, we exclusively observed time period of four years after enrolment of the base generation. There is a need for further perfecting and implementing of Bologna system of high education if we want to make our studies more efficient and qualitative.

Abstract: Data Envelopment Analysis (DEA) is an objective method which assigns weights to criteria for each decision making unit (DMU) separately. This flexibility in assigning can lead to wrong estimates of DMUs as a result of neglecting certain inputs (outputs) that have too large (or too small) values in comparison with other units. On the other hand, multicriteria methods assign weights based on a subjective opinion of decision makers. A new aggregated measure calculated as normalized production of DEA and AHP is introduced to overcome weaknesses of both methods. Furthermore, the aggregated measure is used for the evaluation of the first-year study subjects' relevance for the assessment of future students' success.

Keywords: DEA, AHP, aggregated measure.

1. INTRODUCTION

This paper attempts to make an evaluation of criteria based on their weights, obtained by combining the results of one objective and one subjective approach. Data envelopment analysis (DEA) is an objective method for determining the relative efficiency of Decision Making Units -DMUs. The relative efficiency is calculated as a ratio of the weighted sum of outputs and weighted sum of inputs. At the same time, criteria weights (inputs and outputs) are variables in the model and they are obtained as its solution. When solving DEA models, the complete flexibility in the process of choosing weights is assumed, so it is possible that some criteria might be assigned as highly important only because of their appropriate values (very low for inputs or very high for outputs in comparison with other DMUs under evaluation). This may lead to misjudgement of the importance of the criteria that do not correspond to practical experience. In literature this problem is solved by the combination of the results of subjective and objective methods such as integration of DEA and multicriteria method TOPSIS in (Chen, Li, Xui & Lui, 2009). The authors developed DEA-based optimization models to facilitate identifying parameter information regarding criterion weights and quantifying qualitative criteria in TOPSIS. The weight determination model that incorporates subjective information provided by the Analytic Hierarchy Process (AHP) and objective information to form Data Envelopment Analysis is given in (Liu, 2003).

In this paper, comparative analyses of DEA and AHP and their aggregation are carried out, according to the importance of the first-year study subjects for choosing an appropriate study program on the example of FOS (Faculty of Organizational Sciences). The approach based on DEA for user-oriented ranking that is developed to help students select an appropriate college is shown in (Eff, Klein, & Kyle, 2012). Multicriteria AHP method is used in higher education for selection of candidates for teaching positions (Saaty & Ramanujam, 1983). AHP method was applied to determine the complicity and priority of selection criteria. In the paper (Delibašić, Suknović & Stanačević, 2005) authors have created the system of knowledge management that determines the minimum distance between existing and new cases and gives a recommendation to a student where he/she would be most efficient.

The paper consists of four sections. Apart from the introduction, theoretical basis of DEA and AHP is given. Afterwards, the methodology for study program selection according to the first- year subjects is illustrated on hypothetical examples. The methodology is based on the aggregate AHP-DEA measure. In the fourth section, concluding remarks and further research directions are given.

2. BACKGROUND

The aggregated measure as a combination of one objective and one subjective measure are used to determine the importance of the criteria. The DEA method is used for obtaining objective measures, while AHP method is used for obtaining subjective measures. The bases of these methods are given in this section.

2.1 DEA

DEA has been widely used for evaluating the relative performance of similar decision making units (DMUs) with multiple inputs and outputs. The original DEA model was given by authors, Charnes, Cooper and Rhodes (1978), who tried to generalized single-input to single-output ratio definition of efficiency to ratio of sum of weighted outputs to sum of weighted inputs. Suppose that DMU_j ($j = 1, \dots, n$), within set of n units, uses inputs x_{ij} ($i = 1, \dots, m$) to produce outputs y_{rj} ($r = 1, \dots, s$), absolute efficiency measure (Podinovski, 1999) model is as follows:

$$E_j = \frac{\sum_{r=1}^s u_r y_{rj}}{\sum_{i=1}^m v_i x_{ij}} \quad (1)$$

where v_i ($i = 1, \dots, m$) are input multipliers and u_r ($r = 1, \dots, s$) are output multipliers (weights).

The above definition corresponds to a discrete multicriteria decision making (MCDM) method. The determination of weights is a very sensitive and complicated process. The weights selected a priori, as in MCDM models, can significantly affect the results of the efficiency calculation. Following that idea, the authors of DEA model (Charnes, Cooper, & Rhodes, 1978) allowed each DMU to choose the most appropriate set of weights in order to become as efficient as possible in comparison with the other units in the observing set. Relative efficiency ratio is scaled between 0 and 1, and all efficient units have the same ratio equal to 1. The LP weighted form of the basic CCR model is as follows:

$$(\max) h_k = \sum_{r=1}^s u_r y_{rk} \quad (2)$$

st.

$$\sum_{i=1}^m v_i x_{ij} = 1 \quad (3)$$

$$\sum_{r=1}^s u_r y_{rj} - \sum_{i=1}^m v_i x_{ij} \leq 0, \quad j = 1, \dots, n \quad (4)$$

$$u_r \geq \varepsilon; \quad r = 1, 2, \dots, s, \quad (5)$$

$$v_i \geq \varepsilon; \quad i = 1, 2, \dots, m,$$

The optimal values of efficiency scores h_k are obtained by solving the linear model (2)-(5) n -times (once for each DMU in order to compare it with other DMUs). As a solution of basic CCR DEA models, efficiency score h_k is 1 for all efficient units and lower than 1 for all inefficient units. All inefficient units are enveloped by production frontier, consisted of efficient DMUs, and for each of them an analyst could find benchmark (real-efficient or virtual-composite peer unit lying on efficiency frontier).

2.2 AHP

A subjective model which is widely used in decision-making is the analytic hierarchy process (AHP) introduced by Saaty (1980). Every problem is treated in terms of hierarchies - a system of stratified levels, each consisting of several elements. AHP views the problem as a system and decomposes it into elements. It involves pairwise comparisons of decision variables (e.g., objectives, alternatives according to some attribute they share or a criterion they should meet. Preference is denoted by a vector of weights following an AHP scale of relative importance which is the basis for calculation of a relative weight for each decision variable. Furthermore, inconsistent comparisons are addressed by means of an internal procedure which detects inconsistencies according to an arbitrary consistency ratio of 10%. Remarks on AHP with review of basic axioms and ways of altering weights and rankings are given in detail in (Dayer, 1990). The procedure, however, is limited by the number of factors that can be compared. An individual cannot simultaneously compare more than nine objects without being confused (Saaty, 1980). A comprehensive overview of the AHP method and its application in different areas is given in (Vaidya & Kumar, 2006).

3. CRITERIA WEIGHTINGS

There are four study programs at the Faculty of Organizational Sciences (FOS): Information systems (IT), Management (ME), Quality management (KV), and Operations management (OM). On completion of the first year, which has common subjects for all programs, students choose one of these four programs. The aim of this work was to develop a methodology for determining the weights of these subjects on each of four programs to help in prediction of students' final achievement. For that purpose, comparative evaluation of the first-year subjects based on DEA method, AHP method, Aggregate AHP-DEA measure is done on the data collection as in (Delibašić, Suknović & Stanačević, 2005). The data used here were obtained from the Faculty of Organizational Sciences Students' Service database. The data on 847 graduates who enrolled FOS 2002

and 2006 were selected to be analyzed. For each student, we have collected information on 11 subjects' marks*: Economics (EC), Mathematics1 (MA1), Management (MN), Fundamentals of Information Communication Technology (OIKT), Sociology or Psychology (S/P), Foreign Language 1 (SJ1), Mathematics 2 (MA2), Fundamentals of Organization (OO), Production systems (PS), Introduction to information Systems (UIS), Foreign Language 2 (SJ2). The Average mark (GPA) was used as a key performance that indicates students' success. These data were used in all approaches. Descriptive data statistics is given in Table 1.

Table 1. Descriptive statistics of entry data

		Subjects											Average			
Program	No. of students		EK	MA1	MN	OIKT	S/P	SJ1	MA2	OO	PS	UIS	SJ2	Marks in first year	Marks in the end	
IT	322	Average	7.2	8.02	7.75	8.29	8.02	7.5	8.09	8.48	8.48	8.13	7.66	7.97	8.36	
		SD	1.27	1.24	1.22	1.02	1.28	1.26	1.17	1.17	1.19	1.03	1.32	0.74	0.63	
MN	350	Average	7.12	7.43	7.79	7.75	8.09	7.51	7.49	8.4	8.06	7.72	7.59	7.72	8.35	
		SD	1.2	1.14	1.26	0.99	1.21	1.18	1.2	1.22	1.25	1.08	1.27	0.67	0.62	
KV	144	Average	6.92	7.27	7.44	7.68	7.53	7.11	7.39	8.03	7.92	7.63	7.16	7.46	8.12	
		SD	1.11	1.13	1.23	0.99	1.18	1.08	1.13	1.33	1.24	0.93	1.13	0.65	0.66	
OM	31	Average	7.29	7.84	7.87	8.03	8.23	7.13	8.16	8.13	8.55	7.74	7.26	7.84	8.57	
		SD	1.2	0.81	1.36	0.9	1.21	1.1	0.92	1.1	1.04	0.84	1.16	0.54	0.45	

Table 1 shows that study programs are not unified in terms of the number of students. Students usually choose to study one of the two major programs, IT with 38% and MN - 41.3%. Next on the list is program KV with 17%, while only 3.7% of students choose study program OM. Looking at the average marks in the first year and at the end of the studies it can be seen that students of all study programs tend to improve their results towards the end of studies.

Based on the average marks per subject, we can distinguish three groups of subjects. The first group consists of subjects PS-OO, where students of all study programs achieve similar, high average marks. Another clearly distinctive group consists of subjects where students of all study programs achieve average low marks (EC, SJ1). The third group consists of subjects where no apparent laws could apply to all study programs. Therefore, in-depth analyzes are performed for determining the impact of individual first- year subjects on a particular study program success using DEA and AHP methods.

In determining the priority of the first year subjects that are relevant for predicting future students' success, one objective (DEA) and one subjective (AHP) method are used. The final grade is obtained by aggregating the results of objective (DEA) and subjective methods (AHP). The selection of the first-year subjects that are relevant for choosing a study program, is done based on average weights using DEA method. The value of weights can be reached in two steps. First, we evaluate the relative efficiency of each student. In doing so we determine such a weight for each subject that will show a student as efficient as possible, considering the results during studying, (average mark) compared with other students. In the next step, we determine the average weight for each of 11 first- year subjects.

For assessing the relative efficiency of each student, they are observed as units (DMA). The first-year subjects present 11 inputs, while average mark represents output. Considering the nature of input, information about first- year subject marks are transformed so that they present a deviation of full mark (10). Since the aim of the analysis is to determine the weight of a subject, the input-oriented DEA model (2-5) is selected. Descriptive statistics of DEA results, which are obtained by using specialized software DEA - solver (Cooper, Seiford, & Tone, 2006), divided into study programs according to students' affiliation, is given in Table 2.

Table 2 shows the average values related to efficiency, standard deviation, maximum and minimum values of the efficiency index by study programs. Measured by average efficiency, the OM students are the most successful ones, followed by IT, ME and KV. Approximately equal standard deviation values indicate that homogeneity of all students in all study programs is similar. Maximum efficiency index 1, in the IT study program, is given to the most successful student (with average mark 10) and he/she is the only efficient one and the reference for all other students.

Table 2. Descriptive statistics of DEA results

* Belgrade University ranking system: 5 to 10, where 5 means fail and 10 means full mark.

Program	No. of students	Efficiency			
		Average	SD	Max	Min
IT	322	0.51	0.40	1	0.02
ME	350	0.46	0.40	0.99	0.02
KV	144	0.36	0.38	0.98	0.02
OM	31	0.52	0.40	0.96	0.04

As it is already mentioned, the relative efficiency is calculated as the ratio of weighted sum of outputs and the weighted sum of inputs (eq. 1). This analysis is not focused on determining the efficiency of the student, as is usually the case when applying DEA, but on the weights. One of the DEA output is a matrix of weights for the inputs (outputs). As the ultimate goal of the research is evaluation of subjects which are inputs of DEA, we shall look at the matrix of inputs weights ($v_{ij}, i = 1, \dots, 11, j = 1, \dots, n_k$) with dimensions $11 \times n_k$, where n_k presents the number of students in observed study program ($k=1, \dots, 4$). Based on weights, for every student we calculate average input weights for each study program as follows $z_{ik} = \left(\sum_{j=1}^{n_k} v_{ij} \right) / n_k, i = 1, \dots, 11, k = 1, \dots, 4$.

Their normalized values are given in the table 3.

AHP is used for attribute weightings (determining the weight of subject) of the first- year study subjects, for each study programs. The hierarchy of problem in is set on two levels with a third, pseudo level, similar to (Tadisina, Troutt, & Bhasin, 1991). The described main goal is on the first hierarchy level. As all subjects have different importance (weights) for different study programs ($S_k, k=1, \dots, 4$), the main goal will be observed from different perspectives, that is, for each study program separately. As shown in Figure 1, the study programs are set as pseudo levels below the main goal.

The importance of subjects for each of the study program is determined on the third level criteria: two objective and one subjective criterion ($C_i, i=1,2,3$). The objective criteria are ECTS credits (ECTS) and the average mark. The value of ECTS credits is official information specified in the accreditation program. The values are taken from the Faculty's Student Service database. The subjective criterion is an expert evaluation of relevant subject importance for each study program. It is obvious that subjects are evaluated as set alternatives ($A_i, i=1, \dots, 11$), for each study program separately.

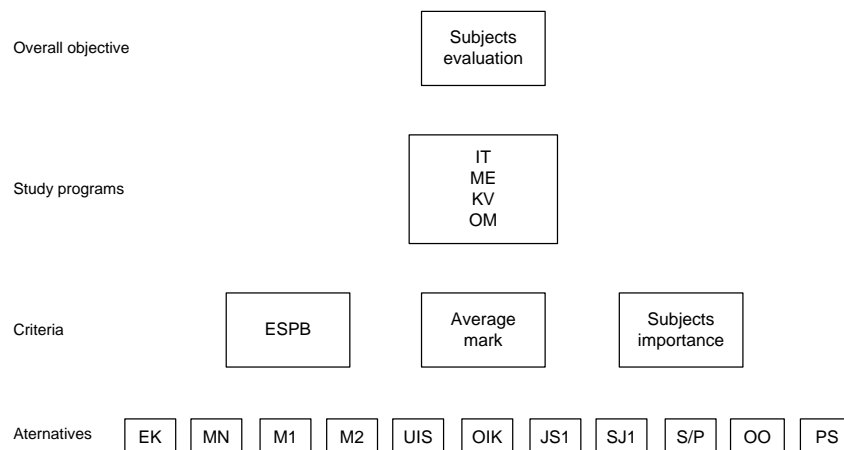

Figure 1. Subject weighting hierarchy

In the first stage of evaluation, the comparisons matrix (pairwise comparison matrix) is created for each study program, based on a subjective expert assessment. In the second phase we enter grades for each alternative, per each criterion. The final result of evaluation is weights of all alternatives (subjects) for each study program separately in relation to the set goal. Weights, which represent the synthesized importance of subjects in choosing study program process ($w_{ik}, i=1, \dots, 11, k = 1, \dots, 4$) are shown in Table 3.

Aggregate AHP-DEA measure

Flexibility in assigning weights when solving DEA model, as an objective approach, can lead to wrong estimates of individual units (students) under consideration. This is the result of neglecting certain inputs (outputs) that have too large (or too small) values in comparison with other units.

In addition, Table 2 shows that standard deviations of subject marks are different. This leads to the situation that DEA cannot make discrimination for subjects with a low standard deviation and that it assigns them very low weights.

On the other hand, when determining the importance of alternatives, AHP does not take into account the information about individual marks, but only the average values and subjective values of decision makers. Since in this research the importance of subjects is crucial, it is necessary to combine objective and subjective assessments. On the one hand, AHP corrects the impact of student marks in some subjects and includes a subjective evaluation of a decision maker and the importance of the subject from the ECTS perspective. On the other hand, the DEA grade brings about objectivity obtained solely only on the basis of empirical values.

The objective weights, determined by DEA and subjective weight w_{ik} determined by AHP, are combined into an aggregate weight ag_{ik} as follows:

$$ag_{ik} = z_{ik} w_{ik} / \sum_{i=1}^{11} z_{ik} w_{ik}, i = 1, \dots, 11, k = 1, \dots, 4.$$

Their values are shown in Table 3.

Table 3. Weighs obtained by DEA, AHP and aggregated DEA-AHP measure

Study program	Method	Subjects										
		EK	MA1	MN	OIKT	S/P	SJ1	MA2	OO	PS	UIS	SJ2
IT	DEA	0.116	0.239	0.089	0.093	0.126	0.076	0.034	0.104	0.105	0.001	0.017

	AHP	0.087	0.082	0.122	0.082	0.084	0.044	0.083	0.141	0.133	0.089	0.053
	AHP-DEA	0.075	0.111	0.189	0.036	0.093	0.025	0.045	0.286	0.138	0.000	0.002
OM	DEA	0.066	0.008	0.344	0.123	0.273	0.005	0.060	0.005	0.115	0.000	0.000
	AHP	0.085	0.096	0.119	0.081	0.084	0.044	0.097	0.123	0.130	0.088	0.053
	AHP-DEA	0.055	0.008	0.402	0.098	0.225	0.002	0.057	0.007	0.146	0.000	0.000

The first thing that can be noticed by weights analysis from Table 3, is that the range of their values is smaller with AHP then with DEA method and that, unlike with DEA, using AHP method, none of the subject has been marked as insignificant.

Normalized weights, according to DEA method, presented in Table 3, show that S/P marks had influence on efficiency of students in all study programs, while subjects ME and OO had significance in determining the efficiency of the students in three out of four student programs. This shows that almost all first-year students have achieved good results from these subjects. The students in IT program have shown good results in MA1. As it was expected this subject will have the biggest influence (0.239) in assessing capability of students to enroll the IT program. The same situation is with the subject of MN in OM study program whose weight is 0.34. But subjects OIKT and UIS, which are expected to be important to IT students, got small weights (below 0.1) which are the result of low standard deviations, that is, there are other subjects that make students more distinctive.

On the other hand, as AHP includes expert evaluation of a subject importance as one of the criteria, subjects OIKT and UIS got highest weights (0.129 and 0.125). The same situation refers to the subject OO in the study program OM. Thus, using DEA method, this subject was given a small value of weighting, while with AHP, where the expert importance grade is high, it was declared as the second most important (0123). By looking at the values in the same table, similar analysis can be made for study programs MN and KV.

Since the aggregated measure is a normalized product of two measures, the objective measure of DEA will have the greater impact on its value because of its wider range of weight values. AHP was able to correct results only for subjects where DEA method has not assigned extremely small weights. Normalized weights of DEA-AHP in Table 3 can be used for predicting future students' success, after completion of the first year of study, resulting in the recommendation which study program they should select. New students' success is estimated by aggregate weight. Potential achievement of five randomly chosen students' on each of four study programs is evaluated based on marks after first year of study as it is given in Table 4.

Table 4.

New student	Subjects' marks											Final mark	Study programs' predictions			
	EK	MA1	MN	OIKT	S/P	SJ1	MA2	OO	PS	UIS	SJ2		IT	ME	KV	OM
DMU1	8	7	8	8	9	9	7	9	9	8	8	IT-8.36	8.05	8.42	8.39	8.32
DMU2	6	6	6	8	7	6	6	9	7	7	7	ME-7.00	6.84	6.96	7.17	6.59
DMU3	7	8	8	7	8	6	7	10	8	7	6	KV-8.09	7.90	8.07	8.36	7.80
DMU4	9	8	10	9	10	8	10	10	10	8	10	OM-9.64	9.15	9.67	9.62	9.83
DMU5	10	10	10	10	10	10	10	10	10	10	10	ME-10.00	10.00	10.00	10.00	10.00

Table 4 shows that the predictions of the students' success are different enough to enable ranking and selection of the most appropriate study program. It can be concluded that some students have not made the right decision, e.g. DMU1 and DMU2, while the above-average students can be successful at each of the study programs, e.g. DMU5. Many students do not opt out of personal interest only, but also for other reasons. The final decision can be made out based on: obtained prediction, students' academic experience, motivation and expectation regarding future career.

4. CONCLUSION

Most students select study programs based on personal preferences related to the subjects the study program includes and career qualification. However, if the study program is to be selected after the first-year of study, we can predict students' success based on the first-year grades evaluation and help them select the most appropriate study program.

In this paper, the prediction of success in each of the four study program is based on the weights assigned to the first-year subjects. First, we have estimated 847 students efficiency using DEA. Subject weights were calculated as the average weight assigned to each subject. Then, using AHP the subjects were evaluated as alternatives based on three criteria: ECTS, average mark, and an expert evaluation of a subject importance to different study programs. Subject weights were identified as synthesized weight alternatives.

Finally, we got weights obtained by aggregate measure which combines the objective DEA and subjective AHP measures. In that way we have reduced the subjectivity of information obtained using AHP, and we have reduced DEA flexibility in assigning weight only on empirical data basis.

Abstract: One of the most popular techniques in strategic planning is the SWOT analysis. The aim of this analysis is to integrate and manage information related to the strengths, weaknesses, opportunities and threats, which the company faces in business. By analyzing this information, we created a basis for selecting the best market positioning strategy for the company. The classical approach to SWOT analysis, however, does not take into account the estimates of the relative importance of these four categories of information, as well as the relative preference of alternative strategies available to the company. Analytical Hierarchy Process (AHP), as a method of multi-criteria analysis, is used to determine the weights for multi-criteria decision making models, and to determine the preferences of the final series of possible alternatives. This method allows defining a quantitative framework for decision making by enabling decision makers to model complex problems of strategic decision making through a hierarchical structure, forming a clear picture about the relationship between objectives, criteria, sub-criteria and alternatives. The integration of algorithms of Analytic Hierarchy Process and SWOT analysis has created a new approach. This approach is known in literature as A'WOT method for making strategic decisions. The procedure of A'WOT method application is presented in this paper.

Keywords: SWOT analysis, Analytical Hierarchy Process, decision making, development strategy of a company

1. INTRODUCTION

The SWOT analysis is a powerful tool in developing and confirming corporate goals and marketing strategy. SWOT is a widely accepted technique used in strategic planning for analysis of internal and external factors relevant for strategic decisions (Wheelen and Hunger, 1995; Hill and Westbrook 1997). The primary purpose of the SWOT analysis is to identify and assign each significant factor, positive and negative, to one of the four categories, allowing decision makers to take an objective look at their business.

SWOT analysis is offering good results, especially for developing and formulating corporate strategies in terms of sudden changes in the business environment. SWOT is a qualitative technique for decision support which relies heavily on the skills and expertise of decision makers, and gives a qualitative overview of internal and external decision-making factors.

However, it appears that there are some problems in the application of SWOT analysis (Hill and Westbrook 1997). Some authors are also proposing more efficient ways of SWOT usage (McDonald 1993). Main problem of the classical SWOT analysis usage is the inability of the analytical approach in assessing the relative importance of the SWOT factors, which results in the problem of evaluating alternative courses of action against those factors.

A promising attempt to support strategic decision-making is combined use of the AHP (Analytic Hierarchy Process) method and SWOT analysis. There is a great potential for strategic decision making in combined usage of AHP (Analytical Hierarchical Process) and SWOT analysis. The main idea is to use AHP for comparison of decision-making factors and determining their relevance, which enables modelling and describing situation in more detailed manner. There are numerous researches about possibilities of using AHP method in the evaluation of SWOT factors, so as alternatives based on that evaluation (Kurtilla et al. 2000; Kangas et al. 2001; Pesonen et al. 2000; Osuna and Aranda 2007). SWOT analysis is offering formal framework for decision making with analytical support of AHP. Combination of these two methods is hybrid algorithm well-known as A'WOT (Kangas et al. 2001, 190). This hybrid method is not so widely accepted, although there are numerous cases confirming advantages of combined method over the classical SWOT analysis.

2. THE SWOT ANALYSIS

One of the most popular techniques used in strategic management is the SWOT analysis. This analysis is used for understanding the current position of the company and defining the strategy to be applied in order to achieve the desired outcome and business goals. SWOT analysis provides detection of positive and negative factors affecting the achievement of strategic goals and provides an opportunity, due to factors affecting, to adapt the ways of achieving strategic goals.

Merits for SWOT analysis is attributed to the research team, consisting of: Albert Humphrey, Marion Doshier, Otis Benepe and Birger Lie from the Stanford University. Also, framework for the SWOT analysis was presented in 1969 by researchers from Harvard University. This framework has become popular in the 1970s due to the assumption that it was built, and which reads as follows: managers can plan the harmonization of enterprise resources with its business environment.

SWOT analysis is commonly carried out within the so-called SWOT matrix in which they are presented qualitative and quantitative dimensions of the enterprise position on the market. SWOT matrix is composed of four elements - field: **S** – *Strengths*, **W** – *Weaknesses*, **O** – *Opportunities* and **T** – *Threats*. Strengths are positive and weaknesses are negative internal factors. Opportunities are positive, while the threats are negative external factors. SWOT analysis is a set of analytical methods by which are possible to compare the strengths and weaknesses with opportunities and threats in the environment (Figure 1). In this way, the SWOT analysis provides a balance between internal capabilities and external possibilities of enterprises.

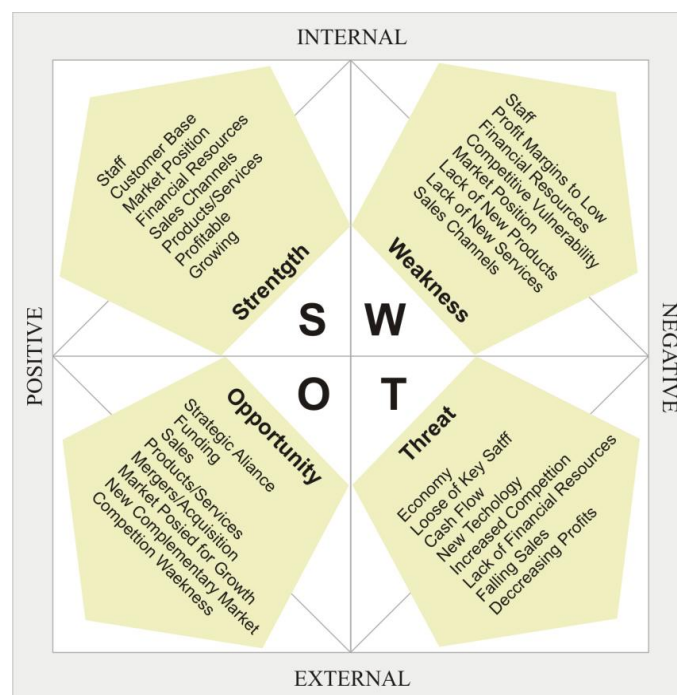

Figure 1: The basic factors in the SWOT analysis

The internal factors (strengths and weaknesses) can be systematized in the following categories:

- 1) Management and organization,
- 2) Operations,
- 3) Finance and
- 4) Other factors

Defining the strengths of the company includes the determination of the “strong points” of the company and answering the following questions:

- Are there unique advantages that make specified company better from the competition?
- Why do clients choose particular company rather than competitors?
- Are there products and services that competitors can not imitate (now and in the future)?

The weaknesses are the weak points of companies. Some of the questions to be answered in defining the weaknesses of the company are:

- Are there any operations or procedures that can be pronounced?
- What and how competitors works better?

Many different factors must be taken into account in the analysis of external environment. These factors, either threats or opportunities, can be grouped into the following categories: economic, social, political - legal, technological, environmental, ethical, and others. The most important part of the external environment is so called industrial environment (customers, suppliers, competitors).

Key issues which must be taken into account in defining the opportunities are:

- What are the attractive opportunities on the market?
- Does the new trends occurring?
- What new opportunities can be predicted for the future?

Threats are external factors beyond the control of the company. It is important that the company is ready to face the threats, even in turbulent situations. Issues to be kept in mind in that case are:

- What competition's actions suppress the development of the enterprises?
- Are there changes in consumer demand, for which they need new features of products and services?
- What harm or change the position of the company on the market?

SWOT analysis has a time dimension too. The time dimension is an extremely important factor in conducting this analysis, and in this context, strengths and weaknesses are treated through the prism of the present based on past business operations, while the opportunities and threats represent the future of a company.

Application of SWOT analysis leads to one of four main conclusions:

1. Strengths overcome weaknesses and opportunities overcome threats - supports the growth strategy,
2. Strengths overcome weaknesses while threats overcome the opportunities – supports the strategy of maintenance,
3. Weaknesses overcome strengths while opportunities overcome threats – supports the strategy of "harvesting".
4. Weaknesses overcome strengths and threats overcome the opportunities – supports the containment strategy.

SWOT can be used for the purpose of wider observing a strategy by the formula: $SA=O/(S-W)$. It provides an answer to an important question- should we invest more in the power company to be stronger (distinctive competence) or to invest in the weakness to do so competitively.

Bearing in mind the above mentioned, it is necessary to emphasize the key benefits of SWOT analysis:

- A key element of strategic options formulation is the alignment of strengths and weaknesses of companies with the opportunities and threats that exist on the market,
- When is used correctly, the SWOT analysis can provide a good basis for the strategy formulation,
- SWOT analysis is widely recognized in the literature as a systematic way to achieve the objective.

However, the SWOT analysis has certain disadvantages:

- According to Mintzberg (1994.), SWOT analysis is rarely effective method, because it is based on the current perception of the company,
- In practice this is often an activity that is not implemented well. After identifying all important "points", decision makers often do not know what to do with the generated data,
- SWOT analysis is not prescriptive, regarding the use of information generated in order to deliver the strategy.

3. ANALYTIC HIERARCHY PROCESS

Analytic Hierarchy Process - AHP is the one of the most popular method of multi-criteria analysis and a tool for decision making on the selection of optimal alternative(s), especially in cases where there is a possibility of a hierarchical structuring of relevant criteria. AHP method is the kind of quantitative technique that can incorporate in the model both qualitative and quantitative criteria (Saaty, 1977, 1994). Multi-criteria decision making problems are those where it is implied that a decision maker suppose to identify the optimal course of action, considering a set of conflict criteria. Complexity in decision making situations involves quantitative and qualitative criteria, different measurement scales, and multiple comparisons. The ability to assign a preference rank for general decision making situations is needed as well as simplicity of methods (Saaty, 1986). The AHP is a suitable method that provides a logical and scientific basis for such multi-criteria decision making problems (Harker, 1988) and has been widely applied to both individual and group decision making scenarios from the early 1980s (Wind & Saaty, 1980; Saaty & Vargas, 1994). AHP is quantitative tool that has been used in almost all problems related to multi-criteria decision making and its application includes about 150 different kinds of problems (Vaidya & Sushil, 2006).

AHP is a method for formulating and analyzing decisions that can successfully be used to measure the influence of many factors relevant to the possible outcomes of decisions made and for forecasting and

performance of relative probability distribution of these outcomes. Applications of AHP can be categorized into two main groups (Saaty, 2010):

- 1) Problems selection, which include evaluation of possible alternative actions for a given decision problem and
- 2) Problems prediction, where it is performed the evaluation future outcomes of alternative for decisions that are taken.

The problem of choice usually involves the evaluation of available alternatives, in terms of fulfillment of the criteria that are considered relevant for the decision. The prediction, by contrast, focuses on evaluating the relative probabilities of future outcomes.

As well, AHP method is well-known subjective approach in determination of relative weights of criteria for other multi-criteria decision-making methods. According to Saaty (1986), the AHP was founded on three design principles: (i) decomposition of the goal-value structure where a hierarchy of criteria, sub-criteria, and alternatives is developed, with the number of levels determined by the problem characteristics; (ii) comparative judgments of the criteria on single pairwise comparisons of such criteria with respect to an upper criteria; and (iii) linear-based synthesis of priorities where alternatives are evaluated in pairs with respect to the criteria on the next level of the hierarchy, and criteria can be given a priority (e.g. preference) expressed as a weight in the AHP matrix.

Let the problem is defined as a general problem of multi-criteria analysis, where it is necessary to evaluate the m of available alternatives, on the basis on n relevant criteria. On the stage of decomposition, the problem is viewed as a hierarchical structure, where the goal is on the top, while the criteria by which a decision is made are treated at the lower levels. At the lowest hierarchical level is a range of alternatives, which comparisons is necessary to make.

The next phase involves, in addition to collecting data and its peer evaluation. There is, first of all, makes pair-wise comparison of criteria and alternatives at a given level of hierarchy, but also in relation to the criteria of the directly higher level. Pairwise comparison of alternatives is done in response to the question of which of the two observed attributes that characterize an alternative to the given criteria, is better in terms of meeting the criteria and contribution to the certain objective. Strength of preference is expressed by the ratio scale with increments of 1-9. The preferential level of 1 shows equality of observed attributes, while the level of 9 indicates absolute, the strongest preference of one attribute over another (Ma & Zhang, 1991, Leskinen, 2000). Such a scale was formed by Saaty (Saaty, 1977) and it is used in essential AHP method and for its entire later advanced variant (revised AHP or ANP). Thus, defined scale allows comparisons in a limited scope, while the perception is a sensitive enough to make a difference in the alternatives importance. Based on pairwise comparison of alternatives, the reciprocal matrix can be formed (dimension $n \times n$ on the criteria level, or $m \times m$ on the alternatives level), where the elements $a_{ii} = 1$, while the elements a_{ji} are the reciprocal of the elements a_{ij} , i.e. $a_{ji} = 1 / a_{ij}$, $i \neq j$ and $i, j = 1, 2, \dots, n$.

The reciprocal matrices of comparison, defined in this way, are the basis for identifying priorities using AHP method. The final result of AHP method application is determination of the priority vectors of alternatives for each criterion, as well as the final ranking of all alternatives with respect to the criteria in the model.

4. A'WOT AS AN INTEGRATED APPROACH OF SWOT ANALYSIS AND AHP METHOD

The integration of SWOT and multi-criteria analysis is based on the fact that the elements of the SWOT analysis can be treated as criteria in the multi-criteria analysis model. In this way they are built on the second level of the hierarchy problem. In that sense, the A'WOT method, which represents a combined technique of SWOT analysis and AHP method, assumes the following procedure (Kangas et al. 2001, 190):

- 1) The SWOT analysis implementation, which includes identification of relevant internal and external factors that are included in the SWOT analysis,
 - 2) Determination of the relative importance of the SWOT groups by pairwise comparison,
 - 3) Implementation of the AHP pairwise comparisons of factors within each SWOT group in order to identify their priorities,
 - 4) Determination of the priorities of each alternative and the alternative strategy for the company, in respect to each SWOT group, as in the classical procedure of AHP method application,
 - 5) Calculation of the global priorities of alternatives in accordance with A'WOT decision making hierarchy.
- From the aspect of decision-making hierarchy supported by AHP method, the A'WOT decision hierarchy is usually structured in three or four levels:

- 1) The goal of the problem is identified at the highest level. Specifically, the goal is the determination of the optimal development strategy of the company.
- 2) The second level is the level of defining the relevant criteria and it consists of a standard four groups of factors in the SWOT analysis : strengths, weaknesses, opportunities and threats.
- 3) At the third level, which is essential for the sub-criteria definition, there are factors which are included in the four groups of previous levels.
- 4) On the fourth level, i.e. the level of alternatives, there are alternatives related to the development strategies of the companies. These alternatives should be evaluated and compared in order to choose the optimal strategy.

The aim of the classical application of SWOT analysis in strategic planning is not always to compare alternative strategic decisions, but the analysis of internal and external factors affecting the companies business. (Arp, R., 2008). The essential characteristic of SWOT analysis is that it is an established method for assisting the formulation of strategy (Dyson, 2004). On the other hand, the ultimate goal of any strategic planning process is to develop and formulate strategies that will be the result of balance between internal and external factors. In this sense, the application of A'WOT method assumes the identification of internal and external factors within the operating environment (SWOT analysis), then a comparison of alternative strategies in relation to the strengths, weaknesses, opportunities and threats (AHP method).

5. MODEL FORMULATION AND RESULTS OBTAINED BY A'WOT PROCEDURE

Suppose that the company by using scenario planning (Montibeller et al., 2007) found that there is a choice of five possible strategies:

Strategy 1: Maintain the existing business with marginal increase of profit in next 5 years period,

Strategy 2: Grow existing business which means the increase of current business and volume of production or services,

Strategy 3: Buy an other company and trough that action find new areas for current business diversification,

Strategy 4: Merge with another company and gain larger market share,

Strategy 5: Sell part of business which means cut of expenses.

The relevant criteria in the model derived from the SWOT analysis are: strengths, weaknesses, opportunities and threats. Graphical representation of the hierarchy for the problem of choosing the optimal strategy is shown in Figure 2.

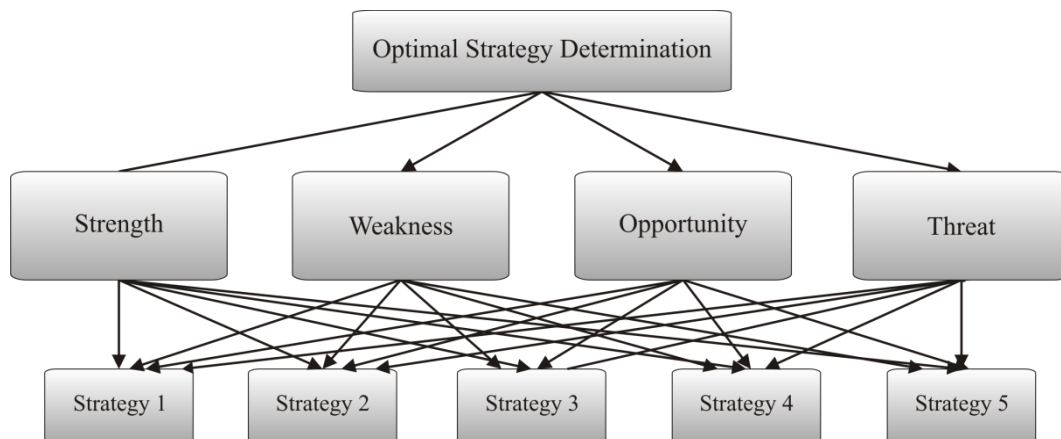

Figure 2: Hierarchy for the problem of choosing the optimal strategy

The further assumption of A'WOT application procedure requires that the management of the company conducted the evaluation of all mentioned strategies in relation to established criteria, and according to their own preferences and perceptions. Such an evaluation provides a basis for comparing pairs of criteria and alternatives and, therefore, it is possible to form the corresponding pairwise comparisons matrices. The AHP method represents a subjective approach to decision making, and according to that, it incorporates the subjective views of decision-makers - managers, or board of managers in the model. The management opinion about interrelated significance criteria in the model, evaluated using Saaty scale, is presented in Table 1. Items marked with brackets represent the reciprocal value of the number in brackets.

Table 1: Pairwise comparison matrix of criteria

	Strengths	Weaknesses	Opportunities	Threats
Strengths	1	2	(2)	4
Weaknesses	(2)	1	(4)	2
Opportunities	2	4	1	8
Threats	(4)	(2)	(8)	1

Similarly, pairwise comparison matrices were formed at the hierarchical level of alternatives, in relation to all the relevant criteria: Strengths (Table 2), Weaknesses (Table 3), Opportunities (Table 4) and Threats (Table 5).

Table 2: Pairwise comparison matrix of strategies according to Strengths

	Strategy 1	Strategy 2	Strategy 3	Strategy 4	Strategy 5
Strategy 1	1	(2)	(5)	(2)	4
Strategy 2	2	1	(3)	1	8
Strategy 3	5	3	1	3	8

The software package Superdecisions (<http://www.superdecisions.com>) was used in order to provide the problem solution. The structure of the described problem, generated by this system supporting the AHP method is shown in Figure 3.

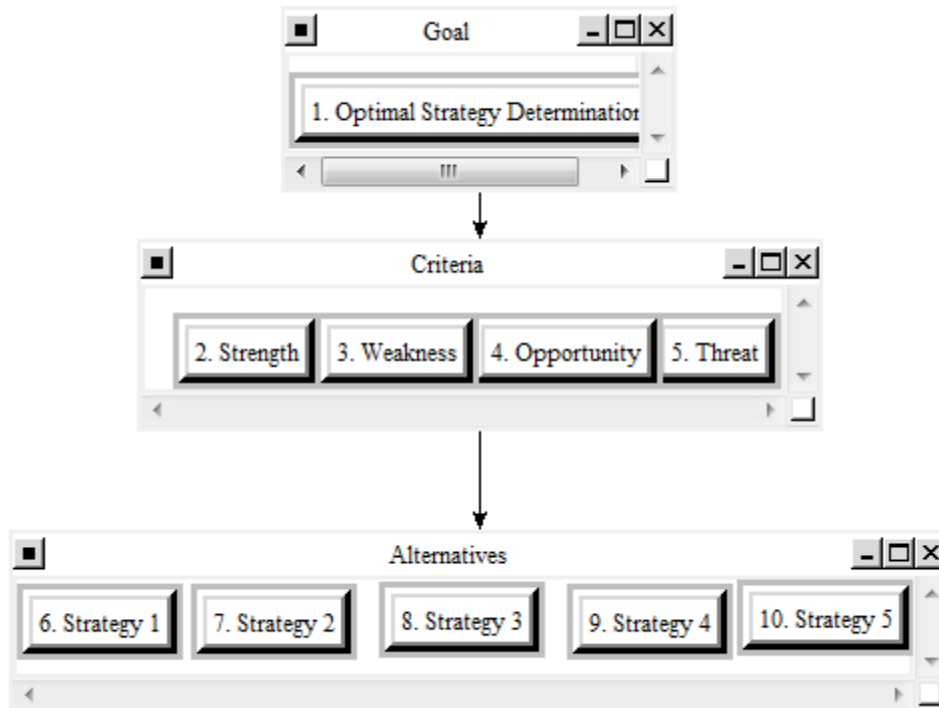

Figure 3: Structure of the problem (designed by Superdecisions decision support system)

The priority vectors of criteria and alternatives are given in Figure 4. It can be seen that management assigned the highest importance to the category Opportunities (weight 0.533). Then follows a group of factors within the criteria Strengths, with the relative importance 0.267, Weakness with weight 0.133, and at the end Threats with 0.067.

Name	Normalized by Cluster	Limiting
6 Strategy 1	0.14657	0.073286
7 Strategy 2	0.18399	0.091997
8 Strategy 3	0.29461	0.147306
9 Strategy 4	0.31543	0.157717
10 Strategy 5	0.05939	0.029694
4 Opportunity	0.53333	0.266667
2 Strength	0.26667	0.133333
5 Threat	0.06667	0.033333
3 Weakness	0.13333	0.066667

Figure 4: Priority vectors of criteria and alternatives

The final order of alternatives by all of the above criteria is presented in Figure 5.

Name	Graphic	Ideals	Normals	Raw
6 Strategy 1		0.464668	0.146572	0.073286
7 Strategy 2		0.583307	0.183995	0.091997
8 Strategy 3		0.933991	0.294612	0.147306
9 Strategy 4		1.000000	0.315434	0.157717
10 Strategy 5		0.188272	0.059387	0.029694

Figure 5: Ranking of alternatives

The solution, obtained using the software package Superdecisions, contains a priority vector, according to the AHP method, in the Raw column. Normalized vector of priorities, where can be read out the relative importance of all strategies observed, is given in column Normals. The strategy with the highest value of relative importance can be considered as the optimal strategy. In the column Ideals are presented linearly normalized values of relative importance, so that the strategy with the value 1.000 in this column can be considered as optimal. According to the data in the Figure 5 it is evident that the Strategy 4 has greatest importance (0.315434) in terms of observed criteria. Thus, taking into account the preferences and perceptions of management expressed through pairwise comparison of criteria and alternatives, it can be concluded that the company should implement the Strategy 4 - Merge with another company and gain larger market share.

6. CONCLUSION

In the decision making process, application of the SWOT analysis, as an analytical method, provides a balance between internal capabilities and external possibilities of enterprises. Therefore, this method can be used in order to define the market positioning strategy of the company. The Analytic Hierarchy Process, as the one of the most popular method of multi-criteria analysis and a tool for decision making. This method provides selection of optimal alternative(s), especially in cases where there is a possibility of a hierarchical structuring of relevant criteria. The A'WOT method represents a combined technique of SWOT analysis and AHP method. Its application assumes the identification of internal and external factors within the operating environment (SWOT analysis), then a comparison of alternative strategies in relation to the strengths, weaknesses, opportunities and threats (AHP method). The advantages of the A'WOT method application in the decision making process are confirmed in this paper.

Abstract: *This paper considers the problem of classifying commercial property in relation to the real market criteria. The method used for solving this problem is the ELECTRE 1 multi-criteria decision making method which allows the grouping of alternatives into different qualitative levels (ELECTRE MLO). The analysis was carried out using the example of commercial property in Belgrade.*

Keywords: *commercial property, multi-criteria decision making, ELECTRE method, multi-level outranking*

1. INTRODUCTION

When one of the more successful foreign companies decides to carry out its commercial activity in another country, which of course includes Serbia, one of the most important prerequisites is high quality commercial space in which to begin its business operations.

Making the right choice is not simple, since in the area of leasing commercial properties, as in other spheres of commercial life in Serbia, the situation is rather technicolour. Namely, at this moment, commercial space can be leased from the state, commercial companies and individuals. As far as the state is concerned, a good knowledge of the subject matter is important, in order to understand all aspects and modalities related to leasing commercial space. There are specialized public companies (and agencies), whose basic function is leasing publicly owned commercial space and collecting its rent as public revenue. Also, as lessors, in the name of the state, there are other subjects who have ownership of commercial premises which they do not use to carry out their own activities (for example, the Ministry of defence has a large number of commercial premises in the Belgrade area, in addition to a public company for the maintenance of air-raid shelters). There are still also non-privatized companies which appear on the market offering their available commercial premises.

With regard to companies, those who most commonly appear as renters are once state-owned and now private companies which have significant assets (in the form of buildings, offices and retail premises), either owned by them directly, or in their possession on a different basis (right of use, long-term lease etc.). Of course, although to a lesser extent, companies do lease out commercial property which came into their possession either by means of construction or purchase.

There are also private individuals who rent out commercial space, thus creating additional income for themselves. Most commonly this is by means of the owner constructing a property, one part of which (usually on the ground floor) takes the form of business or retail premises. In the coming period, it will become more and more common for private individuals to lease properties on the market due to the new restitution law, which when applied will result in a large amount of property, currently owned by the state, being returned to the descendants of those from whom it was confiscated or nationalized.

The purpose of this paper is the classification of commercial space into qualitative levels, in order for the decision maker to make an easier choice in this area. The ELECTRE 1 multi-criteria decision making method, which allows the grouping of alternatives into levels, was used in solving this problem.

2. METHODOLOGY

The ELECTRE 1 multi-criteria decision making method was used for grouping the (commercial space) alternatives into qualitative levels (Anić&Larichev, 1996; Bojković, Anić&Tarle, 2010).

ELECTRE is a group of multi-criteria decision making methods that originated in Europe in the mid-1960s. ELECTRE is an acronym of the French words *E*limination *E*t *C*hoix *T*raduisant la *R*éalité. This approach was first introduced to the theory of decision making by the French mathematician Bernard Roy, along with his colleagues in the consultation company SEMA (Roy, 1968; Kini&Raifa, 1981). The need for such a system of multi-criteria analysis arose because of the unavoidable risk in conventional methods of analyzing usefulness functions. By using ELECTRE methods, the subjectiveness of the decision maker is to a great extent eliminated. These methods gained particular significance in the 70s after psychological research gave preference to qualitative methods (Larichev, 1992; Slovic, Kahneman & Tversky, 1982). Due to their widespread application, ELECTRE methods were later developed in different directions, resulting in the variations ELECTREI, ELECTREII, ELECTREIII, ELECTREIV, ELECTREIS, ELECTRETRI and others.

Labels and Hypotheses

The alternatives to be studied will be known as: A_1, A_2, \dots, A_n . Let them be ranked according to the criteria K_1, K_2, \dots, K_m with weights $\omega_1, \omega_2, \dots, \omega_m$ and scoring scale I_1, I_2, \dots, I_m . Each scoring scale is a subset of the set of natural numbers and their cardinal numbers are: $|I_1|, |I_2|, \dots, |I_m|$. The scoring of the alternatives will be labelled as $a_{1k}, a_{2k}, \dots, a_{nk}$ by the k criteria.

We now consider two alternatives with indices i and j introduce the following signs: $K_{ij}^+ = \{k \mid a_{ik} > a_{jk}\}$, $K_{ij}^- = \{k \mid a_{ik} < a_{jk}\}$, $K_{ij}^= = \{k \mid a_{ik} = a_{jk}\}$

Concordance and discordance indices

In ELECTRE methods, the arguments in favour of the hypothesis that alternative is better than alternative B are included in the so-called index of agreement with that hypothesis, that is, with the concordance index. In the original ELECTRE 1 method the concordance index takes into account the set of criteria by which alternative A is not ranked below alternative B . In this paper, a modification of the ELECTRE 1 method is used (Anić&Larichev, 1996; Bojković, Anić& Tarle, 2010) in which the definition of the concordance index only takes into account criteria in which alternative A is better than alternative B .

Thus, let A_i and A_j be the alternatives which we are comparing. Then the index of agreement with the hypothesis that A_i is better than A_j is defined by the equivalence

$$C_{ij} = \frac{\sum_{k \in K_{ij}^+} \omega_k}{\sum_{k=1}^m \omega_k}$$

What is new in the ELECTRE methods is the principle that a hypothesis for which there is a high enough agreement index is not accepted if there is strong opposition to that hypothesis. The reasons for not accepting the hypothesis are contained in the so-called disagreement or discordance index.

If we examine the hypothesis that alternative A_i is better than alternative A_j we define the disagreement index with this alternative by means of the following relation

$$d_{ij} = \max_{k \in K_{ij}^-} \frac{a_{jk} - a_{ik}}{|I_k|}$$

We also introduce thresholds of agreement and disagreement. They are, in order, numbers p and q so that $0 < q < p < 1$. We will say that the i -th alternative is better than the j -th if it is true

that $C_{ij} \geq p$, $d_{ij} \leq q$. We will mark this with $A_i \succ A_j$. In this way we form a relation between the alternatives. In the original ELECTRE 1 method, this relation is not transitive; what is more, cycles can appear. Modification of the use here gives a relation of strict partial order, which enables the alternatives to be grouped into qualitative levels. This is contained in the following theorem:

Theorem 1 (Anić, Laričev) If the parameter p is chosen so that $p > \frac{l_{ij}}{l_{ij} + 1}$ where $l_{ij} = \frac{d_{ij} \sum_{k \in K_{ij}^+} \omega_k^*}{\sum_{k \in K_{ij}^+} \omega_k^* (a_{ik}^* - a_{jk}^*)}$ for

each i and j then the relation \succ is transitive.

One alternative of which there is none “better”, that is, the maximal elements of the relation \succ are the so-called core of the relation.

Multi-level outranking

The logic behind the performance-level construction is in the specific iterative procedure, which involves repeated identification of preferable alternatives. Namely, in the first stage, the alternatives from the core subset are identified. These are the first-level alternatives and they are not out-dominated. Subsequently, the alternatives from the core subset are excluded and the method is again applied to the remaining alternatives. The new core subset consists of the second-level alternatives. These alternatives are out-performed only by some alternatives from the first level. The procedure is repeated until a core is a non-empty set. The number of iterations corresponds to the number of levels. The mathematical expression of the levels construction is described below.

The definition of the levels is inductive: the first level L_1 consists of the alternatives from the core subset. The alternative A_i which is outside the core subset, belongs to the level L_k if $\max\{t \mid (\exists A_j \in L_t) A_j \prec A_i\} = k - 1$ is fulfilled. This upgrade of the outranking relations, i.e. introduction of the levels in a qualitative way, has several advantages over the classical determination of the levels based on quantitative evaluation.

3. SELECTION OF CRITERIA FOR DECISION-MAKING

Foreign companies, when selecting the commercial space in which they will begin their business, as a rule, and as the key factor, take into account the location of the subject property. If they are in the retail business, the favoured locations are streets and squares with a high flow of pedestrians. In Belgrade this would be Knez Mihajlova street, as well as Kralja Aleksandra boulevard, Kralja Milana street etc. However, if the business in question is some kind of manufacture or craft, priority is given to locations with easy access for delivery vehicles.

After the locality, great importance is placed upon legal assurance, in terms of the long-term planning of the business in a particular location. This, above all, relates to the secure and long-term lease of the chosen property. In Serbia, the highest degree of legal assurance is gained from leasing commercial space in public ownership. Namely, after concluding the lease agreement, according to pre-determined criteria and conditions, the public company which leases the commercial space in public ownership takes care of collecting the public revenue, in which security of tenure (on the side of the lessee) is ensured by regular payment of the agreed rent and respecting the contract provisions (prohibition of subleasing the property, conducting the specified activities, fulfilling maintenance obligations etc.). There is no danger that the owner (the state or local government), as is the case with individuals who lease commercial property, should decide independently to cancel the lease agreement and continue conducting the business that the lessee had developed. Public companies, acting on behalf of the state or local government, in accordance with the Law on public property, simply collect the revenue from the rent, without the legal possibility of carrying out any commercial activity in the property they are leasing out. Also, the price of leasing commercial property in public ownership is decided per square metre by the competent authority (the City Assembly of Belgrade, The Assembly of a city municipality etc.), at most once a year, so there is no danger, as there would be if the

property were in private ownership, of the owner regularly increasing the price if it is seen that the lessee is conducting successful business activities with a high volume of sales.

Because the mentioned restitution law has now come into force, by which a significant number of commercial properties, now in public ownership, will be returned to the original owners, the preferred choice for commercial space will be newly built properties, since they will not be the subject of restitution.

With regard to the area of renting commercial space from private individuals, the possible problem of legal uncertainty, in terms of cutting short the leasing agreement, changes in price or other conditions of use, can be prevented by signing a long-term lease agreement, with clearly defined bases for changes in the rent or unilaterally cancelling the agreement.

After selecting the location where the business will be conducted, as well as carefully studying the situation regarding the right of use for particular commercial properties, foreign investors take into account the structure and location of the premises they want to rent. Even if the commercial space is in a good location (for example in Knez Mihajlova) and is leased by a public company, the ability to successfully conduct commercial activity is significantly reduced if the premises are in a passage or are on a higher floor. The most suitable retail or catering facilities are those which are on the ground floor, which have large windows, and which open directly onto the pavement. The structure of the retail space is also important, since it is better to have a large sales area, as opposed to those premises which have a small sales area with large hallways, shared space and utility rooms.

An important criterion for choosing adequate commercial space is its condition. It is much easier to rent commercial space that is ready to use and in good condition, or which only requires a small amount of adaption in order to make it suitable for a particular business, as opposed to those premises which require a lot of intervention in order to maintain the investment.

The ideal commercial space, according to all of the above, would be that which meets the following criteria:

- It is situated in a good location (city centre or pedestrian zone),
- It is managed by a specialized company for leasing commercial space,
- It is situated on the ground floor, with large windows and an entrance directly onto the street,
- It is in good condition, i.e., it does not require any large investment in adaptations before the business can begin.

On the basis of this, the following criteria for decision making have been recognized

1. Zone (location) – This criterion is given the highest importance (weight 10). The ratings are from 1 to 7 and correspond with the zones in the city of Belgrade (7 is the most desired zone, and 1 refers to suburban residential areas).
2. Surroundings (position) – It is not only the location of the zone which is important when it comes to the position of commercial property, but also the actual position within that zone (building access, the elements surrounding it, orientation, ...). The rating is from 1 to 3, where 3 corresponds to the best position.
3. Legal status – The rating is from 1 to 3, where 1 is for a property owned by an individual, 3 is for publicly owned property and 2 is for all other (e.g. it is owned by a firm whose primary function is not leasing commercial space).
4. Commercial activity – The rating is from 1 to 4, where a rating of 4 is for retail space, 3 for craft space, 2 for office space and 1 for warehouse space.
5. Condition of the property – The rating is from 1 to 4, 1 being for neglected property, 2 for property which needs some adaption, 3 for space which needs no adaption and 4 for luxuriously equipped space.
6. The possibility of carrying out more activities – The rating is from 0 to 2, where 0 is for premises that cannot be adapted for any other function, 1 is for where significant investment is needed to adapt the space for any other function and 2 is for commercial space which is easily adaptable for different purposes.
7. Storey – A rating of 3 is for space on the ground floor, a rating of 2 is for that which is partly on the ground floor, and partly on the lower ground or first floor, and a rating of 1 is for a property which is completely on the lower ground or first floor.

8. Structure of the space – A rating of 1 is for poorly structured space, 2 is for a medium structure and 3 is for property with a structure which completely fulfils its required function.

4. EXAMPLE – CLASSIFICATION OF COMMERCIAL SPACE IN BELGRADE

This section contains an actual example of how the ELECTRE MLO method classifies the alternatives into qualitative levels. In the example, 12 commercial units in the wider centre of Belgrade are considered. Table 1 shows how the alternatives are rated according to the criteria given in the previous paragraph.

Table 8: Scores of alternatives

Title	Weight	Ranking scale	CS1	CS2	CS3	CS4	CS5	CS6	CS7	CS8	CS9	CS10	CS11	CS12
Zone (location)	10	1- 7	6	6	6	6	6	4	5	7	7	5	6	4
Surroundings (position)	5	1-3	2	3	1	2	3	2	3	3	2	3	3	2
Legal status	8	1-3	1	3	3	1	3	2	3	3	1	3	3	2
Activity	5	1- 4	4	4	4	4	2	4	3	4	4	4	4	4
Condition of property	3	1- 4	4	2	3	3	2	3	3	3	3	2	2	2
Possibility for change of use	2	0- 2	1	0	0	0	0	2	1	2	0	2	2	2
Storey	2	1 - 3	3	3	2	3	2	2	3	2	3	3	2	2
Structure of space	2	1- 3	3	3	2	2	3	1	2	2	2	2	2	3

By applying the ELECTRE MLO method with the thresholds $p=0,6$ and $q=0,4$ the following multi-level graph of the preference relations between the alternatives is obtained, shown in figure 1.

Figure 2: Multilevel graph of the preference relations between the alternatives

It can be clearly seen from the multi-level graph that on the first level is commercial space number 8. That is the space with the best characteristics from the luxury zone. On the second level are those facilities of which only CS8 is better, which are commercial spaces 1,2, 9 and 11. These four commercial spaces cannot be compared with each other, which is one of the characteristics of the qualitative method in multi-criteria decision making, i.e., the relation created here is not linear but partial order. Simply, the other levels differ, too.

The decision maker in this situation has a clear picture of the qualitative levels on which the commercial premises are found. The price of leasing commercial space from state firms is fixed within each zone. In this paper, the zone in which the commercial space is situated is the criterion with the greatest weight, but alongside it are other criteria which are important for making a decision, so that if a lessee decides to lease commercial space from a state firm, the choice should be made from those on higher levels, but in the same zone. So, for example CS9 is in an excellent location, but due to its other characteristics it is not on the level above 1,2 and 11 which are in zone 6. Commercial space CS8 which is found in the same zone is a better choice.

6. CONCLUSIONS

In this paper is a presentation of how using the qualitative ELECTRE 1 method of multi-criteria decision making, that is its modification which enables the classification of alternatives into levels, successfully solves a practical problem of choice. It is unlike the quantitative approach, in which each alternative, in this example commercial space, is assigned a number which indicates its value and where there is the possibility of a particular commercial property being very bad according to some of the criteria, but to be highly ranked anyway. In the qualitative approach described here, that kind of space will remain incomparable with others.

The modification of the ELECTRE 1 method which was used in this study establishes a relation of strict order which enables the distribution of alternatives according to levels. These levels are natural, i.e. the alternatives on the same level cannot be compared with each other, which is not the case with the quantitative approach, so this characteristic can be taken as an advantage of the qualitative approach.

This paper proposes the classification of commercial space, not only according to the zone in which it is situated, but also according to other market characteristics. The expert system which is offered can be of significant help to lessees of commercial space, especially in a situation where there are many offers available.

ACKNOWLEDGEMENTS

The work reported in this paper is a part of the investigation within the research project TR 36017 supported by the Ministry for Science and Technology, Republic of Serbia. This support is gratefully acknowledged.

MULTI-CRITERIA ANALYSIS IN THE SELECTION OF ECONOMICALLY MOST ADVANTAGEOUS TENDER FOR PUBLIC WORKS

Sonja Pravilović¹

¹Faculty of Information Technology, Mediterranean University, Podgorica, ksonja@t-com.me

Abstract: *By virtue of the 2008 Decree V, the EU set the conditions for awarding public works contracts, suggesting optimal criteria of the economically most advantageous tender. The establishing of the economically most advantageous tender is based on the plurality of integrated evaluation criteria which imply solving the problem of comparison among the same criteria due to different quantitative or qualitative units of measurement, such as are the complex operations of a realistic tender evaluation. In order to facilitate the work of bodies deciding on awarding a certain concession or public works, in applying this criterion in public tendering and procurement procedures, it was decided to develop guidelines offering information on legal and operational aspects of the most problematic criteria in awarding such contracts. This paper is aimed at highlighting the role of the multi-criteria analysis method in making a decision on the selection of public work contractors on the grounds of economically most advantageous bid. In order to make the evaluation method transparent, consistent and controlled, so as to be able to identify among the alternatives of proposed projects the ones which are the most suitable and which meet the needs of the contracting authority, the multi-criteria decision-making method is used.*

Keywords: *multi-criteria, tender, public works*

1. INTRODUCTION

The Legislative Decree of the European Communities of 12 April 2006 number 163 and the subsequent amendments (hereinafter: the Code), in line with the EU practice, established that there is full equality and fairness between the two criteria when selecting the economically most advantageous tender. This has liberalized the selection of criteria and decisions of bodies with contracting powers, which by extension means that it is an independent decision which type of procedure will be conducted.

In inviting tenders for project development it may involve:

- total project development,
- execution of works only, or
- granting concessions to private companies for a certain period of time.

In order to save time and money, an administrative body inviting tenders for public works frequently instead of inviting tenders for each of the above three elements, does so by seeking entities able to implement all three. This means that the tenderers should be capable of developing a project from its design stage over implementation to its operation and maintenance.

However, given the special procedure for awarding public work concessions, as referred to in Article 142 and onwards, and in project financing, by virtue of Article 153 and other legislative acts 163/2006, given the specific nature of contract and type of services awarded to a private company, the same body introduced the obligation on the part of the body with contracting authorities (the decision-maker) to use the criterion of the economically most advantageous tender.

Such a choice is based on the fact that the economically most advantageous tender enables awarding public contracts not purely on quantitative economic evaluation. It is highly suitable since by a complex integration of economic data, of technical and quantitative nature, it gives the possibility of selecting a private contractor and contract awarding, such as public work concessions, in which contracted services include also work design, its performance, and execution through functional and economic management.

This criterion is characterized by greater flexibility, thus enabling the tendering companies to better express their innovativeness, and thus increase their competitiveness, even as regards addressing the needs of the contracting authority (concession grantor).

Establishing the economically most advantageous tender is based on the plurality of integrated evaluation criteria implying the need to address the problem of comparisons among the same criteria, due to different quantitative or qualitative units of measurement, such are complex real tender evaluation operations.

By the Decree number 5 from 2008, the EU authorities defined the terms for awarding public works contracts, proposing the use of economically most advantageous tender as the optimal criterion.

In order to facilitate the work of the contracting authority for a certain concession or public works, in applying this criterion in public contracts and supplies as referred to in Article 13 of the Code, the designated authority, after hearing the relevant institutions and interest groups, decided to draft guidelines offering information on legal and operational aspects of the most problematic criteria for awarding such contracts.

The analysis of some of the most relevant “multi-criteria decision-making” methodologies towards identifying economically most advantageous tender in the tendering process for all three stages is attached to the document. Based on the above, the EU Council supports the guidelines: “for the application the criteria of economically most advantageous tender in procedures envisaged in Article 153 of the Code”.

The economically most advantageous tender, as mentioned earlier, is based on the plurality of evaluations, given the nature, purpose and features of specific contracts. Article 83.1 of the Code briefly illustrates such criteria.

2. METHOD FOR DECISION MAKING

The contracting authority, seeking to protect the public interest, has a wide discretion in selection of tender evaluation criteria. Thus, the authority may focus on evaluation of criteria relevant from aesthetical point of view more than, for instance, maintenance or efficiency, service management, etc, or even the use of environment-friendly technologies, since the tender may be aimed at meeting specific and anticipated goals.

However, this freedom of choice on the part of the contracting authority must be balanced to ensure the observance of the principles of transparency, non-discrimination, equal treatment, and avoid any risk of abuse.

To that effect, transposing the established EU principles, the selection of evaluation criteria remains a task, although ultimately discretionary, which is strictly controlled by the methodology, in the sense that the contracting authority is obliged to give a clear account of its own choices in the tender dossier, and thus it is “self-binding” for evaluation of future tenders based on the established objective criteria.

The same freedom enjoyed by the contracting authority is seen in the selection of criteria, hence even in weight quotients (“weight quotients” or “score”). Each criterion is assigned the level of importance regarding the goals aspired by the project. “Weight quotient” or a “score” is posted in the tender announcement for each criterion and is publicly available. The Decree no 554/99 stipulates the total sum of “weights” or “scores” awarded to criteria in a tender and it must equal 100. In essence, a “weight” or a “score” reflects the relative importance of certain elements (technical solution, price, maintenance, etc) that the contracting authority considers important in deciding on the final tender evaluation.

As for the selection of “weights” or “scores” awarded to each criterion, the discretion of the contracting authority is, according to the case law, the sole limit or “reflection of irrationality” on the distribution of results given the purpose. This presumption may affect the legitimacy of the tender procedure when, for instance, a certain score is awarded to a certain element or a criterion which is of such weight that all other criteria, by comparison, do not have any special or vital importance, i.e. a large score is awarded to one sole evaluation criterion which is of such weight that practically all others become superfluous.

The complexity of selecting evaluation criteria, possible division of criteria into sub-criteria and awarding of relative “weights” or “scores” have guided the legislator to ensure fairness in Article 83(4) of the Code with the possibility of designating one or more experts that may be entrusted with the identification of such elements.

In an appendix to these guidelines, a methodology is considered which, although with discretionary assessments, aims at directing the contracting authority towards the identification of weight quotients in line with the goals to be pursued.

In order to make the evaluation methodology transparent, consistent and controlled, so that among the alternatives of proposed projects it is possible to identify those best suiting and fulfilling the needs of the contracting authority (Annex B to the EU Directive 554/1999), the possibility of using certain methods, the so-called “multi-criteria decision-making” methods, is given.

The need to use the scientific methodology of “multi-criteria decision-making” stems, as already stated, from two important reasons, which are as follows: the aggregate assessment referring to criteria expressed in different measures and measurement units should be done, preventing mutual comparisons of tenders (such as price, time, technical capabilities), and on the other hand, different weights, i.e. *importance* which the contracting authority awards to certain criteria should be taken into account.

The **multi-criteria decision-making** methodology is a system to support decision-making, i.e. tools enabling explanation of preferences in order to intentionally achieve the adoption of the appropriate solution for the problem.

It is usually stated in literature that multi-criteria decision-making does not aim at replacing human decision with fully automated decision-making tools, but to provide support to decision-makers that is under their full control, i.e. they are able to extend the analysis options, without imposing solutions and predefined choice.

In principle, the multi-criteria analysis is regarded as an “economic optimum” of Vilfredo Pareto, based on the assumption of taking into account the plurality of interests (criteria), many of which are conflicting. The “Pareto optimum” as a criterion offers indeed the plurality and comparability of goals, each of which has certain importance. Hence, it is intended to be of assistance to decision-makers in selection of the appropriate and consistent solution, based on the actual state of affairs, regarding the goals pursued and based on opportunities available (to that effect, these are called “*regulations*”).

Generally, literature explains that multi-criteria analysis has a multi-disciplinary approach, oriented towards problem analysis of modern technological society from different perspectives: economic, social, managerial, ethical and aesthetical. They intend to offer a reasonable basis for the problem of selection characterized by several criteria. The assumption is that in a societal context the goals (for instance, the urban infrastructure and services restoration project, labor market etc.) are characterized from the multidimensional profile, called “vector (w)” i.e. the element including all essential attributes for their full specification.

According to literature, the multi-criteria analysis methods may be classified into three sub-groups:

- a) multi-criteria methods developed primarily in the area of spatial planning, management and environmental management, by authors such as Nijkamp, Rietveld, Voogd, Hinloopen;
- b) methods developed in the area of Operational Research and Decision-making Theory by economists, mathematicians, statisticians and psychologists, such as: Keeney and Raiffa, Roy, Miles, (value analysis) etc.;
- c) hierarchical methods based on basic mathematical principles and axioms (pair-wise comparisons, priority synthesis) and self-evaluation and self-assessment techniques developed mostly by Saaty and Vargas.

According to P. Nijkamp and H. Voogd, the multi-criteria analysis techniques may be categorized among those suitable for evaluation of alternatives changed in a continuous way and those suitable for evaluation of alternatives changed discretely. In addition, they may be classified into those in which the alternatives are characterized by only quantitative or only qualitative data or mixed ones. In case of contracts and concessions, only the multi-criteria analysis techniques which evaluate alternatives characterizing mixed data are appropriate.

The EU Directive 554/99 proposes the use of multi-criteria analysis methods in determining the economically most advantageous tender with the possibility of using any of the methods found in literature. Nevertheless, some are recommended, including: “aggregate compensator” or “weighted amount” method, ELECTRE method, “analytic hierarchy process” (AHP) method, “evamix” method, “technique for order preference by similarity to ideal solution” (TOPSIS) method.

All methods are based on evaluation criteria of weighted quotients or scores awarded to each criterion. For the proper use of methods, it is noteworthy that there is a clear difference between the tender features with which the authority believes to identify the economically most advantageous tender (e.g. price, time of execution, technical and aesthetical advantage, operation or maintenance costs) and weights or scores, i.e. the numerical data of evaluations, expressing the degree of importance of some element in relation to the overall evaluation. These are designed so as to guarantee the ratio between price, quality and technical aspects as essential elements for the contracting authority stipulated in the call for proposals.

Each method, starting from the set criteria and weights, develops a special procedure for determining the best tender.

The evaluation criteria, considered necessary for determining the economically most advantageous tender, must be established based on thorough analysis of contents of public project dossier (feasibility study) so as to anticipate allowable changes in the tender.

Essentially, it is necessary to mark also the functional goals important for the contracting authority in order to provide to the tenderers full and accurate information for completion of tender.

Considering the criteria stipulated in the Code, the table 1 contains several elements indicating their nature (quantitative and/or material or qualitative and/or non-material) whose goal is to reduce or increase.

Table 1: Elements indicating their nature (quantitative and/or material or qualitative and/or non-material) whose goal is to reduce or increase

Evaluation criteria	Nature		Goal	
	Measurable	Immeasurable.	Measurable	Immeasurable.
a) price	X		X	
b) shortened time	X			X
c) quality		X		X
d) technical advantage		X		X
e) aesthetical and functional characteristics	X	X		X
f) environmental qualities and reduced consumption of energy and other resources towards environmental protection	X	X	X	X
g) operation and maintenance costs	X		X	
h) profitability	X			X
i) after-sale services	X	X		X
j) technical support	X	X		X
k) delivery or hand-over date	X		X	
l) responsibility for spare parts	X			X
m) security of supply	X			X
n) concession period	X		X	
o) management support		X		X
p) level and criteria for price adjustment borne by the user	X		X	
r) preliminary draft		X		X
s) economic and financial value		X		X

3. FLOW CHART – ECONOMICALLY MOST ADVANTAGEOUS TENDER

The multi-criteria decision-making methods described in the Directive currently in force in EU, as well as those in new decree no 163/06 are the following: aggregate compensator, ELECTRE methodology, such as the analysis hierarchy process (AHP) methodology, Evamix methodology, methodology of preferences as per similarities to ideal solution (TOPSIS).

In aggregate compensator, the alternatives are classified according to the total score as a weighted sum of values of the tender features. ELECTRE methodology is based on indexes of appropriateness or inappropriateness of the tender characteristics, as well as limit values of appropriateness and inappropriateness. There are several versions of this method. The AHP method is based on prioritizing evaluation criteria by performing pair-wise comparisons at each hierarchical level, as well as the reconstruction of decision-making problem. In the TOPSIS method, alternatives are ranked as per the criterion of minimum distance from the “ideal” desired solution and maximum distance from the worst “ideal” solution.

This paper does not aim at presenting methods so no further details of different methods will be presented here. We will briefly present an illustrative example of problem-solving by using TOPSIS method.

Table 2: Stages of tender analysis may be shown as follows:

Stage one: Transform entry tender parameters by variable quotients between zero and one.		
<div> <div> <p>The evaluation criteria and sub-criteria of qualitative nature (good-quality design, quality of service) are conducted using any of the procedures (should be stated in the tender dossier)</p> <p>a) pair-wise comparison is based on comparison with the data of the main contractor in the comparison matrix;</p> <p>b) pair-wise comparison based on guidelines;</p> <p>c) discretionary awarding.</p> </div> <div> <p>Aiming for a proper definition of the dossier quotient, the criteria need to be stated which determine it (the rules must state, for instance, that the quotients are determined based on discretionary right).</p> </div> </div>		
<p>Quantitative evaluation criteria and sub-criteria (price discount, price, concession period, etc) are determined using mathematical formula (should be stated in the tender dossier):</p> <p>a) the quotient equals one for the most advantageous tender;</p> <p>b) the quotient equals zero if the set value equals the value given in the tender;</p> <p>c) the quotients ranging from zero to one for various tenders obtained by linear interpolation between the two values (the most advantageous and the value given in tender).</p>		
<p>Assuming that percentage-wise decrease is accepted as tender, the values in the formula corresponding to that principle would then be: (offered decrease/ maximum possible decrease); however, the inverse formula (maximum offered decrease/ offered decrease) would not correspond to the principle.</p> <p>Both formulas are fractions, (a/b), but the first envisages that the (a) numerator is a variable, and (b) the denominator a fixed value so as to form linear dependency; the other, however, envisages that (a) the numerator is a fixed value, and (b) the denominator is a variable value, i.e. not a linear function, but an asymptotic function on Cartesian axes x and y.</p>		
<p>Stage two: determining the economically most advantageous tender using the methodology stated in the tender dossier that should be some of those stated in the Annex to the EU directive 554/1999;</p> <p>The economically most advantageous tender is established based on quotients awarded (varies between zero and one) (after division into criteria and sub-criteria - reparameterization). Reparameterization implies that the competitor (tenderer) is awarded a quotient based on weighted sum of quotients of criteria and sub-criteria; quotient one is awarded to the competitor where the offered amount is maximum, and others are determined linearly in proportion to the sum for each evaluation criterion.</p>		
<p>METHOD: TOTAL COMPENSATOR</p> <p>Ranking is decided using the following formula:</p> $P_i = C_{ai} \cdot P_a + C_{bi} \cdot P_b + \dots + C_{ni} \cdot P_n$ <p>where:</p> <p>P_i – is the competitor score;</p> <p>C_{ai} – is quotient criterion a of competitor i;</p> <p>C_{ni} = quotient of criterion n, of competitor i;</p> <p>P_a – weight criterion a;</p> <p>P_n – weight criterion n</p>	<p>ELECTRE</p> <p>Ranking is decided based on the procedure described in Annex to the EU Directive EU 554/1999, which starting from quotient matrix determines:</p> <p>a) differences among quotients;</p> <p>b) weighted indexes;</p> <p>c) unique dominant indicators;</p> <p>d) tender evaluation based on dominant indicators.</p>	<p>TOPSIS</p> <p>Ranking is determined based on calculation of quotient matrix of weighted quotients which gravitate to the ideal and non-ideal solution and identification of tender which is closest to the ideal solution, i.e. the one most distant from the non-ideal .</p>

4. ILLUSTRATIVE EXAMPLE

TOPSIS is a method of multi-criteria optimization. Its name is an acronym for *Technique for Order Preference by Similarity to Ideals Solution*, which means *a technique for confirmation of priority solutions based on similarities towards ideal solution*.

The application of this method requires making a matrix from “I” variants and “k” criteria. Every criterion is joined by certain weight coefficient w_k , where $k=1,2,\dots,K$. Then all criteria are sorted into “benefit” and “cost” types, where the former are maximized and the latter are minimized.

Input data:

	Reliability	Number of functions	Delivery time	Outlook	Price	Service and maintenance	Technical characteristics
WB	2	2	2	1	3	3	3
CB : 1 – max, 0 - min	1	1	1	1	0	1	1
Bidder 1	40	11.6	17	450	0.6	1	3
Bidder 2	45	16.5	15	134	0.7	6	5
Bidder 3	45	17.4	34	120	1	12	6
Bidder 4	35	15	17	310	0.3	1	5
Bidder 5	35	9	15	500	0.4	1	3

WK1	0.12500	0.12500	0.12500	0.06250	0.18750	0.18750	0.18750
-----	---------	---------	---------	---------	---------	---------	---------

SUM	90.00000	31.86801	46.73329	762.20470	1.44914	13.52775	10.19804
-----	----------	----------	----------	-----------	---------	----------	----------

Concretely, TOPSIS method comprises the following steps:

Step 1:

$$r_{ik} = \frac{f_{ik}}{\sqrt{\sum f_{ik}^2}} \quad (1)$$

R(I,J)	0.44444	0.36400	0.36377	0.59039	0.41404	0.07392	0.29417
	0.50000	0.51776	0.32097	0.17581	0.48305	0.44353	0.49029
	0.50000	0.54600	0.72753	0.15744	0.69007	0.88707	0.58835
	0.38889	0.47069	0.36377	0.40671	0.20702	0.07392	0.49029
	0.38889	0.28241	0.32097	0.65599	0.27603	0.07392	0.29417

A matrix from “i” variants and “k” criterion which has to be normalized is formed, i.e. all its values have to come to an interval between 0 and 1. In that way, dimensionless quantity is provided. Step 2: in step 2 all values of the normalized matrix have to be multiplied with adequate weight coefficient w_k which are subjectively selected and normalized (2).

$$v_{ik} = \|w_k^{-1} \cdot r_{ik}\| \quad (2)$$

V(I,J)	0.05556	0.04550	0.04547	0.03690	0.07763	0.01386	0.05516
--------	---------	---------	---------	---------	---------	---------	---------

The two quoted steps represent pre-processing of the task.

Step 3: Within this step, ideal and anti-ideal points I^* and I^- have to be defined, depending on the use of either criterion “benefit” or “cost” type (3 and 4). An ideal point has maximal value by all criteria of “benefit” type, and minimal value by all criteria of “cost” type.

$$I^* = \left\{ \max_i v_{ik} \mid k \in K_{\max}, \min_i v_{ik} \mid k \in K_{\min} \right\} = v_k^* \quad (3)$$

IZ(1,J)	0.06250	0.06825	0.09094	0.04100	0.03882	0.16632	0.11032
---------	---------	---------	---------	---------	---------	---------	---------

An anti-ideal point has maximal value by all expenditure criteria, and minimal value by all income criteria.

$$I^- = \left\{ \min_i v_{ik} \mid k \in K_{\max}, \max_i v_{ik} \mid k \in K_{\min} \right\} = v_k^- \quad (4)$$

IZ(2,J)	0.04861	0.03530	0.04012	0.00984	0.12939	0.01386	0.05516
---------	---------	---------	---------	---------	---------	---------	---------

Step 4: the point closest to the ideal one, and at the same time farthest from the anti-ideal point, is searched within this step.

$$S_i^* = \sqrt{(v_{ik} - v_k^*)^2} \quad (5)$$

$$S_i^- = \sqrt{(v_{ik} - v_k^-)^2} \quad (6)$$

Si*	SI*

	0.00000	0.00001	0.00258	0.00090	0.00268	0.00692	0.00034
	0.00000	0.00000	0.00000	0.00097	0.00820	0.00000	0.00000
	0.00019	0.00009	0.00207	0.00024	0.00000	0.02325	0.00034
	0.00019	0.00109	0.00258	0.00000	0.00017	0.02325	0.00304

Si	SI						
	0.00005	0.00010	0.00003	0.00073	0.00268	0.00000	0.00000
	0.00019	0.00087	0.00000	0.00000	0.00151	0.00480	0.00135
	0.00019	0.00109	0.00258	0.00000	0.00000	0.02325	0.00304
	0.00000	0.00055	0.00003	0.00024	0.00820	0.00000	0.00135
	0.00000	0.00000	0.00000	0.00097	0.00603	0.00000	0.00000

Step 5:

$$C_i = \frac{S_i^-}{S_i^* + S_i^-} \quad (7)$$

	SOLUTION
Bidder 1	0.25566
Bidder 2	0.44626
Bidder 3	0.64449
Bidder 4	0.38641
Bidder 5	0.32453

Here, relative closeness representing a compromise between the proximity of the ideal and the distance of the anti-ideal is calculated.

For the ideal point, the value of closeness equals one, and for the anti-ideal point, its value equals zero. As it is really rarity to obtain the ideal point, ideal solution C_i is usually between zero and one.

Step 6: in accordance with obtained results, i.e. with C_i , a range of variations is formed. The best is the one where C_i is closest to 1. The point is to find a point (solution) which is closest to the ideal and most distant from the anti-ideal.

5. CONCLUSION

Aiming for transparency, consistency and the ability to control awarding public project and public procurement contracts, awarding concessions and their subsequent operation, the EU authorities have set precise criteria of economically most advantageous tender, as well as the methodology for its evaluation. The multi-criteria optimization methodology is proposed. The reason is the existence of the plurality of integrated evaluation criteria. Hence, there is a need to address the problem of comparison between the same criteria, different quantitative or qualitative units of measurement. The paper fundamentally aims at highlighting the role of multi-criteria analysis in making the decision on the selection of the economically most advantageous tender. In essence, the literature explains that the multi-criteria analysis has a multidisciplinary approach oriented at analyzing the problems of a modern-day technological society from various perspectives: the economic, social, management, ethical and aesthetic.

Abstract: *In this paper we will present one new method, the lattice method, which is developed by Žižović M. et al. (2011), and we will point to the application of the obtained method in one practical example of buying a car for a small private company.*

Keywords: *alternative, criteria, multi criteria analysis, lattice method.*

1. INTRODUCTION

Nowadays, there are a number of developed methods and techniques for multi criteria optimization (multi criteria analysis). If you ask an analyst who deals with this issue which of these methods is the best, you can get different answers depending on the type of the problem that is to be treated, as well as the type of solution that is required. On the other hand, if the same analyst is asked to recommend some method, then the answer could be similar as the answer to the previous question, but the best answer is to propose the method that can best be perceived by both the analyst and the decision maker.

In general, there exist two distinctive types of MCD problems due to the different problems settings: one type having a finite number of alternative solutions and the other type having an infinite number of solutions. In problems associated with selection and assessment, it is naturally assumed that the number of alternatives is limited. So, our focus will be on the problems with a finite number of alternatives. In that case, a MCD problem may be described using a decision matrix. Suppose there are m alternatives to be assessed based on n criteria, a decision matrix is a $m \times n$ -matrix with each element a_{ij} being the j -th criteria value of the i -th alternative.

All criteria in a MCD problem can be classified into two categories. Criteria that are to be maximized, for example the profit criteria category, and criteria that are to be minimized, for example the cost criteria category. An ideal solution to a MCD problem would maximise all criteria of the first type and minimise all criteria of the second type. In a natural way, any criterion of the second type can be transferred into a criterion of the first type.

Although MCD problems could be very different in context, they share the following common features: multiple criteria often form a hierarchy and criteria can conflict with one another. Due to lack of information, the conflict among criteria, the uncertainties in subjective judgment and different preferences among different decision makers, the final assessment results may not be conclusive. There are many methods available for solving MCD problems, and for an overview we refer to Hwang C. L. and Yoon K. (1981), and Radojičić M. and Žižović M. (1998).

Recently, the lattice MCD-method is introduced by Žižović M. et al. (2011). This new method is close to the category of compromising ranking methods, but it differs significantly from it. The compromising method first normalises the decision matrix of a MCD problem. Then based on the normalised decision matrix, it calculates the weighted distances of each alternative from an ideal (best) solution and a nadir (worst) solution. A solution relatively close to the ideal solution and far from the nadir solution is evaluated to be the best choice. The lattice method is also based on weighted distances of alternative to the hypothetically best and the worst alternative, but it includes in calculating both the weight between alternatives and the weight of alternatives themselves. Some examples which confirm that lattice method and compromise ranking methods induce two different order relations on the same set of alternatives are given in the previously mentioned paper.

In case that we are dealing with relatively small number of alternatives, then the lattice method has quite nice graphical interpretation, and it can be successfully applied to many practical problems (see for example Žižović M. et al. (2011)b and Damljanović N. et al. (2011)). In this paper we will consider the car selection

problem for one small private company. First, in Section 2., we will explain the basic concept of lattice method, and then, in Section 3, we will apply this method in practical example.

2. THE NEW METHOD

In this section we will give a brief overview on notions, notations and main results concerning lattice method developed by Žižović M. et al. (2011), that will be used in further work. The main intention of the authors of mentioned paper was to propose the method for calculating the preference of one alternative over another, with respect to a given set of criteria, which would include in the preference both the difference between these alternatives and the values of alternatives themselves. In this way, we get fruitful and more accurate information on the observed alternatives and corresponding preference.

Let $A = \{a_1, a_2, \dots, a_m\}$ be the *set of alternatives* and let $C = \{c_1, c_2, \dots, c_n\}$ be the *set of criteria*. We will assume that, for any $i \in \{1, 2, \dots, m\}$, the alternative a_i is represented as n -tuple $a_i = (a_{i1}, a_{i2}, \dots, a_{in})$, or equivalently $a_i = (a_{ik})_{k=1}^n$, where each coordinate a_{ij} , for $j \in \{1, 2, \dots, n\}$, is non-negative real number which can be interpreted as the degree to which the alternative a_i satisfies the criterion c_j . Also, we will assume that all members of the set A are mutually incomparable under standard order relation on A^n .

We will assume that all criteria don't have to be of the same importance and that the decision makers are aware of the degree of importance of each criterion. In other words, we will assume that each criterion c_k , $k \in \{1, 2, \dots, n\}$ is associated with a number $z_k \in (0, 1]$ that represents the degree of importance of that criterion.

Also, for each criterion, we will consider the function that measures the importance of the difference between two given alternatives, i.e., we will consider the specific functions $Z_k : A \times A \rightarrow [0, +\infty)$, for each criterion c_k , $k \in \{1, 2, \dots, n\}$, which joins a nonnegative real number $Z_k(a_i, a_j)$ to each pair of alternatives $a_i, a_j \in A$.

Now we will create two new sets of hypothetical alternatives. These new alternatives will be used as tools in calculation that will be preformed. So, for a given set of alternatives $A = \{a_1, a_2, \dots, a_m\}$, we define the sets \bar{A} and \underline{A} in the following way:

$$\bar{A} = \left\{ \left(\max_{i \in J} a_{ik} \right)_{k=1}^n \mid J \in P(\{1, 2, \dots, m\}) \setminus \emptyset \right\},$$

$$\underline{A} = \left\{ \left(\min_{i \in J} a_{ik} \right)_{k=1}^n \mid J \in P(\{1, 2, \dots, m\}) \setminus \emptyset \right\}.$$

By definition, we have that the set \bar{A} with natural ordering $\leq_{\bar{A}}$ forms an upward semilattice with the greatest element $\max A$ which will be denoted by 1 and which will be called the *best alternative*.

Dually, the set \underline{A} with natural ordering $\leq_{\underline{A}}$ is an downward semilattice with the least element $\min A$ which will be denoted by 0 and which will be called the *worst alternative*.

Then, on the set $L = \bar{A} \cup \underline{A}$, we can define an partial order preserving the orders on \underline{A} and \bar{A} , i. e. for $a, b \in L$ if $a \leq_{\bar{A}} b$ then $a \leq b$ and if $a \leq_{\underline{A}} b$ then $a \leq b$. In fact, (L, \leq) is a partially ordered set regarded as the sum of lower and upper semilattice.

Let $a, b \in L$ be such that a is covered by b , i.e., let $a < b$. Then for every criterion c_k , $k \in \{1, 2, \dots, n\}$, we define the *preference of the alternative b over the alternative a with respect to the criterion c_k* as follows

$$\delta_k(a, b) = Z_k(a, b) \cdot \frac{b_k - a_k}{1_k - 0_k}.$$

Let $a, b \in L$ and let $P: a = p_1 \prec p_2 \prec \dots \prec p_j = b$ be a path in L from a to b . Then the *running preference of the alternative b over the alternative a with respect to the criterion c_k through the path P* is defined as follows:

If $\delta_k(p_i, p_{i+1}) = 0$ for all $i \in \{1, \dots, j\}$, then $\delta_k^P(a, b) = 0$, otherwise we put

$$\delta_k^P(a, b) = \frac{1}{\sum_{i=1}^{j-1} Z_k(p_i, p_{i+1})} \sum_{i=1}^{j-1} \delta_k(p_i, p_{i+1}),$$

which is equivalent to

$$\delta_k^P(a, b) = \frac{1}{\sum_{i=1}^{j-1} Z_k(p_i, p_{i+1})} \sum_{i=1}^{j-1} Z_k(p_i, p_{i+1}) \frac{p_{k+1,i} - p_{ki}}{1_k - 0_k}.$$

Starting with alternative a , the alternative b can be reached via several different paths in L with corresponding running preference weights, so we will define the *preference of the alternative b over the alternative a with respect to the criterion c_k* as follows:

$$\pi_k(a, b) = \max \{ \delta_k^P(a, b) \mid P: a \rightarrow b \}$$

and therefore, the *preference of the alternative b over the alternative a* can be regarded as n -tuple

$$\pi(a, b) = (\pi_k(a, b))_{k=1}^n.$$

The *distance of alternative $a \in L$ from the best alternative 1* is defined as

$$D_1(a) = \frac{1}{\sum_{k=1}^n z_k} \sum_{k=1}^n z_k \cdot \pi_k(a, 1),$$

and the *distance of the worst alternative 0 from alternative a* is defined as

$$D_0(a) = \frac{1}{\sum_{k=1}^n z_k} \sum_{k=1}^n z_k \cdot \pi_k(0, a).$$

Now, for two alternatives $a, b \in A$, we say that the alternative a *prefers* the alternative b if a is closer to the best alternative and the worst alternative is further of a , and we say that the alternative a is *indifferent* over the alternative b if they are equally distanced from the best and the worst alternative. Otherwise, we say that the alternatives a and b are *incomparable*.

This relation offers to a decision maker a graph in which some alternatives are comparable and some are not. This information can be useful in practical applications.

If the decision makers want to have a total order of alternatives than they can form following relation which gives full rank of alternatives, but this rank is poorer in the information and less realistic because it comes to balancing distances from the best and the worst alternative.

For $a \in A$, we define the *difference* as

$$D(a) = D_0(a) - D_1(a).$$

A total order of alternatives is defined as follows: for all $a, b \in A$, a *prefers* b if and only if $D(a) > D(b)$, and a *indifferent* b if and only if $D(a) = D(b)$.

3. MCD FOR THE PURCHASE OF A CAR

In this section we will apply the lattice method to the car selection problem for one small private company. We will observe the investments in core assets, i.e. the investments in movable durable goods. As alternative to own funds, the owner of the company has a bank credit and a financial leasing.

Analysis of interest for loans shows that car loans were by far the most sought in 2008. (31.4 percent), but in 2009 interest in auto loans began to decline (25.07 percent), and in the first half of 2010 tremendously dropped to 13.92 percent (this research is conducted by Internet portal www.kredit.rs).

When it comes to cash loans indexed in euros, the interest is almost equally to the car loans. These loans are attractive because they are unconditional, i.e. citizens receive cash and a procedure of approval is much easier and faster than other types of loans.

Financial leasing are often compared to bank loans, because they have some similar characteristics (in a predetermined repayment instalments, interest, method of recording accounting ...), but basically it differs from it because the lesser is the owner of the subject trough entire period of the lease contract and that subject is the instrument of collateral charges.

In this example, we are not going to observe the cost criteria, and we are looking for the best solution with respect to the strength and functionality, consumption of fuel and other expenses, price maintenance and safety of car failure. So, we are interested in buying the best posible car in the present moment.

We will assume that the owner of a private company has a certain amount of money available to be invested for the purchase of a car. So, using that assets he can buy a new small car for cash, or the same amount of money can be invested as a deposit in the bank for a credit intended for buying a new but larger car, or even larger car on leasing, or buying for cash even larger but used car, or the largest (and most expensive) used car on bank credit. Thus, the set of alternatives is given by Table 1.

Table 9: The set of alternatives

A	<i>Alternatives</i>
a_1	New car for cash
a_2	New car on credit
a_3	New car on leasing
a_4	Used car for cash
a_5	Used car on credit

The set of alternatives will be evaluated by the following set of criteria presented by Table 2. We will assume that all criteria are of the same importance, i.e. we will assume that $z_j = 1$, for every $j \in \{1,2,3,4\}$. Also, to each criterion c_j , $j \in \{1,2,3,4\}$, we associate the function $Z_j : A \times A \rightarrow [0, +\infty)$, that measures the importance of the difference between two given alternatives in a following way: for all $a, b \in A$, we put $Z_j(a, b) = 1$, if $a \neq b$, and $Z_j(a, b) = 0$, otherwise.

Table 2: The set of criteria

C	<i>Criteria</i>
-----	-----------------

c_1	Strength and functionality
c_2	Consumption of fuel and other expenses
c_3	Price maintenance
c_4	Safety of car failure

For each $i \in \{1,2,3,4,5\}$ and $j \in \{1,2,3,4\}$, the degree to which the alternative a_i satisfies the criterion c_j is given by Table 3.

The values given in this table are compatible with the decision maker, i.e. the decision maker proposed these values that represents the degree to which alternatives satisfy the criteria.

Table 3: Degrees of satisfaction

	c_1	c_2	c_3	c_4
a_1	5	9	10	9
a_2	6	8	9	9
a_3	7	7	8	9
a_4	8	6	7	7
a_5	10	5	6	6

By the lattice method, starting with the set of alternatives, the lattice of new alternatives generated by the given ones is formed, and it is illustrated by Figure 1.

Figure 3: The lattice of new alternatives

As it can be seen from Figure 1, for each $i \in \{1,2,3,4,5\}$, all paths from alternative a_i to the top have the same length, and also all paths from the bottom to the alternative a_i have the same length (all these lengths are equal to 4).

Farther, for each $i \in \{1,2,3,4,5\}$, the distances of alternative a_i from the best alternative 1 and the distance of the worst alternative 0 from the alternative a_i are calculated, and thus we obtain the differences of each alternative a_i .

The obtained distances and differences are presented by Table 4.

Table 4: Distances and differences

	$D(a_i,1)$	$D(0,a_i)$	$D(a_i)$
a_1	0.1875	0.0625	0.1250
a_2	0.1688	0.0812	0.0876
a_3	0.1500	0.1000	0.0500
a_4	0.0894	0.1606	-0.0712
a_5	0.0625	0.1875	-0.1250

Now, it is easy to verify that lattice method provides linear ordering of alternatives in a following way.

$$a_1 \rightarrow a_2 \rightarrow a_3 \rightarrow a_4 \rightarrow a_5$$

So, the best solution for the owner of small private company is to buy a small car for cash, and the worst solution is buying a used car for a bank credit.

4. CONCLUSION

New method can be successfully applied to practical examples, and it is crisp in a relatively small number of alternatives. In case that the relative values of certain points are included, in other words, if they are different, then the decision maker preferences can be very good described. Namely, in that case calculating the preference of one alternative over another, with respect to a given set of criteria, include in the preference both the difference between these alternatives and the values of alternatives themselves.

MULTICRITERIA DECISION MAKING IN FRUIT WINE EVALUATION

Lari Hadelan¹, Vjekoslav Par², Tea Karlič³

¹PhD, Agricultural Economics

²PhD, Agricultural Economics

³MSc, Agricultural Engineering

Abstract: *This paper uses the SMART multicriteria decision making method for the evaluation of three fruit wines. Rating the entrepreneurial potential of production of fruit wines has been conducted considering the economic, market and technological criteria. Blackberry wine has achieved the best final score, primarily because of its greatest market potential and technological simplicity. At the same time, apple wine has shown the best economic efficiency, but with a very poor market identity and the highest technological demands. Cherry wine has achieved a better final score than apple wine, with a slightly worse economic performance. Furthermore, the ranking has been changed using different weights of criteria. In this situation, cherry wine has turned out to be the best option. The SMART method has proved to be a useful tool in business decision making providing more objectivity within the decision-making process in complex situations when alternative evaluation should be made based on mutually conflicting criteria.*

Keywords: SMART, multicriteria decision making, fruit wine, rating

1. INTRODUCTION

The most important entrepreneurial job in large part is to make decisions about the business. The entrepreneurs need the right decisions that will increase overall business potential of their company. They have to make decision on how to run their business so as to make a profit. They have to make choices on matters such as what they will produce, how they will produce it and how to finance the production. In order to start running a business, an entrepreneur must decide on what he is going to offer. It is not enough just consider the expected costs and income but also include all other factors that influence this decision. In this paper authors proposed a modern approach of deciding which fruit wine production offers the best entrepreneurial potential.

Production of fruit wines is very popular in the World with a long tradition. Market development of fruit wine varies from country to country with certain region distinctiveness of flavour or technology. Despite many advantages, the production of fruit wines in Croatia cannot be considered as a commercial activity. There are only a few fruit wine producers who succeeded to set up a serious fruit wine business, selling their fruit wine legally in grocery shops or HoReCa sector (abbreviation of the words Hotel/Restaurant/Café). Most of other manufacturers offer small quantities of fruit wines that are not legally regulated, mainly on green markets and fairs.

Since almost all kinds of fruits can be processed into fruit wine that option is definitely not exploited enough, while the economically it can be very attractive.

One of the reasons for small market share of commercial fruit wines production in Croatia is a lack of information about its economic effects, and weak consumer familiarity with this type of wine.

In the last few decades, computers and computers' models became an important tool in the modern agriculture production. Increasingly, farmers are implementing different complex computer models for solution of various planning problems. Hierarchical multi- criteria decision models (MCDM) are aimed at the classification and evaluation of objects defined in attribute-value space.

In this paper wine from blackberry, apple and cherry were evaluated using Simple Multi-Attribute Rating Technique (SMART). This technique belongs to Decision Support Systems (DSS) that is computerized information system which supports decision-making activities. As one of the simplest multicriteria decision making methods, SMART, in this paper, took in the consideration economic, market and technological features of this three fruit wines providing scientific and rational framework for the entrepreneurial orientation.

2. MULTICRITERIA DECISION MAKING METHODOLOGY

A decision is a choice out of a number of alternatives, and the choice is made in such a way that the preferred alternative is the "best" among the possible candidates. Multicriteria decision analysis (MCDA) is a structured approach to analyze problems with several criteria and alternatives. It helps the decision maker (DM) to make consistent decisions by taking all the important objective and subjective factors into account (Mustajoki et al, 2007). Methods for multicriteria decision making (MCDM) have been designed in order to designate a preferred alternative, to classify the alternatives in a small number of categories, and/or to rank the alternatives in a subjective order of preference (Lootsma, 1999). Decision models are typically developed through decomposition of complex decision problems into smaller and less complex sub-problems; the result of such decomposition is a hierarchical structure that consists of attributes and utility functions (Rozman, Pažek, 2005).

Methods of multi-criteria analysis can be found in many papers within the agriculture topics. Among the author from the ex-YU region there are significant numbers of multicriteria methods papers from the Faculty of Agriculture and Biotechnology, University of Maribor. Rozman et al. (2006) apply MCDM in the case of selecting the most appropriate methods of spelt food processing displayed several-criteria decision support model. Pažek et al. (2006) used AHP and DEX-and expert system for decision making on farms with organic production. A large number of papers based on multicriteria analysis in the field of agriculture and water resources management announced Bojan Srđević from the Faculty of Agriculture, University of Novi Sad (2000, 2005).

The Simple Multi-Attribute Rating Technique (SMART) is one of the simplest MCDM methods (Winterfeldt, Edwards, 1986) which was put forward by Edward's in 1977. The cost of this simplicity is that the method may not capture all the details and complexities of a real problem (Brady et al, 1997). However, SMART method leads to results that are easily interpreted and may serve as one of the guidelines for further business action.

The performance of the alternatives under the respective criteria, evaluated via a direct-rating SMART procedure, is expressed in grades on a numerical scale. The ranking value x_j of alternative A_j is obtained simply as the weighted algebraic mean of the utility values associated with it, i.e.

$$x_j = \sum_{i=1}^m w_i a_{ij} / \sum_{i=1}^m w_i, \quad j = 1, \dots, n \quad (1)$$

In the alternatives evaluation procedure, decision makers are asked to rank each of the attributes in relation to the goal. The top rank is given a score of 100. Each other attribute is then tasted against to this standard given a score from 0 to 100. These weights are then normalized to sum to 1 (Parkin, 1996). The alternative with the highest score is determined as the best among all taken in consideration.

In this paper SMART analysis is used for the purpose of comparative assessment of entrepreneurial welfare of the fruit wines production. The best production orientation considering three kinds of the fruit wines, blackberry, apple and cherry wine, is determined based the economic, market and technological criteria. Data on the economic success of manufacturing certain types of wine were collected from secondary sources and were updated by interviews with Croatian fruit wine producers. Furthermore, producers have evaluated technology complexity and demands using the SMART methodology demands. For this purpose opinions of three manufacturers that produce all three types of analyzed wines have been used. Finally, market prosperity of each type of wine is determined by the survey which made on the random sample of 53 respondents.

SMART analysis in paper is made by the software Criterium DecisionPlus 3.0 (CDP). It supports the two leading methodologies for multi-criteria analysis (AHP and SMART) and uncertainty analysis.

3. RESULTS

Economic performance of the fruit wine venture

Economic performance is one of the major motivations of each business venture. Economic results of this business activity were difficult to measure. There is no any relevant source of economic indicators which would give insight to business success of this relatively non commercial fruit wine production. In Croatia there are only a few legalized fruit wine producers who offer their wine in some of HoReCa branches. Some

of them precede fruits to wine from their own fruit plantation while other purchase fruit on the market. On the fruit wine market the most common is blackberry wine that can be purchased in stores, restaurants, pharmacies and healthy food stores. Apple and cherry wine are not so usual in the average stores but they can be found in specialized wine boutiques or can be ordered online from several producers. Calculations of income and costs are made using different recipe sources where the three major ingredients are present – fruit, sugar and different oenological products. Costs of the three fruit wine are presented in the following table.

Table 10: Production costs of 100 liters of fruit wine, EUR

	Blackberry wine	Apple wine	Cherry wine
Cost of fruit purchase	133.50	24.80	111.30
Sugar	16.30	14.40	8.00
Oenological and other products	29.30	29.30	29.30
Legal costs	93.30	93.30	93.30
Labour costs	32.00	48.00	40.00
TOTAL	304.40	209.80	281.90

Because of the effects of economy of scale, the expected average cost would be reduced by increasing the produced quantity of fruit wines. The lowest production cost of apple wine is a result of the lowest fruit price. Apples for industrial processing can be purchased at the price of 0.09 EUR per kilo.¹ On the other hand, approximately the same income can be achieved by selling all three fruit wines. Differences of selling price value are not as significant as in the case of the costs.

Based on the costs and income authors calculated the *Cost/Income ratio* that measures business efficiency using operating costs as a percentage of operating income. The ratio should be as low as possible.

Table 11: Expected net income of 100 liters of fruit wine, EUR

	Blackberry wine	Apple wine	Cherry wine
Selling price per litre	4.70	4.00	5.30
Income	470.00	400.00	530.00
C/I ratio	0.648	0.524	0.532

Market prosperity survey

Market prosperity of the three fruit wines was determined by researching consumer's familiarity with the wines and the frequency of certain fruit wine consumption. Survey was made by phone on the random sample of 53 respondents all over Croatia. The occurrence by gender is 60% female and 40% of men. Most of the respondents (30%) are older than 50 years. Majority of respondents (62%) consumed some of the fruit wines. Out of that, women are more frequent consumers and thus 8% of them consume fruit wine daily. The best known fruit wine is blackberry wine which was consumed by 70% of respondents. Significantly smaller consumption is of cherry and apple wine which was consumed by only 7% and 5% of respondents respectively.

Technological complexity

Technological complexity of the three fruit wine is determined by the producers' estimations. In this survey were included only producers that produce all three kinds of wine having objective insights to technologic specificity of each fruit wine. Unfortunately, only two all-fruit wine producers were found. From interviews with them, blackberry wine was estimated as at least technologically demanding production. Second place by technological complexity went to the cherry wine, while the wine apple is the most demanded. Cherries contain pits that should be removed before wine production while the wine apple is characterised by the lower amount of alcohol and acids, so it is more difficult to preserve this wine against deterioration. However, according to interviewed producers, technological demands for all three kinds of wine have very similar value and differences are irrelevant.

¹ Average purchase price of the largest food industries in Croatia in 2011 by the authors' research.

Building the SMART model

According to the surveyed economic, market and technological criteria value, it is possible to build the SMART model. The top rank is given a score of 100 while each other attribute is given a score from 0 to 100 related to the extent that lagging behind best result. Quantitative data (Cost/ income ratio) can be easily standardised to SMART value, while qualitative data (consumption frequency and technological complexity) are defined by respondent using scale from 0 to 100.

Table 12: SMART model with criteria scores.

	Blackberry wine	Apple wine	Cherry wine
Economic performance – standardised values	80.9	100.0	98.5
Market prosperity	100.0	50.0	70.0
Technological complexity	100.0	95.0	98.0

Based in the built SMART model, the entrepreneurial potential of the three fruit wines can be ranked.

Graph 1: Fruit wine ranking with the same weights of criteria

The blackberry wine is ranked as the first entrepreneurial choice with the highest final score (0.93). The leading position is a consequence of the best market prosperity and technological simplicity. Cherry wine is the second best with a certain lag in respect of market prosperity compare to blackberry wine. Apple wine is on the third place despite the best economic performance.

In the previous graph it is assumed that all three criteria have the same weights. However, each entrepreneur can adopt this model according to his/her preferences and assumed criteria importance. The following graph presents the situation of the different weights of selected criteria. For this purpose, economic criteria are the most important representing 60% of the total grade of fruit wine. Following, the market criteria with 30% impact on the overall score, while technological complexity is the least important factor with weights of 10%.

Graph 2: Fruit wine ranking with different weights of criteria

Using a different weights approach the ranking of fruit wine is changed. Cherry wine became the best entrepreneurial option thanks to better economic performance marked with the highest impact on the final grade.

Accordingly, sensitivity analysis can illustrate how the results will be modified by shifting criteria loading of importance. On the Graph 3, there is an illustration about the influence of the Economic performance weights on the final fruit wine ranking. When the w_1 is applied as the importance of economic criteria is equal to market and technological criteria importance, blackberry wine is the best option. Raising the importance of Economic performance on the w_2 and w_3 , cherry wine and apple wine become the best options respectively.

Graph 3: Sensitivity of wine ranking relate to *Economic performance* weights

4. CONCLUSION

Making decision on "what to produce" is the first and the most important decision of the entrepreneurial venture. In this paper, authors presented a modern approach of rational business decision making. The main strength of a rational decision making is that it provides structure and discipline to the decision making process. It ensures consideration the full range of factors relating to a decision, in a logical and comprehensive manner. Decision of fruit wine production should not include just a simple cost/benefit method but also market prosperity and technological complexity. Even such a comprehensive analysis can be extended by a number of further decisive factors. In this paper authors used a The Simple Multi-Attribute Rating Technique (SMART) as one of the simplest multicriteria decision making methods for the purpose of evaluating entrepreneurial potential of three different fruit wine production. In situation when economic, market and technological aspect of rating had the same importance, blackberry wine is determined as the best business option. Applying weighting where economic performance of venture plays much more significant factor of the fruit wine evaluation, cherry wine was rated as the best alternative. Presented model offers more objectivity during decision making process. It involved determination of economic parameters, interview with related producers and market survey which were, finally, incorporated into a single evaluation grade. However, the model is not fixed and invariable, it should be adjusted by specific situation and preferences of users. Due to this, SMART method, as a part of Decision support systems, do not exclude the man as a final decision-maker but increase his prudence and decision making objectivity.

USING CONJOINT ANALYSIS TO ELICIT EMPLOYERS' PREFERENCES TOWARD KEY COMPETENCIES FOR A BUSINESS MANAGER POSITION

Milena Popović¹, Marija Kuzmanović², Milan Martić³

¹University of Belgrade, Faculty of Organizational Sciences, milena.popovic@fon.bg.ac.rs

²University of Belgrade, Faculty of Organizational Sciences, marija.kuzmanovic@fon.bg.ac.rs

³University of Belgrade, Faculty of Organizational Sciences, milan@fon.bg.ac.rs

Abstract: *This paper attempts to identify those competences for a business manager position which potential recruiters consider to be important. We propose conjoint analysis as an appropriate tool to determine the recruiters' preferences. Conjoint analysis is an experimental approach used as a tool for measuring customer preferences regarding the attributes of a product or a service, and for understanding the development of an individual's preferences. The conducted research and the obtained results have the purpose to inform potential candidates about various recruiters' expectations, and to help university teachers design their courses.*

Keywords: *key competences, business manager, recruiters, conjoint analysis, preferences*

1. INTRODUCTION

The employees are the key to success for any company. Therefore, the companies that recognize this fact and manage to select and retain quality staff are more likely to achieve competitive advantage. To choose good quality staff means to organize the recruitment process properly and to select the candidates capable of being efficient and loyal to the company.

Recruitment is the process of identifying and hiring the best-qualified candidate from a previously generated applicant pool so to meet the goals of a company and to satisfy current legal requirements (Catano et al., 2001). In the recruitment process, candidates' competences have a vital role. There are a number of papers devoted both to concepts of competence and to various models of the key competencies. According to Dalton (1997), a competency model describes "motives, traits, and so forth as a set of desired behaviors for a particular job position or level". As such, a competency model is an "occupational profile" typically developed for individual occupations but also extensible to occupational groups. Competency models are used to tie job specifications to the organizational strategy; the competencies then function as a common language (Lievens et al., 2004) which is used to identify the critical success factors driving performance in organizations (Delamare Le Deistand & Winterton, 2005).

The objective of this paper is to determine the list of key competencies for a business manager position which potential recruiters consider particularly valuable. For that purpose we employ conjoint analysis.

Conjoint analysis is an experimental approach used for measuring customer preferences regarding the attributes of a product or a service (Kuzmanović & Obradović, 2010; Venkatesh et al., 2012). Originally developed in the field of mathematical psychology, conjoint analysis has attracted considerable attention, especially in marketing research, as a method that portrays consumer decisions (Iyengar & Jedidi, 2012). However, few studies have used the conjoint analysis within the labor market. Using conjoint analysis Baker and McGregor (2000) determined the relative importance of seven criteria on hiring accountants and, at the same time, examined whether these values differ among different groups of individuals. Biesma et al. (2007) applied conjoint analysis to estimate preferences of employers for key competencies of master level graduates entering the public health field.

This paper is organized as follows. Section 2 provides an overview of the literature related to the models of key competencies. Section 3 describes conjoint analysis, a method we have proposed as an appropriate tool for determining the importance of a variety of competencies from the recruiters' point of view, as well as to isolate the most important ones in the process of candidate selection. Survey was conducted and most important findings are given in Section 4. Section 5 provides the concluding remarks.

2. MODELS OF KEY COMPETENCIES

In today's environment characterized by high rate of unemployment and high pressure to rationalize production, as a result of increased competition causing an increase in labor productivity, it is crucial for the company to hire the best people. In other words, technological and organizational changes lead to an

increased need for staff equipped with higher and better skills (Elias & McKnight 2001; Green et al., 2001; Stasz, 2001) which is primarily achieved through education and training (Borghans et al., 2001).

To respond to the demands of the modern age, it is necessary for an organization to perform quality and efficient recruitment, selecting the right people for the job, and efficiently using human resources, motivating employees, eliminating the leaves, introducing fair remuneration and promotion systems, and making decisions based on current information (Mitchell et al., 2011). Expert recruitment and orientation of employees enables assigning the employees on the basis of their skills, attitudes and work motivation.

Although there is no direct and linear relationship between the recruitment of personnel and organizational efficiency and performance, it is reasonable to assume that improved personnel selection will result in better performance (Kurtz & Bartram, 2002). In addition to potential benefits directly related to a good recruitment, there are lower costs of poor selection of candidates, as well as the risk of rejection of good candidates who can be hired by competitors (Robertson et al., 2002).

The question is to determine the capabilities, skills and competencies which a candidate should possess so he could be chosen. In addition, some other potential problems can occur, as when candidate's wishes and potentials do not align with demands of the employer.

In response to the above question, numerous studies have been conducted. In terms of qualities and skills a candidate should possess (using notions of many authors) two types of competencies: field-specific competencies and generic competencies. Generic competencies can be defined as the combination of learning, analytical and problem-solving abilities applicable in various domains (Heijke et al., 2003). Several studies investigated the role of key competencies for the labor market (Borghans et al., 2001; Stasz, 2001; Heijke et al., 2003). Some emphasize the role of field-specific competencies on labor market outcomes (Mane, 1999) while others stress the importance of generic competencies (Stasz, 2001).

According to Ruetzler et al. (2010), there are seven criteria to evaluate a candidate: academic grade point average (GPA), interpersonal skills, interview preparedness, the ability to work with others, alignment with organizational culture, and work experience.

Since a student's primary "job" is to study academic materials, a student's GPA is often seen as the equivalent of an employer's performance evaluation. The use of the GPA as a selection variable is controversial; however, when a job candidate has limited work experience, the GPA provides an apparently objective criterion to which recruiters can turn in screening applicants and establishing a candidate's potential (Kuncel et al., 2004). Although some studies suggest that overall GPA is not considered to be an important selection criterion (Baker & McGregor, 2000; Guo et al., 2009; McKinney et al., 2003), there is support elsewhere for the proposition that GPA is used as a selection tool and may well be important when identifying a set of candidates to be interviewed (Roth & Bobko, 2000).

Interpersonal skills, which include listening as well as oral and written communication abilities, are widely identified across the literature as important competencies. Interpersonal skills – sometimes referred to generically as communication skills – have been ranked among the five most important skills for entry-level managers by hospitality industry leaders (Chung-Herrera et al., 2003; Fjelstul, 2007; Mayo & Thomas-Haysbert, 2005; Tesone & Ricci, 2005).

Little research exists that directly examines the preparedness of a candidate for an interview or the impact of such preparation on job offers. A recent study addresses the effects of preparation for interviews that involves faculty members conducting mock interviews so that candidates can "rehearse" performing in the interview setting, concluding that mock interviews lead to increased confidence and enhanced interviewing skills (Hansen et al., 2009).

Having the ability to work with others involves being able to work as a team member as opposed to behaving as an individual who prefers to work alone or does not like to help others. Being teamoriented is a highly valued trait in the most industries. Tesone and Ricci (2005) found that the ability to work as part of a team was the number one skill identified by industry practitioners. In Fjelstul's (2007) research, teamwork ranked as the second most important skill. Baker and Harris (2000) discovered that students specialized in technology or information systems felt that the ability to work with others was one of the two most important traits in the eyes of recruiters.

Alignment with an organization's culture and mission occurs when a candidate's values and beliefs are consistent with those espoused in the organization's internal literature, such as its mission statement. An employee's "emotional commitment" and sense of identity with a company lead to greater performance both of an employee and a firm (Hemp, 2002). A meta-analysis conducted by Kristof-Brown et al., (2005) found that person-organization fit, the compatibility between a person and an organization, correlated significantly with the intent to hire and with actual job offers.

3. CONJOINT ANALYSIS

Conjoint analysis is a multivariate technique that can be used to understand how an individual's preferences are developed. Specifically, the technique is used to gain insights into how consumers value various product attributes based on their evaluation of the complete product (Kuzmanovic & Martic, 2012). Conjoint analysis, sometimes called 'trade-off analysis', reveals how people make complex judgments. The technique is based on the assumption that complex decisions are made not based on a single factor or criterion, but on several factors CONsidered JOINTly, hence the term Conjoint. Conjoint analysis enables the investigator to better understand the interrelationship of multiple factors as they contribute to preferences.

Conjoint experiments involve individuals being asked to express their preference for various experimentally designed, real or hypothetical alternatives. These hypothetical alternatives are descriptions of potential real-world alternatives in terms of their most relevant features, or attributes; hence, they are multi-attribute alternatives (Parker & Schriff, 2011). Lists of attributes describing single alternatives are called profiles. Typically, the set of relevant attributes is generated by reviewing the research literature and performing pilot research with techniques such as focus groups, factor listings, or repertory grids. Two or more fixed values, or "levels", are defined for each attribute, and these are combined to create different profiles.

Obviously, the number of possible profiles increases immensely with the increasing number of attributes or levels. A set of profiles that consists of all the possible combinations of the attribute levels is the full-factorial experimental design. As in most conjoint studies, the large number of possible combinations of attributes and levels make it impossible to generate a design based on all the possible combinations. Namely, such designs are impractical because the subjects' cognitive limitations and time constraints do not allow considering a large number of profiles. Thus, fractional factorial designs, which assume no interactions between attributes and ensure the absence of multicollinearity, are used to reduce the number of profiles.

The experimental procedure involves profiles being presented to respondents who are invited to express their preference by rating or ranking these profiles. Preference functions are estimated from this data, using OLS regression for rating the data, and ordinal techniques when the rankings are obtained.

Having collected the information on individual preference, the responses need to be analyzed. To determine the relative importance of different attributes to respondents, the trade-offs that individuals make between these attributes, as well as the overall benefit taking into account these trade-offs, a relationship must be specified between the attributes' utility and the rated responses. The simplest and most commonly used model is the linear additive model. This model assumes that the overall utility derived from any combination of attributes of a given good or service is obtained from the sum of the separate part-worths of the attributes. Thus, respondent i 's predicted conjoint utility for profile j can be specified as follows:

$$U_{ij} = \sum_{k=1}^K \sum_{l=1}^{L_k} \beta_{ikl} x_{jkl} + \varepsilon_{ij}, \quad i = 1, \dots, I, \quad j = 1, \dots, J, \quad (1)$$

where I is the number of respondents; J is the number of profiles; K is the number of attributes; L_k is the number of levels of attribute k . β_{ikl} is respondent i 's utility with respect to level l of attribute k . x_{jkl} is a (0,1) variable that it equals 1 if profile j has attribute k at level l , otherwise it equals 0. ε_{ij} is a stochastic error term.

The parameters β_{ikl} are estimated by a regression analysis. These beta coefficients, also known as part-worth utilities, can be used to establish a number of things. Firstly, the value of these coefficients indicates the amount of any effect that an attribute has on overall utility of the profiles— the larger the coefficient, the greater the impact. Secondly, part-worths can be used for preference-based segmentation. Namely, given that part worth utilities are calculated at the individual level, if preference heterogeneity is present, the researcher can find it. Respondents who place similar value to the various attribute levels will be grouped together into a segment. Thirdly, part-worths can be used to calculate the relative importance of each attribute, also known as an importance value. Importance values are calculated by taking the utility range for

each attribute separately, and then dividing it by the sum of the utility ranges for all of the factors. The results are then averaged to include all of the respondents. If the market is characterized by heterogeneous customer preferences, it is possible to determine the importance of each attribute for each of isolated market segments.

Overall utility scores can be estimated for different combinations of attributes by inserting the appropriate levels into Equation 1. These utility scores can be further used to predict the market shares for each of the defined combinations. Finally, part-worths can be used to test the internal validity of conjoint analysis, i.e. the extent to which the results are consistent with economics theory, or, more generally, *a priori* expectations.

4. EMPIRICAL STUDY

The main objective of this study was to identify the key competencies of candidates for the business manager position from the employer's point of view, but also to determine a most preferred candidate. The survey was fielded in Belgrade, Serbia, in May 2011. In total, 31 individuals answered the survey. While this sample size may be regarded as relatively small, it is not atypical for conjoint analysis application when the survey goal is investigational work, or to develop a hypothesis about a market (Orme 2006).

Study design

The first stage in the design of a conjoint analysis study is the selection of the attributes. We have defined ten key attributes based on literature review (Biesma et al., 2007; Ruetzler et al., 2010), and opinions of potential employers obtained within pilot research. Having chosen the attributes, levels must be assign to them. These should be realistic, plausible and capable of being traded. The attributes and levels chosen for this study are shown in Table 1.

Table 1. Attributes and their levels

Attribute	Level 1	Level 2	Level 3
Education	Bachelor	Master, general	Master, specialized
Work Experience	None	Internship	Employment
Foreign languages	One language	More languages	/
Computer skills	Basic	Advanced	/
Communication skills	Fair	Good	/
Problem solving skills and creativity	Fair	Good	/
Team working skills	Team worker	Individualist	/
Organizational skills	Average	Good	/
Proactivity	Highly	Insufficient	/
Interview preparedness	Insufficient	Full	/

The first attribute "Education" refers to the fact that candidate entering the selection process must have at least the Bachelor degree. In addition to Bachelor degree, the candidate may have a "general" master degree, or may be specialized in a specific field. The attribute "work experience" is chosen because employers often emphasize its importance during the pilot research. In this study we distinguish work experience in terms of employment or internship. The internship most often refers to the three-month period of work during studies. The assumption is that all candidates are fluent in at least one foreign language (usually English language). Therefore, we define two levels for this attribute. The first level corresponds to excellent reading, writing and good conversation of one foreign language, while the second level assumes the same for more than one languages. Candidate's preparedness for the interview indicates his willingness and desire for a given position. This attribute refers not only to how the candidate is informed about the company but also his attitude, manners and outfit. Therefore, we define two levels of this attribute: full and insufficient prepared. All other attributes are described using two levels, where one of them refers to the fair level while the other refers to a higher level of a certain skill.

Although many previous studies stressed the GPA as an important factor, the results of the pilot research we conducted indicate that this attribute is of negligible importance for the position of business manager. Therefore, we excluded it from this study.

Once attributes and attribute levels are selected, they must be combined to form different hypothetical profile of candidates for survey respondents to assign preference ratings. The attributes and levels in Table 1 gave

rise to 2304 possible profiles ($3^2 \times 2^8$). To reduce this number of profiles to a manageable level, in this study a component of the statistical package SPSS 16.0 (Orthoplan) was used. Thus the 2304 possible profiles were reduced to 16. Two control profiles (holdout tasks) were added to the given design. These 2 profiles were not used by the conjoint procedure for estimating the utilities. Instead, the conjoint procedure calculates correlations between the observed and predicted rank orders for these profiles, as a check of the validity of the utilities. The 18 hypothetical profiles considered are shown in Table 2.

In order to elicit the preferences for the various profiles, in this study a rating approach was utilized. The respondents expressed their preferences for a particular candidate on a scale of 1 to 9, where 1 stands for absolutely undesirable, and 9 stands for absolutely desirable. The survey was conducted using the traditional “paper and pencil” method.

Table 2. Generated list of profiles

ID	Education	Work Experience	Foreign languages	Computer skills	Communication skills	Problem solving creativity	Team working skills	Organizational skills	Proactivity	Interview preparation
1	Master G	none	one	advanced	good	fair	teamwork	good	insufficient	insufficient
2	Bachelor	none	more	basic	fair	fair	individual	good	insufficient	full
3	Bachelor	internship	more	advanced	good	good	individual	average	insufficient	insufficient
4	Bachelor	employment	one	advanced	good	good	teamwork	good	highly	full
5	Master S	internship	more	basic	good	fair	teamwork	good	highly	insufficient
6	Bachelor	employment	more	advanced	fair	fair	teamwork	average	insufficient	insufficient
7	Master G	employment	more	basic	fair	good	individual	good	highly	insufficient
8	Bachelor	none	more	basic	good	good	teamwork	good	insufficient	full
9	Master S	employment	one	basic	good	fair	individual	average	insufficient	full
10	Bachelor	none	one	basic	good	good	individual	average	highly	insufficient
11	Master G	internship	one	basic	fair	good	teamwork	average	insufficient	full
12	Bachelor	none	one	basic	fair	fair	teamwork	average	highly	insufficient
13	Master G	none	more	advanced	good	fair	individual	average	highly	full
14	Master S	none	one	advanced	fair	good	individual	good	insufficient	insufficient
15	Master S	none	more	advanced	fair	good	teamwork	average	highly	full
16	Bachelor	internship	one	advanced	fair	fair	individual	good	highly	full
17	Bachelor	internship	one	advanced	fair	fair	teamwork	average	insufficient	full
18	Master S	internship	one	advanced	fair	good	teamwork	good	insufficient	full

* holdout profiles

Analysis and Results

In the total sample, slightly more than half of respondents were female (54,8%). Table 3 provides detailed demographic data.

Table 3. Demographic characteristics

Characteristics	Description	%
Industry	Bank	9.6
	Production company	19.4
	Sales company	29.1
	Service company	41.9
Position at the company	HR	38.7
	Sales manager	25.9
	Marketing manager	12.9
	Project manager	6.4
	Top manager	16.1
Working experience	Less than five years	54.8
	From six to ten years	32.3
	More than ten years	12.9

Results from the analysis are shown in Table 4 and Figure 1. Table 4 presents the (averaged) part-worth utilities of each level of the attributes, while Figure 1 is the graph description of the attributes importance.

The constant whose value is 5.771 (Table 4) represents a stochastic error obtained through regression analysis, and it is used to calculate the total utility of each profile. A high value of the Pearson coefficient, 0.983, confirms the high level of significance of the obtained results. Similarly, a high value of the Kendall correlation coefficient, 0.899, indicates a high level of correlation between the observed and estimated preferences. The Kendall coefficient for two holdout profiles has a value of 1.000, which is an additional indicator of the high quality of the obtained data.

The signs of the part-worths are in line with the a priori expectations. For example, a negative sign is attached to the level which indicates that there is no work experience. Respondents showed expected behavior for all other attributes, with the highest level having the highest utility. These results can be regarded as an indication of the theoretical validity of the questionnaire, i.e. the extent to which the results conform to the a priori expectations.

As Figure 1 shows, the most important attribute is "Proactivity", with an importance value of 16.69%. Slightly less important is the attribute "Work Experience", with a value of 15.22%. Attributes with a relatively higher importance are also "Interview preparedness" (12.08%) and "Education" (11.02%). Moderate important attribute is "Problem solving and creativity" (9.80%) followed by three equally important attributes "Computer skills", "Communication Skills" and "Team working skills" (importance value = 9.63%). The least important attributes by far are "Foreign Language" and "Organizational skills", whose importance values amount to 3.55% and 2.73%, respectively.

Table 4. Averaged part-worth utilities

Attribute	Attribute level	Part-worth utilities	Std. Error
Education	Bachelor	-0.164	0.114
	Master, general	-0.188	0.134
	Master, specialized	0.352	0.134
Work Experience	None	-0.427	0.114
	Practice	0.109	0.134
	Work	0.319	0.134
Foreign languages	One language	-0.087	0.086
	More languages	0.087	0.086
Computer skills	Basic	-0.236	0.086
	Advanced	0.236	0.086
Communication skills	Fair	-0.236	0.086
	Good	0.236	0.086
Problem solving skills and creativity	Fair	-0.240	0.086
	Good	0.240	0.086
Team working skills	Team work orientation	0.236	0.086
	Individual work orientation	-0.236	0.086
Organizational skills	Average	-0.067	0.086
	Good	0.067	0.086
Proactivity	Yes	0.409	0.086
	Insufficient	-0.409	0.086
Interview preparedness	Insufficient	-0.296	0.086
	Yes	0.296	0.086
Constant	5.771	0.095	
Correlations between observed and estimated preferences			
Pearson's R	0.983	Significance = 0.000	
Kendall's tau	0.899	Significance = 0.000	
Kendall's tau for 2 Holdouts	1.000		

Part-worth utilities reflect the sensitivity of respondents to change of attribute levels (see Figure 2). It may be noted that all attributes included in the study are extremely sensitive to level changes, but in the case of three-level attributes this sensitivity varies depending on the interval. For example, when we observe the attribute "Work Experience", the preferences decline much faster in the interval Internship-None than in the interval Employment-Internship. In the case of attribute "Education", only the best level (master specialized) increases the overall preferences, while the medium (master general) and worst (bachelor) decrease them. These two levels have a negative sign of part-worth utilities.

Figure 1. Averaged attribute importance values

Figure 2. Part-worth utility functions

Characteristics that describe the "best" candidate are: Specialized Master degree in education, has work experience, speaks two or more foreign languages, has advanced computer skills, has strong communication skills, he/she is very creative and skilled in problem solving, oriented to teamwork, possess good organizational skills, he/she is proactive and well prepared for the interview.

6. CONCLUSION

To determine the skills and competencies for the business manager position which recruiters particularly prefer, in this paper conjoint analysis was used. To our knowledge, this is the first study to use this approach for that purpose in Serbia.

Research has shown that potential employers consider the proactivity as the most important attribute, while number of foreign languages and organizational skills are of least importance. They stressed that they more often pick proactive candidates due to lack of time for the training of hired workers. Because of the shorter training, selected candidates must be skilled, resourceful and capable to quickly incorporate into the new work environment.

Since the goal of the research was to show the applicability of conjoint analysis to determine the recruiters' preferences toward key competencies for a business manager position, the findings obtained and presented above confirm that our task is successfully accomplished. The findings of the study are significant both on a theoretical and applied levels. On a theoretical level, they add to our knowledge of the relative importance of some factors influencing recruiters' preferences. On the applied level, the results provide useful information both to students (the potential candidates) and university teachers (those that guide and educate candidates). Indeed, these information could help teachers to provide students more effectively with appropriate skills and competencies needed for their future employment.

Abstract: *Energy is a precondition for the survival of the mankind. It drives everything, sustains life. Consequently, energy efficiency has been one of the most widely discussed topics in the last twenty years. This paper is aimed to investigate the effectiveness of measures for improving energy management in local communities. The analysis is done on the example of the municipality of Bijeljina. The starting point for this research is the Sustainable Energy Action Plan for the Municipality of Bijeljina, which was presented in 2011. The idea of the paper is to examine selected measures from the Action Plan in order to rank them on the basis of their effectiveness. Effectiveness is defined as a logical function that aggregates four different criteria: the cost of their implementation, their impact on reducing CO₂ emission, reducing energy consumption and increasing the usage of renewable energy sources. In this study, logical aggregation is implemented using generalized Boolean polynomials that are based on interpolative Boolean algebra. The results have shown that three factors are of particular importance for efficient energy management: education of population, large infrastructure projects and investment in new production capacities. This paper may be of particular value to those local communities that do not yet have developed awareness of sustainable and efficient energy management, and to all those who are in the process of transformation into energy-efficient communities.*

Keywords: *energy efficiency management, local communities, effectiveness analysis, ranking, logical aggregation, interpolative Boolean algebra, generalized Boolean algebra.*

1. INTRODUCTION

In the uncertain conditions of the global energy market and the scarcity of domestic energy resources to build a sustainable and efficient energy system, the system of balanced relations between environmental protection, competitiveness and security of energy supply, is a significant challenge for any local community. Availability of energy is an essential prerequisite for economic development. Although at the global level connection (correlation) between economic growth and growth in energy consumption weakens (improving the energy intensity), however, the worldwide demand for energy continues to grow. Most European countries are dependent on energy imports. Some countries do not have their own energy sources, and some countries have not developed producing capacity. Some global problems such as exhaustion of non-renewable energy resources (oil, gas, coal, etc.), the insufficient level of cost efficiency of "clean" technologies for energy production, increase in environmental pollution and the impact of global warming and frequent economic crisis on regional and global level in last decades are responsible for the growing importance of energy efficiency.

Efficient energy management has three key challenges: reducing energy consumption, increasing energy production from renewable sources and reducing greenhouse gas emissions. Each of these issues can be observed separately, but only if they are observed integrated, then we can talk about sustainability. Climate change and greenhouse gas emissions have become a priority development issue. The main challenge is the long-term development of the economy with reduced emissions of carbon dioxide. The goal is efficient use of energy, usage of renewable energy sources, efficient transportation system with the use of more neutral fuels in terms of CO₂ emissions and the internalization of external costs of environmental protection through the establishment of rates for emitted carbon dioxide (which gives a clear signal that the economy in the planning and investment must take into account the risks associated with environmental pollution).

Local communities as the nuclei of the social and economic life have a decisive role in creating and implementing measures for sustainable development and within its framework for energy management. This paper deals with the issue of energy management in Bijeljina, municipality of Republika Srpska - one of two entities in Bosnia and Herzegovina. It is based on the Sustainable Energy Action Plan for Municipality of

Bijeljina created in 2011². The Action Plan has identified measures that need to be implemented in order to improve energy efficiency within the municipality of Bijeljina according to main ideas of sustainable development. The idea of this paper is to analyze these measures by their effectiveness. Effectiveness of the single measure is defined through four different criteria: cost of its implementation, its impact on reducing CO₂ emission, reducing energy consumption and increasing usage of renewable energy sources. In order to create criteria function to describe efficiency, logical aggregation based on interpolative Boolean algebra is used to aggregate selected criteria into logical criterion function. Logical criterion function is transformed into applicable form using generalized Boolean polynomials. The results have shown that three main factors are important for efficient energy management: education of population, large infrastructure projects and investments in new production capacities. It is of particular significance the fact that the education of the population resulted in a much higher effectiveness than any other analyzed measure.

The remainder of this paper is organized into four sections. Section 2 will present basic concepts of efficient energy management in the sustainable development framework. Section 3 presents data that are used in this study. In section 4 we describe methodology that is used for the purpose of the analysis. Section 5 will report results along with the analysis. In section 6 we present our conclusions.

2. ENERGY EFFICIENCY OF LOCAL COMMUNITIES

The question is – what is energy efficiency? What parameters indicate that the certain system is energy efficient? Energy efficiency is the sum of planned and implemented measures aimed at using minimum possible amount of energy so that the quality of life and production rate remains preserved (Savic, M., Dimitrijevic P., 2010). Energy efficiency should not be considered as energy saving as saving always implies certain sacrifices, while the efficient use of energy never impairs working and living conditions. Improved efficiency in utilization of energy results in its reduced consumption for the same amount of product or service, which ultimately brings the proportional material savings.

Efficient energy system is energy efficient way of energy production and consumption, with the aim to have the least possible harmful impact on the environment. Therefore, in order to be sustainable, energy efficient systems have to minimize its impact on environment. This impact could be measured on several ways; however, one of them is particularly important – the emission of CO₂ gases into the atmosphere. This impact has been monitored and analysed over the last several decades and represents one of the major element of all strategies of the future energy development (for example EU declared goals by 2020: 20% of energy from renewable sources, 20% increase in energy efficiency, 20% reduction in emissions and 10% of bio fuels in total consumption of gasoline and diesel fuel).

Local authorities are dynamic, complex and vital systems in the sector of the public government. They are marked as one of the key elements in performing of energy activities, according to Strategic Legal Framework. In other words, energy management at local level is very significant part of the overall energy management system in one society, i.e. country. Introducing the system of efficient and sustainable energy management at local level is fundamental for development of “Smart Energy Cities”. As of 2007, European Union adopted a set of documents “Energy for a Changing World”³ and unilaterally committed to decrease the CO₂ emission for 20% until 2020 which will result in increase of energy efficiency for 20% and share of 20% of the renewable energy combined with other sources of energy. By adopting the decision 20:20:20, European cities are motivated, within the “Covenant of Mayors”⁴ to be actively involved in realization of set goals. Bijeljina municipality entered this agreement in October 2010.

In accordance with assumed obligations, the Sustainable Energy Action Plan of Municipality of Bijeljina is developed, covering the period from the reference year 2004 until 2020. Following the recommendations of the European Commission, sectors of energy consumption are differentiated into three main sectors, each having its own subsectors:

- Buildings sector,
- Traffic,
- Public lighting.

²www.sobijeljina.org/dokumenti/odrzivi_energetski_akcioni_plan_opstine_bijeljinasustainable_energy_action_plan_bijeljina.pdf

³ec.europa.eu/energy/index_en.htm

⁴http://www.eumayors.eu/about/covenant-of-mayors_en.html

Energy analysis that has been performed for each of these three sectors showed that all sectors have potential for energy savings.

3. DATA

In order to analyze effectiveness of measures for improving energy efficiency in the municipality of Bijeljina, we used data that are presented in the Sustainable Energy Action Plan of Municipality of Bijeljina. The measures, selected for the purpose of this analysis, are those whose effects are clearly quantified in the Action Plan and expressed in a numeric values that are suitable for analysis. Table 1 shows the selected measures along with its corresponding values.

Table 13: Measures for energy efficiency management in municipality of Bijeljina along with the corresponding values of criteria

Sector	Fields of action	Measure for energy efficiency management	Implementation time	Estimated price (EUR)	Expected Reduction in CO ₂ emission (t/a)	Expected reduction in energy consumption (MWh/a)	Expected production of clean energy (MWh/a)
Buildings, equipment/facilities and industries	Municipal and other building under jurisdiction of municipality	<i>Education and behavior changing of employees at the buildings and premises owned by the municipality of Bijeljina</i>	2012-2020	312.500	1.893	4.373	0
		<i>Installing thermostatic sets in all buildings and premises owned by the municipality of Bijeljina</i>	2012-2020	2.750	274	762	0
		<i>Thermal insulation of the exterior and roof of several buildings owned by the municipality of Bijeljina</i>	2012-2020	500.000	718	2.000	0
	
	Residential buildings	<i>Education of consumers in the houses and apartments sub-sector and in commercial and services sub-sector</i>	2012-2020	395.000	14.735	80.396	0
		<i>Reconstruction of building's exterior thermal protection and roof renovation of residential buildings</i>	2012-2020	9.500.000	7.508	55.732	0
	

Local electricity production	Hydroelectric power	<i>Construction of small hydro power plants, "Vodozahvat" channel, power 0.45MW</i>	2011-2012	700.000	1.677	0	2.600
		<i>Construction of small hydro power plants "ATC" MOK channel, power 0.11MW</i>	2011-2013	300.000	426	0	660

...
District heating/cooling and combined heat and power	Combined heat and power	<i>Project of expanding the district heating network based on geothermal energy</i>	2011-2018	99.190.000	46.826	175.340	0
		<i>Gasification of Bijeljina Municipality</i>	2012-2020	50.000.000	11.903	56.096	0
	Solar energy	<i>Solar system installation in public buildings, 66 buildings</i>	2012-2019	300.000	258	400	0
		<i>Solar system installation in households, 2700 households</i>	2012-2020	1.800.000	364	2700	0

4. METHODOLOGY

Logical aggregation (LA) is a tool for aggregation of primary attributes' values into one resulting representative value using logical Boolean functions with logical operators instead of weighted average function which is the most widely used approach. Logical aggregation approach that is used in this paper is based on the interpolative Boolean algebra (IBA). IBA is a fundamental basis for real [0,1]-valued logic that is developed by Radojevic (2000). In a general case logical aggregation has two steps (Radojevic, 2008A):

1. Normalization of primary attributes' values

$$\|\cdot\| : \Omega \rightarrow [0,1] \quad (1)$$

The result of normalization is a logical value from [0,1] interval that represents realized intensity of the analyzed primary attribute.

2. Aggregation of normalized values of primary attributes into one resulting value by a logical or pseudo-logical functions a logical aggregation operator:

$$Aggr: [0,1]^n \rightarrow [0,1] \quad (2)$$

These logical and pseudo-logical functions need to be translated into the corresponding generalized Boolean polynomials (GBP). Any logical or pseudo-logical function has its' corresponding GBP. GBP is used to obtain generalized value realization (Radojevic, 2008B) of the corresponding logical or pseudo-logical function.

In this paper we use logical function to create criterion function in order to analyze effectiveness of measures for improving energy efficiency of local communities. In order to do so, we define effectiveness of measure on the basis of four main criteria:

- Cost of implementation (A),
- Impact on reducing CO₂ emission (B),
- Impact on reducing energy consumption (C) and
- Impact on increasing usage of renewable energy sources (D).

In order to properly define effectiveness of measure we analyzed the data from Table 1. It is obvious that each measure has values for both criteria A (cost of implementation) and B (impact on reducing CO₂ emission), but do not have for both C (reducing energy consumption) and D (increasing usage of renewable energy sources) but only for one of them. This is very important notice that will be reflected in the following definition of effectiveness.

We define effective measure as a measure that has low cost of implementation, high impact on reducing CO₂ emission and has either high impact on reducing energy consumption or high impact on increasing usage of renewable energy sources. Mathematical representation of this definition is:

$$\phi(x) = A(x) \wedge B(x) \wedge ((C(x) \vee D(x))), \quad (3)$$

where x is the measure that is analyzed, $\phi(x)$ is the function of effectiveness for that measure and $A(x)$, $B(x)$, $C(x)$ and $D(x)$ are normalized values of the corresponding four criteria.

Using transformation rules (Radojevic, 2008C) we can transform this logical function into the following generalized Boolean polynomial:

$$\begin{aligned} (A(x) \wedge B(x) \wedge (C(x) \vee D(x))) &= (1 - A(x)) \otimes B(x) \otimes (C(x) + D(x) - C(x) \otimes D(x)) \\ &= (1 - A(x)) \otimes B(x) \otimes C(x) + (1 - A(x)) \otimes B(x) \otimes D(x) - (1 - A(x)) \otimes B(x) \otimes C(x) \otimes D(x). \end{aligned} \quad (4)$$

$$\begin{aligned} (A(x) \wedge B(x) \wedge (C(x) \vee D(x))) &= B(x) \otimes C(x) - A(x) \otimes B(x) \otimes C(x) + B(x) \otimes D(x) - A(x) \otimes B(x) \otimes D(x) - B(x) \otimes C(x) \otimes D(x) + A(x) \otimes B(x) \otimes C(x) \otimes D(x). \end{aligned} \quad (5)$$

Generalized product (Radojevic, 2008C) is an arithmetic operator, any function $\otimes : [0,1] \times [0,1] \rightarrow [0,1]$ that satisfies all four axioms of T-norms and can be in the following interval:

$$\max\{Y(x) + Z(x) - 1, 0\} \leq Y(x) \otimes Z(x) \leq \min\{Y(x), Z(x)\}. \quad (6)$$

In order to decide what operator to use as a generalized product, we analyzed the nature of the criteria that are aggregated. Criterion A (cost of implementation) is of a different nature than all other criteria (B, C, D) as it concerns costs of implementation and its value is expressed in EUR (currency euro). Therefore, the corresponding operator for the case of aggregating A with one of the other criteria is ordinary product ($\otimes := *$):

$$A(x) \otimes B(x) = A(x) \cdot B(x), A(x) \otimes C(x) = A(x) \cdot C(x), A(x) \otimes D(x) = A(x) \cdot D(x). \quad (7)$$

Similarly, criterion B (Impact on reducing CO₂ emission) is of different nature than all other criteria given that it concerns pollution. Therefore, the same operator ($\otimes := *$) is used in the case of aggregation B with one of the other criteria:

$$B(x) \otimes C(x) = B(x) \cdot C(x), \quad B(x) \otimes D(x) = B(x) \cdot D(x). \quad (8)$$

In the case of aggregation criteria C and D, we took into account the following characteristics of these criteria:

- Values of both C and D are expressed in the same measure MWa/h;
- If we decrease energy consumption we will remain an excess of energy. It has the same effect on the system as if energy consumption remains the same but we increase production of energy nut from renewable sources. This will create the surplus of energy causing no pollution like in the first case.

Bearing in mind these findings, we concluded that criteria C and D can be aggregated using min operator ($\otimes := \min$) inherent in the aggregation of attributes of the same nature:

$$C(x) \otimes D(x) = \min(C(x), D(x)). \quad (9)$$

With selection of adequate operators of generalized product, transformation process is completed and criterion function is obtained:

$$\Phi(x) = B(x) \cdot C(x) - A(x) \cdot B(x) \cdot C(x) + B(x) \cdot D(x) - A(x) \cdot B(x) \cdot D(x) - B(x) \cdot \min(C(x), D(x)) + A(x) \cdot B(x) \cdot \min(C(x), D(x)). \quad (10)$$

This criterion function is a mathematical expression that describes our definition and we used it on the data from Table 1 in order to analyze effectiveness of the selected measures.

5. RESULTS

Results that are obtained using the proposed approach are presented in Table 2

Table 2: Measures ranked on the basis of their effectiveness in energy efficiency management

Measure for energy efficiency management in municipality of Bijeljina	Normalized data				Effectiveness of measure	RANK
	Estimated price	Expected CO ₂ reduction	Expected reduction of energy consumption	Expected production of clean energy		
<i>Education of consumers in the houses and apartments sub-sector and in commercial and services sub-sector</i>	0,00379	0,31468	0,4585	0,0000	0,143738	1
<i>Project of expending the district heating network based on geothermal energy</i>	0,95238	1,00000	1,0000	0,0000	0,047619	2
<i>Reconstruction of building's exterior thermal protection and roof renovation of residential buildings</i>	0,09122	0,16034	0,3179	0,0000	0,046315	3
<i>Gasification of Bijeljina Municipality</i>	0,48008	0,25420	0,3199	0,0000	0,042283	4
<i>Construction of small hydro power plants, "Vodozahvat" channel, power 0.45MW</i>	0,00672	0,03581	0,0000	1,0000	0,035573	5
<i>Construction of small hydro power plants, "Borum" channel GOK, power 0.45MW</i>	0,00672	0,03581	0,0000	1,0000	0,035573	5
...

The results show that education of the population is the far most effective measure and it is probably the best measure to start within those local communities that need to improve their energy efficiency management. Furthermore, we noticed that two of the six most effective measures represent the most expensive infrastructural projects – construction of urban district heating network based on geothermal energy and gasification of Bijeljina. Therefore, large infrastructure projects are of particular importance for development of effective and sustainable energy management in local communities. Investment projects such as building new capacities for production from renewable energy sources (water, wind, solar energy etc.) are also very important for efficient energy management in local communities. Two of such measures are given high rank

in Table 2 which indicates that one of the best ways to become energy efficient within sustainable development framework is to produce more energy from renewable resources.

6. CONCLUSION

Energy is a precondition for the survival of mankind. It drives everything, sustains life. In new circumstances, when fossil fuel reserves that mankind depended on for the last 200 years, are rapidly decreasing, questions of rational energy consumption are being raised as well as search for new sources of energy. The use of renewable energy sources is still expensive investment for many countries. This is why the energy dependence, especially in Europe that consumes large amounts of energy, has become pressing issue. Therefore, energy management has become one of the most discussed topics in the 21st century.

The most of energy is being produced and consumed at the local communities' level. Therefore it is logical that the foundations for efficient energy management should be set there. Local communities in European Union have already begun to give great attention to the problem of energy management (e.g. Covenant of Mayors). The other communities will soon reach the same issue. This paper could be the starting point for them. It gives an answer to the question of what measures for efficient energy management are most effective within the framework of sustainable development. The results of the analysis clearly indicate that local communities, that are still not paying enough attention to energy management, should start with education of people and large infrastructural and investment projects.

Problem of ranking alternatives that involves these of logic cannot be solved by methods based on the concept of weighted sum, which are very common in the existing practice. Logical aggregation approach based on interpolative Boolean algebra allows modelling of such problems. Interpolative Boolean algebra, developed by Dragan Radojevic, has enabled modelling with logical aggregation to be consistent with the basic theories and axioms of classical logic. Within its framework, it is possible to quickly and easily create logical criteria functions and translate them into precise mathematical forms suitable for calculating. This paper presents only one possible use of this approach. The results show strong justification for further exploration of this method.

Abstract: Business environment of today demands highly reliable organizations in order to be competitive on the global market. Practice suggests that the organizational vulnerabilities must be treated permanently because in the time of crisis they may lead to catastrophe. This paper proposes a new fuzzy model for assessment of management of keystone vulnerabilities with the goal to increase the achievements of regular management. It is assumed that the fuzzy rating weights of uncertain parameter values in this paper are described by linguistic expressions, which are modelled by triangular fuzzy numbers. The proposed algorithm determines: (1) the indicators on the level of enterprises with the highest possible probability to be critical with respect to keystone vulnerabilities, (2) process on the level of enterprise with the lowest level of management of keystone vulnerabilities value, (3) business process of small and medium enterprises which have the lowest level of performances according to the management of keystone vulnerabilities and (4) beliefs that some business processes are in an equally bad state. Results marked with grades (1) and (2) are very important for the operation management. The rest of the given results are very important for defining economic plans on the regional level and the state level. The functioning of proposed fuzzy model and its corresponding software is illustrated through the data collected from small and medium enterprises in central Serbia.

Keywords: management of keystone vulnerabilities, small and medium enterprises, uncertainty, fuzzy set

1. INTRODUCTION

One of the basic assumptions of modern business success is coping with the keystone vulnerabilities of treated organization. Keystone vulnerabilities represent the most relevant causes of the decline of organizational business performance and may lead to its complete collapse. There are different ways to overcome the vulnerabilities of the organization and one of the most effective forms to overcome them is effective management of keystone vulnerabilities. In literature, this way of coping vulnerabilities is often treated as a part of organizational resilience (McManus, 2007). Increased use of the word resilience exists in the areas of development, engineering, climate change, ecosystems, weather disasters, etc. due to its own semantic capabilities. Entities that can be described by using these words, in most cases have the ability to bounce back to the initial condition in a short period of time. Initial condition relates to the time that preceded the impact of any disorder. As a contrast to that, the academic approach tries to define multiple meaning of this word, which is dependent on the discipline and practice that has analysed it. Relationship between resilience and vulnerabilities is an issue in many science fields, from environmental change to socio-economical systems (Vogel, 2007).

Steps, that set direction to the process approach which is one of the foundations of this thesis, can be observed in the papers which treat resilience of social - ecological systems. In the terms of process approach, resilience can be seen as the ability of a system to recover and adapt to disturbances in the environment, while continuing to operate as if the characteristics of change have never occurred (Manyena, 2006). Based on this, it can be concluded that resilience is a process, not an outcome. The characteristics of a system which has high level of resilience and can cope with natural disasters are related to the focusing on the recovery from disturbances, i.e. adaptation to the disorder.

In the terms of business, organizational vulnerabilities must be treated permanently because in the time of crisis they may lead to catastrophe. Components and features of resilience in a social system can be defined through five thematic areas where the appropriate action is possible to be implemented (Twigg, 2007): (1) management, (2) risk assessment, (3) knowledge and education, (4) risk management, (5) decreasing vulnerabilities and preparing for disturbances and reaction to them. One of the most complex issues in this area is to define keystone vulnerabilities and to quantify the measure of its management. Vulnerability is a complex subject thanks to its own nature, so it cannot be easily reduced to a single metric which makes it hard to quantify. One of the most difficult issues to accomplish is to define a unique threshold of risk, danger or harm for an organization in general. Similarly, a measure of resilience is still extremely difficult to acquire

so this field is open for further research, especially in organizational science (McManus, 2007, Stephenson, 2010).

In this paper, uncertainty in relative importance of business processes, the relative importance of indicators and parameters values are modelled by fuzzy sets (Klir and Folger 1988, Pedrycy and Gomide 1998, Zimmermann 2001). Fuzzy set theory can provide a valuable framework for handling imprecise and ambiguous data. Fuzzy set theory resembles human reasoning in its use of approximate information and uncertainty to generate decisions (Kaur and Chakraborty 2007). It has been shown that fuzzy approaches of treating uncertainties in real-world applications, have numerous advantages such as: (a) they are conceptually easy to understand, (b) they can capture most nonlinear relations in problems of arbitrary complexity, (c) they are based on a natural language, (d) they can be built based on the expertise and (e) they could be combined with conventional methods and techniques for dealing and reasoning with uncertain data (FazelZarandi, Türkşen, and Saghir 2002).

In the current business environment, organizations need to be engaged in a comprehensive and systematic process of prevention, preparedness, mitigation, response and recovery and business continuity. It is not enough for organizations to have a draft plan that provides scenarios for disaster or emergency. Threats in business require direct facing and solving in the course of a business process, a dynamic and interactive relationship that aims to ensure the continuation of the main activities of the previous organization, during and after major crisis events. The concept of resilience has become incorporated into the knowledge of the corporate strategy of a number of leadership companies on a global scale (Booz Allen Hamilton 2004). During the process of strategy implementation, the most used technology is information technology (IT). Information technology (IT) has big influence on business operations and capability, organizational capability and core capabilities from the resilience perspective (Pham and Jordan, 2006). In the time of crisis, improvisation concept in the terms of resilience can be valuable solution. The positive result of improvisation is learning: (1) how to improve, (2) through the re-utilization of improvisation, (3) through the action component of improvisation. Other technologies and resources are also valuable for organizations. Modern trends of management bring together different approaches in pursuit of sustainable resource use and social-ecological resilience (Plummer and Armitage, 2007). Considering the sustainability of organizations, it is very important to carry out an evaluation in natural resource management and to recast it in the light of complex adaptive systems thinking. An evaluative framework for this brings three broad components: ecosystem conditions, livelihood outcomes and process and institutional conditions. One of the best ways for achieving sustainability is overcoming vulnerabilities. That can be analysed from the organizational level perspective, management of organizational resources, etc.

This paper is proposing the model for assessment of keystone vulnerabilities management on the organizational level of small and medium enterprises (SME) in the production sector. Organization is presented through its own processes and management of keystone vulnerabilities is described through the set of indicators (McManus, 2007) which needs to be quantified on each process level. Quantification is defined by linguistic expressions and calculations that rely on fuzzy sets. In order to be resilient, an organization needs to have resilient processes and in the same time, management of the keystone vulnerabilities must be on the high level.

The paper is structured as follows: literature review of fuzzy approach and organizational vulnerabilities is presented in the section 1, physical model for management of keystone vulnerabilities in SME of production branch is presented in section 2, fuzzy quantification model for quantification of management of keystone vulnerabilities in organization is presented in section 3, in the section 4 the case study on the sample of 25 SME in Serbia is presented and section 5 sets the conclusion.

2. THE NEW MODEL FOR MANAGEMENT OF KEYSTONE VULNERABILITIES ASSESSMENT

The demands of modern market shape the organizations that can manage its own vulnerabilities and strive in the moments after disturbances, emphasizing the process approach. This way, one organization can be described by its processes and their interconnections. Different reference models - PERA (Purdue Enterprise Reference Model), GRAI / GIM (Group de Recherche en AutomatisationIntegree / Integrated Methodology), etc. can be used to represent the organization as well as reference standard (ISO 14258 - Concepts and Rules for Enterprise). In this paper, the organization is represented by its processes. In theory and in practice there is a large number of the process distribution. Classification framework of processes comprises four divisions of the master processes (Arsovski, 2006): (1) management, (2) management of resources, (3)

implementation and (4) measurement, analysis and improvement. Besides the division into four master processes, the basic classification is also used (Oakland, 2004): (1) process of management, (2) the main processes and (3) support processes. From the aspect of value creation, the processes are divided into key processes and support processes, which involve the management process.

By the size, enterprises that enter the scope of this research can be categorized as SMEs (Small and Medium Enterprises) of economy production sector. This type of organization is very dependent on ICT technology, which has been considered in defining the model. By using ICT it is possible to increase the availability and the speed of documents and information flow. Besides that, it is possible to raise the skills and the quality of employees' work and to enable the geographic complexity of the organization, etc. This indicates the great impact of ICT on the organization. In the model, which represents the type of SME production sector, there are four major processes: (1) production, (2) marketing and sales, (3) procurement, (4) design and development. Support processes are observed regarding the assessment of their influence on the organizational resilience, which is significantly lower than the influence of main processes. Process of management is viewed as a single entity. Other part of the model is related to the indicators of management of keystone vulnerabilities.

The basis for management of keystone vulnerabilities assessment can be described as mapping related factors which are the same in every science field that treats vulnerabilities. In the field of ecology which has treated the key vulnerabilities of ecosystems for many years, generally accepted definition of vulnerability is presented as a multidimensional concept that consists of exposure, sensitivity and adaptive capacity (e.g. Turner II et al., 2003, Metzger et al., 2005). Since there is no clear demarcation of concepts that treats the key vulnerabilities of organization, this paper is proposing the ecological conceptual model that is adapted to the needs and characteristics of organizations and their processes according to the work of McManus (2007). The components of keystone vulnerabilities are not assessed in this paper but the management of those components is assessed. The concept of ecosystem exposure corresponds to the criticality of organizational processes. The concept of ecosystems adaptive capacity corresponds to the preparedness of the organization processes. The term susceptibility has the same meaning in the ecosystem theory and in the organizational processes. The key assumption in the process criticality evaluation is in what way that process affects the resilience of the entire organization, i.e. how it affects the organization's ability to respond to the disorder. The assessment of process preparedness in terms of organizational resilience needs to focus on how defined plans and redundant resources will prevent loss of the process function in the case of disturbances. During the susceptibility assessment of a process, it should be considered how exposure to various risks affects the overall organizational resilience. This means that it is necessary to perform analyses that will answer how the processes will be affected if a disruption occurs. In the table 1, the model for quantification of management of keystone vulnerabilities with relevant indicators is presented.

Table 1: Quantification of management of keystone vulnerabilities with relevant indicators

Indicators of management of keystone vulnerabilities	C – Criticality P – Preparedness S – Susceptibility	Referent processes in SME of production sector					
		Process of management	Marketing and sale process	Design and Development process	Procurement process	Production process	Support processes
1.Planning Strategies	C						
	P						
	S						
2. Participation in Exercises	C						
	P						
	S						
3. Capability and Capacity of Internal Resources	C						
	P						
	S						
4. Capability and Capacity of External Resources	C						
	P						
	S						
5. Organisational Connectivity	C						
	P						
	S						

The defined indicators of management of the keystone vulnerabilities in organizations are the subject of interest on the organizational level (McManus 2007, Stephenson 2010) as well as the supply chain management (Pettit, 2008). Indicators of management of the keystone vulnerabilities presented in this paper are adapted from McManus 2007 because this set of indicators has very good correspondence with the selected type of organizations.

3. MODELLING OF UNCERTAINTIES

This Section describes modelling of uncertainty applied in proposed fuzzy model. The number and type of linguistic expressions, which represent relative importance of business processes and indicators of keystone vulnerabilities management, are determined by the management team.

3.1 THE RELATIVE IMPORTANCE OF BUSINESS PROCESSES AND KEY INDICATORS OF VULNERABILITIES

The importance of each business process depends on multiple factors, such as the type of economic activity, firm size and others. It can be assumed that the relative importance of business processes on the enterprise level has different values. Weight value of business processes are almost unchanged during a predefined period of time and involve a high degree of subjective assessment of the management team. In this paper, the weight of business processes and the weight of management of keystone vulnerabilities indicators are given by matrix pairs of comparison of the business processes and indicators relative importance, respectively (analogous to the AHP method). It is believed that this approach is closest to the human way of thinking. In conventional AHP, the management team presented their assessment using a numerical scale, which is defined on the set of real numbers. The scale proposed in AHP is a simple and easy to use, but it is not always possible to review the decision makers to map the precise number. Thus the next assumption is introduced – the members of management team express their assessment using linguistic expressions. In this paper, set R, consisted of five linguistic expressions (very low importance, low importance, medium importance, high importance, and very high importance) is defined. These expressions are modelled by using triangular fuzzy numbers defined in interval [1,5], where 1 denotes as the lowest relative importance and 5 denotes as the highest relative importance:

- Very low importance - $\tilde{R}_1 = (x; 1, 1, 2)$
- Low importance - $\tilde{R}_2 = (x; 1, 2, 3)$
- Medium importance - $\tilde{R}_3 = (x; 2, 3, 4)$
- High importance - $\tilde{R}_4 = (x; 3, 4, 5)$
- Very high importance - $\tilde{R}_5 = (x; 4, 5, 5)$

The importance of business process p compared to the business process p' , $p, p' = 1, \dots, P$, and the importance of indicator i compared to the indicator i' in every enterprise f , $f = 1, \dots, F$ is described by one of five predefined linguistic expressions which are modelled by fuzzy triangular number $w_{pp'}^{\sim f}$, and $w_{ii'}^{\sim f}$, $i, i' = 1, \dots, I$, respectively. The highest and the lowest limit of these fuzzy numbers is highlighted as $l_{pp'}^f$, $u_{pp'}^f$, and $l_{ii'}^f$, $u_{ii'}^f$ and modal value is $m_{pp'}^f$ and $m_{ii'}^f$ respectively.

If the importance of process p' compared to the process p , and the importance of indicator i' compared to the indicator i in the enterprise f , $p = 1, \dots, P_f$; $f = 1, \dots, F$ is significantly greater, respectively, then the value of element in the pairs matrix of comparison process must be presented by fuzzy triangular number:

$$w_{pp'}^{\sim f} = \left(\frac{1}{u_{pp'}^f}, \frac{1}{m_{pp'}^f}, \frac{1}{l_{pp'}^f} \right), \text{ and, } w_{ii'}^{\sim f} = \left(\frac{1}{u_{ii'}^f}, \frac{1}{m_{ii'}^f}, \frac{1}{l_{ii'}^f} \right) \text{ respectively.}$$

If the importance of the matrix elements described above is equal, it can be represented by a single point whose value is 1 and which is represented by triangular fuzzy number (1,1,1).

3.2 FUZZY RATING OF PARAMETER VALUES

Every indicator of keystone vulnerabilities management $i, i=1, \dots, I$ can be described by 3 parameters: criticality, preparedness and susceptibility. These parameters are indexed by $j, j=1, 2, 3$. Inevitably, the values of parameters on the process level $p, p=1, \dots, P$ in the enterprise $f, f=1, \dots, F$ involve subjective judgments of and individual preferences of each decision maker of management team. In general, we propose a method for determining the values of indicators parameters of keystone vulnerabilities management, which is based on Delphi method (Hu and Sandford, 2007). In this paper the small and medium enterprises are in the focus so it can be assumed that decision makers of management team can made decisions by consensus.

It is closer to human reasoning if decision makers express their opinions and evaluations by using linguistic expressions rather than numeric values. In this paper, fuzzy rating of management team is expressed by predefined linguistic expressions, which are modelled by triangular fuzzy numbers,

$\tilde{v}_{ij}^{pf}, i=1, \dots, I; j=1, 2, 3; p=1, \dots, P_f; f=1, \dots, F$. The lowest and the highest limit of this modal value of

triangular fuzzy number \tilde{v}_{ij}^{pf} are set as $L_{ij}^{pf}, U_{ij}^{pf}, M_{ij}^{pf}$, respectively.

The values in the fuzzy triangular domain, \tilde{v}_{ij}^{pf} belongs to the interval [1-9] and they have the same meaning and values as a standard scale which is defined by AHP (Saaty, 1990).

In this paper, we use five linguistic expressions for describing the fuzzy rating of indicators value, which are defined by triangular fuzzy numbers in the following way:

- Very low value - $(y; 1, 1, 2.5)$
- Low value - $(y; 1, 3, 5)$
- Medium value - $(y; 2.5, 5, 7.5)$
- Large value - $(y; 5, 7, 9)$
- Very large value - $(y; 7.5, 9, 9)$.

3.3. THE PROPOSED FUZZY MODEL

For the management team carrying out the resilience of small and medium enterprises according to management of keystone vulnerabilities, the following tasks are important: (1) to determine which indicator in process $p, p=1, \dots, P_f$ has the smallest value, (2) to rank indicators of management of keystone vulnerabilities on the enterprise level, (3) to rank the processes on the enterprise level and (4) to elaborate the statistical analysis of gained results and to suggest actions that will lead to process and overall resilience improvement.

The proposed fuzzy model is realized in the following steps:

Step 1. Setting the matrix pair of comparing the relative process importance in enterprise f ,

$\left[\tilde{w}_{pp'}^f \right], p, p' = 1, \dots, P_f; f = 1, \dots, F$. The weight of process $p, p = 1, \dots, P_f$ is calculated as:

$$\tilde{w}_p = \frac{1}{P_f} \cdot \sum_{p'=1}^{P_f} \tilde{w}_{pp'}$$

$$\tilde{w}_p = \left(\frac{1}{P_f} \cdot \sum_{p'=1}^{P_f} \tilde{l}_{pp'}, \frac{1}{P_f} \cdot \sum_{p'=1}^{P_f} \tilde{m}_{pp'}, \frac{1}{P_f} \cdot \sum_{p'=1}^{P_f} \tilde{u}_{pp'} \right)$$

Step 2. Setting the matrix pair of comparing indicators importance in enterprise f ,

$\left[\begin{smallmatrix} \sim f \\ w_{ii'} \end{smallmatrix} \right]$, $i, i' = 1, \dots, I$; $p = 1, \dots, P_f$; $f = 1, \dots, F$. The weight of indicators i , $i=1, \dots, I$ is calculated as:

$$\begin{aligned} \sim f w_i &= \frac{1}{I} \cdot \sum_1^I \sim f w_{ii'} \\ \sim f w_p &= \left(\frac{1}{P_f} \cdot \sum_1^{P_f} \sim f l_{pp'}, \frac{1}{P_f} \cdot \sum_1^{P_f} \sim f m_{pp'}, \frac{1}{P_f} \cdot \sum_1^{P_f} \sim f u_{pp'} \right) \end{aligned}$$

Step 3. The weight of indicator i , $i=1, \dots, I$ on the level of process p , in enterprise f , $\sim f w_{ip}$, $i = 1, \dots, I$; $p = 1, \dots, P_f$; $f = 1, \dots, F$ is calculated:

$$\sim f w_{ip} = \bigcup \left(\sim f w_p, \sim f w_i \right) = \left(x; \mu_{\sim f w_{ip}} \right)$$

where:

$$\mu_{\sim f w_{ip}} = \min \left(\mu_{\sim f w_i}, \mu_{\sim f w_p} \right)$$

Step 4. Determining of the scalar value of fuzzy number $\sim f w_{ip}$, w_{ip}^f by applying moment method (Zimmermann, 1996):

$$w_{ip}^f = \frac{\int x \cdot \mu_{\sim f w_{ip}}}{\int \mu_{\sim f w_{ip}}}$$

Step 5. In general, the parameters can have cost and benefit nature. The value of each parameter can be described through the fuzzy number $\sim pf v_{ij}$ by a management team. Applying the normalization process, domain of the triangular fuzzy numbers, $\sim pf v_{ij}$ is mapped into a set of real numbers on the interval [0-1] and in that way they are becoming comparable. The value 0, and the value 1 denote that treated parameter j , $j=1,2,3$ of indicator i , $i=1, \dots, I$ on the level of process p , in the organization f , $p = 1, \dots, P_f$; $f = 1, \dots, F$ has the lowest or the highest value, respectively. Normalized values of triangular fuzzy numbers are triangular fuzzy numbers and they are presented as $\sim pf r_{ij} = (z; a_{ij}^{pf}, b_{ij}^{pf}, c_{ij}^{pf})$. In this paper, a linear normalization procedure is applied (Shih, et al, 2007).

For the benefit type of criteria:

$$\sim f r_{ijp} = \left(\frac{L_{ijp}^f}{U_{ijp}^{f*}}, \frac{M_{ijp}^f}{U_{ijp}^{f*}}, \frac{U_{ijp}^f}{U_{ijp}^{f*}} \right)$$

For the cost type of criteria:

$$\sim f r_{ijp} = \left(\frac{L_{ijp}^f}{U_{ijp}^f}, \frac{L_{ijp}^f}{M_{ijp}^f}, \frac{L_{ijp}^f}{L_{ijp}^f} \right),$$

where:

$$U_{ijp}^{f*} = \max_{y=1, \dots, Y_{ip}^f} U_{ijp}^y, \quad L_{ijp}^{f-} = \min_{y=1, \dots, Y_{ip}^f} L_{ijp}^y$$

Step 6. The assumption which sets the equal importance of all management of keystone vulnerabilities indicators can be introduced. With respect to this assumption, the values of indicators $i, i=1, \dots, I$ on the level of process $p, p=1, \dots, P_f$ can be represented by the volume of polyhedron which is denoted as $V_{ip}, i=1, \dots, I; p=1, \dots, P_f$.

$$V_{ip} = \begin{vmatrix} b_{i1}^{pf} & b_{i2}^{pf} & 0 \\ b_{i1}^{pf} & 0 & b_{i3}^{pf} \\ 0 & b_{i2}^{pf} & b_{i3}^{pf} \end{vmatrix} = 2 \cdot b_{i1}^{pf} \cdot b_{i2}^{pf} \cdot b_{i3}^{pf}$$

Step 7. The value of weighted indicator $i, i=1, \dots, I$ on the level of process $p, p=1, \dots, P_f$ in the enterprise $f, f=1, \dots, F$ is calculated:

$$d_{ip}^f = w_{ip}^f V_{ip}^f$$

Step 8. The lowest value of indicator $i, i=1, \dots, I$ with respects to all considered business processes in the enterprise $f, f=1, \dots, F$ is denoted as $(d_i^f)^*$. The rank of key indicators of keystone vulnerabilities management at the enterprise level is determined by relation $\min_{i=1, \dots, I} (d_i^f)^* = (i^{*f})$.

Based on practices in the field of organizational resilience, it can be considered that if the value of indicators in one or more processes is critical it can lead to very poor process efficiency and it can imply the impossibility of organization recovery.

Step 9. The value of management of keystone vulnerabilities of process p in the enterprise $f, p=1, \dots, P_f; f=1, \dots, F$, is calculated:

$$KV_p^f = \frac{1}{I} \cdot \sum_{i=1}^I d_{ip}^f$$

Step 10. The ranking of business processes is calculated according to the next relation: $\min_{p=1, \dots, P_f} KV_p^f = KV_{p^*}^f$.

Business process in the enterprise $f, f=1, \dots, F$ to whom the lowest value is adjoined $KV_{p^*}^f$, is denoted as $(p^*)^f$. The management team should take appropriate actions in order to increase the value of management of keystone vulnerabilities of the process p^* which will lead to the enterprise $f, f=1, \dots, F$. improved resilience.

Step 11. Calculating the value of management of keystone vulnerabilities on the level of enterprise $f, f=1, \dots, F$ is calculated:

$$KV^f = \frac{1}{P_f} \cdot \sum_{p=1}^{P_f} KV_p^f$$

4. CASE STUDY

Developed fuzzy model and its corresponding software are tested on the real data which are gained from the 25 SME of Central Serbia production sector. The relevance of this type of enterprise can be illustrated through the data of the Republic Statistical Office of Serbia: (1) 99.4% of all enterprises belong to SMP in 2010, and (2) the most of employees work in the production sector of industry. The data from EU claims that 80 million workers are employees of SME which gives approximately 60% of total GBP of EU (Lukacs E., 2005). From the perspective of joining EU, SMEs are very important for Serbian economy.

The management team has identified six most significant processes of SME production sector and five indicators of management of keystone vulnerabilities (see Table 1). The indicators are ranked on the enterprise level by the application of developed fuzzy model and its corresponding software. The results of ranking are presented in the tables 2, 3 and 4. By using the proposed Algorithm (from Step 1 to Step 8) the rank of indicator is given and presented in Table 2.

Table 2: The lowest level of indicators on the enterprise level

Indicators which are ranked as the the first in the 25 SMEs	Enterprises
i=1	f=1; f=7; f=1; f=9; f=11; f=13; f=23
i=2	f=4; f=25
i=3	f=14; f=18; f=21; f=24
i=4	f=2; f=3; f=5; f=13; f=6; f=8; f=10; f=12; f=15; f=16; f=17; f=19
i=5	f=20

Based on the gained results, it can be claimed that in 28% of treated SMEs indicator i=1(Planning strategies) has the lowest value. One of the main reasons of this is global economic crisis, which dictates new business trends. In this situation, many enterprises in Serbia do not have the clear picture of future market demands, so they cannot have confident future business plans and active strategy for determining them. Indicator i=2 (Participation in exercises) has the lowest value in 8% of treated SMEs. This indicator can be significantly improved by defining appropriate programs of exercises that cover the area of occupational health and safety, improvement of production technologies, potential hazards scenarios, etc. Examples from practice indicate that fire exercises are the only one that has actually been demonstrated in most of the organizations. The lowest level of indicator i=3 (Capability and Capacity of Internal Resources) is measured in 16% of treated SMEs. This result indicates that some of enterprises use old equipment which is not very reliable or an enterprise infrastructure needs to be renewed. Indicator i=4 (Capability and Capacity of External Resources) is the most critical indicator with the lowest value of 48% in the whole sample of SMEs. This indicates the weak connections of enterprises, low level of partnership deals and unsecure relationship with great amount of stakeholders. Indicator i=5 (Organisational Connectivity) has the lowest value just in one enterprise which makes this 4% of treated SMEs. This indicates the need for improving enterprise connectivity within its organizational borders, but in the same time the improvement the channels with external stakeholders. This can be accomplished through the implementation of new connectivity models or through the modernization of connectivity technologies, such as information and communication technologies.

In Table 3 rank of business processes is presented. It is performed by using proposed Algorithm (from Step 1 to Step 9) and corresponding software.

Table 3: Business processes which are mapped with the lowest value of management of keystone vulnerabilities on the level of enterprise

Processes ranked on the fist place	Enterprises
p=1	
p=2	f=4; f=6; f=7; f=8; f=10; f=11; f=12; f=14; f=15; f=16; f=17; f=18; f=20; f=21; f=22; f=23; f=25
p=3	f=2; f=3; f=5; f=19; f=24
p=4	f=9; f=13
p=5	
p=6	f=1

With respects to keystone vulnerabilities, in treated SMEs the most effective processes are p=1 and p=5. Management team should put the most efforts in order to improve management of keystone vulnerabilities in

processes $p=2$ (the lowest value in 68% of SMEs) and $p=3$ (the lowest value in 20% of SMEs) and $p=4$ (the lowest value in 8% of SMEs). This demands developing new marketing strategies, modification of products or designing new products, and emphasizing partnership relations and improving relations with suppliers.

For making strategic decisions in the field of management of keystone vulnerabilities, it is necessary to perform ranking process at the level of treated group of SMEs. By applying Algorithm (from Step 10 to Step 11) rank of business processes is given. It is presented in Table 4.

Table 4: Rank of business processes for SMEs in central Serbia

Business process	The average value of management of keystone vulnerabilities on the level of enterprise	Rank of business processes for SMEs
$p=1$	0.087	4
$p=2$	0.04419	1
$p=3$	0.05281	2
$p=4$	0.08504	3
$p=5$	0.15934	6
$p=6$	0.10064	5

According to the rank of business processes for SMEs in Central Serbia, the lowest value of management of keystone vulnerabilities is present on the level of process $p=2$ – Marketing and sale process. On the strategic management level, this means that new marketing strategies are needed and beside that, new market segmentation in order to stabilize the sale. According to the acquired data, the best management of keystone vulnerabilities is present on the level of $p=5$ – production process. In treated companies, managers of production process are well educated and experienced. On the other hand, the equipment is well known and new production models and maintenance can be implemented and operated.

Important issue for decision making process is information about the possibility that process ranked on the second place ($p = 3$) can be as equally bad in terms of keystone vulnerabilities as the first ranked process.

Using two statistical tests about the difference of means assuming that variances are equal, it can be concluded that both processes are equally bad. The test about the relation of two variances samples at risk of 5% shows the same. It means that management team should take measures to improve both processes in the same time.

5. CONCLUSION

The industrial management practice shows that in almost every enterprise, keystone vulnerabilities represent the most relevant causes of the decline of organizational business performance and may lead to its complete collapse. There are different ways to overcome the vulnerabilities of the organization, and one of the most effective forms of overcoming them is effective management of keystone vulnerabilities. They must be treated permanently because in the time of crisis they may lead to a catastrophe. In this paper, a new fuzzy model for evaluation and ranking of management of keystone vulnerabilities on the process level and on the enterprise level is proposed. The proposed model was tested on a selected group of SMEs of production sector in Central Serbia. The analysis done by proposed model was in a very good alliance with the real situation in SME management in practice.

The following conclusion is made:

- It is possible to describe the considered problem by formal language that enables to look for the solution by exact method.
- The uncertainties which exist in the model can be described by fuzzy numbers.
- The relative importance of the business processes and indicators of key vulnerabilities are stated by pair-wise matrix of relative importance. All the changes, as the changes in the number of processes/indicators (or relative importance) can be easily incorporated into the model.
- The procedure for determination of indicator weight on process level is developed.

The further research will cover the scope of process improvement measures as well as improve the overall organizational resilience.

Abstract: The paper presents initial results in the development of a new simplified analytical model for grouping combat efficiency task functions. The new fractal parts of joint task functions appeared as efficiency representatives. Based on the previous estimations of effective probabilities combat function efficiencies, caused by technology and equipment of units, a new performance named as relevancies was generated. These values are dimensionless random arguments for probability functions joining in fractals. Variables correlated to random fractal changes and reflected as arguments on the efficiency functions. Efficiency probabilities expressed as semi-empirical functions related to the new arguments become deterministic using one pair of probability values and relevancies in reference point. Semi-empirical curves are determined, by the level of technology performances in combat units and its flexible use in different missions. This was possible to represent by the new coordinate frame which provides linking of all functions on 2-D figures. The rotation of axes in a new frame refers to changes of relevancies arguments in flexible conditions of combat units' deployments. The frame is projected from 3-D efficiency coordinates by imaging in to the 2-D figure. The method has limiting opportunities by supposing flexible capabilities in the military tasks of opposite goals. Model used is aimed at varying effective technologies in the combat tasks balancing roles. The flexibility of units could consider readiness of technology for full combat tasks and also for less combat tasks in peace keeping missions by variation of fractal values.

Keywords: combat systems efficiency, probabilistic empirical functions, efficiency estimation methodology, efficiency frame, flexible operations, efficiency model

1. INTRODUCTION

Capabilities of combat units expressed by probabilistic efficiency relations is constraining determined by available technology performances. Best practice of their flexible use, in the particular missions, is not visible from efficiencies expressions. To answer on this, efficiencies caused by technology performances required explanation with additional representative measure, in the form of relevancies. New representative has to estimate importance of related technologies in constrained and oriented types of missions, where combat unit applies achieved level of efficiency. Mathematical expressions and relations that refer probability efficiency of combat units quality was the, leading edge, in estimations of technology efficiency influences on the capabilities of considered combat system.

Full efficiency combat systems, (Ventcelj, 1973, Kovač at all, 2006), are determined by grouping of main task in three particular efficiencies general functions. These are:

- efficiency of command control and information referred as E1
- efficiency of fire power and maneuver, including mobility, referred as E2
- efficiency of protection, logistic functions and other mission sustainability functions referred as E3.

Grouping criterion in this manner, is the consequences of military forces nature, and could be considered as independent of operation, mission, or types of forces. This is more or less accorded with defence technologies grouping by their structure. Efficiency of technology performances as contribution to unit's

* This paper is the part of research on the project III 47029 MNP-RS in 2012 year.

general functions could not be considered in the similar manner. Efficiency functions, as components of full unit efficiency, are structural linked with all combat elements in military deployment (*Ventcelj, 1973, Kovač at all, 2006*). They can assume as the independent in the designed efficiency estimations determined by technology readiness, but with dependable constrains for the variables of combat systems deployment. This is because system requires flexible approach of operational and tactical tasks referring to variable missions. Military missions and flows of operations in new ages, sometimes requires more, less or full missed using of some technology performances which reflects functions efficiency. So called, weight coefficients, as efficiency relevancy measures, cannot answer on question how variations are naturally linked with changes of efficiency probabilities. Variations of relevancies of technology by effects of their performances are used to achieve flexible effects. This not vary their based performances expressed as efficiency values E_1, E_2 and E_3 but vary their importance in linking relations during deployment. Interfering linked relations, for pairs of particular task functions, would be the better base for the new technology grouping. This linking could refer technology contributions in full efficiency during deployment. Constituent's labels for these links are particular efficiency functions. Manner of their new integration is fractal designing of pairs of their functions. Corresponding fractal parts are the elements of full efficiency probabilities. Fractals values can vary by the relevancies of their technology performances, changing more or less, the full required function of efficiency. Improving contribution of technologies, in selected function pairs in fractals, provides variations in their importance regarding the combat or peace keeping mission. Each fractal has its own relative relevancy depend of mission but their constitutive functions depend of initial efficiencies, based on available technology and equipment. Relevancies depend of opposite requirements in the tasks, and, they are variable random arguments. Their variations correspond to fractals variations regarding using of initial technology, as invariant readiness estimated at the beginning. This required promoting new model of efficiency as the function of relevancy arguments which is initially provided by fractals grouping and estimations of their linked behaviour.

2. DETERMINATION OF EFFICIENCY FRACTALS

Composition of three axes of efficiency probabilities, fig. (1) inclined at the angles of 120 degrees makes representative coordinate frame. Frame is projected from 3D, for the efficiency of three particular functions, (*Kovač at all, 2006 and Mlinović at all, 2011*). Triangle surface of full combat units efficiency is composed of particular triangles fig.(2). Two of three main task efficiency functions make fractal space of functions efficiency pairs. Fractals are able to be represented by particular closed triangle surface which composes as constituents of full efficiency triangle fig2. Each fractal triangle has two sides of probability values and one links with them making closed surface structure. Values of surfaces are considered as fractals contribution to the full efficiency estimations, fig.(2), similar as before exposed in ref. (*Mlinović at all, 2011*).

Ideal value of total efficiency is represented by maximum summarized composed equality-triangle surface, for each of efficiency probabilities taken as 0.997, (*Mlinović at all, 2011*), fig. (1), which surface is,

$$\sum_{sbs}^{ID} \approx \frac{\sqrt{3}}{4} \times 3 \times 0,997^2 \approx 1,2897 \quad (1)$$

Task function has limiting ideal efficiency probabilities of about 0.997 which corresponds to three standard deviations (SDEV), for the circular random variable as representative argument for two dimensional distribution law or around three in the case of semi-empirical estimated laws. Roots of probability function are two dimensional normal distribution laws with equal standard deviations redesigned as the special case exponential one dimensional. (*Przemieniecki, 2000*). Argument is taken as the ratio to standard deviation and in that sense of meaning is dimensionless. Real full efficiency triangles is determined for the real measured or estimated expected probabilities of efficiency performances inside of this maximized surface triangles fig.(2). Summarized surface for this real triangle is less than ideal composition fig. (1), (*Mlinović at all, 2011*), and is given by expression,

$$E_{bs}^{st} = 0.4325 (E_1 \cdot E_2 + E_2 \cdot E_3 + E_1 \cdot E_3) \quad (2)$$

Ratio surfaces of real eq.(2) and ideal triangles eq.(1). is taken as combat unit full efficiency probability given by expression,

$$e_{bs}^{st} = \frac{E_{bs}^{st}}{\sum_{sbs}^{ID}} \leq 1 \quad (3)$$

Composed F with eq.(2), eq.(3) becomes,

$$e_{bs}^{st} = 0.335(E_1 \cdot E_2 + E_2 \cdot E_3 + E_1 \cdot E_3) \quad (4)$$

The particular initial efficiency functions has values according to the technologies refers to their declared performances, but virtual vary depend of used conditions. Articles in expression (4), designed as the particular probability functions makes conditions of fractal compatibility considered in the summarized full efficiency. Fractal composition of two interactive technology functions by meaning of their contribution values to the full efficiency is given further.

Fire power and maneuver E_2 linked with command control and information functions E_1 makes structure of first fractal which integrates efficiency in missions and represented joint efficiency of capabilities to defeat targets. This could be determined as the **targets efficiency fractal**, in the form,

$$F_t = F_1 = f_1 E_1 \cdot E_2 \quad (5)$$

Links of fire power and protection have to include efficiency of the all types of self protection capabilities resistances, sustainability linked with urgent logistic support, transport etc. Combat units referred by their technologies and manner of their uses, contributes different in this linked functional pair fractal, used in different missions. This links determined, second, **vulnerability fractal** expressed in the form,

$$F_v = F_2 = f_2 E_2 \cdot E_3 \quad (6)$$

Third constitutive fractal linked pair in this considerations, is protection logistics and sustainability, integrated with command control and information functions. This function pair represents efficiency which does not depends of full fire power and maneuver capabilities in the units missions, but links their efficiencies in considerations. Their efficiency contribution, conditionally, is not influenced by weapon, ammunition and fire control systems technology efficiency, but respects indirect influences through logistic functions, protection transport etc. All relevancy questions which provide sustainability performances can be included in this fractal linked directly or indirectly. This could be determined as the **sustainability influenced fractal in the form**,

$$F_{st} = F_3 = f_3 E_1 \cdot E_3 \quad (7)$$

Final expression of efficiency developed by interactive interferences of main task functions grouped in fractals, becomes sum of probability product particulars as fractal elements in the form,

$$e_{bs}^{st} = \sum F_k = F_t + F_v + F_{st} \leq 0,997 \quad (8)$$

Ballancing contribution of each fractal is $f_1 = f_2 = f_3 = 0,335$, corresponding to the eq.(4) in referencing conditions. These conditions of combat units efficiency refers composed technologies performances implemented in task functions. It is obvious that two particular task functions E_i , and E_j contribute together in the new determined contribution, F_k of efficiency fractals for all i or j , taken as indexes $i, j = 1, 2, 3$, where $i \neq j$, and referring to them $k=1, 2, 3$. This exposed linked manner providing balancing performances of two technology functions in the fractal links. Geometrical form in full and particular fractal triangles, fig.(2), represents how particular efficiency probability efficiencies reflects on changes of both full and fractal triangle values, in composition of final efficiency .

Frame is designed to consider always efficiency as sum of the fractals. Values expressed by eq. (8) are expectations of technologies contributing when they are integrated in the combat unit by variable tasks expressed by expected fractals contributions in them. Fractals provide composition of different applications of particular functions efficiency E_1, E_2 and E_3 , keeping unchanged their technology performances declared values. Denoted names for the fractals maybe, are not précised determined, but, expressed main sense of function pair's integration as interaction of technology. This could approximately orientated the new approach of technology efficiency considerations as reflect to the main combat units capabilities. Compatibility conditions of fractals connections in this triangle are values of task functions efficiency probabilities content in different fractals. Three fractal labels interact different in the different operations. Their constituents' fractal functions, contributing more or less to the overall efficiency.

3. FLEXIBLE VARIATIONS OF TECHNOLOGY EFFICIENCIES IN FRACTALS

Variation of relevancies of technologies performances and their roles in the different missions and operations can be expressed by axes rotation in 3D space, toward compression or extension of fractal surfaces fig. 1 and 2. 3D meaning of these changes corresponds to triangles planed point of view which is not referred in this paper. They decreasing or increasing by axes rotation constrained by two selected angles and one complementary to the 360 degree. This exposes dependable manner which refers flexibility of technology use for each of two functions content in the fractals, and for all considered flexible capabilities. Surface fractals changes express more or less effective use of technology in flexible circumstances. Fractal values do not expressed analogy of mathematical serial or redundant probabilities and reliabilities as noted in (Przemieniecki, 2000). Their composed abilities in this approach are independent of their task orders, which provide to treat technology accordance of task functions also independent. Same fractals contributions coefficient f_k , in the all fractal expressions eq. (6), (7), (8), which are 0.335, means their equal relevancies for their all included function pairs. These equality properties are presented by the equal angles between three coordinate frame axes of 120 degrees. This could mean equal initial relevancies for all technology functions as contribution to tasks. Ideal efficiency triangle in this frame has maximum ideal surface. Ideal triangles surfaces of different central angle values than, 120 degrees, are not equal to this maximized. Angles variations changes, affects full efficiency, because they also changes their fractal values. This could mean different initial relevancies of task function roles expected in mission changes. Proportionally to the rotated angles between i and j efficiency functions, where, $i \neq j$, values becomes somewhere between, $120^\circ \geq \Phi_{i,j} \geq 120^\circ$ of fractal central angles. Angles changes decreasing or increasing the values of fractal triangle surface corresponding to its rotated axes proportional to the expression,

$$1 \geq \left(\frac{\sin \Phi_{i,j}}{\sin 120^\circ} \right) \geq 1 \quad (9)$$

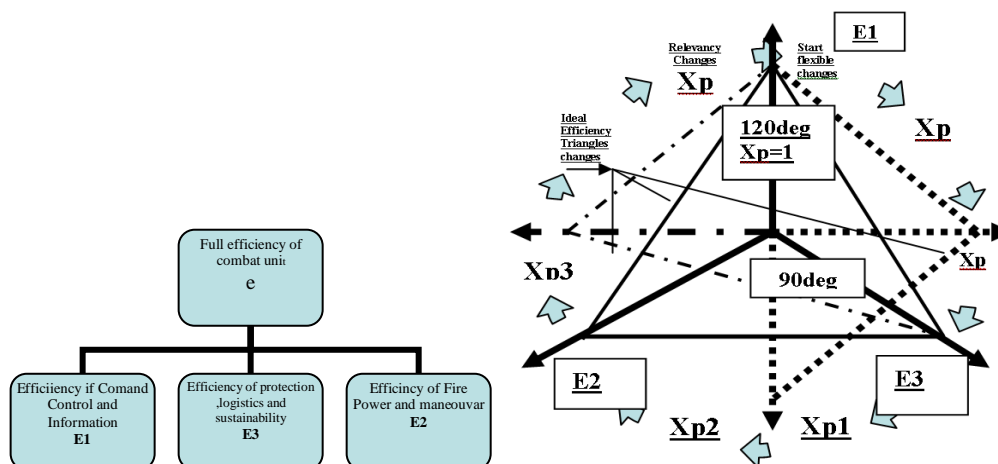

Figure 4: Maximum probabilities of three basic functions exposed on three represented axes

This happens for each fractal respectively, but also, causally to the other neighbors fractals, which shares same i or j efficiency function fig. 2. Changes reflected to full initial efficiency relevancies. Coefficient of technology adaptability, as relevancy performance of this action is representative of combat unit technology used in the new considered circumstance. Adaptability and referencing relevancy values presented by frame **axes rotation** in this model are taken as coefficient,

$$\bar{e}_{id} \equiv \bar{x}_p^{-1} = \frac{\sum_t}{\sum_{bs}^{st}} \leq 1 \quad (10)$$

Their meaning is equal to the inverse values of performances relevancies. Higher relevancies in technology possibilities are less rigid then adaptability equal to one. Value \sum_{bs}^{st} is full ideal efficiency for referencing capabilities. That means that all functions in frame have relevancies $\bar{x}_p = 1$ as the declared by rigid performances conditions of used technology. This value contributes to each initially available function efficiency in fractals, as referencing argument in combat unit, which is preliminary evaluated by appropriate

equipped technologies. Value, Σ_i is also representative of possible ideal efficiencies composition, for all ideal referred function probability values, but forced by new conditions and new flexible requirements. New conditions means new coordinate frame for relative measurement and, corresponding to them, new relevancies estimated from eq. 10. Adaptability refers how big was the price of this new forcing, because technology is not used with its own full capacities or is used as degenerated by performances in the new flexible tactical requirements. This degrades their initial ideal efficiency conditions but distinguish their relevancies as higher than 1 for $\bar{\mathbf{x}}_p$, in eq. 10, as valid argument value for the all efficiency functions.

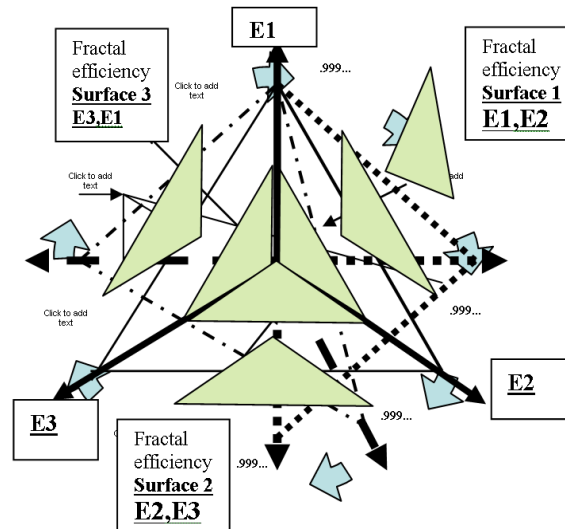

Figure 2: Geometrical expression of real combat system performances by their efficiency functions fractals. Ideal sum of triangle fractals, in eq 10, rotated at the angles $\Phi_{i,j}$ is,

$$\Sigma_i = 0.497 \sin \Phi_{1,2} + 0.497 \sin \Phi_{2,3} + 0.497 \sin \Phi_{1,3} \quad (11)$$

Differences caused by axes angles rotation, makes different values of $\bar{\mathbf{x}}_p$ in eq. (11) and Σ_i in eq.(10) respectively. Less than one **coefficient of adaptability**, as the relative measure represents dynamically degradation of initial ideal probability capabilities which in density probabilities laws functions, (Przemieniecki, 2000), could corresponds to the moments or standard deviations virtual changes. This approach is simplified in paper by semi empirical functions of efficiency probabilities. Changes of axes angles expose behavior that the parts of technologies become more important sometimes and the other parts less important in flexible circumstances. In approach aimed for flexible operations treatment, more significant becomes relative changes then absolute. Some of the fractals in this model behaves in increasing manner representing contributing role of technology properties and some of them decreases, refers same technology functions as less important in the new circumstances. This exposes also relative variations of efficiencies functions proportional to their contributions to each fractal as decreasing or increasing around new relevancy point in eq. (10). How big are these tolerances it is given in the further considerations? Contributing values of fractal surfaces relative to full efficiencies depend of rotating angles is

$$F_k = \left(\frac{E_i(\bar{\mathbf{x}}_p) \cdot E_j(\bar{\mathbf{x}}_p) \cdot \sin \Phi_{ij}}{2\Sigma_i} \right)^{-1} < 1 \quad (12)$$

Values in eq. (12) rearranged in equations (8), gives new expression for efficiency e_i in eq. (8). Combinations of $\Phi_{i,j}$ offers new possibilities to express relative efficiencies as the level of flexibilities, which also refers relative property of technologies, depend of missions.

Examples of considerations using are next. It can considered that one fractal remains same by form and central angle value with 120 degrees, second required to be maximized, changing central angle between functions on the 90 degrees, and third fractal consequently decreasing its values by changing central angle of 150 deg. In this case full relative efficiency is represented as,

$$e_{i,\Phi_{\max}} = \sum F_k \cong \frac{0.5 \cdot E_1 \cdot E_2 + 0.25 \cdot E_2 \cdot E_3 + 0.4325 \cdot E_1 \cdot E_3}{\Sigma_i} \quad (13)$$

Second threshold case could be intermediate which changes 15 deg central summarized angles and achieved also maximized value of third remained fractal triangle.

Third manner of variation reject any interactions in one fractal, as not used in operation or mission. Considering two remained fractals, both can be maximized for the values of 90 deg in the central fractal angles, fig 2. In this case efficiency function is,

$$e_{t, \Phi^2_{\max}} = \sum F_K \cong \frac{0.5 \cdot E_2 \cdot E_3 + 0.5 \cdot E_1 \cdot E_3}{1} \quad (14)$$

and represents maximum of two fractals balancing in efficiency. This could be maximum adaptability and maximum initial relevancies of new frame with referenced relevancy value, $\bar{x}_p \approx 1,2897$. This third function has best representative to explain accommodations of one task function as it Command and control or information significant in the interoperable missions and unit's integrations.

4. RELEVANCIES OF FRACTALS AND EFFECTIVE EFFICIENCY FUNCTIONS OF TECHNOLOGIES CONTRIBUTION

Efficiency expressed by probabilistic functions faced with question which probability distribution law is the best to explain the nature of probability changes referred to the considered values taken as random arguments changes. If model take relevancies of efficiency as the random arguments, the nature of requirement could be not to change initial values of efficiency probabilities but estimated them by variable relevancies as arguments. New arguments then became equal for expression of comprehensive random changes of considered functions. Efficiency probabilities of available initial technology by quality are not changeable. Augmenting efficiencies are virtual, as new relative quality for the available technologies. This explanation is offered by relevancies, as their random arguments in the appropriate probabilistic distribution laws. Assumptions for efficiency dependence between references dimensionless variables as relevancies and probabilities, has simple base in exponential distribution law, redefined in the so called Relay's law. This was base for axes ideal probabilities of all functions but also base for new approach in the considerations. Circular argument is composed by two dimensional opposite arguments as ratio of equal deviations. Their probability distribution integral, (*Živanov, 1973* and *Przemieniecki, 2000*), refers behavior of probability vs. dimensionless relevancies, arguments, $\bar{\omega}$, in the form,

$$\mathbb{F}_{\bar{\omega}}(\bar{\omega}) = 1 - e^{-\frac{1}{2}(\bar{\omega}^2)} \quad (15)$$

fig.(3a). Function has determined fixed values, and does not give experts variations and changes of initial efficiency required by flexibilities. But their form is referencing to explain changes of probabilities by relevancies, using rotated axes. Threshold properties of function are for, $\bar{\omega}=0, \mathbb{F}(\bar{\omega})=0$, and, $\bar{\omega} \rightarrow \infty \mathbb{F}(\bar{\omega}) \rightarrow 1$. Referencing maximum of probability density function, as probability first derivation, in the eq.(15), have argument $\bar{\omega}$, equal one. For the $\mathbb{F}(\bar{\omega}=1) = 0.3935$, their first derivation, is, $\mathbb{F}'_{\bar{\omega}}(\bar{\omega}=1) \approx 0.6065$, and their second derivation is, $\mathbb{F}''_{\bar{\omega}}(\bar{\omega}=1) = 0$. Modern probabilistic theories provides different variations and opportunities to explain the most of variable probabilities behaviors and their changes. Some of them could be employed in this modeling also very successfully using first and second orders moments, of probability density functions. But preliminary estimations with less reliable initial input data as used in older literature (*Mujić J. & Jovanovic M. 1975*), do not need sophisticate theoretical or numerical models. Model derived in this paper, could have semi empirical approvals as the base for experts training in efficiency estimations and their relevancies for the flexible missions. This orientated to the less sophisticated mathematical expressions but with selected properties similar with mentioned exponential distribution law. Requirements are to be more flexible and simple in the initial assumed values then classical assumed known probability functions. Functions extracted from family type, given in the form,

$$F(\bar{x}) = \frac{k\bar{x}^n}{k\bar{x}^n + p} \quad (16)$$

satisfies similarity with exponential distribution function eq. (15). For the values, $n > 1$, function is $F(\bar{x}) = 0$ for $x=0$, and, $F(\bar{x}) \rightarrow 1$ for $\bar{x} \rightarrow \infty$. Function refers to express probabilities semi empirically by the relevancies arguments \bar{x} . Coefficient p, k and exponent n are the dependant of relevancies \bar{x}_p and their probabilities,

$F(\bar{x}_p)$ chosen as the referent, in the point where curve has second derivation equal to zero value, fig 3 a. Their final form, is, only, function of probability efficiency in zero second derivation $F(\bar{x}_p)$, and relevance coefficient \bar{x}_p . Form of this expression extracted from simple functional analyses of eq. (16), if $F(\bar{x}) = E(\bar{x})$, related as efficiency function in this model as,

$$E(\bar{x}) = \frac{E(\bar{x}_p) \cdot \bar{x}^{\left(\frac{1}{1-2E(\bar{x}_p)}\right)}}{E(\bar{x}_p) \cdot \bar{x}^{\left(\frac{1}{1-2E(\bar{x}_p)}\right)} + [1 - E(\bar{x}_p)] \cdot \bar{x}_p^{\left(\frac{1}{1-2E(\bar{x}_p)}\right)}} \quad (17)$$

Values of $\bar{x}_p = 1$ for the each $i=1,2,3$, of efficiency functions, $E_i(\bar{x}_p)$, eq. (17), fig.(3b), which participate in the fractals, eq.(5), (6) and eq.(7) means equal initial relevancies of function probabilities in the frame, which axes are equal inclined, on the 120 degrees. Initial technology performances reflected as considered contributions to efficiency have equal relevancies in this case as the initial readiness expressed by each of the constitutive referencing efficiency $E_i(\bar{x}_p)$.

Figure 3a: Approximated semi-empirical function of efficiency probabilities vs. variable initial points

Figure 3b: Approximated semi-empirical function of probabilities vs. equal relevancies

Referencing value can be taken in eq.(17) for all three functional curves in the fig.(3b) also for old $\bar{x}_p = 1$, as for new $\bar{x}_p \geq 1$ relevancy arguments estimated from eq. (10). Then all task functions efficiencies could be considered as values for the new relevancies argument $\bar{x}_p \neq 1$ and compared with old values. Composition of efficiency in fractals put the question which relevancies corresponds to each of particular efficiency functions, after all curves, rearranged their initial position by higher initial relevancies \bar{x}_p . Virtual probabilities of efficiency of i function linked with function j , is new values $E_i(\bar{x}_{ij})$, not same as old one. Each of, $E_i(\bar{x}_{ij}), j \neq i$, functions, have two values, for two different j in their linking at the fractals. Functions, once contributes decreasing of fractal surfaces, and once contributes to increasing of their surfaces by same action of axes rotating in one of directions. This could be flexibility of particular function, $E_i(\bar{x}_p)$, in the new relevancies point eq. 10, expressed over fractals changes. Virtual effective changes corresponding as decreasing or increasing initial efficiency probabilities depend of decreasing or increasing fractal surfaces by new variations of function relevancies around new value of \bar{x}_p . Relevancies values around of new \bar{x}_p point, extracted from the fractals content determined by i and j efficiency functions angle is,

$$\bar{x}_{ij} = \bar{x}_p \left(\frac{2 \sin \Phi_{ij}}{\sqrt{3}} \right) \geq \bar{x}_p \quad (18)$$

It is obviously these changes of fractals values in the new conditions referred as new relevancies \bar{x}_{ij} are not function of fractal values then only of compressing or extending of fractal spaces between function axes. This proves their dimensionless independent character as used variables. This, also, refers about more or less technology flexibilities which are function of initial efficiency, and new probabilities as their virtual tolerances, in the flexible operations. This values corresponds to the efficiencies calculated from eq. (17). Effective relevancy pair of coefficients, \bar{x}_{ij} , applied for two i efficiency functions $E_i(\bar{x}_{ij})$, for each of two $j \neq i$, functions is given from, eq. 17, by,

$$\frac{\bar{x}_{ij}}{\bar{x}_p} = \left[\frac{1 - E_i(\bar{x}_p)}{E_i(\bar{x}_p)} \left(\frac{E_i(\bar{x}_{ij})}{1 - E_i(\bar{x}_{ij})} \right) \right]^{(1 - 2E_i(\bar{x}_p))} \quad (19)$$

The new effective pair of efficiency probabilities for each of task function has to be generated as effective efficiencies caused by its initial values $E_i(\bar{x}_p)$ around new equilibrium relevancy point \bar{x}_p different of 1. Two Fractals making new relevancy, \bar{x}_{ij} , for each of functions as labels of fractals. Also, anyone efficiency function $E_i(\bar{x}_p)$ is vary in two fractals by different relevancies, \bar{x}_{ij} , referring to eq. 17. This could be treated as flexibility, of their technologies using in each of particular efficiency functions. Fractals relative contribution to the summarized new efficiency, e , also corresponds to similar manner as for their surfaces variable values referred in eq. 12. Fractals have new Φ_{ij} , angles between efficiency functions i and j , and exposed as redundant composed links, in the flexible designed full efficiencies. This makes possible to design particular fractals flexibility estimations by compromising variations of their contributions to full efficiencies of combat units.

5. CONCLUSIONS AND CONTRIBUTIONS TO EFFICIENCY METHODOLOGY

This method is not finished yet and is actual research as constrained applicable possibility, but initiates new chapter in efficiency considerations. This is attempt to efficiencies considering as probabilities sum of function links.

Fractal expressed new combat efficiency elements as unit elasticity capabilities in correlation with an old efficiency functions. They integrate efficiency function of combat units by their unchanged technology performances efficiency probability values. Fractals deliberate new considerations of flexible use of some fixed determined technology performances as efficiency properties declared in combat equipment. This provides estimations of multipurpose use of equipment and their adaptability on the mission or operation.

Approach generated new representative variables which become efficiency arguments named as the relevancies, able to be estimated by fractals changes and reflected to the efficiency probabilities.

To simplified fractals approach and probabilities variations usually analyzed by numerical models semi-empirical consideration is designed using excellence special property function which redefines arguments, but not function probability properties by referencing point, where second derivation is zero. This was led regarding the requirements of compatibility conditions expressed by same random arguments.

Angular coordinate frame refers by three functions which compose three interactive function pair's in new fractals. Rotation of axes achieved maximizations minimization or excluding some functional efficiency interactions depends of mission or dynamical flexible battlefield requirements but never exclude efficiency of all three functions. The importance property of the method proves functions native character for the military units at all.

New approaches in the simulations have to provide compatibilities with this approach and technology performances referred in the efficiency functions. The most of new requirements reflects to consider interoperable flexibilities and or their flexible equipment requirements. First approximation could be based on exposed method in this paper.

³University of Defence, Military Academy, nkomazec@gmail.com

Summary: *This paper presents risk management in the process of making military decisions from the aspect of the engagement of units in various Army operations. Particular emphasis is placed on a complex approach to risk management and procedures applied in the process of risk identifying and assessment.*

Key words: *risk, military decisions, risk management*

1. INTRODUCTION

Contemporary environment in which the Army performs its tasks is characterized by a wide specter of threats that may cause various injuries, accidents etc. These threats and new technologies drive the commanders and commands to a constant creativity so as to undertake protection measures referring to their soldiers, units, arms and other equipment.

There is a need for determine guidelines and procedures for risk management in a complex environment in which the units perform their tasks. A broad line of approach is necessary for practical reasons, since the risks come from various sources. Risk management should become a standardized and institutional document, technique, tool and procedure for successful solving of risk management problems on all decision-making levels.

The process of risk management is not an independent process. It is an integral part of decision-making and in no way should be separated from it. It is necessary that it be so integrated that an intuitive risk assessment in a situation that needs urgent reaction is made, thus presenting the integral part of the military decision-making process.

2. THE MILITARY DECISION-MAKING PROCESS

Speaking about the military decision-making process (MDMP), it is defined by the Instructions for operative planning and work of commands in the Serbian Army (Guidance) (*General Staff of the Serbian Army, 2008*). Application of procedures defined by the Guidance should meet the goals of the decision-maker, i.e. various levels of unit commands. This process is formally performed through seven phases of decision-making processes: initiation, orientation, courses of action development, courses of action analysis, courses of action comparison, courses of action approval and work on documents. One of the characteristics of the MDMP is that each of the phases stated is based on data and conclusions from the previous one and that each phase can commence only after the previous one has ended (*General Staff of the Serbian Army, 2008*).

Decision-making divergence of views is caused by peculiarity of the matter researched. This is characteristic for the military decision-making process, as well, since the nature of researched problem analysis seeks for extension of decision-making phases. If the final result is compared, i.e. the decision implementation, there is no difference in connection to decision-making as a universal category (*Karovic, S., Pušara, M., Radončić, H., 2010*). A vital segment to be emphasized in the elements of military decision-making processes refers to risk management.

3. COMPLEX RISK MANAGEMENT

There is uncertainty in every military operation. The commander bears both full responsibility and risk in decision-making. Confronted with an uncertain situation during the process of making military decisions, there exists a natural tendency towards gathering additional information and lessening the suspense. However, waiting and gathering information can lessen the suspense but will not eliminate it. Waiting can also increase the uncertainty because the enemy is given space to take over the initiative which will only make matters worse.

The process of risk identifying, measuring and management is known as risk management. Risk management is an activity designed to improve the chances for realization of a project within the defined time, costs and performances. Complex risk management in the Army is the primary part for identifying hazards and risk control in the process of making military decisions for engagement of units in the mission spectre performed by the Army.

Guidance to operative planning and work of commands in the Serbian Army (*General Staff of the Serbian Army, 2008*) only addressed the risk evaluation segment in the decision-making process. The procedure of the risk evaluation which is necessary in the military decision-making process is not explained, actually the risk management is not explained. The risk is an occurrence which, if it occurs, influences the goal achieving capability in a negative way and has two aspects. The first one is that it will probably happen, and the second is its influence (or consequence) on the performing of the operation. Equation 1 gives the general term for risk.

$$\text{Risk} = F(\text{probability, impact}) \quad (1)$$

Uncertainty means vagueness as to the result of the situation. That is exactly the basic problem because the decision-making process is also performed in conditions which are uncertain. The difference between risk and uncertainty is that risk always carries loss or injury chances. In a situation which includes a favorable and an unfavourable event, risk is the probability of unfavorable event occurrence. In this specific case, uncertainty for the needs of risk measurement is analyzed.

Why is the form of probability used in risks management? Probability is used to express the chance that the event will happen since risk represents the event probability potential. The nature of these events is frequently such that a subjective probability measure in analysis is used instead of objectively gained measures.

Risks management in military decision-making processes for a goal has identification and management of events with uncertain results. Precisely, the focus is on events which, if they occur, have unwanted effect or consequences on the execution of operation. Complex risk management is a consistent process applied in the entire military training and operations, whether individual or team training, and everyday activities as well as in operations performed by units. It is a cyclic process used for continual hazard identifying and assessment, developing and conducting control and result assessment. In that case only and with such approach does it get full meaning becoming an integral part of the military decision-making process.

4. STEPS IN RISK MANAGEMENT

Work on a reasonable assessment and deliberate acceptance of risk is a fundamental question for the execution of operation. Rational assessments and deliberate acceptance of risk is not gambling. Careful risk determination, analysis and hazard minimization by carrying out plans for their elimination, give contribution to a successful execution of mission. As opposed to this, gambling with improbable event heedlessly brings into question the success of the entire mission as well.

Army missions demand the commander to take reasonable risks and to act decisively. Command and other organs primarily orientated on battleground intelligence preparation, enable the commander to identify the risks and give recommendations of how to lessen them. Essential in deciding refers to the element of taking into consideration certain types of risks, i.e. "are they worth taking into consideration".

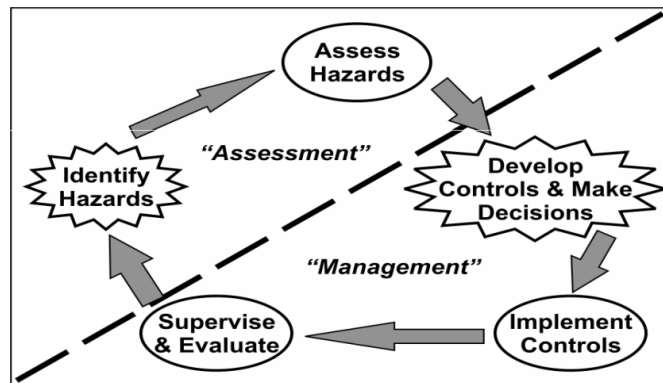

Fig. 1: Complex risk management process
Headquarters Department of the Army Washington (2006) FM 5-19 (p. 1-3)

The most important aspects of command include risk identifying, making decision of how and how much the risk can be minimized, which effects of the accepted risk are, maintaining control for risk alleviation and commanders readiness to accept the risks and to make a rational decision. Complex risk management goes in five steps:

- Step 1- Identify hazards
- Step 2- Assess hazards for determine risk
- Step 3- Risk control and decision-making
- Step 4- Decision implement control
- Step 5- Supervision (monitoring) and risk evaluation (assessment)

Risk management steps are given in figure 1. Steps 1 and 2 are assessments, while 3 to 5 represent managerial functions.

4.1. Hazards Identification

Hazard is such a condition which has potentials to cause various injuries, health problems or death of soldier's damage or loss of equipment and assets or to degrade execution of the mission. It can be a situation or event which can lessen the ability of execution of the mission or its failure. Hazards are present in all types of operations, combat and uncombative. Risk identification defines a cluster of future events which, if they occur, may have unwanted influences on the operation or any other specific criteria defined by the command. Risk identification goal is to number known risks, and the standard format for risk identification in the Army operations are mission factors (fig.2). The stated factors are institutionalized and adopted as key factors in executing Army operations. They are part of the adopted standards expressed through military decision-making process.

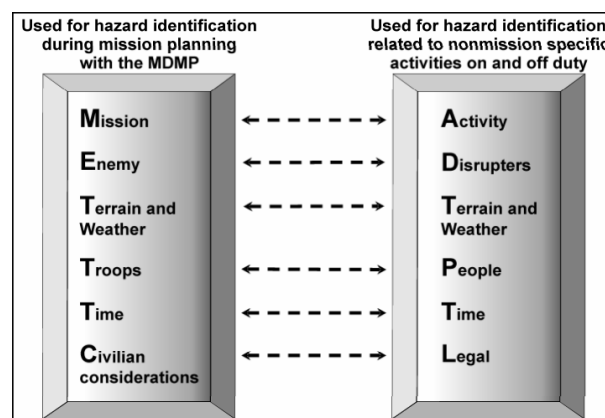

Fig 2: Factor assessment, *Headquarters Department of the Army Washington (2006) FM 5-19 (p. 1-3)*

Risks can be identified and confirmed by systematic command analysis, such as modeling and simulation, observation, assessment and experience. Risks identification includes written material contents analysis efforts and interviews with specialized experts in specific operation fields. Risks interdependence should be

identified through risks identification process, as well. Risk of failing to achieve a goal, in that sense, often influences the ability of achieving another, higher goal.

Hazards can be of various origin. They can be connected to enemy activities, accidents, and weather and environment conditions as well as to certain material and equipment impact. Complex risk management does not make a difference between the hazard sources. The loss of men, equipment or material has the same complex risk management process, in any dangerous situation, no matter of the source, because it affects the execution of mission efficiency (*Headquarters Department of the Army Washington, 2006*).

Institutionalized hazard factors (table 1), provide standardized method for identifying hazards. In the particular case, it will be dealt with the basic factors identified in fig.2, primarily those relating to operations execution.

Table 1: Institutionalized factors for risk assessment

Factors	Definition/explanation
Mission	The very nature of specific operations execution understands risks. It is expressed, particularly, in elements of combat activities between units and conditioned by specific types of maneuver. Therefore a detailed operational plan is significant.
Enemy	The command should first identify the enemy's abilities which represent mission execution hazard. What are the enemy's capabilities to incapacitate execution of the mission? The key segment for the enemy's threat identification is battlefield intelligence which should include both possibilities and weak points.
Terrain and weather	When considering terrain the primary orientation is in how developed are the road, i.e. communication networks, way blocking possibilities, combat activities, and protection characteristics. It is important as well, to perceive the elements that are not characteristic for the Republic of Serbia and refer to altitude, traffic density, quality of roads etc. This is important to be considered in case of multinational or peacekeeping missions. Characteristic weather hazards are weather conditions such as cold weather, ice, snow, rain, fog, wind, high temperature, bad visibility, dust etc. All the mentioned elements of weather should be assessed.
Man-power and material assets	Risk assessment concerning man-power, primarily directs its attention to the level of training and logistics security, i.e. the possibility of equipment quality maintenance. Special care is also taken concerning soldiers' and units' moral-psychological aspects, physical and emotional health.
Preparing process	According to the current and accepted standards, for the command preparing and work process in connection to the decision-making process with the objective of risk lessening, the subordinate structures are given two thirds of the time, and command one third. The units can so prepare to carry out the mission, while commands have opportunities to control realization of preparations as well.
State or legal grounds	This function broadens hazards consideration, especially during any kind of multinational operation. The objective is, primarily, to lessen the civilians' collateral damage, since this can have effects during carrying out the mission. This understands that first of all there are many civilians going on with their everyday activities, then the traffic density which can endanger supplying or say, the existence of criminal groups whose activities could be a hazard for accomplishing the mission.

Factors given in fig. 2 which refer to the everyday Army activities are not the subject of discussion in this paper. It can only be concluded that they are implemented in the sphere of everyday Army activities and are inseparable part of the functions which have direct implications on the units' operational capabilities.

4.2. Hazard assessment for risk defining

This process is realized by applying various methods with the objective of achieving risk level probability. The method of risk assessment will be described in a particular case per elements stated in fig.2, taking into account, primarily, that the assessment is based on experiences and intuition. This arises from the need of understanding risk on all commanding levels. Hazards and risks are assessed during mission analysis, i.e. in the second step of military decision-making process. It refers directly to the intelligence battlefield assessment connected to the aspects that might have effects on accomplishing the mission. The final result of this analysis is an initial risk assessment for every identified hazard expressed as **extremely high, high, moderate** or **low**. These categories are defined by standardized risk assessment matrix (fig.3).

RISK ASSESSMENT MATRIX						
Severity		Probability				
		Frequent A	Likely B	Occasional C	Seldom D	Unlikely E
Catastrophic	I	E	E	H	H	M
Critical	II	E	H	H	M	L
Marginal	III	H	M	M	L	L
Negligible	IV	M	L	L	L	L
E – Extremely High		H – High		M – Moderate		L – Low

Fig. 3: Risk assessment matrix

Headquarters Department of the Army Washington (2006) FM 5-19 (p.1-3)

There are three steps, within this step, that are accomplished, and refer to:

- Assessment of event or occurrence probability,
- Assessment of expected event or occurrence result and
- Risk level determination for given probability and difficulties.

4.2.1. Assessment of event or occurrence probability

This is the first assessment based on familiar information or on previous experience information. Probability is assessed according to frequency of a similar event. For the needs of risk management in military decision-making process, and according to the American rule FM 5-19 (*Headquarters Department of the Army Washington, 2006*), there are four probability levels: **often, probable, occasional and rare**. The meaning of these probabilities is displayed in table 2.

Table 2: Probability meanings

Levels	Definition/description
Often	Known as a regular occurrence. Expected to happen to someone for sure. Often examples are thermal injuries, collision of vehicles and similar.
Probable	Happens several times. Occurs habitually and will happen in a certain moment. Examples may include unintentional dropping weapons, unintentional firing a shot and similar.
Occasional	Happens sporadically but is not unusual. Examples may include unexploded agents elements or warfare against friendly units and similar.
Rare	Is supposed not to happen but is not impossible. Examples may include ammunition explosion during transport.

4.2.2. Assessment of expected event or occurrence result

The sensitivity of an assessment is expressed in the level the incident will affect the operational capability or the success in accomplishing mission. The level of sensitivity is evaluated for every hazard based on knowing the results of similar events that occurred and are graded as:

- catastrophic
- critical
- marginal and
- negligible

The events to be characterized as *catastrophic* :

- the mission on the whole is endangered and cannot be accomplished,
- death and permanent invalidity,
- the loss of critical equipment for accomplishing mission,
- dangerous environmental pollution,
- security jeopardized mission and
- unacceptable collateral damage

The event to be characterized as *critical*:

- units' operational capability is seriously violated and so is the mission, ,
- permanent or partial invalidity or temporary incapability up to three months,
- massive weapon and equipment damage

- property and environment significant damage,
- security failure and
- significant collateral damage.

The event characterized as *marginal* is most often manifested through:

- reduction of units operational capabilities or mission accomplishment,
- minor damages of equipment, property or environment and
- days lost due to injury or illness up to three months.

Characteristics of *negligible* events:

- little or no negative influence on the units' operational capabilities and accomplishing mission,
- first aid or minor medical treatment,
- minor technique damage, but in function and repaired and
- minor or none environment damage.

4.2.3. Level of risk defining

Using risk assessment standard matrix (fig.3), the possibilities and gravity for each identified hazard is converted in a certain level of risk. Figure 3 represents the classic 5 x 5 risk ordinal matrix. The level of probability is given down the vertical side of the matrix (fig.3) and influence (consequences) along the horizontal side of the matrix. The higher the level of probability is, the greater is the risk event occurrence. The lower the probability level is, the less probable is risk event occurrence. Similar is the relation for consequences. Higher influence level - the greater are risk event consequences referring to operation or mission. Lower influence level - the less are risk event consequences referring to operation or mission. This matrix gives probability and gravity assessment expressed in the terms of standard level of risk. The assessment is not absolute and might only be an indicator, or need not, of the given work, activity or event relative hazard. The levels of risk are given in the lower left angle of the matrix. All the accepted residual risks of the matrix must be approved by the appropriate commanding level. Certain risk levels and their implications concerning the mission are given in the ordinal table3.

Table 3: An Ordinal Scale for Occurrence Probability (*Headquarters Department of the Army Washington (2006) FM 5-19 (p.1-3)*)

Ordinal Scale Level (Score)	Definition/Context: Occurrence Probability
Extremely High Risk (E)	Loss of ability to accomplish the mission if hazards occur during mission. A frequent or likely probability of catastrophic loss (IA or IB) or frequent probability of critical loss (IIA) exists. This implies that the risk associated with this mission, activity, or event may have severe consequences beyond those as associated with this specific operation or event. The decision to continue must be weighed carefully against the potential gain to be achieved by continuing this course of action (COA).
High (H)	Significant degradation of mission capabilities in terms of the required mission standard, inability to accomplish all parts of the mission, or inability to complete the mission to standard if hazards occur during the mission. Occasional to seldom probability of catastrophic loss (IC or ID) exists. A likely to occasional probability exists of a critical loss (IIB or IIC) occurring. Frequent probability of marginal losses (IIIA) exists. This implies that if a hazardous event occurs, serious consequences will occur. The decision to continue must be weighed carefully against the potential gain to be achieved by continuing this course of action (COA).
Moderate (M)	Expected degraded mission capabilities in terms of the required mission standard and will result in reduced mission capability if hazards occur during mission. An unlikely probability of catastrophic loss (IE) exists. The probability of a critical loss is seldom (IID). Marginal losses occur with a likely or occasional probability (IIIB or IIIC). A frequent probability of negligible (IVA) losses exists.
Low (L)	Expected losses have little or no impact on accomplishing the mission. The probability of critical loss is unlikely (IIE), while that of marginal loss is seldom (IIID) or unlikely (IIIE). The probability of a negligible loss is likely or less (IVB through IVE). Expected losses have little or no impact on accomplishing the mission. Injury, damage, or illness are not expected, or may be minor and have no long term impact or effect.

4.3. Risk control and decision-making

The hazards and certain initial level of risks are identified in the second step of risk management process. To implement control and make decision is essential in the following step. The hazards are assessed by

residual risk determination. Decision - making is based on residual risk assessment and the process of developing control and risk reconsidering continues till the acceptable level of risk is achieved. Risks should be reduced to the level that their performances are below the potential gain. This process runs in steps of development courses of action, courses of action analysis, courses of action comparisons and their approval in the process of defined standard procedures of military decision-making (*General Staff of the Serbian Army, 2008*).

The commander performs control to eliminate or reduce the risk (its probability), once the assessment of all hazards is done. The basic function of control is shown through: *degree level of training (level of competence) of units, physical control and warning (avoiding)*. Degree level of training control comprises elements characteristic for qualifying, i.e. whether the performances of the defined standards of training processes have been achieved. The segment of physical control is performed through physical protection of certain localities or placing certain warning signs. Finally, avoiding refers to physically eliminating contact with identified hazards.

According to the American Manual for risk assessment (*Headquarters Department of the Army Washington, 2006*), for the control to be efficient, it should fulfill the following criteria: that it is convenient, feasible and acceptable. Control convenience is manifested through removing or reducing hazard risk to an acceptable level. Control feasibility represents the quality of the unit to perform control, while the control acceptability expressed in subjective justification of time and resources spent, through gained benefits.

The important thing to be kept in mind is the so-called residual risk remaining even after control. Controls cannot completely eliminate risk reduction of certain hazards. Total residual risk will be higher or equal to the highest identified risk residual. Keeping in mind the complexity of remaining controls and potential synergistic effect of all hazards the commander can decide that the accomplished mission residual risk is high.

The very decision-making represents defining what acceptable level of risk is. Risk or potential loss should be coordinated according to expected gains. All decisions, this is to be pointed out, on all commanding levels, should be based on adequate risk assessment.

4.4. Decision implementation control

The fourth step in risk management, which refers to decision implementation control, gets its significance when commander gains access to certain command executions, directives, orders etc. Each segment included in the reducing of risk control in this phase turns into an operational action which is to be executed in order to justify the execution of control and reduce risk to acceptable level.

4.5. Supervision (monitoring) and risk evaluation (assessment)

The last, fifth step of the comprehensive risk management in military decision-making, represents supervision and risk assessment as means to secure realization of risk control according to defined standards. The adequacy of means for confirming chosen control measures in support of objectives and wanted results is provided as well. This consistent process provides probabilities of influence on identified weaknesses and the possibilities of changing or correcting control results.

Supervision should be apprehended in terms of control measure and it represents an integral part of risk management in the military decision-making process. Supervision enables the subjects to understand how, when and where the controls are performed. It secures from standards inadmissible deviation or violation of policy and risk control which might jeopardize mission accomplishment. Supervision and control enable the commander to predict, identify and assess some new hazards and if needed risk controls to be modified.

Evaluation (assessment) is performed throughout all stages of operation, as well as upon accomplishing the operation or a certain phase. Evaluation should:

- identify all hazards that have not been identified as a segment of the initial assessment, i.e. identify new hazard which appeared during the operation or other activities,
- assess efficiency in giving support to operative goals and tasks (have the controls influenced in a positive or negative way on training or mission goals achievements),
- assess the residual risk accuracy and control efficiency in hazard elimination and risk reduction and
- secure coordination with the leading principles of complex risk management. It is integrated in all stages of military decision-making process. (Are all assessments accurate? Are they on the defined

level? Have there been needless risks? Was the process cyclical and consistent during military decision-making?)

These are the most important elements referring to supervision and evaluation of risk assessment. It is important to stress out, however, that the complex risk management is realized in a standard manner in order to keep consistency with the mission and task demands. For risk management various tools adapted to show information for complex risk management can be used. Particular tools in the form of specific patterns which serve for definite assessments are not the subject of discussion in this paper, it would be a new paper which would also include particular questions for definite hazard analysis and assessment.

5. SUMMARY

Risk management is based on comprehending that risky event by its nature will probably occur, and condition is significant for it to be identified, i.e. reflection of what is familiar today. That is the root of identified risky event cause. Therefore, condition is an event that happened, that is currently going on or will definitely happen. Venture events are future events which can occur due to the conditions of the present times.

It can be concluded that complex risk management in the military decision-making process represents integral part of the decision-making process and accompanies all military decision-making stages and steps on all levels of command. It began as a necessity simply because the army executes missions and tasks on different locations with various hazards. Risk management in military decision-making has as goal to identify and manage events whose results are uncertain. It is, therefore, important to secure the success of the mission with acceptable losses and which in a way can be the criteria for accomplishing mission objectives.

The American rule Field Manual no. 5-19 for risk assessment served as basis to this paper. Work on this paper indicated that risk should be managed in a complex way. Ordinal scales of the meanings of certain risk probabilities, which serve as standard values for defining level of risk in operations and army missions. are specially identified.

This paper does not cover the tools used immediately for risk analysis and assessment in a particular type of operation. It would be, therefore, advisable in future similar papers to concentrate on creating standard tools for risk assessment for the particular type of operation. The risk management standards in the military decision-making process would so be provided as well as a standard tool for risk analysis.

Matrix 5 x 5 for risk probability assessment which defines the level of risk as well, served as basis for the assessment of level of acceptability of specific type of risk. Complex risk management never ends and represents the cyclic continuity which demands constant warnings in the process of military decision-making and undertaking steps for its reducing or elimination and bringing to an acceptable level.

Abstract: *Corporate reputation is the overall assessment companies follow based on the opinions of stakeholders, previous actions, and potential future actions, regardless of their interest in the company's products, whether they work for the company or invest in company's shares. Reputation and risk are inseparable social institutions, and studies analyzing this relationship are still unfinished. Reputation can affect the shareholders, the public, voters, investors and policy makers (stakeholders), so that they think that a private organization or a public institution is reliable and there is no doubt about risk when this company is concerned, but have a real aversion when there is a possibility of the reality to be different. Reputation often has an impact on many social situations, especially where participants are required to make decisions, but also whether reputation really affects the existence of risk or it is just a psychological phenomenon in stakeholders and a PR mask.*

Keywords: *Risk, reputation, stakeholders' perception, organization.*

1. INTRODUCTION

A significant number of organizations recognize value based on good reputation and even consider it their greatest asset. Often, false presumptions on reputation could have a dangerous reality which is not instantly obvious. Nowadays, it is possible to ruin reputation unless it is maintained, especially since public and private is almost equal as a consequence of the Internet and social networks. Companies try to anticipate this and this way protect the reputation and provide ways to handle possible risks. Reputation is seen as an intangible asset with a value potential (Bebbington J., 2008), it is hard to make and easily erodes. Reputation is the main factor in risk, particularly in the organizational and managerial context. Essential reputation is a socially built phenomenon. (Kewell, 2007)

Risk management concept is based on a basic premise that risk management is a planned, far-sighted, structured, informative and constantly changeable technique. The key to successful management risk is early planning and aggressive implementation. Good planning enables an organized, comprehensive and iterative process of identification and risk assessment and an appropriate response. (Malbašić S., 2006) Often, the concept of risk management is related to finance, but does not have to be. Risk is present everywhere, from occupational safety, the health of employees, environmental protection, information security and the sufferings of passengers in a vehicle or surgical intervention risk in health care institutions. Risk does not only threaten the security of a system but also the probability with which a loss may occur. (Cvetković, 2006) In other words, risk is a combination of the probability of it occurring and its consequences and according to the OH&S risk: Risk is a combination of probability of occurrence of a hazardous event or exposure and the severity of injury or threat to health that may be caused by the hazardous event or exposure in relation to work. (OHSAS, 2008) Risk is often associated with uncertainty and insecurity. Uncertainty is generally defined as a lack of knowledge about the outcome and risk has known probability, while uncertainty, even when we have knowledge about it, we lack in a precise probability. (Vincent-Wayne, 1998) *By integrating these definitions which describe the concept of risk we can conclude that the risk apart from the probability of the occurrence of an adverse event and its consequence, it represents the possibility of occurrence of events which will affect the attainment of goals i.e. risk is the description of the possibility of a different outcome than that expected.*

The paper will show the relationship between reputation and risk, mutual influence, examples of bad influences and the importance of reputation in risk analysis. The elements which influence the making of a good or bad business image, when assessed by individuals are also a part of this paper.

2. THE PERCEPTION OF REPUTATION

Stakeholders and the interested parties often associate reputation and risk in the sense that good reputation reduces or even excludes the possibility of risk, which will be shown through several examples in this paper. The above mentioned leads to the conclusion that dependence on finance, quality management, corporate social responsibility, staff and the quality of products/services creates the image of a company's reputation. Reputation is a set of assumptions, beliefs, ideas and images that reflect the position and respect of the given object, person, social group, product, organization, etc. (Kewell, 2007) Positive corporate reputation is an important driver of a successful organizational relationship with our clients, who may have a significant impact on the business of a company. Also, the reputation of an organization allows the company to rise above and differentiate from the competition in their geographical area. Reputation of a company can gradually increase or decrease depending on how much the organization deals with the public, how present it is in the media, depending on vendors, employees and other stakeholders. It is important to build reputation and constantly think about it because if it is once damaged, it is extremely difficult to restore it.

The following five elements influence reputation:

- Financial management;
- Quality control;
- Performance of social and environmental responsibility;
- The employees and
- The quality of goods or services.

It could be argued that these aspects are used by individuals when evaluating reputation and those which managers believe that individuals can use when forming their own perception of reputation. The main elements of reputation are the public's awareness of you, recognition, trust and quality they relate you with. It is the most important intangible value of a company. Reputation is not just what other people are talking about the company. It is also the function and the result of what the company is doing both internally and externally. Clients often find that respectable companies have products or services of high quality and that their high cost justifies it; which does not necessarily mean it is true, but it works. The process of management of social reputation makes employees, business partners and suppliers an important target group of users, stakeholders and other "outsiders". Reputation can be defined as an ambassador of companies and firms and as a key in marketing. All organizations with their work/inaction affect their own reputation which differentiates them from the competition. Good reputation affects the stakeholders so that they often filter the negative information about the organization.

The concept of reputation is mistaken with image and identity. Identity of an organization is in fact what it is – beliefs, attitudes, culture, etc. On the other hand, image is the impression that the public has about an organization or a person. Image and identity of an organization will be formed even if nothing is done. Reputation, corporate reputation or image can be represented as a value judgment about a company based on a corporate identity and image. A company which respects reputation becomes the target group for all stakeholders.

Deephous (2000) point out that: "Significance of reputation:

- Attracting and keeping good employees,
 - Assistance in doing business with suppliers,
 - Influencing political and regulatory considerations,
 - Keeping and attracting clients and users of services and products,
 - Development and support of all brands,
 - Improving relationships with investors,
 - Help with strengthening internal communication and interpersonal relationships of the employees,
- while the key elements for reputation are the following:
- Products and services – values and qualities
 - Social responsibility,
 - Good working conditions and environment,
 - Financial and emotional conditions,
 - Technical ability and
 - High level of intellectual capital and knowledge management"(p. 1101).

Positive reputation is important as a competitive advantage because it informs the interested parties wishing to negotiate with it about its attractiveness. Also, the media play a significant role in gaining positive reputation. One study found that local newspapers have a stronger effect than television, and in 1991 it was found that 67.3% of the respondents in a national survey received the news about local businesses from local newspapers, television or radio. (Deephous, 2000) Nowadays, in addition to newspapers and television, one of the major media providing information on organizations, their activities, achievements and responsibilities is the Internet.

3. REPUTATION AND ORGANIZATIONAL RISK

Stakeholders used knowledge about and recognition of reputation to estimate the value of such entities, reliability and ethics at a given time, risk, as an opportunity and a threat it poses, the quality of products and services they provide and the organizational level of overall effectiveness. The processes which form reputation are mainly based on the exchange of images, impressions, telling, from "word of mouth" and the descriptions of experiences among social actors. Micro-processes are the basis for the growth and spread of reputation among social actors within and across social networks and organizational fields. Many potential users do not want to test new companies with no previous record, experience and good practice, especially with regards to large projects, because they fear the negative consequences and possible risks. An example where the image had great influence is the example of "Gerber" company, a baby equipment manufacturer with reputation similar to "Chicco" company, which withdrew plastic baby bottles from the market last year because they contained harmful Bisphenol A (BPA), a chemical used to produce plastics for which research has shown that it can seriously jeopardize children's health. And hundreds of parents, loyal to the brand and reputation of the company on the market, used these bottles before withdrawal, not thinking about the possibility of risks to the health of their children. This is another proof that reputation has a very strong impact on the perception of customers.

The discussion held so far raises some important questions. How and why could those who research risk analyze the relationship between risk and reputation further? How could social problems and situations apply this? What methods and approaches could be used? The paper will show the following three strategies for exploring these issues like Kawell point out that:

1. "Traditional established research methods
2. Stakeholders method
3. Discussion method". (p.1101)

In the first strategy, the participant expects that not only will his current behaviour affect the immediate consequences which he will be faced with in the current situation in the future, but also the subsequent behaviour of his partner and therefore have consequences for himself, so he has an incentive to compromise between short-term effects of his current decisions, and their long-term effects on reputation. This compromise can significantly affect the behaviour of participants. In this model, reputation is seen as central to human decision making, along with human knowledge and risk analysis.

In the second strategy, reputation is seen as the absence of uncertainty in stakeholders when estimating firms as potential suppliers of products or services. Participants who are in authority are key and have access to stakeholders and have a tendency to influence the choice stakeholders would make in decision making, helping them to shape their attitudes. Stakeholders are seen as a part in the creation of organizational reputation, but under some circumstances it does not necessarily apply. The importance of the relationship developed between different stakeholder groups and organizations is closed. The analysis shows the entities/subjects as a large company that aspire to see some stakeholders that are more powerful than others. The methodology of the research of the findings on reputation and risk among the participants would include a combination of statistical analysis, statistical survey of stakeholder opinion. The goal of this approach should consider how knowledge of the model distinguishes between stakeholder groups and what actually affects their personal and/or collective sense.

The third approach refers to research of the role of reputation in language games promoted by managers and professionals and their stakeholders. Reputation is a part of managers' and other political actors'

weapons they rely on when engaging in the struggle to manage programs and resources. Its influence is effective in situations where organizational actors, especially executives, are trying to create legitimacy for making plans and proposals and strengthen their control over decision-making. Such images and narratives can be aimed at very powerful forms of propaganda, and often succeed in creating a viable and compelling support for managerial activities.

This means that although focused on different things, they share similar ontology, research-based study of relationships between participants in networks of both social and organizational fields. They are different but potentially complementary, and share a common foundation as a reference point. Methodologically, they can be investigated using the normative methodology of social sciences, such as questionnaire, interview, mathematical modelling and so on. Stakeholders and interested parties should be aware of the fact that there is no entrepreneurial activity without risk and when reaching a goal, there is still a minimal risk or a chance of risk which needs to be predicted on time, defined in ISO 31000:2009 where risk is: "The impact of uncertainty on objectives", referring to business objectives. (ISO, 2009)

3.1 EXAMPLES OF RISK AND REPUTATION PERCEPTION

An example of the relationship between reputation and risk, where risk was reduced by increasing the company's reputation, is the famous ship Titanic. The myths regarding the construction of Titanic and the belief of experts in its infallibility as a sailing vessel, and if it can be an extreme example, such processes go through a myriad of settings in order to form our concept of security, threat, risk and resilience in different ways. Doubts and risk that something might happen to the ship were minimal. This is an obvious example when good reputation, owing to the media and the opinion of experts in public, influenced the user's perception of risk, security and threat. These notions were not even present in the minds of travellers; yet, the tragedy happened. The effort of public relations, media and spreading effects clearly play a role in the harmony of institutionalized prestige and reputation. They are an important factor in strengthening or weakening of the image of reputation through time and space.

Another example of the relationship between these two concepts, which also shows that reputation does not necessarily exclude risk, is the Bristol tragedy, sometimes called the BRI disaster, where the false assumptions about reputation often have a hidden dangerous reality. The BRI case acts as a starting point for discussion. BRI was the only teacher lecturing Hospital in southwest England that had been awarded the status of the "centre of excellence" for paediatric surgical operation in mid 1980. Although there are many facets of the tragedy, the key actors (stakeholders), the events that occurred, including parents and guardians, status of the award for excellence is associated with security and has an aversion towards risk. In 2006, the Bristol tragedy resulted in the death of 34 children who were cardiac patients. This incident points to the effects of reputation that have long been regarded as virtues, and devices for incubation of threats and the crisis of the incident. The Bristol disaster marked the emergence of two opposing beliefs about the reputation among doctors. There are certain beliefs that show paediatric (baby) cardio surgery in a positive light and point to the fact that the work of the Bristol paediatric team was in line with normal expectations from a "centre of excellence." However, the emergence of new physicians and surgeons who were recruited in the hospital from other centres of excellence from Britain and abroad between 1988 and 1994, admitted that the operation and performances were dangerous and beyond tolerable, i.e. out of range. Kawell (2007) point out that "Critically speaking, these new participants were able to perceive the danger that their colleagues were not able, and this way actually begin the process of the destruction of the localized reputation of the hospital. This case shows how the perception of reputation may be different among social actors. It also highlights the dangers that may arise from the effect of reputation. In this scenario, different groups of social participants have different opinions about the reputation and risk".(p.254) A proposal for further research is to consider how relations between the participants affect the occurrence of certain events of tragedy or crisis, or how their perceptions regarding the organization differed before and after the disaster.

In contrast to these examples, Michael Ewing, Albert Caruana, and Ernest Loy conducted research that measured the impact of reputation of consultant companies to risk, by the customer. The results show that clients prefer to use a consultant company with a good reputation, and only those with international cooperation, since they recognize the room for improvement of their projects. However, this study suggests that reputation is a measure of risk, and that these factors are different concepts, and that the organization which does not have a good reputation may still be eligible for co-operation. Also, it does not mean that a company with good reputation excludes the presence of risk. Working with organizations of high reputation can provide the client with a psychological advantage to not think about the threats but the uncertainties,

challenges, surprises, mistakes and the strengthening of competition should be seen as part of the company's life when it comes to the role and finances. (Ewing M., 1999)

4. INDIVIDUAL'S AND ORGANIZATION'S PERCEPTION OF RISK

Managers dedicate the most of their working time to the analysis and decision making. The consequences of decisions are fully recognized and felt only in the near or distant future that is always more or less uncertain (Vujošević, 2008). Modern, proactive management concept does not tolerate errors and does not recognize the justification for a bad outcome. It is promoted by the slogan: "Create the Future", i.e. make the future to be what suits you best. (Slovic P., 2004) Dealing with risk requires an understanding of processes that can lead to undesirable outcomes. This is the subject of risk analysis, which is a prerequisite to sound and effective risk management. The perception of risk can significantly be affected by an individual's sense when viewed from the psychological side. Earlier studies have shown that a sense of fear in humans affects the perception and acceptance of risk and hence the reputation. The opinion about an activity or technology is not only what we think about it, but what we feel as well. If a person has a fear of flying, their view of risk is at a maximum i.e. risk is seen as one hundred percent, regardless of good practice and the reputation of the organization.

Paul Slovic found that there is a positive and a negative impact connected to Information on risk and benefits in individuals. If there is a good feeling then they think the likelihood of the risk is less and the benefit great, and if a feeling is bad or negative, then the opinion of the risk is high and benefit is small. The information to be placed may affect the perception of risk, as one study found. Information "benefit is great" implies the opinion "risk is lower," and vice versa, the information "risk is small" implies "benefit is great," and both inputs have a positive impact. While the information "benefit is small" implies "risk is higher" and "risk is higher" implies "benefit is small" generally have a negative impact. (Slovic P., 2004)

Another study regarding the personal perception of risk is that white men tend to differ from all others in their attitudes and perceptions, on average, they are much more accepting of risk than other people. These results suggest that factors such as socio-political power, status, alienation and trust are a powerful tool for people's perceptions and acceptance of risk. (Flunn J., 2004)

Corporate governance is based on responsible management in achieving strategic directions and goals of business, risk management and disposition of resources. An important area for each organization where risk management is primary is finance. It should be noted that risk management is a skill based on the experiences and assessments of management. Risk management is not an end in itself but is primarily a means for achieving these goals. Enterprise risk management is closely linked to the process of corporate governance in the way that the board of directors (management) provides information on major risks and how they are managed. In addition, this approach of risk management can help organizations ensure compliance with laws and regulations, avoid loss of reputation and other negative surprises. (Lukić S., 2011)

When speaking about reputation, the practice has shown that organizations often give priority to risk, talk about and "take care" of it when it comes to social responsibility. Management often uses environmental or safety of employees at work for marketing purposes. They are aware of the sensitivity of their environment on sustainable development; therefore we may get the impression that risk management in this area is the only business of that company, according to media coverage. Such example is the Pancevo industrial zone. For days, the measures of protection, safety and security against air pollution were promoted, promises of filters and improvement of processes were made; finally, in 2009/2010 the air pollution crossed all limits and sirens disturbed citizens who watched in fear the values of the parameters increasing and closed windows. It was said that politics interfered in order to gain election points and opportunities for new promises. From that day on, the citizens have no more trust in the right risk management of industrial zones due to the poor reputation of the media; they are scared and aware of their own risk when staying in the city, but no media mentioned that the parameter values were above limits in the previous years; only that was not published. If the measures to keep the pollution within the specifications would be implemented, the citizens would need a few years to mitigate the perception of risk and feel safer through media appeal.

Management, which has a major role in the management of risk, is perceived differently when it comes to economic risk and the risk of social responsibility (CSR - Corporate Social Responsibility). What they find more important is profit and survival, but when you need to build reputation and prestige, then social responsibility takes precedence. CSR reports can be seen as the result and part of reputation of risk

management. It is arguable whether reputational risk can be managed directly. If managers believe that they can do it and if they see a CSR report as a part of that process, then further investigation is justified. Companies increasingly recognize that risk management, when it comes to reputation, is one of the main drivers of corporate social responsibility and are aware of the need to manage a wide range of environmental, social and ethical risks, and that the public is informed about it (Bebbington J., 2008). Often organizations meet the needs of the "powerful" stakeholders than the "less powerful", i.e. they are more likely to meet the demands of powerful financial interest groups than the demands of environmentalists. Most companies are interested in having some kind of visible social responsibility and are not aware of the risk of not managing it.

It is recommended to establish a special organizational unit for analyzing and managing risk, as it is drafted in Figure 1. Acceptance and observance of standards plays an important role in the process, as well as training employees, motivation and awareness of risk. What is interesting is that modern successful managers are more prone to risk than not. On the other hand, almost all people become averse to risk when the stakes are very high, regardless of the expected profit. (Vujošević, 2008) Therefore, the conclusion is that management is responsible for risk management, but at the same time management should not ignore the reputation of the company they manage, because breaking the connection between risk and reputation can only have a negative impact on the organization. The paper gives examples which presume that good reputation reduces perceptions of risk in stakeholders and increases the benefit of the organization, which does not mean that risk should be managed and reduced to the same minimum in each area (finance, information security, safety and health at work, environmental protection, etc.).

Figure 1: Organization for risk management

5. CONCLUSION

The systematic study of risk connected to reputation remains one of the key management challenges. Positive corporate reputation is an important driver of a successful organizational relationship with clients, who may have a significant impact on the business of a company. There are no definite studies showing a correlation between reputation and risk, although it often seems that way. Reputation can help attract interested parties but risk is always present, in greater or lesser extent. The focus of each organization should be on preventive measures, whether it be in finance, safety, environmental protection or the protection of data, caution is always desirable. The public needs to know not only the risks but also what managers responsible for the risk are doing to restrict it, and what individuals and communities can do to mitigate the potential bad effects on them. Also, what may affect the perception of risk are the communication capabilities of a PR manager. This person informs the public about whether there is risk, and if it exists, processes it on different levels, both within and outside the organization, and depending on the target, decreases or increases the perception of risk with stakeholders. The objective of risk management is not only to avoid losses, but also to improve the reputation, incomes and competitive advantage. The paper showed that the evidence from the BRI tragedy suggest that reputation may play a role in mitigating the impact of organizational disasters. Risk can also be viewed through the emotions of individuals (fear of flying); in this case, the reputation can have absolutely no impact. However, stakeholders choose which company they will do business with and which organization they will invest in for financial security. In this case, reputation can play a major role in decision-making, but it does not mean that security is guaranteed and the risk is excluded. The risk is present daily in every process, but people's awareness of this issue may be lower or higher concerning the reputation of a company, personal emotions, fears, or good/bad experience. Further research could go in the direction of a more detailed involvement of employees, as a

part of stakeholders, in the perception of reputation and risk as well as the inclusion of quantitative methods in the analysis of the costs of reputational risk.

Abstract: In this paper we present a new GVNS based heuristic for solving Traveling Salesman Problem with Time Windows. New procedures for feasibility checking of 2-opt and Or-opt moves are proposed. The method is tested on benchmark instances from the literature. The obtained results show that our new method is very efficient in solving large scale problems.

Keywords: Travelling Salesman Problem, Time Windows, Variable Neighbourhood Search

1. INTRODUCTION

The Traveling Salesman Problem with Time Windows (TSPTW) is a variant of the well-known Traveling Salesman Problem (TSP). Suppose that is given a depot and a set of customers (each customer has its service time (i.e. the time that must be spent at the customer) and a time window defining its ready time and due date). The TSPTW problem consists in finding a minimum cost tour starting and ending on a given depot, visiting each customer exactly once before its due date. The traveling salesman is allowed to arrive at some customer before its ready time, but in that case the traveling salesman has to wait. The cost of a tour is the total distance traveled.

Suppose that is given graph $G = (V;A)$, where $V = \{1, 2, \dots, N\}$, 0 is depot and $A = \{(i; j) : i, j \in V \cup \{0\}\}$ is the set of arcs between customers. The cost of traveling from i to j is represented by c_{ij} that includes both the service time of customer i and the time needed to travel from i to j . Each customer i has an associated time window $[a_i, b_i]$, where a_i and b_i represent the ready time and due date, respectively. So, Traveling Salesman Problem with Time windows can be stated, mathematically, as a problem of finding a Hamiltonian tour starting from the depot, that satisfies all time windows and minimizes the total distance traveled.

TSPTW is NP-hard problem since it is a special case of the well-known Traveling Salesman Problem which is NP- hard problem. Because of that there is a need for a heuristic which will be able to solve efficiently realistic instances in the reasonable amount of time. In that direction, some steps have been already made. For example, Carlton and Barnes use a tabu-search heuristic with a static penalty function, that considers infeasible solutions. Gendreau et al. propose a insertion heuristic based on GENIUS that gradually builds the route and improves it in a post-optimization phase based on successive removal and reinsertion of nodes. Calvo solves an assignment problem with an ad hoc objective function and builds a feasible tour merging all found sub-tours into a main tour, then applies a 3-opt local search procedure to improve the initial feasible solution. Ohlmann and Thomas use a variant of simulated annealing, called compressed annealing, that relaxes the time windows constraints by integrating a variable penalty method within a stochastic search procedure. Two new heuristic was proposed in 2010. One heuristic was proposed by Blum et al., while the other was proposed by Urrutia et al. These two heuristics are, currently, the state of the art heuristics.

In this paper we propose new two stage VNS based heuristic for solving the TSPTW problem. At the first stage we are using VNS to obtain feasible initial solution, while at the second we are using VNS to improve initial solution obtained at previous stage. This idea was originally proposed by Urrutia, but our implementation of this idea is more efficient than that of Urrutia since we succeed to improve some best known solutions.

2. CONSTRUCTION OF AN INITIAL SOLUTION

Construction of a feasible solution for TSPTW problem is also NP -hard problem. So, there are several heuristic for building a feasible solution. In this paper we proposed heuristic for building a feasible solution similar to heuristic proposed by Urrutia et al. The only difference between these two heuristic is the way of exploring neighborhood structures. The scheme of VNS heuristic is given below (Figure 1) .

Urrutia proposed VNS based heuristic for minimizing the sum of all positive differences between the time to reach each customer and its due date, that is $\sum_{i=1}^n \max(\beta_i - b_i)$. Obviously, each permutation of customers for which the value of the objective function is equal to zero represents one feasible solution of the TSPTW problem, so VNS heuristic finish itself work when such permutation is found.

As a local search VNS heuristic use *1-shift* local search. *1-shift* local search tries to improve current solution by moving some customer from the current position in the sequence to another. This local search induces neighborhood structure which contains all solutions which can be obtained from the current solution by displacing some customer. The dimension of that neighborhood is $O(n^2)$. It is easy to conclude that all customers, if the solution is not feasible, can be divided into two disjoint sets:

- set of violated customers - customers which is visited after their due date
- set of non-violated customers - customers which is visited before their due date

So, neighborhood induced by *1-shift* local search can be divided into two disjoint neighborhood; one which is induced by movements of violated customers and the other which is induced by movements of non-violated customers. These two neighborhoods can be further divided into four neighborhoods depending on whether some customer is moved backward or forward.

If we have more than one neighborhood structure as we have, it is important to define order in which they will be explored. Urrutia et al. in their paper performed extensive testing and concluded that the following order of exploring were the best, (the best means that a feasible solution can be obtained faster than for the other orders of neighborhood structures):

- backward movements of violated customers,
- forward movements of non-violated customers
- backward movements of non-violated customers
- forward movements of violated customers

We say that customer j can be located after customer i in feasible solution if the following inequality is satisfied: $a_i + c_{ij} \leq b_j$. For each customer i we build so-called Nearest Neighbor List which contains customers which can be after customer i in feasible solution sorted in increasing order according to travel cost. Since, each 1-shift move is defined by choosing two customers, customer i , the customer which will be moved and customer j , the customer before which customer i will be placed, for chosen customer i , customer j is chosen according to Nearest Neighborhood List of customer i . But, there is some restriction for choosing customer j depending on neighborhood structure which is examined. If we examine neighborhood induced by backward movements, we will exclude from the Nearest Neighbor List customers who are after customer i in the current solution. Similar restriction is made when neighborhood defined by forward movements is explored. Also we allow that customer i can be located after some customer, i.e. k only if the following inequality is satisfied $a_k + c_{ki} \leq b_i$. In the other words, customer i is moved between two adjoint customers, i.e. k and j only if $a_k + c_{ki} \leq b_i$ and $a_i + c_{ij} \leq b_j$. As a search strategy we are using the first improvement strategy.

Function *Perturbation(X; level)* is used as a shaking function. It performs level random 1-shift moves on given solution X.

Algorithm 1: VNS for building a feasible solution

```

Function Construct Feasible Solution;
1 Make Nearest Neighborhood List for each customer;
2  $X \leftarrow RandomSolution()$ ;
3  $level \leftarrow 1$ ;
4 repeat
5   while Solution is not feasible and level ≤ 8 do
6      $X' \leftarrow Perturbation(X, level)$ ;
7      $X'' \leftarrow LocalSearch(X)$ ;
8     if  $X''$  is better than  $X$  then
9        $X \leftarrow X''$ ;
10       $level \leftarrow 1$ ;
11    else
12       $level++$ ;
13    end
14  end
until Solution is not feasible;

```

Figure1: Scheme of VNS for Building a feasible solution

3. GVNS for TSPTW

The feasible solution built by previously described VNS has been improved by GVNS which steps are represented on Figure 2.

Most common moves which is performed on some TSP solution are **2-opt** moves and **OR-opt** moves. **2-opt** move broke down two edges of current solution and make two new edges inverting part of solution in such way that resulting solution is still a tour. If the **2-opt** move is performed on four consecutive customers such move is called **1-opt** move. In the other hand, **OR-opt** move relocate chain of consecutive customers. If the length of the chain is equal to k we will call such move **OR-opt-k** move. If the chain of k consecutive customers is moved backward that move is called **backward OR-opt-k**. Similarly, if the chain is moved forward move is called **forward OR-opt-k**.

Previously described moves can be performed on each feasible solution of TSPTW problem since TSPTW is a variant of TSP, but we must be careful because some movements can lead to unfeasible solutions. So, it is important to check whether some move yields feasible or unfeasible solution. For that purpose we built an array named **Gap** where $Gap[i]$ denotes maximal value for which arrival time at node i can be increased so that the feasibility on the final part of the tour which starts at node i is kept. If we suppose that node j precede node i than $Gap[j]$ is calculated in the following way:

$$Gap[j] = \min(Gap[i], \beta_j - b_j) \quad (1)$$

If we want to check feasibility of some move we have to recalculate arrival time at each customer between first and the last customer involved in move, and also at these two customers (first and last customer according to resulting tour if the move is performed). If all those customers are still non-violated and arrival time at last customer involved by move is increased for value less or equal to its Gap value then new solution will be feasible otherwise it will be unfeasible.

As a local search we decide to use **Seq-VND** which explore the following neighborhood structures respectively: 1-opt, backward OR-opt-2, forward OR-opt-2, backward OR-opt-1, forward OR-opt-1, 2-opt.

Algorithm 2: GVNS

```

Function GVNS();
1  $X \leftarrow \text{ConstructFeasibleSolution}()$ ;
2 repeat
3   while  $\text{level} \leq 30$  do
4      $X' \leftarrow \text{Perturbation}(X, \text{level})$            /* Shaking */;
5      $X'' \leftarrow \text{SeqVND}(X')$                    /* Local Search */;
6     if  $X''$  is better than  $X$  then
7        $X \leftarrow X''$ ;
8        $\text{level} \leftarrow 1$ ;
9     end
     $\text{level}++$ ;
  end
until  $t \leq n/2$ ;

```

Figure 2: Steps of GVNS

4. COMPUTATIONAL RESULTS

The proposed method is tested on three sets of benchmark instances from the literature. The first set has been proposed by Urrutia et al. and it contains 25 test instances. The second test set has been proposed by Olhmann and Thomas, while the third has been proposed by Ascheuer. The first two set contains symmetric test instances, while the third contains asymmetric test instances. The name of each instance from the first two test sets is consisted of n , number of customers, w and maximal width of time window. For example, name of test instance n350w300 denotes that the instance contains 350 customer and maximal width of time window is 300. In the other hand, the number in the name of each instance from the set proposed by Ascheuer represents the number of customers.

Computational results of our GVNS procedure is given below and they are compared with results of current state of the art heuristics. It can be concluded that our GVNS method is very efficient in solving instances with large number of customers since it offers new best known solutions on the 24 instances (of 25) proposed by Urrutia et al. However, it finds worse solutions than bestknown solutions at almost all instances proposed by Olhmann and Thomas. Similarly, on some small asymmetric instances GVNS method finds worse solutions than bestknown solutions but on some large instances it is able to find new bestknown solutions. Obtained results for asymmetric test instances are compared with bestknown solutions and with those proposed by Blum et al.

5. CONCLUSION

In this paper, we presented new two-phase VNS based heuristics for solving Traveling Salesman problem with time windows. In the first phase, we built a feasible solution using GVNS and Nearest neighbor lists, while in the second, improvement phase, we improve obtained solution using GVNS. Also, we introduce new way for checking feasibility of 2-opt and Or-opt moves using array Gap.

Computational results show that our method is much better in solving problems with a large number of customers than in solving those with small number of customers. So, the direction of further research will include improving this method and generating new large scale problems since, up to now, the largest problem has only 400 customers.

²Mathematical Institute SANU, bgdnpop@gmail.com

Abstract: The vehicle routing problem (VRP) is one of the most investigated combinatorial problems in operations research. In this paper we introduce a set-covering-based algorithm that uses an efficient extended savings algorithm to generate good routes in order to construct a feasible set for many different optimization problems as Capacitated VRP, Distance-Constrained VRP, Time-Constrained VRP or CVRP with heterogeneous fleet of vehicles. We have developed a software package that implements the mentioned algorithm in order to perform a wide class of experiments for Capacitated VRP.

Keywords: vehicle routing problem, set-covering based algorithm, heuristic

1. INTRODUCTION

The vehicle routing problem (VRP) was introduced by Dantzig and Ramser in 1959. They described a real-world problem and introduced the mathematical programming formulation. A wide description of the VRP can be found in Laporte and Semet 2002.

Stanojević *et al.* 2012 proposed a new way of merging routes and a corresponding formula for calculating savings. This kind of savings is a generalization of savings defined by Clarke and Wright 1964 and it was used to develop an extended savings algorithm (ESA). In this paper we present a set-covering based algorithm (SC-ESA) that uses ESA to generate routes for the feasible set of a capacitated vehicle routing problem (CVRP). A set-covering-based approach for CVRP was first suggested by Balinski and Quandt 1964. The classic set-covering-based algorithm for CVRP, called Column Generation gives exact solution by starting from an initial set of routes, solving an exact model in order to identify a solution for CVRP and, if possible, adding routes that can decrease the cost. SC-ESA is an approximate algorithm. It generates many good routes and then, among them it searches for a subset of feasible routes that represents a solution for CVRP. Due to its last step, SC-ESA can be easily adapted to solve a wide class of vehicle routing problems by adding constraints (e.g. for routes length and time, for a fleet of different types of vehicles, etc.) to the mathematical model.

The rest of the paper is organized as it follows. In Section 2 we set up notation and terminology. In Section 3 we formulate SC-ESA. Section 4 presents our experimental results. The results are compared with results obtained by running other heuristics. Section 5 contains some conclusions and ideas for further research.

2. VRP – NOTATION AND TERMINOLOGY

VRP concerns the distribution of goods by vehicles using an existing road network in order to serve customers. The solution of a VRP consists of a set of routes fulfilling some constraints, such that the global cost of the transportation is minimal.

The road network is described by a graph whose vertices represent the customers and the depot, and whose arcs represent the shortest paths between customers. We assume that the graph is complete; both arcs that connect two vertices have the same weights; and arcs' weights satisfy the triangle rule.

In this paper the capacitated vehicle routing problem (CVRP) will be considered. It means that only one depot exists and all vehicles have the same capacity. The characteristic of each vertex except the depot is the demand of the corresponding customer. The characteristic of the arc is the cost of the transportation along it.

Each route is a cycle that contains the depot. The cost of a route is the sum of costs of arcs that belong to the route. Capacity of a route is the sum of the vertices' demands that belong to the route. The CVRP is to

find a set of routes such that each customer belongs to a route, each route has the capacity less than or equal to the vehicle's capacity and the total cost of routes is minimal.

We will denote by 0 the depot and by $1, 2, \dots, n$ the other vertices of the graph. We will denote by (i, j) the arc between vertices i and j and by c_{ij} the cost of the arc (i, j) , for all $i=0, 1, \dots, n$ and $j=0, 1, \dots, n$, $i \neq j$. The notation $r = (0, \dots, i, j, \dots, 0)$ means that the route r contains the arc (i, j) . The notation $a \in r$ means that arc a belongs to the route r . We will denote by \bar{r} the route that contains the same arcs as r but they are passed in opposite direction.

3. SET-COVERING BASED APPROXIMATE ALGORITHM

The idea of a set-covering-based exact algorithm for CVRP is to enumerate all feasible routes \mathcal{R} and then to select a minimum-cost set of feasible routes such that each customer is included in some route. A route is feasible if and only if it starts and ends at the depot and picks up a total load not exceeding the vehicle capacity.

SC-ESA is an approximate algorithm based on set-covering approach. It generates “good” feasible routes (the set \mathcal{R}' in Model (1)-(4)) and then, it selects a minimum-cost set of routes that is solution for CVRP.

The model for obtaining the optimal set of routes among a subset \mathcal{R}' of \mathcal{R} is the following.

$$(\min) \sum_{r \in \mathcal{R}'} c_r y_r \quad (1)$$

subject to

$$\sum_{r \in \mathcal{R}'} \alpha_{ir} y_r \geq 1, \forall i \in C \quad (2)$$

$$\sum_{r \in \mathcal{R}'} y_r \leq K \quad (3)$$

$$y_r \in \{0, 1\}, \forall r \in \mathcal{R}' \quad (4)$$

where C is the set of customers, α_{ir} is a binary constant equal to 1 if the customer i belongs to the route r , y_r is a binary variable equal to 1 if the route r belongs to the optimal solution, K is the number of available vehicles and c_r is the cost of route r . Constraints (2) require that each customer appears in at least one route. Constraint (3) imposes that at most K routes will be used.

The generation step is the following. Deviations of the initial instance are formed by generating random costs of arcs (c'_{ij}) that follow a normal distribution with mean equal to the original costs (c_{ij})

and variance increasing from 0 by a given step (v). Each deviation is solved by the extended savings algorithm introduced by Stanojević 2012 and all generated routes (final and intermediate) are collected. The variance (Var) is increased when l unsuccessful iterations were done (no new routes were found). The use of normal distribution assures that the new costs are, with big probability, close to the original ones, hence the solutions of the deviated instances will be “good” routes for the original instance. The instances generation continues till a given number (NR) of routes are obtained.

In what follows we present the steps of SC-ESA with input parameters n , $(c_{ij})_{n \times n}$, NR , v and l .

1. Initialization: the set of routes $S = \emptyset$, the number of generated routes $k = 0$, the variance $Var = 0$, the number of unsuccessful iterations $it = 0$.
2. Routes generation: While $k < NR$ do

- Generate the new deviated instance with costs $C' = (c'_{ij})_{n \times n}$, $c'_{ij} = N(c_{ij}, Var)$ using the normal distribution generator $N(\mu, \sigma^2)$.
 - Run ESA with costs C' and record all (intermediate and final) routes in set \mathcal{R} .
 - If $\mathcal{R} \subset \mathcal{S}$ (i.e. no new routes were found) then $it = it + 1$, otherwise $it = 0$, $\mathcal{S} = \mathcal{S} \cup \mathcal{R}$, $k = | \mathcal{S} |$.
 - If $it > I$ increase the variance: $Var = Var + v$, $it = 0$.
3. Solve Model (1) - (4) using the set of routes $\mathcal{R}' = \mathcal{S}$.

Model (1) - (4) solved in Step 3 of SC-ESA can be replaced by other models depending on the characteristics of the original problem. For example,

- for Distance-Constrained VRP, $\mathcal{R}'' = \{r \in \mathcal{R}' \mid d_r < D\}$ will be used instead of \mathcal{R}' , where D represents the upper bound constraint for distance and d_r represents the length of route r (see for instance Laporte 2002);
- for Time-Constrained VRP the following constraint has to be added to the original model

$$\sum_{h \in H(r)} (s_h + t_r - T) y_r \leq 0, \forall r \in \mathcal{R}'$$

where $H(r)$ represents the set of vertices (except the depot) on route r , s_h represents the time spent in vertex h , t_r represents the time spent travelling on route r and T represents the upper bound constraint for time (see for instance Laporte 2002);

- for a heterogeneous fleet of vehicles for CVRP the following model (see Baldacci *et al.* 2008) will be used.

$$(\min) \sum_{k \in M} \sum_{r \in \mathcal{R}'_k} c_{rk} y_{rk}$$

subject to

$$\sum_{k \in M} \sum_{r \in \mathcal{R}'_k} \alpha_{irk} y_{rk} \geq 1, \forall i \in C,$$

$$\sum_{r \in \mathcal{R}'_k} y_{rk} \leq m_k, \forall k \in M,$$

$$y_{rk} \in \{0, 1\}, \forall r \in \mathcal{R}'_k, k \in M.$$

where $\mathcal{R}'_k = \{r \in \mathcal{R}' \mid q_r \leq Q_k\}$ is the set of generated routes feasible for a vehicle of type $k \in M$ (q_r is the capacity of the route and Q_k is the maximal capacity of vehicles of type k), y_{rk} is a binary variable equal to 1 if the route r is selected for a vehicle of type k , m_k is the maximal number of routes selected for vehicles of type k and c_{rk} is the corresponding cost.

Moreover, some generalized vehicle routing problems may be solved by SC-ESA if they can be transformed into capacitated vehicle routing problems (see for instance Pop and Pop Sitar 2011).

4. EXPERIMENTS

We have developed a software package that implements SC-ESA. The programs as well as their source code written in Haskell are freely available at <http://esavrp.sourceforge.net>.

For our numerical experiments, the benchmark set is composed of seven instances (CMT) from Christofides 1979, eight instances (E) from Christofides 1969 and seventy-three instances (A, B and P) from Augerat 1995. All these instances may be downloaded from the site <http://branchandcut.org>. All instances that we

have considered were defined as Euclidean graphs and we have calculated the costs of arcs as Euclidean distances rounded to whole numbers.

For each instance the solution costs c^{obt} were obtained by running SC-ESA and the relative deviations $c^{rel} = \frac{c^{obt} - c^*}{c^*}$ from the best known solution cost c^* were computed. Values c^* were taken from Altinel and Oncan 2005 or were obtained by running Groer's meta-heuristic 2012.

Table 14: Relative deviations and running times on Augerat *et al.*'s test set A

Averages:	4518.52			677	78.93	0,16%

Tables1, 2, 3, 4, 5 and 6 contain number of generated routes, best known value, obtained value time needed for generating routes and for solving mathematical model and the relative deviations from the best known solutions values obtained by our implementation of SC-ESA on each test set A, B, CMT, E and P respectively.

Time spent for generating routes using SC-ESA is, on average, 77.25% of the total running time.

Table 2: Relative deviations and running times on Christofides et al.'s test set CMT

	Number of generated routes	Best known value	Obtained value	Time needed for routes generation	Time needed for solving the model	Percentage deviation
CMT-n51-k5	5000	521	521	387	0	0,00%
CMT-n76-k10	6000	830	838	980	90	0,96%

Comparing to classic implementation of savings algorithm and its extensions, see Stanojević *et al.* 2012, and analyzing the ratio *relative-deviation / running-time* we consider that the results obtained by SC-ESA are very good. The average percentage deviation decreased from 5.13% (obtained by running Clarke-Wright algorithm) to 0.58% (obtained by running SC-ESA) on the same instances. The average running time of SC-ESA was 15 minutes. Negative values obtained in Table 3, for instances B-n51-k7 and B-n57-k7, are due to the number of routes in the solution. SC-ESA does not take into account the predefined number of vehicles.

When SC-ESA is used, the trade-off between relative deviation and time can be easily manipulated. Moreover, the routes generated once can be used with different models defined for different kind of constraints on time, distance, number of vehicles, types of vehicles, etc. Spending more time for generating routes and solving model, a better solution is obtained.

5. CONCLUSION

In this paper one set covering based algorithm for capacitated vehicle routing problem was presented. SC-ESA uses an extended savings algorithm for generating many good routes and then selects a minimum-cost feasible set of routes as solution for CVRP. Due to its last step, SC-ESA can be easily adapted to solve a wide class of vehicle routing problems on the same graph, using the same routes generated only once, just by adding/removing constraints in the set-covering-based model. Models for solving

New group of experiments will be done with Distance-Constrained VRP, Time-Constrained VRP and heterogeneous fleet of vehicles for CVRP.

Abstract: The Quadratic Assignment Problem (QAP) is one of the most interesting and most challenging combinatorial optimization problems in existence. In this paper, a survey of some of the most important formulations available is presented as well as its classification according to their mathematical sources. The main motivation for this survey was continuous interest in QAP, shown by a number of researchers worldwide, for the theory, applications and solution techniques for this problem. The main task was to determine the role of mathematical programming in a wide range of different methods for solving QAP. The mathematical models and techniques for solving QAP are implemented in various solvers, and among them, GAMS solver is the one most frequently used. This paper investigates how far the solutions obtained by GAMS are from the global optimum. Method for this study was testing solvers on a representative instance of the problem and comparison of these results with those obtained by searching a complete feasible solution set. Conclusions can be made that the payoff for speeding the search for the solution is an average of 6% deviation from the optimal solutions.

Keywords: model, solver, NP-hard problem, combinatorial optimization, integer programming, MILP

1. INTRODUCTION

Main reasons, which make the quadratic assignment problem (QAP) extremely attractive, are that the number of real life problems, which are mathematically modeled by QAPs, has been continuously increasing. Also, a number of other well known combinatorial optimization problems can be formulated as QAPs. Typical examples are the traveling salesman problem and a large number of problems in graphs such as the maximum clique problem or the graph partitioning problem. Finally, from the computational point of view the QAP is one of the most difficult problems to solve: solving instances of size larger than 20 is nowadays still considered intractable.

QAP was introduced by Koopmans and Beckmann (1957) as a model for a plant location problem. It was considered the problem of allocating n facilities to n locations, with costs depending on the distance between the locations and the flow between the facilities increased by the costs associated with a facility being placed at a certain location. The objective is to assign each facility to a location such that the total cost is minimized.

Due to its high computation complexity, the QAP has been chosen as the first major test application for the GRIBB project (GReat International Branch-and-Bound search). This project is seeking to establish a software library for solving a large class of parallel search problems by the use of numerous computers around the world accessed by Internet. This paper aims at describing different, but equivalent mathematical formulations, which stress different structural characteristics of the problem, which lead to different solution approaches based on different points of view. This paper propose to collect these formulations, highlighting their most important features to classify them according to used techniques, such as integer programming, discrete and combinatorial mathematics and graph theory. Most of these formulations are equivalent and they allow mathematical resources for the development of new solution techniques.

The paper is organized as follows. Integer models for QAP having quadratic objective function and representations of the feasible set are presented in Section 2. Mixed integer linear programming formulation based on the linearization of the objective function is presented in Section 3. One of the best known solvers, GAMS, was used for solving QAP on the known instance from QAPLIB database of the QAP's problems in Section 4. Obtained results were compared with the global optimal solution obtained by exact algorithm in Section 5.

2. INTEGER QUADRATIC MODELS FOR QAP

QAP represents three $n \times n$ input matrices with real elements $F = \{f_{ij}\}$, $D = \{d_{kl}\}$, and $C = \{c_{ik}\}$, where f_{ij} is the flow between the facility i and facility j , d_{kl} is the distance between the location k and location l , and c_{ik} is the cost of placing facility i at location k . The Koopmans – Beckmanns version of the QAP can be formulated as follows: Let n be the number of facilities and locations and denote by N the set $N = \{1, 2, \dots, n\}$. QAP is finding the permutation σ of elements of N , which minimize Z in (1).

$$Z = \sum_{i=1}^n \sum_{j=1}^n f_{ij} d_{\varphi(i)\varphi(j)} + \sum_{i=1}^n c_{i\varphi(i)} \quad (1)$$

Each individual product $f_{ij} d_{\varphi(i)\varphi(j)}$ is the cost of assigning facility i to location $\varphi(i)$ and facility j to location $\varphi(j)$. In that context, matrices F and D are symmetric with zeros in the diagonal and all the matrices are nonnegative. An instance of a QAP with input matrices F , D and C has quadratic and linear terms and will be denoted by $\text{QAP}(F, D, C)$, or by $\text{QAP}(F, D)$, if there is no linear term. Since the linear term of (1) is easy to be solved, most authors discarded it.

A more general QAP version was proposed by Lawler (1987) and involves costs b_{ijkl} that do not necessarily correspond to products of flows by distances. The Lawler formulation is as follows:

$$Z = \sum_{i=1}^n \sum_{j=1}^n b_{ij\varphi(i)\varphi(j)} + \sum_{i=1}^n c_{i\varphi(i)} \quad (2)$$

Koopmans – Beckmanns version of QAP can be obtained from (2) using $b_{ijkl} = f_{ij} d_{kl}$ for all i, j, k, l where $i \neq j$ or $k \neq l$ and $b_{iikk} = f_{ii} d_{kk} + c_{ik}$ otherwise.

Introducing permutation matrices, objective functions (1) and (2) can be reformulated from permutation to mathematical programming problems. Relationship between permutations and permutation matrix are stated as:

$$x_{ij} = \begin{cases} 1, & \text{if } \varphi(i) = j \\ 0, & \text{if } \varphi(i) \neq j \end{cases}$$

The most commonly used models with permutation matrices are Integer Quadratic Programming model, trace formulations and Mixed Integer Linear Programming model based on the linearization of the objective function.

Integer program with quadratic objective function is given by equations (3) to (6).

$$(\min) \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^n \sum_{l=1}^n b_{ijkl} x_{ik} x_{jl} + \sum_{i=1}^n \sum_{j=1}^n c_{ij} x_{ij} \quad (3)$$

s.t

$$\sum_{i=1}^n x_{ij} = 1, \quad j = 1, 2, \dots, n \quad (4)$$

$$\sum_{j=1}^n x_{ij} = 1, \quad i = 1, 2, \dots, n \quad (5)$$

$$x_{ij} = 0 \text{ or } 1, \quad (i = 1, 2, \dots, n; j = 1, 2, \dots, n) \quad (6)$$

Hereinafter $(x_{ij}) \in X_n$, where X_n is the permutation matrix, stands for equations (4) to (6). Term b_{ijkl} in this model has different meaning from $b_{ij\varphi(i)\varphi(j)}$ in the permutation model. In the permutation model b can be presented as $n!$ matrices B of order $n \times n$, in this model b represents one matrix of order $n^2 \times n^2$ which can be defined using Kronecker product $B = F \otimes D$ (Fig. 1).

$$F \otimes D = \begin{bmatrix} f_{11} D & \dots & f_{1n} D \\ \vdots & \ddots & \vdots \\ f_{n1} D & \dots & f_{nn} D \end{bmatrix}.$$

Figure 1. Kronecker product $F \otimes D$

Trace formulation is supported by linear algebra and exploits the trace function (the sum of the matrix main diagonal elements) in order to determine QAP lower bounds for the cost: Finke, Burkard and Rendl (1987). This approach allows for the application of spectral theory, which makes possible the use of semi definite programming to the QAP: De Klerk and Sotirov (2010). It can be proved that exist a matrix with the trace equal to the QAP objective function. The trace formulation, by Edwards (1977, 1980), can be stated as:

$$\min \text{tr} (FXD^T + C)X^T \quad (7)$$

$$\text{s.t. } (x_{ij}) \in X_n$$

Using $\text{tr}(AB) = \text{tr}(BA)$, $(AB)^T = B^T A^T$, $\text{tr} A = \text{tr} A^T$ and $F = F^T$ for symmetric matrices, quadratic term in

(8) can be written as:

$$\text{tr} FXD^T X^T = \text{tr} FXDX^T$$

where D can be non-symmetric. If the instance of the QAP has only one symmetric matrix, problem can be transformed to the problem with both symmetric matrices by introducing a new symmetric matrix $E = \frac{1}{2}(D + D^T)$:

$$\text{tr} FXE^T X^T = \frac{1}{2} \text{tr} (FXD^T X^T + FXDX^T) = \text{tr} FXD^T X^T$$

3. MIXED INTEGER LINEAR PROGRAMMING MODEL

The QAP, as a mixed integer programming formulation, is found in the literature in different forms, all of them replacing the quadratic terms by linear ones: Zhang, Beltran-Royo and Ma (2010), Pryor and Chinneck (2011), Patel and Chinneck (2007). The linearization of the objective function is usually achieved by introducing new variables and new linear (and binary) constraints: Xia and Yuan (2006), Ostrowski, Linderoth, Rossi and Smriglio (2011). The very large number of new variables and constraints, however, usually poses an obstacle for efficiently solving the resulting linear integer programs. Most commonly used linearization of the QAP are Lawler's linearization (1963), which was the first, Kaufmann and Broeckx's (1978) which has the smallest number of variables and constraints, Frieze and Yadegar's (1983) and the linearization of Adams and Johnson (1994). The last linearization which is a modification of Frieze and Yadegar's (1983) unifies most of the previous linearization.

Lawler replaces the quadratic terms $x_{ik}x_{jl}$ in the objective function by n^4 variables: $y_{ijkl} = x_{ik}x_{jl}$ and obtains linear model:

$$(\min) \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^n \sum_{l=1}^n b_{ijkl} y_{ijkl} + \sum_{i=1}^n \sum_{j=1}^n c_{ij} x_{ij} \quad (8)$$

s.t

$$(x_{ij}) \in X_n \quad (9)$$

$$\sum_{i,j=1}^n \sum_{k,l=1}^n y_{ijkl} = n^2 \quad (10)$$

$$x_{ij} + x_{kt} - 2y_{ijkt} = 0, \quad (i,j,k,t = 1,2,\dots,n) \quad (11)$$

$$y_{ijkt} = 0 \text{ or } 1, \quad (i,j,k,t = 1,2,\dots,n)$$

It can be observed that this 0-1 linear program has $n^4 + n^2$ binary variables and $n^4 + 2n^2 + 1$ constraints. Kaufmann and Broeckx define n^2 new real variables by rearranging terms in the objective function.

$$\sum_{i,j=1}^n x_{ij} \sum_{k,l=1}^n b_{ijkl} x_{kl} \quad (12)$$

Frieze and Yadegar replace the products $x_{ik}x_{jl}$ of the binary variables by continuous variables $y_{ijkl} = x_{ik}x_{jl}$ and Adams and Johnson introduced a new 0-1 linear integer programming formulation, which was based on all of the previously described linearizations.

4. SOLVING QAP PROGRAMMING MODELS

The continuous interest in QAP is shown by a number of researchers worldwide, for the theory, applications and solution techniques for this problem. Figure 2 presents the number of publications related to the different QAP formulations, classified as Permutations (PM), Integer Programming (IP), Mixed Integer Linear Programming (MILP), Trace (TR), SemiDefinite Programming (SDP) and Graphs (GR). It can be observed

that the QAP approach that identifies solutions with permutations is mostly used followed by IP and MILP formulations. The formulations derived from semidefinite programming and the ones using exclusively graphs are less contemplated in the literature.

Figure 2. QAP formulations in literature

Conclusion can be made that QAP approach that finds solution using mathematical programming model plays significant role in publications. The main task of this paper is to investigate the solution time and solution quality of the applications having this approach.

Substantial progress was made with the development of algorithms and computer codes to solve large mathematical programming problems. Solution procedures formed only a small part of the overall modeling effort. A large part of the time required to develop a model involved data preparation and transformation and report preparation. Each model required many hours of analyst and programming time to organize the data and write the programs that would transform the data into the form required by the mathematical programming optimizers. Furthermore, it was difficult to detect and eliminate errors because the programs that performed the data operations were only accessible to the specialist who wrote them and not to the analysts in charge of the project. Answer for these obstacles were commercial and open source solvers providing a high-level language for the compact representation of large and complex models and permitting model descriptions that are independent of solution algorithms.

One of the best known solvers with the references from the authors of QAPLIB, a famous collection of electronically available data instances for the QAP, is GAMS from *GAMS Development Corporation, Washington, DC, USA*. Complete procedure is described on the small instance of order 7 in the sake of the clarity of explanation. Modeling language is simply, allowing changes to be made in model specifications simply and safely.

GAMS model for QAP is presented on Figure 3.

Figure 3. GAMS model for QAP

The problem types and their identifiers, which are needed in a solve statement, are listed in Table 1.

Table 1: Types of mathematical programming models

LP	Linear programming. There are no nonlinear terms or discrete (binary or integer) variables in your model
QCP	Quadratic constraint programming. There are linear and quadratic terms but no general nonlinear term or discrete (binary or integer) variables in your model
NLP	Nonlinear programming. There are general nonlinear terms involving only smooth functions in the model, but no discrete variables
DNLP	Nonlinear programming with discontinuous derivatives. This is the same as NLP, except that non-smooth functions can appear as well. These are more difficult to solve than normal NLP problems. The user is strongly recommended not to use this model type
RMIP	Relaxed mixed integer programming. The model can contain discrete variables but the discrete requirements are relaxed, meaning that the integer and binary variables can assume any values between their bounds
MIP	Mixed integer programming. Like RMIP but the discrete requirements are enforced: the discrete variables must assume integer values between their bounds
RMIQCP	Relaxed mixed integer quadratic constraint programming. The model can contain both discrete variables and quadratic terms. The discrete requirements are relaxed. This class of problem is the same as QCP in terms of difficulty of solution
RMINLP	Relaxed mixed integer nonlinear programming. The model can contain both discrete variables and general nonlinear terms. The discrete requirements are relaxed. This class of problem is the same as NLP in terms of difficulty of solution

MIQCP	Mixed integer quadratic constraint programming. Characteristics are the same as for RMIQCP, but the discrete requirements are enforced
MINLP	Mixed integer nonlinear programming. Characteristics are the same as for RMINLP, but the discrete requirements are enforced
MPEC	Mathematical Programs with Equilibrium Constraints
MCP	Mixed Complementarity Problem
CNS	Constrained Nonlinear System

5. OBTAINED RESULTS

The output from a GAMS run is produced on one file, which can be read using any text editor. The output from GAMS contains many aids for checking and comprehending a model. Elements of the standard output are presented in Fig. 4.

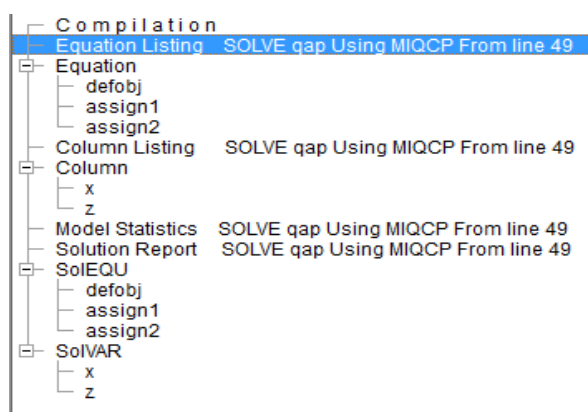

Figure 4. Output of the GAMS solver

One part (SolVAR) of the output of the GAMS solver for the given input instance is presented in Table 2.

5	3 2 1 6 4 5 7	63804	1.0513	7 4 6 3 2 5 1	102094	1.6822
6	1 6 3 7 2 4 5	64162	1.0572	7 4 6 2 3 5 1	102030	1.6812

From these results it can be observed that the value obtained with GAMS solver is not optimal and is fifth best result. The best schedule is 6 7 3 5 2 4 1 when the target function value is 60,690 which is for 3,114 better result, i.e. deviation of the GAMS result is 5.13%.

6. CONCLUDING REMARKS

QAP, though being relatively young, is widely considered as a classical combinatorial optimization problem. As exact algorithms can only solve small size instances of the QAP, and as finding an approximate solution remains NP complete, heuristics with good performance in both solution time and solution quality are highly desirable. In this paper, we survey some of the most important formulations available and classify them according to their mathematical sources. Mathematical models and techniques that have been used for solving QAP were implemented in various solvers, and among them, GAMS (GAMS Development Corporation, Washington, DC, USA) solver is frequently used. Solvers for quadratic programming obtain only local optimum solutions, so this paper investigates how far these solutions are from the global optimum.

The first conclusion that can be derived from described approach is that the QAP approach that finds solutions using permutations of facilities is mostly used. Despite this, solutions using mathematical programming models play significant role among all types of solution approaches. Unlike other approaches, which require development of special algorithms and programming techniques, solutions based on mathematical models can use the existing solvers. The following conclusions that can be derived from this work are related to the use of solvers, namely, GAMS, one of the most popular for this purpose.

Even for problems of small size, GAMS solution is not optimal one. It can be stated as a significant disadvantage, especially when one considers that the complete search of such a small feasible solution set is not time consuming. For larger problems calculated deviation of an average of 6% is really satisfactory given the enormous savings in computer timework.

Abstract: *The purpose of this paper is to provide support for wide adoption and implementation of the Efficient Consumer Response (ECR) in the Serbian market. The categorization of ECR components has been done on secondary data sources, while desk research has been applied in combination with conversational research for the identification of obstacles for implementing ECR in Serbia. This study has shown that in Serbia, beside general obstacles that are present in nearly all business environments, there are also specific obstacles specifically related to the Serbian environment. Results of this work can be helpful for both practitioners and academics in the field of logistics and supply chain management, interested in the implementation of the ECR concept.*

Keywords: *supply chain, supply chain management, Efficient Consumer Response, ECR, retail industry.*

1. INTRODUCTION

Efficient consumer response (ECR) is a supply chain management concept that leads to overcoming the inefficiencies in the grocery supply chain. ECR has been successfully adopted since 1993 in the US and in Europe business practice one year later. The ECR Europe Executive Board (ECRE) is founded in 1994 and now includes 24 European ECR national initiatives. In Serbia, ECR is becoming increasingly popular in the academic environment (e.g. Bogetic, 2007; Bogetic & Acimovic, 2009; Jovanovic, 2009; Jovanovic, Vasiljevic & Ilic, 2009; Stankovic & Popovic, 2009) but unfortunately their popularity is still far short in the Serbian business environment. This paper has four objectives: first, to present origins of ECR; second, to categorize ECR components; third, to identify obstacles for implementing ECR, both general and specific which are related to the Serbian environment; and fourth, to contribute to the popularity of ECR in Serbia.

2. THEORETICAL BACKGROUND

ECR was developed during the nineties in order to overcome problems in the US retail and consumer goods industry. It was based on the idea of Quick Response (QR) concept which is applied in the clothing and textile industry. The first Efficient Consumer Response Working Group (ECRWG) was founded in 1992 in the US by representatives of the following companies Borden, Inc., Campbell Sales Company, Coca-Cola Company, Crown/BBK Incorporated, Kraft General Foods, Kroger Co., Nabisco Food Corporation, Procter & Gamble Co., Ralston Purina Company, Safeway Inc., Sales Force Companies, Inc, Scrivner Inc, Shaw's Supermarkets, Inc., SUPERVALUE INC. and The VONS Companies, Inc. with the aim to improve the performance of grocery supply chains (Kotzab, 1999). The plan was to analyse the mass merchant channel with its main competitors Wal-Mart, Target and K-Mart (according to Browning, 1997. given into Kotzab, 1999). ECRWG was engaged the consulting house Kurt Salmon Associates (KSA) for performing needed research because of their experience in the analysis of textile supply chains and development of QR. In 1993, KSA was identified the set of practices which could lead to improvement of the total supply chain performance for consumer goods. KSA showed that ECR could enable distributors and suppliers a higher level accuracy of demand forecasting (Tyana & Wee, 2003).

In 1993, KSA defined ECR as the "grocery industry strategy in which distributors, suppliers and brokers jointly commit to work closely together to bring greater value to the grocery consumer" (Kotzab, 1999, p.366). The project team Joint Industry Project for Efficient Consumer Response in »An ECR Best Practices Report« in 1994 defined ECR as the "strategy in which the grocery retailer, distributor, and supplier trading partners work closely together to eliminate excess costs from the grocery supply chain" (Hoffman & Mehra, 2000, p. 366). According to them, the focus of ECR should be on the following four issues:

1. How to optimize store assortments and space allocations to increase category sales per square foot and inventory turnover?
2. How to streamline the distribution of goods from the point of manufacture to the retail shelf?
3. How to reduce the cost of trade and consumer promotion?
4. How to reduce the cost of developing and introducing new products?

The merits of transfer the ECR concept to the European market belong to the Coca-Cola Retailing Research Group (CCRRG). In 1994, this group presented their meaning of ECR, so-called supplier retailer collaboration (SRC) as acceptance of both retailers and suppliers to “share proprietary internal or external data, and/or share policies and processes” which they used in decision making with the aim of sharing the achieved benefits (Kotzab, 1999, p. 369).

According to these ideas, the ECR Europe Executive Board (ECRE) is founded in 1994 by the group of leading European manufacturers and retailers which consisted of Albert Heijn, Birds Eye Walls, Coca-Cola Germany, Coca-Cola France, Fegro/Selgros, Henkel, ICA, Johnson & Johnson, Mars, Procter & Gamble, UK, Procter & Gamble, Italy, PromodeAs, Tesco and Van den Bergh Foods (Kotzab, 1999; Harris, Swatman, & Kurnia, 1999). The aim of ECRE was to develop ECR models and practices suitable for European business situations (Kotzab, 1999). In January 1996, on the first European ECR Conference which was held in Geneva, the ECRE presented their ECR model, according to (Alvarado & Kotzab, 2001). In the final report »European Value Chain Analysis Study« published in 1996 from the ECRE, ECR is defined as “a “strategic initiative” working to overcome traditional barriers between trading partners, thus eliminating internal barriers that result in costs and time that add little or no value to consumers” (Kotzab, 1999, p. 366). Seven years later the ECRE suggested the following definition of ECR – “the realisation of a simple, fast and consumer driven system, in which all links of the logistic chain work together, in order to satisfy consumer needs with the lowest possible cost” (Reyes & Bhutta, 2005, p. 348). Today, the vision of the ECRE is “working together to fulfill consumer wishes better, faster and at less cost with a shared business process leading to shared benefits across the value chain” (ECR Community, 2012).

ECR is focused on the achievement of some kind of forms of closely cooperation between retailers and their suppliers in order to create possibilities for direct response to the needs of customer in supply chain. The aim is to increase efficiency of flow of goods and use of data which are electronically collected in retail stores, according to Jespersen & Skjott-Larsen (2006). ECR is directed to combination of customer orientation and value-added process orientation. It supposes that companies work together on integration their operations and elimination of obstacles to satisfied customers and eliminated unnecessary costs.

2.1. ECR-US vs ECR-Europe

The first ECR process model, which is recognized as an American model (hereafter ECR-US model), is presented by KSA in 1993 (Figure 1). ECR-US model represents a combination of the following four strategies which lead to improvements in customer satisfaction:

1. Efficient store assortment – represents providing, grouping and arranging the products that customers want;
2. Efficient replenishment – represents maintaining of determined inventory levels for required assortment of products;
3. Efficient promotion – represents harmonizing the promotion activities between manufacturer and retailer; and
4. Efficient product introduction – represents developing and introducing new products that customers really want.

The ultimate goal of ECR-US model is to develop customer-driven distribution system which allow continuous production control based on the point-of-sales (POS) data, according to Kotzab (1999).

The first upgraded form of ECR-US model is a SRC process model which was realized by CCRRG in 1994. The CCRRG was recognized the characteristics of European market and according to them tried to adapt the ECR-US model to their needs.

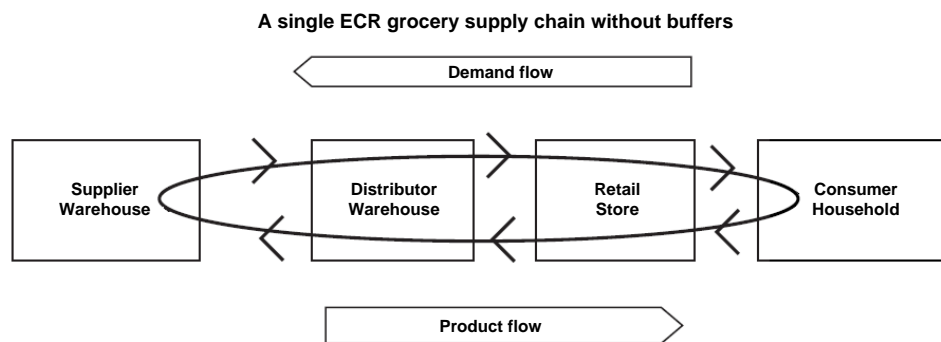

Figure 1: ECR-US model (KSA, 1993, p. 12; Kotzab, 1999, p. 367)

The model adapted for European business environment, known in literature as the ECR-Europe model, was presented by ECRE in 1996. “The ECR-Europe model is a cooperative strategy between retailer and manufacturer to fulfil consumer wishes better, faster and at less cost”, (ECRE, 1996, cited in Kotzab, 1999, p. 370). The group ECRE recommended harmonization of ECR processes through the establishment of focus areas and that will be reflected the deletion of boundaries between functional departments within an organization and between several participating organizations (Figure 2). Focus areas are: production and distribution, logistics and inventory management; sales and marketing; and buying and merchandising. “The interaction of these focus areas leads to improvements of the overall performance, in- and outside the companies involved. Thus, the result is a higher consumer value, which is represented in the ECR-Europe model as a function of quality, trust, variety, service, response time and price”, cited according to Kotzab (1999), p. 371.

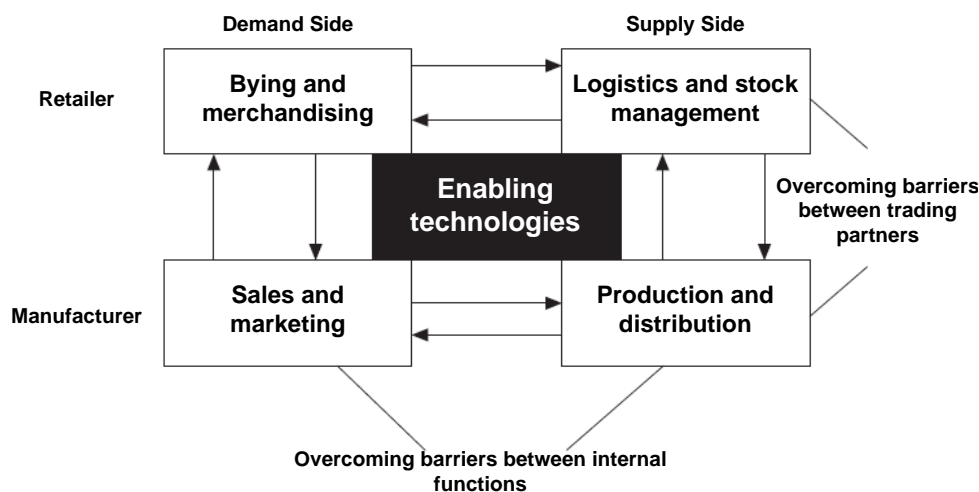

Figure 2: ECR-Europe model (ECRE, 1996, p. 3; Kotzab, 1999, p. 371)

The ECR-Europe model differs between the supply and demand sides, unlike the ECR-US model. The supply side contains all activities in relation to the flow of goods and is defined as a category logistics, (Kotzab, 1999). The action areas of category logistics are: efficient sourcing, efficient replenishment, efficient systems and efficient controlling. The demand side contains all additional activities related to strategic management and is defined as category management, according to the same source.

3. METHODOLOGY

In order to provide support for wide adoption of ECR in the Serbian market, first the theoretical background is given with emphasis on difference between ECR-US and ECR-Europe model, then the categorization of ECR components is suggested, after that the obstacles to implementation of ECR in Serbia are identified, and finally the conclusion and future directions of research are presented. Secondary data (e.g. Zikmund et al., 2010), mostly from the Internet sources and libraries are used for the categorization of ECR components. Desk research (Halldorsson & Arlbjorn, 2005) in combination with conversational research (Zikmund et al., 2010) is used for identification the obstacles to implementation of ECR in Serbia.

4. ECR COMPONENTS

Several different components of ECR and their relations have been considered in practice and literature. For example, consulting house Coopers&Lybrand in 1996 identified 14 ECR components and separated them into the following three categories: category management, product replenishment and enabling technologies. In 1998, Kurnia, Swatman and Schauder, discussed as ECR components four strategic initiatives supported by two operational programs and five enabling technologies. In 2008, Soret, de Pablos and Montes presented a list of ECR components divided into four categories: collaboration strategies, ECR practices, enabling tools and associate concepts. The problem of integration ECR components is emphasized by numerous authors (e.g. Coopers&Lybrand, 1996; Brewer, Button & Hensher, 2001; Aastrup, et al., 2008) because individual implementation of ECR components is not sufficient condition for a truly application of ECR concept. If companies want to achieve full benefits of ECR, they must work on integration of ECR components. For the requirements of this work, the ECR components are categorized into basic and additional.

The basic ECR components are:

- Efficient store assortment;
- Efficient promotion;
- Efficient product introduction;
- Efficient replenishment.

The additional ECR components are:

- Category management (CM);
- Continuous replenishment program (CRP);
- Integrated suppliers;
- »Fast« distribution strategies;
- Activity-based costing (ABC);
- Enabling information systems and technologies; and
- Enabling standards.

Efficient store assortment refers to providing, grouping and arranging the products and services that customers want. Efficiently use of available store shelf space and elimination of stock out risks are necessary to influence increase in customer satisfaction in a purchase. POS data, sales data from earlier periods, as well as some demographic studies can be helpful in analysis the product assortment and in choosing the product shelf location. „The relationship between manufacturers, distributors and retailers is crucial in achieving efficient store assortment” (Kurt Salmon Associates, 1993; Wood, 1996; Harris, Swatman & Kurnia, 1999; Reyes & Bhutta, 2005). Manufacturers, wholesalers and retailers have benefits from more accurate forecasts which are reflected in fewer days products stay on inventory, lower levels of safety stock and lower operating costs in the supply chain (Reyes & Bhutta, 2005). It is recommended that manufacturers, wholesalers, distributors and retailers should accept the CM concept in order to achieve efficient store assortment.

Efficient promotion refers to harmonizing the promotion activities between manufacturer and retailer. The proposition is to eliminate inefficient trade promotions and introduce better solutions for organization of promotion activities. Examples of good ideas for promotion introduction, based on Harris, Swatman & Kurnia (1999) and Reyes & Bhutta (2005) are:

- rewarding system for retailers on the basis of the quantity of sold products (»pay for performance«) – which mean rewarding retailers on the basis of how many products they sell to customers, rather than how many products they order from manufacturers;
- one order – several smaller deliveries (»forward commit«) – refers to organization and realization of shipment of one order into several smaller deliveries;
- electronic coupons;
- every day low prices (EDLP); etc.

The reengineering promotion activities enable elimination of all unnecessary and excessive costs. It is recommended to accept the CM concept in order to achieve efficient promotion.

Efficient product introduction refers to developing and introducing new products that customers really want. Manufacturers should to involve other primary supply chain members in the early phases of development of new products in order to reduce risks of wrong development and introduction new

products into marketplace. „Manufacturers, distributors and retailers must work together as allies to reduce the costs of product development and to produce only products anticipated and demanded“ by the customers (KSA, 1993; Harris, Swatman & Kurnia, 1999; Reyes & Bhutta, 2005). The proposition is to accept the CM concept in order to achieve efficient development and introduction new products on the marketplace.

Efficient replenishment refers to maintaining of determined inventory levels for required product assortment. The process focuses on delivering of required product mix to the store shelves with minimal time and costs, according to Kotzab (1999). It is based on a pull system driven by customer demand, and it is controlled by POS data which enable the product replenishment ordering and delivery (Reyes & Bhutta, 2005). The aim is to optimise time and cost in the inventory replenishment system by ensuring the right products to the right place, at the right time, in the right quantity and in the right way (adapted according to KSA, 1993; Harris, Swatman & Kurnia, 1999; Reyes & Bhutta, 2005).

The efficient replenishment is the basic „holder“ which supports the ECR concept and it contributes to more than half savings from ECR implementations (according to KSA, 1993; Harris, Swatman & Kurnia, 1999; Reyes & Bhutta, 2005). It coordinates the flow of goods and information in the supply chain in order to create a continuous flow of products, according to Reyes & Bhutta (2005). This ECR component enables retailers to keep smaller quantities of products in stock, which leads to a reduction in holding costs and shorter lead times, according to the same source. Numerous authors (see Harris, Swatman & Kurnia, 1999; Reyes & Bhutta, 2005) suggested the application of CRP concept in order to eliminate inefficiency in product replenishment.

Category management (CM) represents joint interactive process of retailer and manufacturer which enables management of categories as strategic business units within each retail object in order to gain customer loyalty. The essence of CM is a strategic assortment management (Seifert, 2003). The term CM was first appeared in 1987 when some companies (e.g. Procter & Gamble) changed orientation from brand management to management »by category«, according to Harris, Swatman & Kurnia (1999). The retail chain Real, a division of Metro Group, has first introduced the concept of baby care centres in retail objects, according to Seifert (2003).

Category includes all products and services which can satisfy specific customers' needs. Category is a group of products and services – substitutes and complements. Substitutes can replace each other from the customer viewpoint (e.g. milk from two different manufacturers). Complements can supplement each other from the customer viewpoint (e.g. milk and instant cocoa beverage).

The CM planning process aims to provide the structured application of CM (Seifert, 2003). This process „creates a balance between product and process investment and takes into consideration all required activities of the whole system from manufacturer to retailer to consumer“, cited according to Seifert (2003), p.13. It is consisted of the following nine phases: (1) strategy analysis; (2) category definition and segmentation; (3) determination of category roles; (4) category assessment; (5) category performance analysis; (6) development of category strategies; (7) determination of category tactics; (8) category plan implementation; and (9) category performance measurement and continuous improvement of CM.

Continuous replenishment (CRP) supposes a leaving of push strategies by which the products are „pushed“ from inventories, and adoption of pull strategies by which the products are „pulled“ on the retail store shelves according to real customer demand. Retailer shares sales and inventory data with supplier which continually replenish their inventories. On the other hand, supplier have opportunity to better manage with its inventories and capacities based on available sales data and inventory levels at retailer.

The concept of Integrated Suppliers (IS) represents achieving a form of business cooperation between manufacturer and their suppliers of ingredients, raw materials and packaging in order to eliminate all activities which lead to losses in time and money. The idea for development of IS concept was came in 1996 from »ECR Europe VCA Study« which presented the sources for potential costs reduces in the total supply chain. In 1998 ECR Europe Supply Side Steering Committee founded a working group tasked with analyzing the benefits of application the IS concept. The IS concept incorporates demand management, efficient product change management, synchronized production, Supplier Managed Inventory (SMI), methods and tools for reliable and efficient supply and self billing. The Global Upstream Supply Initiative (GUSI) develops the Upstream Integration Model (UIM) based on idea of IS concept. The UIM model

enables standardization of business processes and data interchanges upstream between manufactures and suppliers in order to support interoperability between them, according to GUSI (2006).

Under the »fast« distribution strategies that support ECR here are supposed direct-to-store distribution strategy and cross-docking. These distribution strategies enable fast delivery of right products from suppliers to retail objects. Direct-to-store delivery refers to direct delivery of products from suppliers to retail objects without crossing through the distribution center. Cross-docking refers to delivery of products from suppliers to retail objects with crossing through distribution center that have the role of product coordinator.

Activity-Based Costing (ABC) enables consideration of real costs required for realization of determined activities. The prerequisite of application ABC are accurate data in relation with real costs of products, services, processes, activities, distribution channels, customer segments, contracts and projects (according to Miller, 1996 in Harris, Swatman & Kurnia, 1999). Real direct and indirect costs have been allocated to activities, and then better solutions for costs reduction tend to be found.

Computer-Aided Ordering (CAO) is one of the enabling specialized software tools that can be used for ECR support. It is a module of retail system whose function is to automatically (or semi-automatically) release procurement orders for products which reach predetermined signal inventory. The most frequently used technologies for support ECR are: e-mail, Electronic Data Interchange (EDI), bar-code, Radio Frequency Identification (RFID), extranet.

Development of ECR is supported by numerous standards. Voluntary Inter-industry Commerce Standard (VICS), which is a subset of the American National Standards Institute Accredited Standards Committee X12 (ANSI ASC X12), is widely used in merchandise retail industry. Uniform Communications Standard (USC) for interchange key EDI documents, also subset of the ANSI ASC X12, is used in grocery and food industry. GS1 is the most widely used system of global standards for identification and communication of information in relation with products, services, assets and locations in supply chains. It is developed by the same name global association GS1 (Global Standard One) which has over 110 member organizations in over 100 countries. GS1 system includes, according to GS1 (2012): global standards for application of bar codes that use GS1 identification keys for automatic identification trade items, locations, logistic units and assets; global standards for electronic business messaging that allow fast, efficient and accurate transmission of business data between trading partners; Global Data Synchronization Network (GDSN); and global standards that combines RFID technology, existing communications network infrastructure and the Electronic Product Code (EPC) to enable immediate and automatic identification and tracking of an item through the whole supply chain.

5. OBSTACLES TO IMPLEMENTING ECR IN SERBIA

The process of transition in Serbia trade lags behind most countries in Europe. Serbian market has been opened for foreign investments since the end of 2000, and in trade sector, interest has been observed for green-field investments like in other sectors, according to Bogetic, Veljkovic & Stankovic (2011). Changes in customer buying behaviour, importance and role of retail objects and relationships between retailers and their suppliers are some of the most important changes in the Serbian market. Serbian customers are increasingly going shopping once a week or once in two weeks and looking to purchase high quality products with low prices. The economic crisis forced Serbian customers to decrease their spending on non-essentials products and in some cases to go shopping less frequently (Euromonitor, 2012). The importance and role of large retail chains is strengthening and the importance and role of small and medium-sized retail objects is weakening in the Serbian market (see e.g. Bogetic, Veljkovic & Stankovic, 2011; Radosavljevic, Maksimović & Borisavljević, 2011). Small and independent retailers are striving to survive beside large retail chains and their positions are even more affected by economic crisis. Large retailers are increasing the pressure on their suppliers, and for them the "ideal supplier" (according to researches of Bogetic, Veljkovic & Stankovic, 2011) is one which give best prices and margins, have supply continuity, wide assortment of quality products, do business professionally and honestly and have short lead times. On the other hand, they demand long terms of payment and even then they will not probably meet time deadlines for payment. Position of suppliers are more complicated with their obligations to pay value added taxes after sending invoice, whether products have been charged or not. These changes put pressure on all supply chain members to apply customer driven supply chain strategy and to make their operations more efficient (Lohtia, Xie & Subramaniam, 2004). ECR is one concept that can contribute to these objectives and can provide numerous benefits to supply chain members.

Potential benefits for the Serbian retail supply chains from ECR can be gain through cost reductions and increases in revenue in the supply chain. Some benefits from the ECR “winning combination” between customers, retailers and manufacturers are given in Seifert (2003). A detailed consideration of numerous ECR benefits is presented in Bogetic & Acimovic (2009). Lohtia, Xie & Subramaniam (2004), Soret, de Pablos & Montes (2008), etc are some of the other authors that indicated benefits from successful ECR implementation.

Obstacles to wide implementation of ECR in Serbia are identified and categorized as follows:

1. General obstacles and
2. Specific obstacles.

General obstacles are presented in nearly all business environments and they are:

- Lack of ECR understanding, expertise and skills. Members in the supply chain are usually not enough familiar with ECR and their potential benefits (see e.g. Lohtia, Xie & Subramaniam, 2004; Aastrup et al., 2008). Lack of necessary expertise for organization and use of ECR initiative is particularly presented in developing countries, according to Reyes & Bhutta (2005).
- Lack of cooperative orientation. Supply chain members generally have sceptical attitudes towards information sharing, common goals, mutual trust, common decision-making and benefits and risks sharing. Non-cooperative relationships between members in the supply chain are still present although numerous initiatives were undertaken in order to contribute to the improvement of collaboration between them.
- Lack of technology capabilities. ECR requires technology skilled workforce, compatible hardware and software, management information system resources and the integration of systems across members in the supply chain (see e.g. Lohtia, Xie & Subramaniam, 2004).
- Costs of ECR implementation. Financial reasons are always big barrier to change and adoption of any new concept and the situation is the same in the case of ECR adoption. Accurately estimation of initial investments and implementation costs is prerequisite for successful ECR implementation.

Specific obstacles are related to the Serbian environment and they are:

- Lack of national ECR initiative. To date, the ECR Serbia has not been formed (ECR Europe, 2012). Some steps have been taken in this direction (GS1 Serbia, 2009), but without the final realization. Over the last few years several academic researchers often talked about the importance of formally organized initiative ECR Serbia (see for example Bogetic, 2007; Jovanovic, Vasiljevic & Ilic, 2009). It is also interesting to note that the only one former Yugoslav republic has established the national ECR initiative in 2006.
- Insufficient legal protection of manufacturer rights. Manufacturers in Serbia are subordinated by the large retail chains and one gets the impression that they don't have adequate state support. For example, the payment due dates can go up to 180 or 240 days. The new Law governing regularity of payments for goods and services is still in preparation and it is expected that it will be promulgated as soon as possible.
- Insufficient legal protection of customer rights. The new Law on Consumer Protection entered into force on January 1, 2011, but in practice customers continue to have problems with exercising their rights. It should also be noted that the National Consumer Organisation of Serbia is still not a member of the European Consumers' Organization (BEUC The European Consumer Organization, 2012).

6. CONCLUSION

Application of modern supply chain management concepts in Serbia lags behind most countries in Europe; and the situation is the same with the implementation of ECR. This study identified prevailing obstacles to wide adoption and implementation of ECR in the Serbian retail and consumer goods industry. The three specific obstacles related to the Serbian environment are identified besides general obstacles which are presented in nearly all business environments. They are: lack of national ECR initiative, insufficient legal protection of manufacturer rights and insufficient legal protection of customer rights. Ways for overcoming these specific obstacles must be find as soon as possible, while parallel coping with general obstacles is done. Thus, the ECR Serbia initiative must be included, as soon as possible, in ECR Europe, the new Law governing regularity of payments for goods and services must be entered into force and applied in practice in a right and fast way, and better legal protection for customers on the Serbian market must be provided. Further researches and initiatives in the Serbian retail and consumer goods

industry are needed in order to support the vision of the ECRE - "working together to fulfil consumer wishes better, faster and at less cost with a shared business process leading to shared benefits across the value chain".

Abstract: *Theme/Problem:* Experts in production practice are well aware of the fact that the Bullwhip Effect (BWE) is one of the problems encountered by Supply Chain (SC) member companies. A phenomenon where every member of the SC plans its own business activities and inventories based on the forecasted demand of its first downstream member within the SC, by getting farther away from the source of end (consumer) demand (of the market), will cause even greater variations in the forecast demand for every following predecessor within the SC. Consequently, this will lead to even greater exaggerations when it comes to planning the business volume and 'safety stocks' of the observed SC member; with respect to the graphical interpretation of this phenomenon, it was named the Bullwhip Effect (BWE). BWE significantly reduces the quality of SC management (by unrealistic planning that leads to an increase not only in material resources inventory, but also in costs and time of commitment of assets), and thus reduces the final business result and competitiveness of the SC (members). (Out of three most important groups of management performance – quality, deadlines, and price/costs – BWE most visibly affects (through safety stocks) the costs (prices), but the other two groups (of performance) are also associated with BW. That is why we are looking for solutions – innovations in the SC management, which are to reduce BWE.

Idea/Intention/Purpose: The presumption (idea) is that the modern science and practices of production companies have already developed solutions for reducing BWE in the SC. Therefore, there is an intention to investigate/examine the possibility of applying modern solutions for management (firstly for planning) over production companies in an attempt to improve/innovate management in the SC and overcome problems caused by BWE. Performances that examine the validity of an idea refer to amounts and costs of inventory holding in the SC (for every SC member, and integrally – for the entire SC). The expected solutions should improve the SC management and make its products more competitive and cheaper. For that reason, the ideas presented in this paper are mostly intended for planners within SC member companies.

Result: This paper generates some (potentially applicable) solutions for BWE problems in the SC: a) The application of the 'modern planning tools' package (Advanced Planning and Scheduling – APS) in all SC members, b) Change of practice, i.e. true management collaboration among SC members, that would result in increasing the planning quality in every SC member – by creating their plans on the same initial data on end-demand, and c) other innovative solutions from the 'Package 4' for eliminating or reducing (discussed in this paper) the four causes of BWE.

Key words: improvement of Supply Chain Management, Bullwhip Effect, Advanced Planning and Scheduling (APS)

1. INTRODUCTION

The overall Supply Chain (SC) for an item, from the moment of preparing for production (resource supplying), through production, until the moment of product placement at the shelf of retail facilities, is accompanied by a great amount of inventories in every 'inter-station' – SC member company. The lack of information or/and incomplete information, the same as fear of impossibility to meet the demand (and thus miss the income and maintain or improve market share) affect stock creation in every SC member – starting from stocks in the raw material warehouse of producer, through inventory of finished goods of the producer, stocks in the central distribution warehouse, in local wholesale warehouses, and even in the warehouses of retail facilities. (The SC members are the first, the second, the third, etc. successor to each other (observed from the raw material suppliers, through producers, to retail companies), i.e. the third, the second, the first predecessor – observed in the reverse direction).

As a rule, the inventories are the indicator of the malfunction of managing the business system, including the SC. With the goal of increasing the successfulness of SC members and the SC as a whole (supply chain needs to increase the competitiveness since it competes other supply chains in the market), the quantities of goods on stock need to be reduced, the same as the time of keeping them – as (here observed) performances of management quality. This further requires improving not only the quality of business system management (Omerbegović-Bjelović J., 1998) but the management of the SC as well, after which follows generation of ideas for innovating systems of SC management.

The ideas for the SC management innovation are looked for in the existing business practice of the SC 'production' members, since the production companies participate in different chains, i.e. supply chain networks. Management (and meta-management) solutions (concepts, models, methods, tools...) – that improve stock management (with planning and total management) in the production practice – should be reexamined and eventually adjusted, and then applied on all SC members. The expected result is the improvement of stock management (and even the management of SC members and the SC as a whole) within the entire SC, i.e. the reduction of BWE.

2. BWE PROBLEM AND HOW TO SOLVE IT BY APS & PACKAGE 4

Hence, we thoroughly investigate: a) The BWE phenomenon (causes, manifestation, consequences), and b) Practice of good, contemporary management (firstly the 'advanced planning'). The solutions could contribute to BWE reduction. We further observe the possibilities/conditions of solution transfer – as innovative ideas for improving the SC members' behaviour, that is, for improving the management quality (and planning) of the SC. Therefore, we could expect the quality of the SC management (improved by introducing innovative solutions) to improve performances such as amount and duration of stock keeping, and also to improve competitiveness of the SC and successfulness of business subjects – SC members. .

2.1. Bullwhip effect

Supply chain (SC) could be observed as a set of activities that provide the transformation of raw materials into final products, with the delivery of finished goods to the buyer. Certain activity groups are being realized in separate economic entities/companies. Management over supply and meeting the demand, as a component of business management, has a goal of satisfying customer demand, and it is accomplished through: understanding of demand flows (within a SC), identification of market relations, and providing additional value to the buyer. Discrepancy between the planned and future/real activity scope (and also between the forecasted demand and real future demand) increase in every preceding member within the SC due to the increase in safety of adequate response to future demand of the first successor within the SC. Therefore, the orders (towards the SC 'source') increase. In some cases, the order from the retail sale to the wholesale is the smallest; the order from the wholesale to producer is bigger, while the order from producer to supplier of raw materials is even bigger.

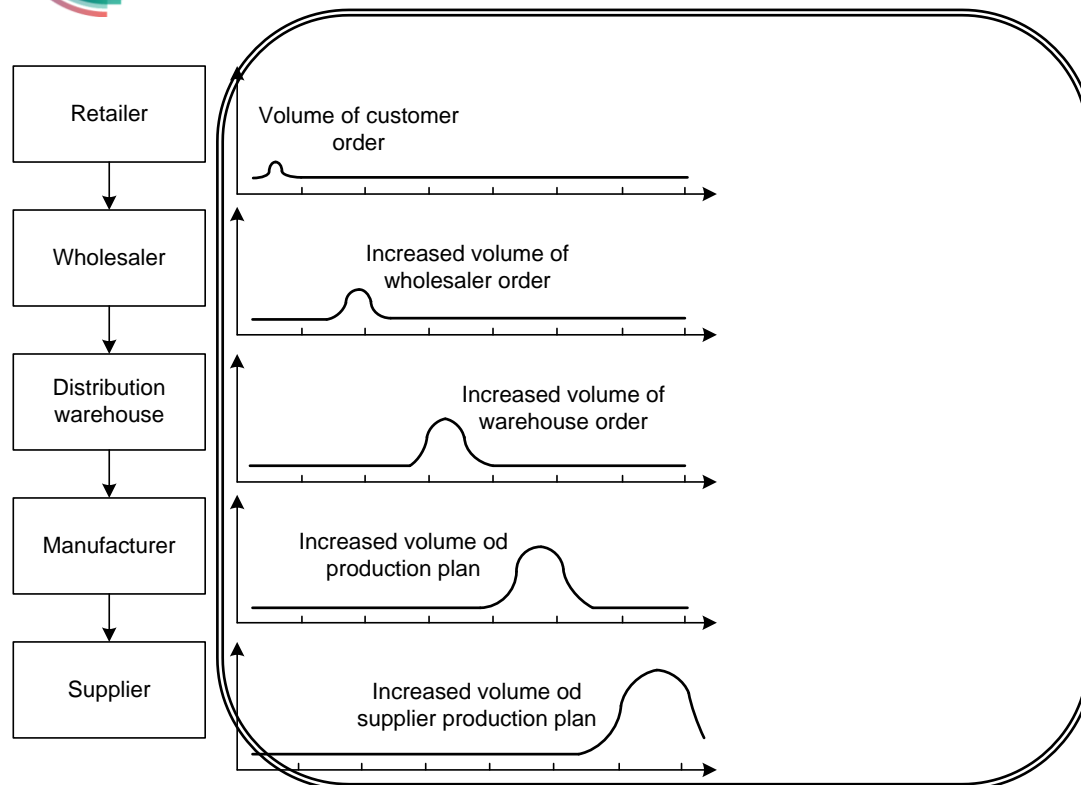

Figure 1: Bullwhip effect on planned business volume in SC members

(Adopted and modified from Warburton, 2004)

The basic reason for keeping the unwanted amount of stocks is to be recognized in a desire to prevent following situations from emerging: a) Lack of goods on stock, and b) Failure to sell and thus losing incomes, i.e. failing to provide adequate customer service (through complete and timely satisfaction of their orders). Therefore, the management of every SC member company brings decisions on increasing the 'safety' stocks, which results in unwanted amounts of stocks in the SC. Even in case when the demand of end buyer/user in the SC (in terms of amounts and delivery terms) is known and stable, the orders forwarded by seller (certain retail facility) to distribution warehouse exceeded it (i.e. they vary by dynamics and amount), while the orders forwarded by distribution warehouse to producer vary even more. The increase in variation of stocks in every next predecessor in the SC leads to an increase in amounts (and keeping costs) of goods on stock, not only for individual members of the SC, but for SC as a whole. This phenomenon is known as the 'bullwhip effect' (BWE). APICS defines BWE as 'an extreme change in the supply position upstream in a supply chain generated by a small change in demand downstream in the supply chain' (Blackstone J., Cox J., 2005).

Lee & Padmanabhan & Whang (1997, p. 94) gave a full scale definition of BWE; they have observed BWE on the relation between retailer and his supplier (producer or distributor/wholesaler). They have identified the discrepancies between the demand of end customer (hereafter: end demand) and size of orders delivered by the retail facility to supplier/deliverer. As stated by Warburton (2004) when defining BWE through '*Law of Industrial Dynamics*', if the signal on demand has been processed with the goal of determining amounts needed for replenishing own stocks, the demand variations increase with every new use of demand signals (for planning and determining the amount for stock replenishment) in every predecessor within the SC (Figure 1).

It is common for SC members to communicate only with their first predecessor (supplier) and first successor (buyer). For that reason, the forecast of future demand of the first successor and the decision on necessary amounts are based only on current and historical information on needs/demand obtained from the first successor/buyer. The history of orders (reports on previous demand) is greatly the reflection/model of customer behaviour (the first successor in the SC) and SC infrastructure (consisting of SC members, rules of their behaviour, communication means, etc.).

Lee & Padmanabhan & Whang (1997, pp. 95-98) have identified four major causes of the BWE appearance:

C1) Demand forecasting: Companies in a SC ground their business on forecasting demand of their first successor, which results in plans for necessary capacities, stocks (own output), necessary input (materials and raw materials), etc. Demand forecasting is based on the order history that the SC member company (supplier) obtained from the first successor in the SC (buyer). In this way, every time a buyer sends an order form, those responsible for demand forecasting (at the supplier's) identify this as a signal for future demand. In line with (regularly updated) *order history*, demand forecasting affects certain company (planning of stocks, amounts for production, capacities), the same as the predecessors in the SC (suppliers). In this way, every participant in the SC creates its own demand forecasting and further operations. Every increase in discrepancies in new orders, compared to the historical average of ordered amounts, forces company to update (usually increase) the level of safety stocks in order to be able to meet (potential) future demand. Due to such increase, variations in orders transmit to every preceding member in the SC, and consequently, the need for creating bigger amount of safety stocks 'spillover' to every predecessor in the SC.

C2) Order batching: In the SC, a company creates its own order in line with actual inventories and needed amounts, taking into consideration the economic logic of making orders. A company does not send an order form to the supplier (predecessor in the SC) just for one (the first) moment that identifies need for new entries; it *selects optimal moment for order making* in which (for which) to order bigger amount (transport packaging, entire palette, a whole truck) – in order to make cost saving through the economy of scale (lower unit price for bigger amount ordered, lower transportation costs per unit of product, etc.). Such ordering logic brings to weekly, monthly, or even quarterly orders, which increase risks in assessments of future needs for input, increase in inventory, and increase in the intensity/influence of BWE. The practice shows that the BWE effect is getting weaker due to shortening the period between orders.

C3) Price fluctuation: Continual market game led both manufacturers and distributors to periodically offer *special promotions* like *price discounts* and *quantity discounts*. In the same way, price fluctuations occur between every two members of the SC. The result of such phenomena is that customers buy in bigger quantities then needed in the following period, and stock up for the future, which affects the increase in BWE intensity. Economic profitability of such purchases is transient (i.e. disputable), bearing in mind that the accomplished positive price difference should exceed costs of warehousing and using funds during this prolonged period of 'keeping' extra stocks. In this case, bigger orders deviate from historically based purchase trends; this leads to creating bigger amounts of 'safety' stocks in the SC (not only in case of retailers and distributors, but the manufacturers as well), thus increasing the BWE intensity.

C4) Allocation of limited capacities/stocks: In cases when demand (of first successors, for example, couple of retail stores in the same town) exceeds the availability of the observed member of the SC to deliver orders (because of limited capacities), follows the allocation of available amounts in line with the proportional participation of order of individual customer/successor in the overall amount. On the other hand, buyers create '*artificial*' demand with the goal of maximization of amounts to be delivered. Such demand is based on orders of buyers that have been unrealistically amplified (also known as '*phantom*' amounts). Upon the end of such situation, i.e. upon the abatement of limited supply (reduction of real demand, increase in capacities, outsourcing production, etc.), buyers simply cancel such 'artificial' orders and return to real-necessary amounts. However, the manufacturers have taken into consideration such 'artificial' orders as a real demand, and based on that, they have created data on safety stocks for future deliveries, increasing their own orders of raw materials and materials (in this way leading all predecessors in the SC to do the same).

Bearing in mind the adversity of the existence of unjustifiably large inventories, the SC members tend to establish a system of BWE control. Until now, two approaches of reducing BWE have been used in the practice (Lee & Padmanabhan & Whang, 1997, p.95):

- a) Modification of SC infrastructure, i.e. change in behaviour of SC members of one to another (for example, using the right of SC members to 'skip'/omit some SC member in certain circumstances, if his participation is not necessary);

- b) Affecting the common behaviour of buyers (which requires changes: calculation techniques of necessary quantities, ways of making decisions on ordering date, defining priorities in case of limited financial means, existing model of stock management, etc.).

Better understanding of BWE allows for more reliable conclusions with respect to potential ways for reducing BWE in the SC. Identified characteristics of BWE have implied to direct relation between the planning process and BWE intensity (Chen et al., 2000, pp. 436-443). Availability of information on demand directly affects not only the quality of planning (and management), but the intensity of BWE as well. According to Kaipia & Korhonen & Hartiala (2006), fluctuations in demand - that occur in the end of SC (in the retail store) – and identified changes in demand and stocks in predecessors in the SC are quite different. Every SC member analyses demand from own perspective and puts it in the context of characteristics of own management (and even planning and demand forecasting) and operations (available resources, limited capacities, etc.). Therefore, this paper examines the possibility and justifiability of the application of modern tools for planning (and for management as well) in ‘fight’ against BWE in the SC.

2.2. Advanced planning and scheduling

In order to come to more credible conclusions on the idea for application of modern planning tools in ‘fight’ against BWE in the SC, we need to get to know basic characteristics of these tools, as well as conditions/possibilities of their application in the SC.

Advanced Planning and Scheduling (APS) system allows for immediate response to customer demands by providing timely and reliable information from business system. APS approach has been developed as a solution intended for production companies, with the goal of including two important factors in their business planning – company’s resource limitations, and demand/sale forecasting. The concept on which the APS system is based on is applicable in cases when a company plans to produce final products based on available production capacities, capacities of distribution and transportation. According to APICS Dictionary (Blackstone & Cox, 2005), APS system is ‘a computer program that uses advanced mathematic algorithms or logic with the goal of optimization or simulation of fine planning (of capacities, terms, supplies), resource usage, tactical planning, forecasting, and demand management’.

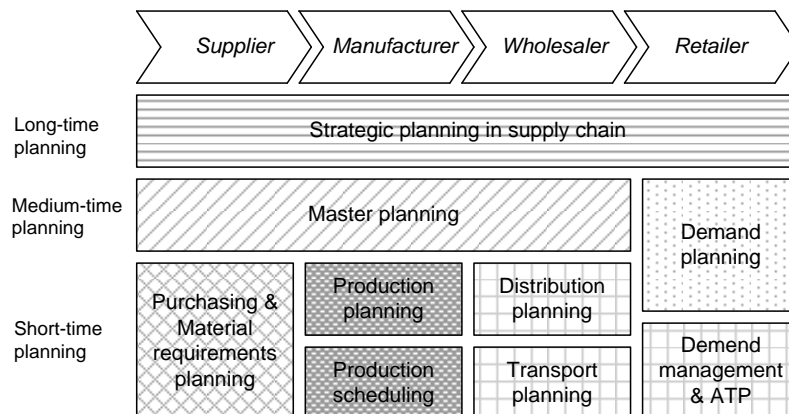

Figure 2: Basic APS modules and appropriate business functions (Adopted from Lambert & Pohlen, 2000)

These techniques simultaneously examine limitations and business rules with the goal of timely provision of plans, adequate decisions, responses to demand questions; for example, the concepts applied are ATP (*Available-to-Promise*, i.e. the demand is accepted having in mind that there are wanted amounts already on stock), and CTP (*Capable-to-Promise*, i.e. demand is offered stocks that will be available in near future).

Modularity is also an important feature of APS. Modular system of APS (approach to examining planning tasks grouped into modules), called ‘APS matrix’ and developed by Gruat-la-Forme & Botta-Genoulaz & Campagne & Millet (2005), indicates to which area of SC a certain module of APS system refers to. Authors Lambert & Pohlen (2000) present the improved APS matrices by grouping the APS activities in

line with the functioning of the SC. The improved APS matrices (Figure 2) shows that production planning and scheduling terms make one subgroup, while distribution planning, demand planning and demand satisfaction (Demand management & ATP) make other subgroup of related activities.

Stadtler & Kilger (2005) identified three basic characteristics of APS system:

- (1) Integrated planning of the functioning of the overall business system/company (including its buyers and suppliers), i.e. planning in the company – from the supplier to buyer;
- (2) Optimization of clearly defined variants of models (goals and limitations) for different business situations and the application of optimization and heuristic methods in planning;
- (3) Hierarchical system of planning that allows for the expression/accomplishment of the previous two characteristics.

The possibilities of APS system in managing capacities, optimization of distribution network, scheduling, resource planning, management over limitations, tracking the performances, etc., are discussed/given in Table 1 (that emerged by modifying sources Setia & Sambamurthy & Closs, 2008).

Table 1: Application capabilities and solution details of APS systems (Adopted from Setia et al., 2008)

APS capabilities	Description	Example Application and Solutions
Capacity modelling	Exact definition of resources and constraints	
Route modelling	Create routing on a product by-product basis, set up alternate workstations and operations workflows that help tie workstations together and allocate/split operations to separated tasks, and identify limitations or special setup for specific operations	Demand planning , supply chain planning, factory planning, transportation optimization
Scheduling and optimization	Schedule and optimize various jobs and process performance criterion based on available operators and resource constraints	
Planning capabilities	Plan resource and facilities for the long term, through what-if analysis support the available to promise quantities improve processes and identify production constraints, and allocate resources to specific tasks	Demand planning, supply management, network design and optimization
Constraint management and analysis	Identify constraints and reschedule resources, allocate resources according to demand priorities	Production planning and detailed scheduling, available to promise (ATP)
Execution control	Manage the operations by exceptions and real time reporting	

Companies implement APS in order to efficiently manage the funds in use, and also due to stock optimization, harmonizing demand and supply, minimize time loses and reduce transportation costs. The expected benefits from the implementation of APS system are not only based on possessing information technologies (which represent the ground of APS system), but also on clearly identified business processes and adequate training of human resources. Benefits from APS could be divided in quantitative and qualitative (Adopted from Louw, 2006).

Expected quantitative benefits from the implementation of APS system are identified through the improvement of key performance indicators:

- Increase accuracy in demand forecasting (from 40 to 80 pct)
- Improving customer service (from 70 to 90 pct)
- Stock reduction (by 13-50 pct)

- Increase in coherence of production launching with identified customer needs (improvement from 43 to 82 pct), so that the final product is held on stock for shorter period of time
- Reduction of time period (duration) of stock shortage – Stock out (reduced by 5 pct)
- Sales increase through reduction of stock out situations (increase in sales by 5 pct)

Expected qualitative benefits from the implementation of APS System:

- Improvement of precision of demand forecasting, which contributes to the reduction of stock level or/and improvement of service level with the same stock level
- Optimization of combination (type and/or quantity) of stocks, so that the overall stocks remain unchanged (in quantities or/and value), while the products on stock are in line with the participation in the overall demand
- Capability of planning stock location in order to prevent situations where company disposes of stocks of certain product, but not on the location (in the warehouse) where the demand is identified (which would require additional time and costs of stock transfer)
- Better planning of deliveries and transportation
- Offering real insight into demand, stocks on hand, and planned supplies through integrated survey and coordination, etc.

2.3. Possibilities for BWE effect reduction with APS system & Package 4

The efficiency of SC directly depends on coordination between different SC members, which imposes the necessity for them to recognize their role in this complex business system. All companies in the SC have a unique task, which is to provide the desired level of customer service – satisfying the identified end demand. Even though every company in the SC is independent in its operating, it is necessary for the performances of one company to directly affect other members of the SC. Namely, a problem of one member creates issues both to predecessors and successors in the SC, thus putting into question the effectiveness of the entire SC (Paik & Bagchi, 2007, pp. 308-324).

The understanding of BWE causative agents provides valid foundation for creating the adequate strategy of elimination or at least partial BWE reduction – in some segments or/and in the entire SC. This is a reason to present ‘**Package 4**’ for earlier stated four major causes of BWE (that is, adequate, innovative solutions for reduction/elimination of 4 causes of BWE through application of APS tools and other potential innovations).

S1) Solution for elimination/reduction of BWE caused by the method of demand forecasting: The fact is that every following predecessor of the retail sale in the SC (being the last ‘link’ in the SC) base its demand forecast on the demand of the first successor (and thus makes plans for needed capacities, necessary stocks – own output, necessary input of materials and raw materials). In this way, the reality in demand forecasting and planning (structure and volumes) of business engagement is lost. In other words, going upstream towards the ‘source’ of SC, mistakes in assessment and planning (management) become even bigger. This results not only in unjustifiably great amounts of safety stocks and ungrounded costs, but also in the loss of competitiveness and endangering the survival of SC members.

With the goal of preventing mistakes in demand forecasting (and planning), the recommendation is to make information from the source of demand (end demand, customer demand) available not only to the first predecessor in the SC, but for all other predecessors in the SC (Figure 3). Based on the *availability of information on end demand* for all members of the SC, every participant in the SC has a possibility to develop his plans with regard to the same source (end demand), and to suffer less influence of BWE (thanks to omitting the ‘middleman’ in the SC).

Figure 3: Forecasting of end demand in SC – graphical model

S2) Solutions for eliminating/reducing BWE caused by the model of order-making on behalf of the customer: In SC, company-members create their orders in line with own logic (and also in accordance with actual stocks, needed quantities, transportation, costs); at the same time, they decide both on quantities and the moment the order is made for. They prolong periods for which they order needed resources, thus increasing the BWE.

However, in order to avoid danger from jeopardizing the actuality of structure and volume of orders that could occur due to an increase in time horizon for which the order is made for, i.e. in order to avoid excessive ordering, it takes a lot of information and efficient management (planning) mechanisms. Here, the reduction of BWE is due to reorganization of planning function in the entire SC.

The idea is for the members of SC to switch from classic planning of own supply to an advanced method that is 'suitable' for SC. In this way, every predecessor plans supply (own delivery/sales) for its first successor. Hence, the recommendation is that the supplier/deliverer should plan the supplies for his own customer. In this case, it is necessary for a vendor to dispose information on end demand, the history of supply of the observed buyer, the needs of the customer in (the shortest) systematic period, current inventory at the buyer's, and maximal allowed level of stocks at the observed buyer. Based on this (and on circumstances), he creates a supply plan for his customer. In this case, the customer becomes a passive participant in the SC. Such approach is called VMI (*Vendor Managed Inventory*). Special case is when/if the supply plan is confirmed by a customer, which is called CMI (*Co-Managed Inventory*). Except for helping to eliminate customer supply planning problem by input, such approach also affects the reduction of BWE in the SC.

The second solution that is applicable with the same goal of reducing BWE concerns the *logic of choice (and costs) of transportation* (since excessive amounts are being ordered from the predecessors in the SC with the goal of maximization of transportation use). The recommendation is to use some of the variants of the ordering model that could significantly contribute to order reduction, and even to mitigating the BWE intensity through: a) Organization of transportation of different kind of products (from seller to buyer – first successor) with the same transportation means (for example, by truck; b) Transportation of products of different suppliers for the same buyer (if the buyer is in charge of the transportation); or c) Transportation of products of the same supplier for different buyers – with proportional allocation of transportation costs. (Of course, it is not important whether we talk about own transportation, or *outsourcing*).

S3) Solution for eliminating/mitigating BWE caused by price fluctuations: As stated earlier, the oscillations in product prices also exert significant influence on BWE, which could be reduced by elimination of promotions and limited time period of price discounts – at least for the SC members (since the common interest of all SC members is to contribute to SC competitiveness with real prices). In addition, the elimination of quantity discount (at least for the members of the same SC) reduces the possibility (and need) to order goods without real end demand. The SC members must be aware of the fact that they act as a single system (and compete with other SC), and they are motivated in mutual cooperation to be realistic (or/and to design and contract the allocation of business results accomplished by SC in timely manner). Adequate sale techniques that could be applied in the practice (in the concrete SC) are as follows: *Everyday Low Price* (EDLP), and *Value Pricing Strategy*. Generally, the members of a concrete SC are advised to analyze the profitability of purchasing unnecessary amounts at favourable prices (through *Activity-based costing system*).

S4) Solution for elimination/reduction of BWE caused by the method of allocation of limited capacities/inventory: Having in mind the phenomenon of 'artificial' demand (when the capacity of delivery of the first predecessor of the observed member of the SC is lower than the total demand of its first successors), and also with respect to the danger of distortion of data on safety stocks (which would lead to an increase in BWE), the allocation of limited funds must be grounded on the logic different than 'allocation of available quantities in line with the proportional participation of orders of individual buyer/successor in total order'.

Elimination of the phenomenon of 'artificial' orders is possible if suppliers (first predecessors in the SC) carry out the *allocation of limited quantities in line with the history of orders* from the buyers/first successors, and also in accordance with end demand, and not in line with currently placed orders.

However, irrespective of 'Package 4' innovative solutions for reducing BWE in the SC, the idea is *for all members of the SC* (no exceptions) *to apply modern APS solutions* (for innovative planning, thus improving the quality of SC management). APS system of SC grounds its functioning on phase and independent (according to SC members) analysis of the latest available information from the market (in the process of end demand forecasting), with the goal of creating more quality plans for the members in the SC. Based on the latest available information, and after applying APS, manufacturers – members of the SC generate new plans or update the existing ones and launch new production orders and place new orders of raw materials and materials. On the other hand, the members of a distribution warehouse, wholesale and retail sale, create orders for stock replenishment. Raw material supplier in the SC (who is at the same time at the greatest distance from the end demand) base his decision (plan for supplying buyer-manufacturer) on the history of production needs, as well as on information on end demand and forecasting needs of his successor – manufacturer. Manufacturer (who is by one position 'closer' to end demand) grounds his decision on the size of production series on the history of needs of distribution warehouse, end demand from the market, and forecasting needs of his successor – wholesale. After that comes the wholesale, which uses the history of orders from the retail sale (the first successor in the SC) with the goal of generating the decision on the size of the order for stock replenishment, as well as information on end demand and forecasting the needs of its successor – retail sale. Retail sale (which is the 'closest' to end demand) base its decision on the size of order for stock replenishment on the end demand from the market and forecasting trends of end demand oscillations. Such arranged APS system in the SC allows for an arranged approach to planning and demand forecasting through analysis and planning needs of every 'buyer' – successor in the SC - on one hand, and analysis and forecasting market needs as a final buyer of the overall SC, on the other hand.

When the system of advanced planning in the SC is arranged/designed in the previously defined way, then the APS system is to be implemented/used. It minimizes BWE in the overall SC. The authors of this paper came to a conclusion that the implementation of APS system in every participant of the SC could lead to accomplishing maximal effect in reducing BWE (see Figure 4). Starting from the justifiability of applying the principle of APS in a company – member of the SC, APS could be applied on the entire SC the same way. In this case, the retailer would base his sale plans on own demand forecasting. However, while defining the stock level in the retail facility, he would use information he receives from his predecessor (by applying available-to-promise and/or capable-to-promise techniques), as a result of their APS system, as well as actual end demands and histories of end demand. The wholesale would base its demand forecasting on information on demand that it receives as a result of the application of APS system in its successor (retailer) and predecessor (manufacturer), as well as based on own insight into current condition of end demand and its history. The same way, the manufacturer would base his plans on the results of the application of APS system in the wholesale (as a successor) and supplier (as a predecessor), including the current condition of end demand and its history.

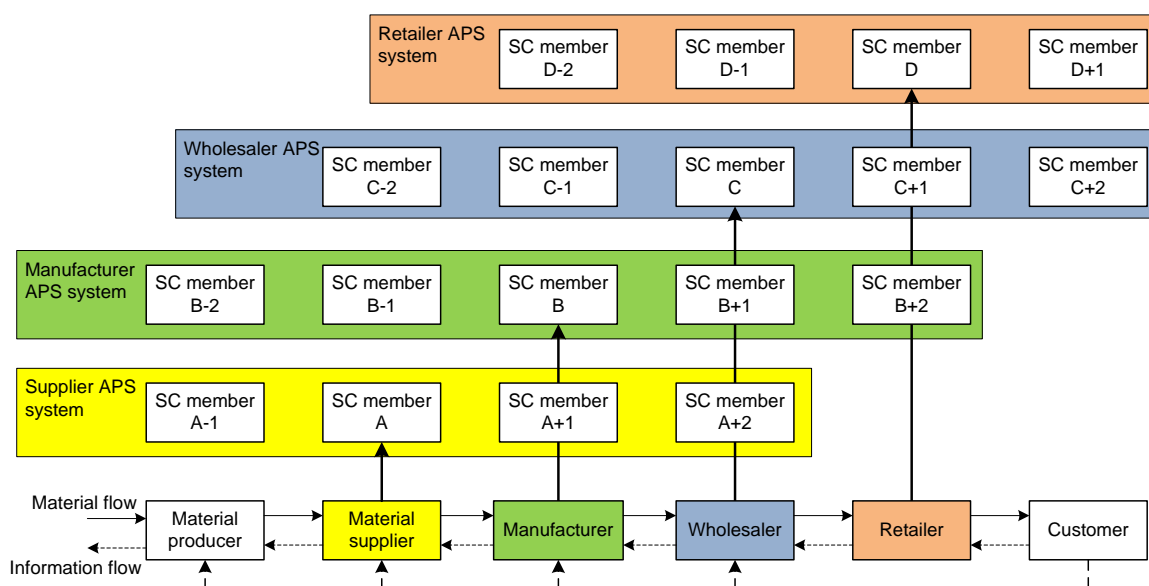

Figure 4: Overlapping APS systems of different supply chain participants

Direct benefits from APS system applied in the SC (without Package 4) are also mentioned in PWC publication (1999):

- a) Increase in sale – due to higher level/quality of customer service (2-15 pct)
- b) Stock reduction (20-70 pct)
- c) Cost reduction in SC (12 pct), and
- d) Reduction of assets - through lower level of inventories (15 pct).

The abovementioned benefits from the implementation and adequate application of APS system confirm the presumption that the adverse effects of BWE are possible to eliminate, or at least to mitigate its intensity, and thus accomplish significant improvements of management performances over production company and other companies – members of the SC, and also to increase efficiency and competitiveness of the entire SC, with coherent application of APS in all SC members.

3. CONCLUSION

As presented, the APS of production could represent an 'umbrella' that covers the overall SC and allows for securing timely information for its participants. Timely and reliable information in the SC allow for generating the acceptable/quality (real, unique, timely, feasible, etc.) plans for supplying, production and distribution with the goal of accomplishing the desired SC management quality, competitiveness and preferable customer service. The role of APS systems and Package 4, as innovations in classic planning (and management) over SC, in planning (stocks, etc.) and scheduling, and even in the overall SC management, is based on the consideration of end-demand and available capacities while creating the 'feasible plan' – in every SC member. (After that, the proposed plan is applied to operative and schedule plans with the goal of creating a detail list of operations, by showing the method of booking resources/allocation of available capacities of those resources. After that, future available capacities are being identified based on the schedule, the same as the possibilities of meeting future customer orders).

It should be stressed that every SC member allows the implementation of APS in line with its own possibilities and business characteristics. By accumulating profit from the implementation of APS systems, every SC member provides the improvement of business performances with the improvement of indicators' value: precision of demand forecasting, inventory optimization, number of cases with inventory shortage, assessment of the customer service, etc. As earlier stated in this paper, the expected benefits from the implementation of APS system in SC and the application of other innovative solutions in SC management (from Package 4) directly affect the BWE reduction, which contributes to performance improvement (greater efficiency and competitiveness) not only in the SC, but in all SC members as well.

Abstract. *The aim of this paper is to elaborate the implications of risks generated by natural hazards to the functioning of supply chains, from the point of view of up-to-date and relevant scientific literature. The starting point is the explanation of the nature of risks and forms of their manifestation within the supply chains. Finally, the paper offers insight into economic influences of such risks caused by three natural disasters on the supply chains of particular companies.*

Key words: *risk, supply chain risk, risk sources, types of risk, natural hazards.*

1. INTRODUCTION

Risk is an everyday notion. The basis of a risk is the lack of knowledge about events that may affect companies, and incapability of managers to manage these events. Company managers cannot still measure accurately the levels of their own exposure to supply chain risk, and, consequently, they cannot manage such risks. Moreover, the common terms regarding supply chain risks, which would be widely accepted, have not been used in referential literature yet. Nevertheless, the number of companies in which the management of supply chain risks is of a strategic importance increases.

To define the concept of risk has been a challenge for the scientists and managers for more than a century. This concept is understood quite differently. For that reason there are probably as many definitions as authors concerning this topic.

Negative effects of natural hazards force company managers to pay more attention to implementation of strategies for efficient management of supply chain risks. Such a strategy becomes a key to global competition and survival of companies.

Numerous *unexpected natural phenomena* cause serious problems in supply chain functioning. Having that in mind, we start this analysis by the description of disturbances in supply chain of Nokia and Ericsson company, caused by the fire at their supplier in New Mexico. In the second part of the work we briefly present the problems in supply chain functioning in European air transport companies, caused by the volcano activation in Iceland in 2010. In the last part of the work we analyze the problems that the Japanese companies faced in 2011 due to interruption of supply chain after the disastrous earthquake.

2. RISK UNDERSTANDING

Definition of the notion of a "risk", as well as of the instruments used for the risk measurement, mostly depends on the chosen research area [1, p. 5]. The risk definitions are most frequently based on volatility of possible returns, lack of adequate information and readiness to accept possible loss when expecting positive returns. According to traditional decision-making theory risk is defined as a variation of potential results distribution, probability of their occurrence and their subjective values. In this case, deviations (both positive and negative) of real value from the expected value are quantified by the means of variance. However, *March and Shapira* claims that, in everyday business running, the risk means negative deviations of the real value from the expected value, whereas positive deviations of the real value from the expected value are treated as "chances". Analogous to this, risk can generally be defined as the product of probability of negative event occurrence and the consequence (damage) caused by such event [2, pp. 1404-1418].

In academic literature, risk is frequently defined as “quantitatively presented possibility of the occurrence of defined danger. Thus, the risk combines the level of probability of primary event(s) occurrence with the scope of consequences of such event(s)” [3, p. 4]. So, risk estimation means measurement of probability of a particular event occurrence and measurement of consequences of that event. In accordance to this, the risk in business can quantitatively be expressed as following:

$$\text{Risk} = \text{probability of a particular event occurrence} \times \text{impact of that event on the business}$$

This definition makes it easier to classify risks into the matrix whose dimensions are *probability* and the *impact of a risk on business* [4].

Figure 1: Risk matrix [4]

Risk classification by the means of the matrix shown is a precondition for identification of the risks and for taking measures to alleviate them.

Risk is also presented as the level of uncertainties exposure of a company, which must be understood and efficiently managed [5]. In practice, the expressions *risk* and *uncertainty* are frequently used as synonyms, although they technically describe different situations. Uncertainty is often considered to be the risk generator, since the decision-maker, due to lack of information or knowledge, cannot identify all possible returns, their consequences or the likelihood of their occurrence. Usually, uncertainty is the result of the lack of information and knowledge about potential returns and about likelihood of occurrence of particular events, as well as the possible consequences of those events. However, the clear risk, which is located on the other end of the continuum, usually represents a completely defined scenario of the possible returns, objective likelihood of the event occurrence and completely determined consequences of all returns. The way the periods of decision-making, variables and returns are increased, the bigger are the difficulties in identifying, estimating and measuring those parameters, i.e. uncertainty increases.

Ritchie and Brindley [6, pp. 303-322] claim that risk definitions mostly have three elements in common: 1) *likelihood of occurrence*, 2) *consequences* of the event that occurred and 3) *causal pathways (sources)* of the event. In theory, these elements are measurable and easily recognizable. But, practical determination of these elements, for the purposes of risk management, is accompanied by a great number of various challenges.

Likelihood of occurrence of an event, which can be estimated both objectively and subjectively, can certainly be measured. The objective estimation of likelihood of occurrence is based on available data on the event. The subjective estimation of likelihood of occurrence of a certain event relies more on the previous experience and intuition concerning that particular event. In practice, subjective estimations of the likelihood of occurrence of an event have been made on the basis of certain objective data.

Consequences of the event that occurred are commonly expressed as multiple, simultaneous returns, many of which are in interaction. For example, an unsuccessful launching of a new product can have a negative impact on the reputation and profitability of the company, as well as on the leadership position of

its products. Consequences should not be considered as necessarily, or primarily, negative, since taking risks, in its essence, represents a possible chance for generating positive returns.

Causal pathways have significant implications on risk management. Getting to know the causal pathways (sources) and nature of events or circumstances which may have an impact on the type and the scope of consequences (both positive and negative), as well as getting to know the likelihood of occurrence of consequences, is the basic demand of a successful risk management.

3. SUPPLY CHAIN RISK

The supply chain risk can be defined as a consequence, estimated on the basis of the likelihood of its occurrence, caused by the event in the company, in its supply chain or in its surroundings, which has a negative impact on the business process of at least one company in the supply chain [7]. Unlike the general risk definition mentioned above, this definition includes the origin and the sources of potential risks, as well as all companies that the risks have an impact on.

The risks of a company can be classified by their sources. On the basis of this parameter, different classifications of risks can be found in referential literature. For example, Christopher and Peck state five groups of risk sources within 1) a company, 2) supply chain and 3) surrounding [8, pp. 1-13]. Process risks and control risks are located inside the company. Process risks include the interruptions in the production process, whereas control risks include the mistakes in management and wrong, or inflexible decisions which lead to numerous problems in the company business. The supply chain risks are mainly caused by the interruptions of material, information or capital flows among the chain members. Starting from the risk direction, they can be divided into risks of offer and risks of demand [9, pp. 120-141]. When a company moves its, mostly internal, risks to its partners, what happens is the increasing of risk portfolios of all companies in their supply chain. However, companies often cannot react to their risk portfolio thus widened because the risk sources are unknown to them, or because they cannot control them. Thus, companies mark such risks as offer risks and demand risks. As opposed to this, the surrounding risks are generated by socio-political, macroeconomic or technical changes [10].

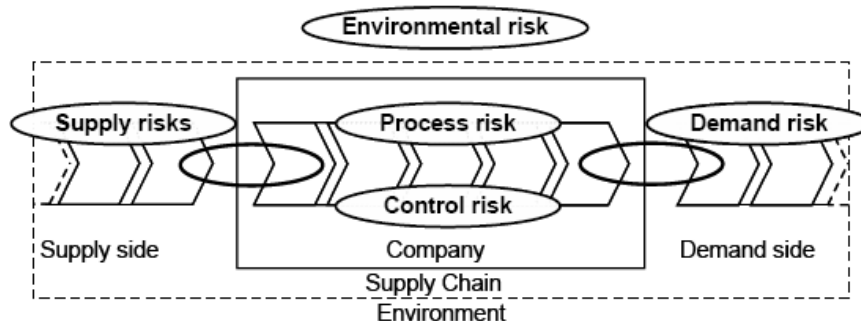

Figure 2: Risk sources in supply chain [11]

Besides, demand risks, which are caused by the quality or financial problems, occur very frequently. When Delphi company filed a petition for bankruptcy in 2005, serious interruptions occurred in the supply chain in majority of car manufacturers [12, pp. 109-127].

The high risk levels in business nowadays, especially those caused by natural disasters, are the explanation of increased interest of the researchers in supply chain risk management (SCRM), which consists of identification, estimation, analysis and processing (decrease) of vulnerability and risk in supply chains. Further on, we are paying attention to the analysis of business implications of risks caused by certain natural disasters.

4. RISK CAUSED BY NATURAL DISASTERS

This kind of risks includes the events which have enormous consequences for companies and their supply chains. Indeed, in many world regions, *natural hazards* such as tsunami, thunderstruck, droughts, earthquakes, hurricanes and floods represent a constant threat to societies in general, and especially to companies [13]. The negative impacts of such disasters on supply chains are obvious. Production and

transport are particularly endangered by those catastrophes. Due to market globalization and global supply chain operations, local natural disasters cause more indirect global consequences.

There are numerous examples of unplanned natural disasters that significantly decrease the stock values and financial result of the affected companies. We are going to explain the impacts of three events of this kind on the functioning of supply chains. The first one is the interruption of supply chain in Nokia and Ericsson, caused by the fire at their supplier – the Phillips factory for microchips manufacturing in New Mexico. After that, we are going to analyze the consequences of the volcano eruption in Iceland in the course of 2010 for the functioning of supply chains of European airline companies. Finally, we are going to focus on the economic implications of the interruptions of supply chains in Japanese companies, caused by the tsunami that hit Japan in March 2011.

The number of risks in most companies is significantly changing because of the changes in market conditions. Beside the “traditional” risks, caused by the business activities of every single company, the new risks appear, which is often the result of cooperation [14, pp. 698-713]. Juttner [9, pp. 120-141] set the following risk sources:

- globalization of supply chains,
- decrease of the safety supply levels,
- centralization of distribution,
- lessening of the number of suppliers,
- outsourcing and
- production centralization.

Those sources generate the increasing of the number of risks for all members in a supply chain.

For example, globalization increases geographical complexity of supply chains, whereas outsourcing and centralized distribution increase organizational complexity of the company, as well as of logistic processes. The function of outsourcing and lessening of number of suppliers contribute to greater interdependence of the companies in supply chain. The risks related to supply interruptions caused by insufficient levels of the company supplies can be resolved by increasing of the safety supplies levels.

The company relying on a few or on just one single supplier can result in the interruption of global production operations of the company. It can be more thoroughly explained using the example of the supply chain of the companies Nokia and Ericsson.

4.1. The supply chain interruption in the Nokia and Ericsson companies caused by the fire in the Philips factory in New Mexico

The fire caused by a thunder struck in the Royal Philips Electronics, N. V. in Albuquerque, New Mexico, on March 17th, 2000 damaged millions of microchips and caused the 400 million dollars loss in the sale of Telephone AB L. M. Ericsson [4]. The fire was extinguished in less than ten minutes. According to the routine investigation, nobody was hurt in the incident, and the damage was minor, so the report wasn't sent to the main offices management of the Philips company in Europe. But, the true drama had just started since nobody could imagine that this minor accident would have such negative effects on the future of these two Scandinavian companies. When the managers of Nokia were informed about the problem, they began thinking in two different directions: 1) to compensate the deficiency of microchips from the supplies or 2) to cooperate with other microchips suppliers.

The representatives of the Philips company promised to revive the production within seven days. They refused the help that Nokia had offered to them. About fifteen days after the fire, the managers of the damaged factory informed the Nokia representatives that the reparation would last for several weeks, or even several months. The Nokia experts estimated that would cause the sale decline for 5 percent, so they made a team of thirty experts who found new suppliers for three out of five types of microchips that Nokia was purchasing from the factory in New Mexico. Nokia chose the pressing orders within five days and succeeded in continuing its production. The Philips factory in Eindhoven (the Netherlands) delivered 10 million microchips to Nokia. Another Philips factory, in Shanghai, worked with maximum capacity for the demands of Nokia, as well. The Nokia engineers suggested new alternatives in order to produce another two million microchips until the factory in New Mexico starts working again.

On March 20th 2000, three days after the fire, the Ericsson managers were also informed about the incident. However, they reacted in a completely different way than the Nokia managers. The Ericsson managers were passive and consensual, which is characteristic for Swedish culture, whereas the Nokia managers, due to Finnish culture, shown more individuality and aggressiveness.

Since the fire didn't cause serious damage, the Ericsson management assumed that Philips would be able to deliver the microchips within seven days after the information about the production interruption had reached them. When people in Ericsson finally realized that Philips wouldn't be able to fulfill the promise, it was too late. In order to solve the problem, Ericsson turned to Philips for help, but they said that their full capacities were assigned to the demands of Nokia. Ericsson then turned to other components manufacturers, but they found out that there was no adequate substitution for the components produced in the factory in New Mexico. Jan Ahrenbring, the marketing vice president, admitted that Ericsson hadn't had a reserve option!

It can be said that Philips suffered the clear damage in the amount of about 39 million Euros [15] because of the fire in Albuquerque. The loss of sale of this company amounted less than 0.6 percent in respect to 6.8 billion dollars worth transmitter production in the year 2000. However, since Ericsson didn't provide the necessary components in the spring 2000, which was necessary in respect to the dynamics of the demand of cell phones, they suffered the loss in the amount of between 430 and 570 million dollars [16] prior to taxation. The loss itself many times exceeded the loss of Phillips. By the end of 2000, Ericsson suffered the loss of 2.34 billion dollars in cell phones production division.

Six months after the fire, Nokia has increased its market share from 27 percent to 30 percent, whereas the share of Ericsson decreased from 12 percent to 9 percent. One year after the fire the representatives of Ericsson declared the continuation of manufacturing. In April 2001, the Ericsson managers concluded a joint venture contract with Sony.

4.2. Interruption of supply chains of European airline companies caused by the volcano eruption in Iceland

There are about 140 volcanoes in Iceland, 26 of which are active. Reykjavik (translated "the city of surprise") is the most northern capital on our planet. Eruption of Eyjafjallajökull volcano in Iceland in April 2010, made airline companies cancels their flights all over Europe. Over 120,000, out of 300,000 population of Iceland, live in it. The volcano dust caused cancellation of 100,000 flights, and eight million passengers couldn't reach their destinations. The overall loss of airline companies is estimated to be about 2 billion dollars. Besides, the air traffic over Iceland was stopped on May 1st 2011, after the eruption of Grimsvoten volcano. The eruptions of those volcanoes not only paralyzed the air traffic of European companies, but they also caused the disturbances in supply chain functioning of the airline companies all over the world.

It has been shown, due to connections of airline companies in supply chains, that if one of them meets a risk – other companies are at risk, too. The business problems of one company are quickly transferred to its partners in the complete supply chain, regardless of the fact that they are often dispersed over the world. Thus, the benefits of airline companies, when motivating their partners in supply chain to efficiently manage their internal risks, have become more emphasized.

It is obvious that the increase of the number of partners in supply chain of the main European airline companies led to the higher level of complexity of coordination and management of their processes in that chain. It also becomes more clear that in such supply chains different levels of responsibilities must be respected, both within a single company and within the supply chain of that company. According to that, the focus on risks management had to be moved from a single airline company to the complete supply chain of the company, even to the supply chains of transport companies all over the world.

The volcano eruption in Iceland imposed the question of risk share among airline companies in their supply chains. Although the company managers and the researchers in academic fields have become more conscious of this problem, in the referential literature, unfortunately, an adequate answer to it has not been given yet.

4.3. Interruptions of supply chains caused by the earthquake in Japan

The earthquake which occurred in Japan in March 2011 enlarged the threats to supply chain members. The interruption of the supply chains of Japanese companies significantly slowed down the growth of Japanese economy, as well as of the economies of other countries. Nevertheless, the company managers all over the world recognized the importance of implementation of new strategies in risk management, both in their own companies and the supply chains.

The devastating earthquake that hit Japan on March 11th 2011 caused the interruptions of supply chains of the leading companies in *car industry*, as well as in *microchips production*. The supply chains of these companies were resistant to the consequences of the earthquake to a different degree. The Japanese companies which had more supplies and globally dispersed manufacture capacities suffered minimum damage.

The earthquake has an extremely negative impact on car manufacturers and car components manufacturers in Japan. They were affected by electricity shortage and damaged infrastructure. Since the end of March 2011, in the report of Japanese Association of Car Dealers, it is emphasized that the car sale in Japan decreased in March 2011 for about 37 percent in respect to March 2010, because of the earthquake. In their report, the experts of IHS Automotive Institute emphasize that the deficiency of Japanese car components could contribute to the decrease of car manufacturing in the world for about 30 percent [17], just in March and April 2011.

Because of the shortage of car components and electricity, Toyota suspended all 12 car assembly factories and postponed the presentation of two new hybrid models in Japan. The company couldn't bring deliveries and demands into line, which caused the interruption of manufacturing and the sale decline. In the end of March 2011 Toyota suffered the 46 percent sale decline, except for model Lexus, 38 percent for Nissan and 28 percent for Honda Motors [18]. It has been the biggest car sale decline in Japan since 1968.

According to the IHS Automotive Institute experts' estimation, the global daily production could be decreased for 100,000 cars, because of the shortage of car components after the earthquake. The car manufacturing decrease was not the case only in Japan, but in North America, Europe and China as well. In March 2011 General Motors stopped the manufacturing of multi-purpose trucks in their factory in Shreveport (Louisiana), because of the problems with components delivery from Japan. Immediately after the earthquake, Honda stopped the production until April 3rd 2011. Opel, the branch of General Motors, due to the interruption in electronic components delivery from Japan, introduced restrictions in two European factories in which the Corsa model was made – the first was in Eisenach, where two out of three shifts were called off, and in Saragosa (Spain) where they stopped manufacturing on March 21st 2011. Some Toyota factories in North America decreased and/or stopped their production in March and April 2011, since 15 percent out of 20 percent of components used for car manufacture by Toyota in North America are being delivered by the suppliers from Japan.

The consequences of the earthquake in Japan were felt in Peugeot – Citroen alliance (PSA) as well. In the end of March 2011, they had to temporarily lay off several thousand workers because of the shortage of components from Japan. But, the Nisan company production was less affected by the earthquake since about 95 percent of the components were being produced in their factories outside Japan, and only the rest in Japan [19].

Because of the interruption of supply chain after the earthquake, the Toyota managers intensively started to consider the option of moving some factories in which components are produced to China. One of the reasons for such option was the fact that they couldn't predict how long would the slowed work last in the factories in the USA, Canada and Mexico. The majority of car components (about 70 percent) in China are delivered by local manufacturers and foreign companies which have their factories there. The Japanese car manufacturers are not motivated to start the local production of the key components in China, regardless of the fact that their share in total car sale in China was 23 percent in 2010. However, in case an earthquake, or any similar event happens, that is, if they face any bigger difficulties in supplying the Chinese assembly workers, they can decide to change their opinion.

The earthquake in Japan temporarily also stopped the production of flash memory microchips which are the major component of tablet computers and smart phones. Thus, immediately after the earthquake, the American SanDisk company, which is supplied with NAND chips by the Toshiba factory located in Yokkaichi, stopped the production for a while. The reason was the discontinuity of production in the Yokkaichi factory, caused by the problems in railway, road and other kinds of transport.

The interruptions in manufacturing high technology products in Japan, caused by electricity shortage, negatively affected the economies of other countries in the region, especially of China, since Japan is the biggest importer of Chinese products. Some estimations have been made that the stopping of production in Toshiba factory for NAND chips manufacturing for a bit of a second, in the end of 2010, would cause the production decrease up to 20 percent in the following two months, so it is not difficult to estimate the consequences of production interruptions in the companies all over Japan which lasted for several days.

5. CONCLUSION

The terms risk and uncertainty are frequently used as synonyms, since risk often includes decisions which are somewhere in the middle of risk – uncertainty scope. The consequences are not always negative. Essentially, risk taking is a possible chance for obtaining positive results (returns).

The level of vulnerability of the supply chains in respect to natural hazards is proportional to the level of interdependence of their members. Since companies are mutually connected in a supply chain by cooperation, and the importance of cooperation for companies' performances is constantly growing, the vulnerability of the whole supply chains and of some of the companies within them, is going to enhance.

The greater the level of integrations of the companies within the supply chain is, the bigger is the probability of dependence of one company on particular partners in that chain. The companies in which such relations are not recognized, or they are ignored, often fail.

The supply interruption by one company can make business problems to other partners in the supply chain, regardless of their geographical dispersion. Nokia and Ericsson have never imagined that a thunder struck into a factory which manufactures five kinds of microchips in New Mexico, can decide on the result of the battle these two companies had been waging in cell phones industry. Namely, Ericsson, unlike Nokia, did not succeed in finding other suppliers quickly after the stoppage of cell phones chips delivery by Phillips factory in New Mexico, so they suffered an enormous decline in sale of their products. A slow reaction to the interruption of supply chain cost Ericsson much more than Nokia.

The eruption of Eyjafjallajökull volcano in Iceland, in 2010, paralyzed the air traffic in Europe for almost eight days. The bigger airports in Europe were closed, and the European airline industry suffered the damage which exceeds 2 billion dollars. Apart from that, these interruptions caused problems in supply chains of transport companies worldwide.

The earthquake which hit Japan in March 2011 caused the frequent electricity shortages, as well as the problems in infrastructure, so the deliveries of orders, both to the national and foreign markets, were problematic for several weeks. The earthquake caused the interruptions of supply chains of car manufacturers, car component manufacturers, computers and electronic components manufacturers, both in Japan and other countries' markets. Because of that, while developing strategies for management of supply chain risks, the Japanese companies managers are more devoted to the principle that " nothing should be ordered from one source only".

Abstract: Location choice is a strategic decision which has influence on both revenues and costs, and the main question for starting a business is where to locate the facility, particularly in this age of global markets and global production. Retail services have also seen rapid growth over the past decade, so their facility location was one of the most frequent questions in business. An important step in location analysis is the identification of factors affecting location choice and determining relative importance for each factor. Various theories and methods so far have been developed to provide insight into the factors that determine retail option demands. Nevertheless, these have often been of limited use. The objective of this paper is to propose a methodological framework for location choice which takes into account customers' preferences and decision makers' demands. To determine relative importance of key factors affecting customers' choice, we propose a conjoint analysis. By using a conjoint analysis it is possible to determine which attributes regarding retail location are important to certain customers or market segments. The represented steps in making retail location decisions may assist companies in conducting, analysing and evaluating their location choices. The findings may be of benefit to companies by bringing more understanding and a broader view of factors important in dealing with retail location choices.

Keywords: Location analysis, criteria selection, customer preferences, conjoint analysis.

1. INTRODUCTION

Retailers need to think about shoppers not just about a format as understanding the shoppers' dynamics holds the key to such a business. Retailers would have to create new delivery formats that can cater to the huge mass of consumers. The choice of a store location has a profound effect on the entire business life of a retail operation. A bad choice may all but guarantee failure, a good choice success (Jain, 2009).

To ensure the efficient execution of spatial location, it is essential that the authorities have adequate knowledge of the various factors which determine the choice of location. To date, policy makers lack this information. That was the reason to undertake a study with as objective to gain more insight into the determinants behind retail service facilities choice of location (Van Noort & Reijmer, 1999).

Various theories and methods so far have been developed to provide insight into the factors that determine retail option demands. Nevertheless, these have often been of limited use. Poor quality of available data at high costs, or the impossibility of obtaining better data, has resulted in untested models as well as models that do not include the variables that are managerially the most relevant.

The objective of this paper is to propose methodological framework for location choice which takes into account customers' preferences and decision makers' demands. Application of this framework will lead us to getting answers to the following questions: (1) What factors determine the choice of location for retail? (2) What is the factors relative importance?

To determine relative importance of key factors affecting customers' choice, we propose conjoint analysis. It is a consumer research technique developed to provide a method for determining the relative contributions of multiple factors to consumer satisfaction. Using conjoint analysis it is possible to determine which attributes regarding retail location are important to certain customers, or market segments. This information allows stakeholders to efficiently allocate resources to best respond to consumers demand.

The main advantage of conjoint analysis over other analytical techniques is that it incorporates realistic trade-offs when measuring consumer preferences. It has been widely used in several fields of economics as well as in marketing research (Dellaert et al., 2003; Kuzmanović, 2006). However, there have been only few applications in retailing. Some researchers used conjoint analysis to model the customers' choice of a shopping centre or retail destination (Oppewal, 1995). Dariana et al. (2005) used conjoint analysis to investigate the relative importance of prices and salesperson service attributes to consumers, while Louviere and Johnson (1991) used it to measure the retail image. Certain researchers used conjoint analysis to measure retail service quality, or for preference-based segmentation (Oppewal & Vriens, 2000). In particular, Amirani and Baker (1995) used conjoint analysis to determine which cues potential customers use to form service quality expectations, and what the importance of those cues is in their decision making process. Kuzmanovic et al (2011) used conjoint analysis to investigate the relative importance of price and selected service attributes to the consumers of supermarket chains in Serbia.

The paper is organized as follows: section 2 describes location choice basics with a detailed view on criteria selection. The Conjoint analysis, including the procedure for the determining the criteria importance is given in the Section 3. The proposed methodological framework location choice which takes into account customers' preferences and decision makers' demands is given in the Section 4. Finally, main conclusions are summarized in Section 5.

2. LOCATION CHOICE

Location choice is strategic decision which has influence on revenue and costs also, and the main question for starting a business is where to locate facility, particularly in this age of global markets and global production. Dramatic changes in international trade agreements have made the world truly a "global factory," allowing companies greater flexibility in their location choices (Bartness, 1994). Two most important competitive imperatives in facility location choice is: (1) The need to produce close to the customer due to time-based competition, trade agreements, and shipping costs; and (2) The need to locate near the appropriate labour pool to take advantage of low wage costs and/or high technical skills (Bartness, 1994).

The choice of business location differs from sector to sector. Enterprises in the services sector, because of their public function, are mainly in the urban area. Industrial enterprises are usually to be found on industrial sites and are often suppliers for large companies. Wholesale enterprises also have an affinity with industrial sites because of the easy accessibility to highways. Construction companies, because office functions are not part of their core business, have no specific preference and are well represented at all types of locations. The commercial service enterprises are located mainly in towns (town centre and residential areas) because of their important public function. The industrial enterprises are mostly on industrial sites; wholesalers are also on industrial sites because of the easy access to the highway (Van Noort & Reijmer, 1999). Because of the variety of service firms and the relatively low cost of establishing a service facility compared to one for manufacturing, new service facilities are far more common than new factories and warehouses (Bartness, 1994).

Retail services, also has rapid growth in last decade, so their facility location was one of the most frequent questions in business. Where you choose to locate your retail business will have a major impact on everything your shop does. The difference between selecting the wrong location and the right site could be the difference between business failure and success (Waters, 2012). Facility location problems are solved to minimize the total cost of serving all customers (e.g. a service center). Retail location problems, on the other hand, center on how to identify a location that can maximize the number of shoppers (Cheng & Heng, 2004). Generally, most of the objectives can be classified into one of the four general objective function categories suggested by Current et al. (1990), which are cost, demand, profit and environment. One of the important steps in location analysis is identification of factors affecting location choice and determining relative importance for each factor.

To identify factors or criteria for location choice it should start from product or service characteristics. Product and service characteristics include very varying types of product, the quality of the product, the nature of the product, the serviceability of the product, delivery time and delivery date. All these product properties make certain demands on the production process and, indirectly, also on the business location. When a business has to deliver a product frequently, then accessibility is an important location factor. In practice this usually means that the enterprise is situated close to a road in the proximity of a highway or port (Van Noort & Reijmer, 1999).

It is very important for retail store to consider if it is a convenience store, a specialty shop or a shopping store. Convenience goods require easy access, allowing the customer to quickly make a purchase. A mall would not be a good location for convenience goods. This product type is lower priced and purchased by a wide range of customers. Specialty goods are more unique than most products and customers generally won't mind travelling out of the way to purchase this type of product. This type of store may also do well near other shopping stores. A shopping store usually sells items at a higher price which are bought infrequently by the customer. Furniture, cars and upscale clothing are examples of goods found at a shopping store. Because the prices of these items are higher, this type of customer will want to compare prices before making a purchase. Therefore, retailers will do well to locate their store near like stores (Waters, 2012).

MacCarthy and Atthirawong (2003) identified a comprehensive set of location factors and sub-factors relevant in the decision making process for facility location, and those factors are represented at table 1.

Table 1: Summary of major factors and sub-factors affecting international location decision (MacCarthy & Atthirawong, 2003)

Major factors	Sub-factors
Costs	Fixed costs; transportation costs; wage rates and trends in wages; energy costs; other manufacturing costs; land cost; construction/leasing costs and other factors (e.g. R&D costs, transaction and management costs etc.)
Labour characteristics	Quality of labour force; availability of labour force; unemployment rate; labour unions; attitudes towards work and labour turnover; motivation of workers and work force management
Infrastructure	Existence of modes of transportation (airports, railroads, roads and sea ports); quality and reliability of modes of transportation; quality and reliability of utilities (e.g. water supply, waste treatment, power supply, etc.) and telecommunication systems
Proximity to suppliers	Quality of suppliers; alternative suppliers; competition for suppliers; nature of supply process (reliability of the system) and speed and responsiveness of suppliers
Proximity to markets/customers	Proximity to demand; size of market that can be served/potential customer expenditure; responsiveness and delivery time to markets; population trends and nature and variance of demand
Proximity to parent company's facilities	Close to parent company
Proximity to competition	Location of competitors
Quality of life	Quality of environment; community attitudes towards business and industry; climate, schools, churches, hospitals, recreational opportunities (for staff and children); education system; crime rate and standard of living
Legal and regulatory framework	Compensation laws; insurance laws; environmental regulations; industrial relations laws; legal system; bureaucratic red tape; requirements for setting up local corporations; regulations concerning joint ventures and mergers and regulations on transfer of earnings out of country rate
Economic factors	Tax structure and tax incentives; financial incentives; custom duties; tariffs; inflation; strength of currency against US dollar; business climate; country's debt; interest rates/exchange controls and GDP/GNP growth, income per capita
Government and political factors	Record of government stability; government structure; consistency of government policy; and attitude of government to inward investment
Social and cultural factors	Different norms and customs; culture; language and customer characteristics
Characteristics of a specific location	Availability of space for future expansion; attitude of local community to a location; physical conditions (e.g. weather, close to other businesses, parking, appearance, accessibility by customers etc.); proximity to raw materials/resources; quality of raw materials/resources and location of suppliers

Plainly, small retailers are expected to use less sophisticated methods since their location selection depends on a small number of key factors. Whereas, large projects are more complicated and should take more key factors into account (Cheng & Heng, 2004).

Shari Waters (2012) emphasized seven important factors in retail store location:

- Population and target customer - it is important to research the area thoroughly before making a final decision in terms of area's population, income and age, to make sure to find a location where customers live, work and shop;
- Accessibility, Visibility and Traffic - Retailers want to be located where there are many shoppers but only if that shopper meets the definition of their target market. Small retail stores may benefit from the traffic of nearby larger stores. Depending on the type of business, it would be wise to have somewhere between 5 to 8 parking spaces per 1,000 square feet of retail space. In many cases, the better visibility retail store has, the less advertising needed;
- Signage, Zoning and Planning – It is important to understand rules, policies and procedures related to your retail store location;
- Competition and Neighbours - Other area businesses in your prospective location can actually help or hurt your retail shop. Determine if the types of businesses nearby are compatible you're your store. For example, a high-end fashion boutique may not be successful next door to a discount variety store. Place it next to a nail or hair salon and it may do much more business;
- Location Costs - Besides the base rent, decision maker should consider all costs involved when choosing a retail store location (lawn care, building maintenance, utilities and security, how much additional marketing will it take for customers to find a store, property taxes etc.);
- Personal Factors – If decision maker work in the store, his personality is important, the distance from the shop to home and other personal considerations. Also, many restrictions placed on a tenant by a landlord, management company or community can hamper a retailer's independence;
- Special Considerations - Retail shop may require special considerations (special lighting, fixtures or other hardware installed, crime rate, parking lot and building exterior, etc.)

Table 2: Examples of the key factors for retail chain business in Hong Kong (Cheng & Heng, 2004)

Retail chain business	Common location	Key specific factors
Supermarkets	Mainly in residential areas	Easy to access; car-parks
Convenience stores	Everywhere	Easy to access
Department stores	Commercial areas	Busy areas, shopping malls
Fashion	Commercial areas	Busy areas, shopping malls
Fast food business	Everywhere	Easy to access, busy areas
Banks	Everywhere but not as many as fast food outlets or convenience stores	Safety areas, busy areas
Oil stations	Major roads	Heavy road demanding
Gift shops	Commercial areas	Busy areas, shopping malls
Groceries	Mainly residential areas	Busy areas, shopping malls
Cake shops	Everywhere	Busy areas
Restaurants	Commercial and residential areas	Fewer competitors in residential; form a restaurant zone with competitors in commercial areas
Service centers	Commercial areas	Minimum rental fees

Van Noort and Reijmer (1999) described the location factors which are characteristic for the various sectors use through classification of factors which corresponds with the three different environments in which a business has to operate (see figure 1):

- Market environment; the commercial relations which a business maintains with other parties in the market e.g. relations with customers, banks, suppliers etc.
- Physical environment; items such as infrastructure, buildings, (tele) communication provisions etc.
- Institutional environment; this is the governmental policy according to which a business has to tune its strategy. The relationship can be expressed in the form of legislation, regulations to stimulate business etc. relationships with trade organisations and employee and employers organisations.

The physical and institutional environment places restrictions on trading by an enterprise. Factors which are connected to these two dimensions are therefore called conditional location factors. These factors

affect the attractiveness of a location. They must not be seen separately from the market environment. After all, a poor location can lead to higher costs because, for example, customers are difficult to reach (Van Noort & Reijmer, 1999).

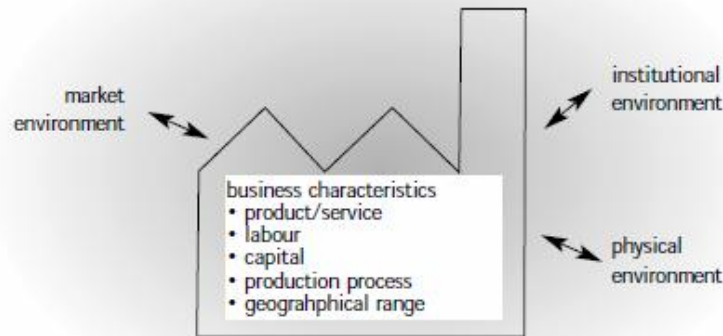

Figure 1: Business environment and business characteristic (Van Noort & Reijmer, 1999)

3. CONJOINT ANALYSIS

Conjoint analysis is a technique to find out how consumers trade off different attributes of a product or service. The method is also known as “trade-off analysis” or “utility analysis”. Two basic assumptions are made in conjoint analysis (Gil & Sanchez 1997). Firstly, a product/service can be described as a combination of levels of a set of attributes. Secondly, these attribute levels determines consumers’ overall evaluation of the product/service.

Gustafsson et al. (1999) proposed the following steps for conducting a conjoint analysis:

1. Determine the research problem and objectives and estimate the amount of available resources;
2. Decide on the sampling approach;
3. Select a survey format;
4. Determine the relevant attributes and the levels of each attribute;
5. Configure attributes and levels into individual concepts;
6. Design the data collection instrument;
7. Conduct the survey;
8. Analyze the data;
9. Validate the results, both internally and externally; and
10. Interpret the results and draw conclusions.

The attraction of using conjoint analysis is that it asks the respondents to make choices between products defined by a unique set of product attributes in a way resembling what they normally do - by trading off features, one against the other. When asked which attributes they would like, most customers will choose everything on the wish list. Conjoint analysis can establish the relative values of particular attributes and identifies the trade-offs the customers are likely to make in choosing a product and service and the price they are willing to pay for it.

Conjoint analysis produces two important results (Levy 1995):

- *Utility of attribute:* It is a numerical expression of the value consumers place in an attribute level. It represents the relative “worth” of the attribute. Low utility indicates less value; high utility indicates more value.
- *Importance of attribute:* It can be calculated by examining the difference between the lowest and highest utilities across the levels of attributes.

To determine the relative importance of different attributes to respondents, a relationship between the attributes’ utility and the rated responses must be specified. The simplest and most commonly used model

is the linear additive model. This model assumes that the overall utility derived from any combination of attributes of a given product or service is obtained from the sum of the separate utilities of the attributes. Thus, respondent i 's predicted utility for concept j can be specified as follows:

$$U_{ij} = \sum_{k=1}^K \sum_{l=1}^{L_k} \beta_{ikl} x_{jkl} + \varepsilon_{ij}, \quad i=1,\dots,I, \quad j=1,\dots,J, \quad (1)$$

where K is the number of attributes and L_k is the number of levels of attribute k . β_{ikl} is respondent i 's utility with respect to level l of attribute k . x_{jkl} is such a (0,1) variable that it equals 1 if profile j has attribute k at level l , otherwise it equals 0. ε_{ij} is a stochastic error term.

The parameters β_{ikl} , also known as part-worth utilities, are estimated by a regression analysis. The relative importance of each attribute are further calculated as the utility-range (i.e. difference between the highest and the lowest utility for that attribute) divided by the sum of utility ranges of all attributes:

$$FI_{ik} = \frac{\max\{\beta_{ik1}, \beta_{ik2}, \dots, \beta_{ikL_k}\} - \min\{\beta_{ik1}, \beta_{ik2}, \dots, \beta_{ikL_k}\}}{\sum_{k=1}^K (\max\{\beta_{ik1}, \beta_{ik2}, \dots, \beta_{ikL_k}\} - \min\{\beta_{ik1}, \beta_{ik2}, \dots, \beta_{ikL_k}\})}, \quad i=1,\dots,I, \quad k=1,\dots,K \quad (2)$$

The calculations are done separately for each respondent, and the results are then averaged to include all of the respondents.

Part-worth utilities can be also used to obtain overall utility values for all possible combination of attribute levels, i.e. for all possible profiles. It will be done by inserting the appropriate part-worths into equation 1. These utility scores can be further used to predict the market shares for each of the defined combinations. For that purpose, a model that uses exponential transformation, also known as the logit model, can be used: A logit model represents the probability that customer i will choose the j^{th} profile from a set of m existing profiles on the market (P_{ij}). The logit model is expressed as

$$P_{ij} = \frac{e^{bU_{ij}}}{\sum_{j=1}^m e^{bU_{ij}}}, \quad i=1,\dots,I, \quad j=1,\dots,J \quad (3)$$

The exponent b is used to fine-tune the results so that they reflect the current customer behaviour on the market more accurately. However, the real power of conjoint analysis is the ability to both predict preferences for profiles that weren't rated by the respondents, and to perform a what-if analysis. This can be done using market simulation models.

4. FRAMEWORK FOR LOCATION CHOICE IN RETAIL INDUSTRY

Here is presented framework proposed to help the decision maker to choose location for retail facility. Framework consists of three phases (figure 2):

- Identification of target customers (and stakeholders),
- Identifying of decision maker demands and customer preferences,
- Comprehensive analysis and selection of "best" location.

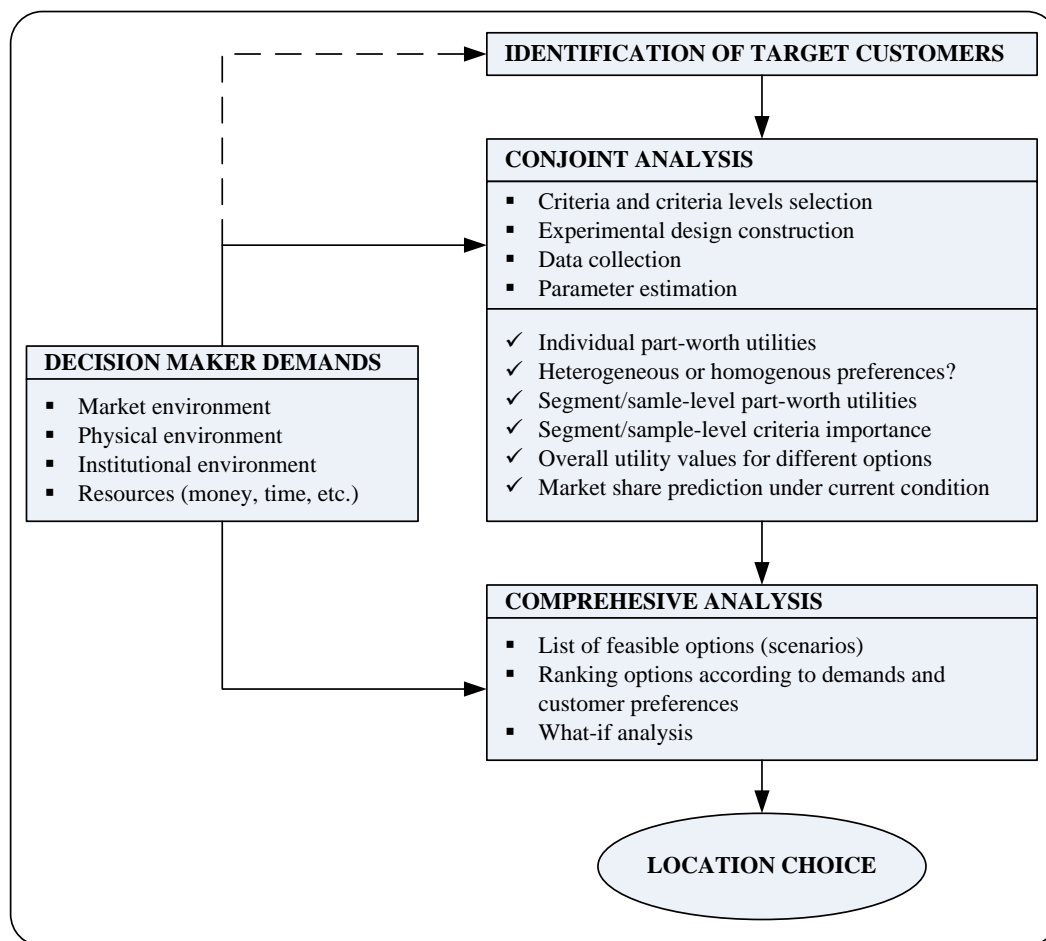

Figure 2: Framework for choosing location using conjoint analysis

The first phase of proposed framework is identification of target customers depending on specific retail sector. For example, target customers for car retailers are different from target customers for baby stores.

The second phase consists of identification of decision maker demands and customer preferences. Decision maker demands are related to market, physical, institutional environment and valuable resources. In this phase, conjoint analysis should be conducted. Based on the research objectives, literature review, expert opinions, selection of the key attributes and their levels are performed. After the data are collected, conjoint parameters estimation should be done, as described in Section 3. In the real-world applications, the parameters obtained from conjoint analysis shows respondents' preferences to the particular criteria.

Results from Conjoint analysis can be further used for creating different scenarios, then ranking options according to decision maker demands and customer preferences, and also what-if analysis can be done.

5. CONCLUSION

This paper has suggested framework for choosing location using conjoint analysis as supporting tool for more realistic criteria selection. The customer preferences obtained by conjoint analysis represents starting point for making the most suitable combination of criteria used in next phase of framework.

The represented steps in making retail location decisions may assists companies in conducting, analysing and evaluating location choices. The findings may be of benefit to companies by bringing more understanding and a broader view of what the important factors are in dealing with retail location choices. This framework may provide guidelines for companies to ensure that appropriate and relevant factors are taken into consideration in the early stages of the decision making process. Represented framework may also help policy makers in formulating retailing policies and may help relevant national and local government officers to improve their abilities and roles in assisting the location process and in attracting

and meeting the requirements of foreign investors. Further research is to conduct a survey and apply this framework in retail industry. Main steps of framework can be applied in any industry, only factor affecting location would be different.

Abstract: *This paper describes inventory control system modeling, based on the control theory. Models are developed in spreadsheets, for the purpose of planning and managing inventories in supply chains. The problem of inventory control is one of largely explored problems in modern business systems. In order to develop high qualitative models of inventory control, it is necessary to use different approaches and ways of modeling. One of the approaches uses methodology of the Modern Control Theory. The control theory deals with influences on the behavior of dynamic systems. That is an interdisciplinary subfield of science, which originated in engineering and mathematics, and evolved in usage by the social and management sciences, like psychology, sociology, criminology, financial system, operations management and supply chains. The external input of a system is called reference. When one or more output variables of a system have to follow a certain reference over time, a controller manipulates the inputs to a system with the goal of obtaining the desired effect on the output of the system. The most common objective of the control theory is to calculate solutions for a proper controller corrective action, which result in system stability. System stability implies that a system will hold the set point and not oscillate around it. The main contribution of this paper is the presentation of a concise and insightful view of using the knowledge of spreadsheets modeling in the control systems feedback for an inventory control model. In this paper, we present a spreadsheet “push” model of inventory control for five distribution centers and a spreadsheet tool for the control feedback in inventories. The intention of a spreadsheet model as a tool presented in the paper is its usability for diverse audiences of scientists, practitioners and engineers who are interested in understanding and utilizing the feedback in inventory control models. This paper is based on the author’s personal experience in the planning, controlling and organizing of inventories in coffee distribution.*

Key words: spreadsheets, inventory control, theory control, control systems, supply chain, model, modeling

1. INTRODUCTION

Modern Control Theory is an interdisciplinary area of research where many mathematical concepts and methods work together to produce an impressive body of important applied mathematics. The word control has two main meanings. First, it is understood as the activity of testing or checking that a physical or mathematical device has a satisfactory behavior. Secondly, to control is to act, to implement decisions that guarantee that device behaves as desired, (Andrei, 2005). Control idea trace back in times of Aristotle (384-322 BC). In his book “Politics”, one of the most influencing books ever written, in Chapter 3, Book 1, he has written: “... if every instrument could accomplish its own work, obeying or anticipating the will of others ... if the shuttle weaved and the pick touched the lyre without a hand to guide them, chief workmen would not need servants, nor masters slaves.”, (Bennet, 1979). Without control systems there could be no manufacturing, no vehicles, no computers, no regulated environment - in short, no technology. Control systems are what make machines, in the broadest sense of the term, function as intended. Control systems are most often based on the principle of feedback, whereby the signal to be controlled is compared to a desired reference signal and the discrepancy used to compute corrective control action, (Doyle & Francis & Tannenbaum, 1990).

The process of designing a control system generally involves many steps. A typical scenario can be presented as follows:

- Study the system to be controlled and decide what types of sensors and actuators will be used and where they will be placed.
- Model the resulting system to be controlled.
- Simplify the model if necessary so that it is tractable.
- Analyze the resulting model; determine its properties.
- Decide on performance specifications.
- Decide on the type of controller to be used.
- Design a controller to meet the specs, if possible; if not, modify the specs or generalize the type of controller sought.
- Simulate the resulting controlled system, either on a computer or in a pilot plant.
- Repeat from step 1 if necessary.
- Choose hardware and software and implement the controller.
- Tune the controller on-line if necessary.

The most elementary feedback control system has three components, presented in Figure 1. a system (the object to be controlled, no matter what it is, is always called the system or plant), a sensor to measure the output of the plant, and a controller to generate the plant's input.

Figure 1: Concept of the feedback loop

The external input of a system is called the reference. When one or more output variables of a system need to follow a certain reference over time, a controller manipulates the inputs to a system to obtain the desired effect on the output of the system. The usual objective of control theory is to calculate solutions for the proper corrective action from the controller that result in system stability, that is, the system will hold the set point and not oscillate around it. The concept of the feedback loop to control the dynamic behavior of the system: this is negative feedback, because the sensed value by sensor is subtracted from the desired value to create the error signal, which is amplified by the controller, (Doyle & Francis & Tannenbaum, 1990).

Sensor can be define as device that converts a physical stimulus or input into a readable output, which today would preferably be electronic, but which can also be communicated via other means, such as visual and acoustic. As perhaps the simplest example, consider the sensor on keyboard switch actuator - which provides a signal when the associated key is pressed. The role of a sensor in a simple automation system is depicted in Figure 2. The detection and measurement of some physical effect provides information to the control system regarding a related property of the system under control, which we are interested in regulating to within some "set point" range. The controller outputs a command to an actuator (a valve, for example) to correct for measured deviations from the set point, and the control loop is thereby closed. Because of the simplicity of example in Figure 2 control system, it represents a fair number of practical control systems. In especially simple systems, a distinct controller may not be immediately evident (for example, Thermostat), (Zook & Bonne & Samad, 2008).

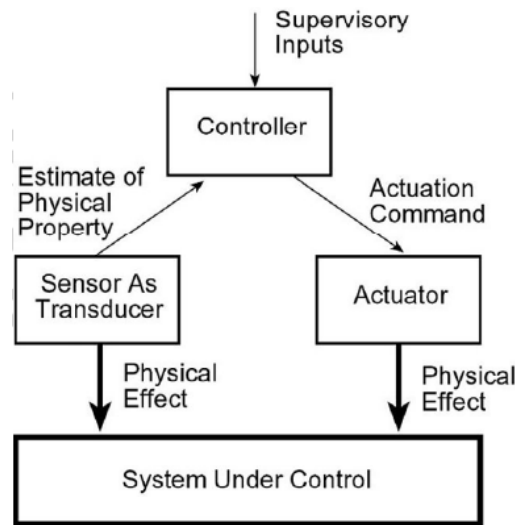

Figure 2: Example of a simple control system

A *dynamical system* is a system whose behavior changes over time, often in response to external stimulation or forcing. The term *feedback* refers to a situation in which two (or more) dynamical systems are connected together such that each system influences the other and their dynamics are thus strongly coupled. Simple causal reasoning about a feedback system is difficult because the first system influences the second and the second system influences the first, leading to a circular argument. This makes reasoning based on cause and effect tricky, and it is necessary to analyze whole systems. A consequence of this is that the behavior of feedback systems is often counter intuitive, and it is therefore necessary to resort to formal methods to understand them. In Figure 3 (a) the output of system 1 is used as the input of system 2, and the output of system 2 becomes the input of system 1, creating a closed loop system. In Figure 3 (b) the interconnection between system 2 and system 1 is removed, and the system is said to be open loop. A system is said to be a closed loop system if the systems are interconnected in a cycle, as shown in Figure 2., (Åström & Murray, 2009).

Figure 3: Open and closed loop systems

The cruise control system of a car, presented in Figure 4, is a common feedback system encountered in everyday life. The system attempts to maintain a constant velocity in the presence of disturbances primarily caused by changes in the slope of a road. The controller compensates for these unknowns by measuring the speed of the car and adjusting the throttle appropriately (Zook & Bonne & Samad, 2008).

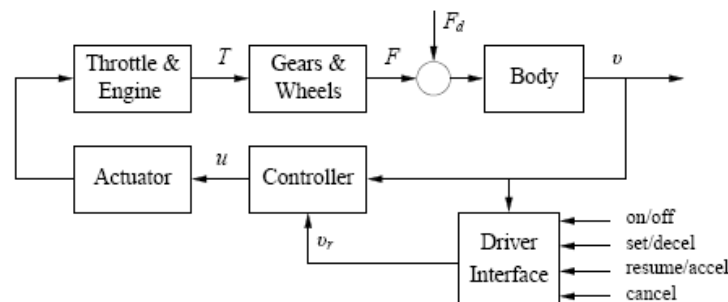

Figure 4: Block diagram of cruise control system for automobile

Feedback is one of the most important contribution of Charles Darwin (1805-1882). According to his theory feedback over long time periods is responsible for the evolution of species. Later, Vito Volterra (1860-1940) used this concept to explain the balance between two populations of fish in a closed pond. But, the most influencing was Norbert Wiener (1885-1964) who introduced the fruitful concepts of positive and negative feedback in biology. In engineering, this term has been early introduced by the engineers of the Bell Telephone Laboratory (Mayr, 1970). Now it is an active concept in practically all area of activity. A feedback process is one in which the state of the system, or its output, determines the way in which the control has to be computed at any time instant, (Andrei, 2005). Feedback has potential disadvantages as well. It can create dynamic instabilities in a system, causing oscillations or even runaway behavior. Another drawback, especially in engineering systems, is that feedback can introduce unwanted sensor noise into the system, requiring careful filtering of signals. It is for these reasons that a substantial portion of the study of feedback systems is devoted to developing an understanding of dynamics and a mastery of techniques in dynamical systems. Feedback systems are ubiquitous in both natural and engineered systems. Control systems maintain the environment, lighting and power in our buildings and factories; they regulate the operation of our cars, consumer electronics and manufacturing processes; they enable our transportation and communications systems; and they are critical elements in our military and space systems. For the most part, they are hidden from view, buried within the code of embedded microprocessors, executing their functions accurately and reliably. The term *control* has many meanings and often varies between communities. We define control to be the use of algorithms and feedback in engineered systems. For example, the thermostat, in particular, is a simple example of feedback control that everyone is familiar with. The device measures the temperature in a building, compares that temperature to a desired setpoint and uses the *feedback error* between the two to operate the heating plant, e.g., to turn heat on when the temperature is too low and to turn it off when the temperature is too high (Åström & Murray, 2009). Another representation of feedback loops is *optimal control* and *estimation* in feedback loops. Johann Bernoulli (1667-1748) was the first who articulated the principle of optimality. In 1957 Richard Bellman formulated the *dynamic programming* principle to the optimal control of discrete-time systems (Bellman, 1957), and in 1958, Lev Pontryagin developed the *maximum principle* for solving nonlinear optimal control problems (Pontryagin & al., 1962). Both these optimality principles characterize the optimal control by means of a feedback law. The main idea of Bellman was to introduce the *value function* (the Bellman function) as feedback law.

2. SYSTEM MODELING

A model is a precise representation of a system's dynamics used to answer questions via analysis and simulation. The model we choose depends on the questions we wish to answer, and so there may be multiple models for a single dynamical system, with different levels of fidelity depending on the phenomena of interest. There are two specific methods commonly used in feedback and control systems to represent the concept of modeling: differential equations and difference equations. A model is a mathematical representation of a physical, biological or information system. Models allow us to reason about a system and make predictions about how a system will behave. In this paper, we will mainly be interested in models of dynamical systems describing the input/output behavior of systems. Roughly speaking, a dynamical system is one in which the effects of actions do not occur immediately. For example, the velocity of a car does not change immediately when the gas pedal is pushed nor does the temperature in a room rise instantaneously when a heater is switched on. Similarly, a headache does not vanish right after an aspirin is taken, requiring time for it to take effect. In business systems, increased funding for a development project does not increase revenues in the short term, although it may do so in the long term (if it was a good investment). All of these are examples of dynamical systems, in which the behavior of the system evolves with time. The input/output framework is used in many engineering disciplines since it allows us to decompose a system into individual components connected through their inputs and outputs. Thus, we can take a complicated system such as a radio or a television and break it down into manageable pieces such as the receiver, demodulator, amplifier and speakers. Each of these pieces has a set of inputs and outputs. These components can be interconnected to form of the entire system through the proper design. To deal with large, complex systems, it is useful to have different representations of the system that capture the essential features and hide irrelevant details. In all branches of science and engineering, it is common practice to use some graphical description of systems, called *schematic diagrams*. They range from stylistic pictures to drastically simplified standard symbols. These pictures make it possible to get an overall view of the system and to identify the individual components. Schematic diagrams are useful because they give an overall picture of a system, showing different subprocesses and their interconnection and indicating variables that can be manipulated and signals that can be measured. A special graphical representation of model, called a *block diagram* has

been developed in control engineering. The purpose of a block diagrams is to emphasize the information flowed to hide details of the system. In a block diagram, different process elements are shown as boxes, and each box has inputs denoted by lines with arrows pointing toward the box and outputs denoted by lines with arrows going out of the box. The inputs denote the variables that influence a process, and the outputs denote the signals that we are interested in or signals that influence other subsystems. Block diagrams can also be organized in hierarchies, where individual blocks may themselves contain more detailed block diagrams, (Zook & Bonne & Samad, 2008). The economy is a large, dynamical system with many actors: governments, organizations, companies and individuals. Governments control the economy through laws and taxes, the central banks by setting interest rates and companies by setting prices and making investments. Individuals control the economy through purchases, savings and investments. Many efforts have been made to model the system both at the macro level and at the micro level, but this modeling is difficult because the system is strongly influenced by the behaviors of the different actors in the system. One of the reasons why it is difficult to model economic systems is that there are no conservation laws. A typical example is that the value of a company as expressed by its stock can change rapidly and erratically. However, there are some areas with conservation laws that permit accurate modeling. One example is the flow of products from a manufacturer to a retailer as illustrated in Figure 5. The products are physical quantities that obey a conservation law, and the system can be modeled by accounting for the number of products in the different inventories. There are considerable economic benefits in controlling supply chains so that products are available to customers, while minimizing products that are in storage. The real problems are more complicated than indicated in the figure because there may be many different products, there may be different factories that are geographically distributed and the factories may require raw material or subassemblies. Considerable economic benefits can be obtained by using models to minimize inventories. Their use accelerated dramatically when information technology was applied to predict sales, keep track of products and enable just-in-time manufacturing. Supply chain management has contributed significantly to the growing success of global distributors. Products flow from the producer to the customer through distributors and retailers as indicated by the solid lines. There are typically many factories and warehouses and even more distributors and retailers. Multiple feedback loops are present as each agent tries to maintain the proper inventory level, (Zook & Bonne & Samad, 2008).

Figure 5: Supply chain dynamics

3. INVENTORY „PUSH“ MODEL FOR INVENTORY CONTROL

A significant growth of interest in supply chains inventory management can be noticed in the last few years. One thing has become certain, large companies tend to reduce costs through the more efficient supply chain management. Companies have realized importance of costs that arising from keeping large stock amounts in the distribution chain. Too much inventories in warehouses allow daily demand satisfaction and meeting of changes in products demand, but with very high distribution prices due to high costs of products shipment and transportation. GRAND PROM company was established in 1997. Main activity of this company is coffee production and sale. As a technologically modern, high quality and original product Grand coffee quickly became very popular and today is the leading brand among the coffees on the market of Serbia. The company is constantly expanding, thanks to constant investment in technology and monitoring of recent trends in the global coffee market. In late 2003, the company began to develop its own distribution network. Today, company has six distribution centers for direct supplying of more than 15.000 retails with its products. The development of distribution centers (hereinafter referred to as DC) is a necessity for supply chains management in the manufacturing systems business. Distribution centers are the simplest way of achieving direct links with customers, by the full control of the market. In

addition to the direct control of the market, DC contribute to the strengthening of the company's brands, market share increasing, billing control, customer service improvement, winning the leading position on the market, providing customer services, as well as faster and safer delivery.

Inventory management is an especially complex process for companies that producing articles which selling. This means that production must have data about the quantities of products required to produce for delivery, or in addition to the annual and monthly sales plans, continuously carrying out plans on a daily basis is necessary, in order to optimize the use of production and storage capacity. The parent company or main warehouse receiving daily information about quantities required for the delivery, from DC. According to these data, production section producing goods that will be received in the parent company's warehouse for finished goods. On behalf of logistics managers, finished goods are transported to DC or to key customers. It is important to note that the distribution centers supplying customers not only as direct distribution (small retail), but also key customers (key accounts), with demand that in most cases has a high degree of uncertainty. The unpredictability of the amount of product for delivery is often a big incentive for companies to create inventory planning and inventory management system as better as possible. In order of better planning of inventory management, companies often use information technology and various software solutions to address the problem of inventory management. The use of computers, internet, cross-links in the data transmission, i.e. modern IT infrastructure, is today an indispensable activity for each company. However, despite the well-developed IT infrastructure, companies are often wary of buying different material flows management software solutions, because the implementation of solutions requires some changes in work processes. In reality, most companies have major problems with company organization adapting to various software solutions and vice versa. Data transfer from geographically distant locations in real time can be extremely expensive and complex. If company needs 24h inventory tracking and the number of customer orders tracking, in geographically remote distribution center, it is necessary that during this period exist a constant transverse connection (GPRS) and database should be updated at the same time during the day with all queries sets of user in the parent company. This process of data exchange is limited and often ineffective because of cancellation possibility not only for the company's IT resources, then because of permeability of telephone networks also. Hence the update and data transfer is performed once per day (eg: in the afternoon, after work hours), the servers have enough time to process and store data in the database until the next business day. However, if the information about stock of one distribution center is available a day later, the question is how we can plan delivery for the next working day in the present moment, for the distribution center. Because of these reasons, companies employees using the internet, in order to obtain data from a geographically distant location, in a short time, and simple applications for data analysis, that enabling the use of a large number of tools for data processing. The application, which in most cases meets user needs for sharing and processing information is spreadsheet, with a large number worksheets. Spreadsheets can be a good choice for databases creation, because: databases creation is simple, better understanding, many users know how to use spreadsheets applications, data analysis tools are easier to use, receiving and sending data in various formats is simple and possible. Spreadsheet applications uses a powerful tool for working with databases and searching stored data by various criteria, sort their order of preference, statistical analysis and can be used in any Windows applications (Word, Power Point ..). At any time user can sort and search entered data by different keys. Moreover, it can use and powerful tools for the specific solutions simulation.

Organization of inventory management in supply chain distribution centers is often an inefficient. Lack of organization is reflected in the decentralized inventory ordering, where distribution centers make supplies ordering from the main logistics distribution center in excessive quantities, mostly because of the creation of additional reserves in order to avoid sudden peaks in sales. Often, this not well-defined activity is added by bed defined terms of ordering supplies, poor form of documents for inventory levels tracking and lack of well trained employees for supplies ordering. As a simple solution for these problems, companies started with using of the "push" principles for inventory management in distribution-logistics centers. This model was reflected in the automatic orders definition of stock replenishment for distribution centers, from the central logistics distribution centers. In that way distribution centers should only forward inventory level in time, and based on that information to get delivery of the necessary and sufficient amount of supplies. The system for inventory management was modeled in order of solving this problem. System was modeled by using of the methodology of feedback in control systems. During the model creation, all elements of a feedback loop were created. It was necessary for model to analyze a large number of numerical data, because of that model was developed as a spreadsheet application. Each of distribution centers should have to send a report - level of stocks status to central LDC, at the beginning of each working day. This

report was defined as prescribed form and format of the Excel spreadsheet (Figure 6). Employees in DC were responsible for DC stock reporting and submission of this report to a central logistics-distribution center.

Figure 8. Planned stock level report in spreadsheet

When orders arrive from DC to the LDC, the same shall be entered in a separate spreadsheet file in order to be translated to the number of inventory selling days. Order forms from all five distribution centers are compiled into a separate spreadsheet worksheets by using macros. That spreadsheet represents all comparative orders of all distribution centers in one place. In this way, we define the sensor function of model, which should prepare data for comparison in the model comparator.

Figure 9. Sensor and comparator element of model in spreadsheet

Comparator is used to determine the difference between the planned inventory levels and the actual state of the stock. Defined differences in the output of comparator are used for making final decisions about quantities of items that will be delivered in each distribution center. Defined differences are shown as the number of days, with four different colors, which indicate the current stock level or result in a distribution center. Conditional Formatting command in Excel's toolbar is used to denote high, optimal, low and critical limits of inventories by different colors to define how many stocks we have in selling days number. According to the colors, current stock level is compared with planned level of inventories. These differences are switching to a new spreadsheet worksheet by especially made macros, which now realize functions of the model controller. Model controller function is realized in position of Coordinator of inventories. His control role is to confirm quantity of products for delivery of each item and if it is necessary to make a change of order, according to distribution center reedmen's. This report compares and control ordering forms from DCs, in compliance with level of stocks in the central warehouse. Immediately, after ordering forms from DCs are approved, orders control report is sent to production to create production

work orders. These actions as an effect has inventories planned level filling of the central warehouse. In addition, after approval, requisitions are converted to orders for delivery distribution centers.

Figure 10: Controller element in spreadsheet model

Results of control are inventory supplies tailored to the needs of distribution centers and delivers adjusted to the maximum utilization of delivery vehicles (full-trucks-load shipments).

6. CONCLUSION

Finally we can say that the spreadsheets are an indispensable tool for simple, quick and easy processing and data analysis for activities of planning, modeling and control of inventories. Apart from logistics, spreadsheet models have great importance in many other disciplines and fields such as finance, quality management, human resources, quantitative methods and etc. Design of spreadsheet models is very simple if the modelar is familiar with methodology for developing and organization of data in control models.

Abstract: *The purpose of this study is to determine to what extent companies in Serbia had adopted process management practices, what is their process maturity level according to CMMI model, and what are the problems and challenges those companies in Serbia encounter while trying to implement process change initiatives. Survey method were used for research and it was mailed to general managers, CEOs, process analysts at a random sample of 300 manufacturing and service organizations in the Serbia. Results showed that most of the companies in Serbia are at Level 1 or 2, they do not have a formal group for process management and they are mostly focused on incremental improvement. This is the first research of this kind in Serbia which shows the state of the BPM in Serbia and this paper suggests steps for further efforts in process management practice.*

Keywords: *Business process management, process change, companies in Serbia*

1. INTRODUCTION

Availability of competing manufacturers and the ability to easily change supplier are reasons why companies think about improving their processes. Companies often think about process improvement through IT usage, and ignore the total set of changes that business system should undergo in order to improve its processes, to acquire and maintain long-term relationships with customers and sustain a competitive position in the market. These changes should permeate all levels of the company, and only comprehensive process improvement approach can bring the desired results.

The essence of maintaining the competitive position based on quality relationships with customers is in building a network of effective and efficient business processes. While Business Process Management (BPM) has been applied for decades now in developing countries, Serbia (as a transitional country) is relatively new to the entire concept. BPM presents a good opportunity for transitional countries, as its application can bring visible results in relatively small amount of time, and with little investments.

The aim of this paper is to evaluate the current state of BPM in Serbian industry. Companies' understanding about BPM will be analyzed, as well as general situation of process maturity in Serbian industry. The research was done through questionnaire which was sent to nearly 300 Serbian companies. The results show that, although Serbian companies are not unfamiliar with BPM concepts, BPM application is still rudimentary. The purpose of the paper is to highlight potential benefits that BPM can bring to Serbian companies, and to encourage other transitional countries to look for their development opportunities in BPM.

The paper is organized as follows: after a short introduction, a brief literature review will be given where basic concepts of business process management will be presented. Chapter four will shortly present research methodology that was used for the purpose of this paper. Results of the research will be given in chapter 5. These results will be discussed in chapter 6, and the conclusion will be given afterwards.

2. THEORETICAL BACKGROUND

Porter identified two ways for obtaining competitive advantage: to carry out activities differently from the competition; or to perform similar (or identical) activities as competitors, but in a better way (Porter, 1998). Companies operating in the same industry achieve different results by using different resources and having different capabilities (Peteraf, 1993). Processes are one of main resources of any company, and are difficult to imitate (Biazzo and Bernardi, 2003). Business process can be defined as a series of

activities carried out in order to produce a specified output, or to create a result that has value for the customer (Davenport, 1993; Hammer and Champy, 1993). Processes are vital for any organization, and they must be seen as resources that need to be managed. They are not only resources, they constitute a business system and things that it does, so it can be said that any business system can be managed by managing its processes.

Business Process Management (BPM) represents all of company's efforts to level its processes with strategic goals. It is a structured approach to analyzing, improving and controlling processes of a company (Elzinga et al., 1995). BPM is often identified with Business Process Management Systems (BPMS) or Enterprise Systems (ES, such as ERP or CRM systems). BPM should be viewed in a broader context, as a way for managers to organize and control processes (Harmon, 2007). A number of models have been developed for the purpose of managing processes. All of them suggest a series of stages or steps that should be applied in order to establish a BPM system (Elzinga et al., 1995, Sinclair and Zairi, 1995; Gardner, 2001). Most models emphasize certain aspects of process management (process measurement, process improvement), and do not give a complete picture of what is to be done in order to establish a system for process control. However, by analyzing these models, a conceptual model can be developed, that includes following aspects of process management (Biazzo and Bernardi, 2003): a) process architecture; b) process visibility; c) monitoring mechanisms; and d) improvement mechanisms.

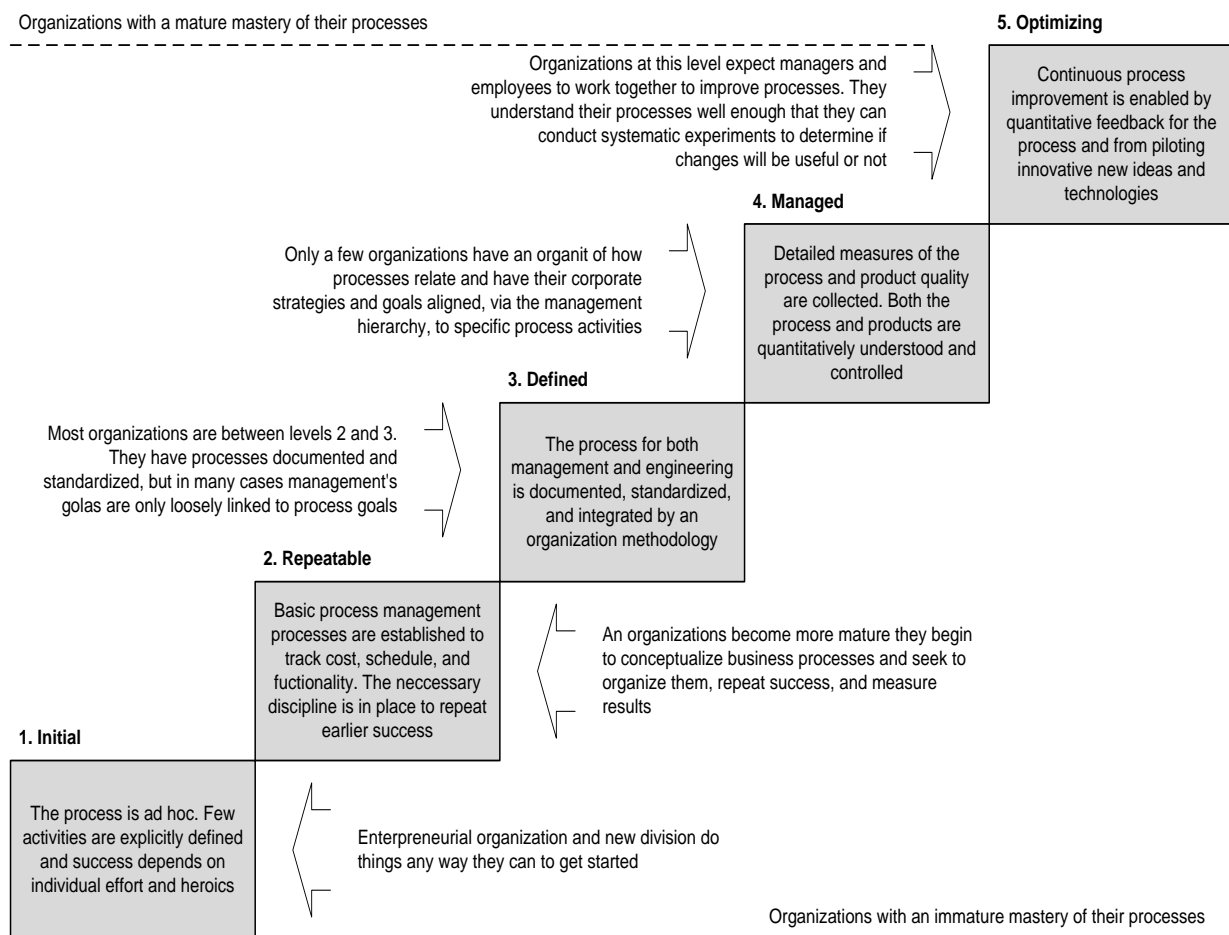

Figure 1: CMMI process maturity model

CMMI (Capability Maturity Model) is a model which follows the company's evolution from immature to very mature understanding of their own processes through five stages or levels (Paulk, 1995). It is originally developed for use in business systems dealing with software development, but it is equally applicable to any company (it is often applied in large companies, but it can be used in small and medium-sized organizations with the same success). The key point of the model is to understand where the organization is today and where it wants to get (the model provides basic guidelines on the road to maturity). A key assumption of the model is that immature companies cannot provide the consistency of their performance,

while mature companies make quality products at effective and consistent manner. Graphic display of the CMMI model is given in Figure 1. Continuous monitoring and improvement of business processes makes sense only if the business system achieved a certain level of maturity of its processes. Although the CMMI model suggests that organizations that are just starting up are at the first level of maturity, the fact is that many business systems, even after many years of doing business of the market, do not move away from the first level of maturity.

3. RESEARCH METHODOLOGY

The purpose of this study is to determine to what extent companies in Serbia had adopted process management practices, what is their process maturity level according to CMMI model, and what the problems are and challenges that companies in Serbia encounter while trying to implement process change initiatives.

The survey instrument used in this research was developed after an extensive literature review of business process management and process maturity level and problems associated with the use of process improvement practices. The instrument consisted of questions requiring single and multiple choices. Some questions included an open form in case when offered answers couldn't reflect the views of the respondents. A group of academicians examined the instrument for validity and clarity. After review a few changes were suggested which were later incorporated into the survey instrument.

As said before, one of the main objectives of this research was to determine the process maturity level of companies in Serbia according to CMMI model. Since this is the first research of this kind in Serbia (as far as authors know), the authors decided to design some of the questions as if there were three levels of process maturity instead of five, where respondents were asked if their organization "Never" did something (representing Level 1), "Frequently" did something (representing Levels 2 to 4), or "Always" did something (representing Level 5 of the model). The authors introduced this relaxation since there was a fear that the answers offered to the respondents will be too complicated for companies that have never been previously faced with such research, and that it may deter them from participating in research. One question had five answers offered, where participants were asked to explicitly position their company at one of the levels of the CMMI model.

The research instrument was mailed to general managers, CEOs, process analysts at a random sample of 300 manufacturing and service organizations in the Serbia. The cover letter accompanying the survey contained a note suggesting that respondents' confidentiality will be preserved. In addition, the letter addressed the nature of the study, and provided brief descriptions of the process approach and process management initiatives. Respondents were asked to either complete the survey or pass it on to the officer in the company that would have oversight of or responsibility for implementing BPM and business process improvement initiatives mentioned in the survey. A total of 41 usable responses were returned, resulting in a response rate of 13,66 percent. All of these responses were included in the results presented in this paper. Questionnaire included 23 questions divided into two groups: general information about companies and BPM understanding, practices and issues.

After the questioners were filled by the participants, the statistical package SPSS was used which automatically calculates frequencies and conducts χ^2 test (with significance set to 0.05).

4. RESULTS

Among 41 respondents in the research, 7,3% were general managers, 7,3% were executive officers, 43,9% were business function/department managers, 19,5% were business analyst, while 22% of respondents stated that their position was something else. Majority of the companies included in the research were large companies (61%) with more than 250 employees. When it comes to business field that the company is operating in, 46,3% were service oriented, 31,7% were manufacturing companies, while 22% were operating both in service and manufacturing industry. Most companies were domestically owned (53,7%), about a quarter of them have foreign owners (26,8%), and with the rest (17,1%) the ownership was shared between domestic and foreign owners.

To better understand how our respondents use the term Business process management, we asked respondents to choose among four options, or to suggest an alternative to the four options we presented. (see Figure 2).

Figure 2: Companies' understanding of Business process management concepts

Figure shows that a significant percentage of respondents (46,30%) indicated that their organizations understand BPM to refer to a top-down methodology designed to organize, manage, and measure the organization, based on the organization's core processes. The view of BPM as a cost-saving initiative holds second place at 29,30%. It is also important to note that all of the participating companies have showed some form of interest in BPM, where most of the companies (41,50%) identified their interest as significant commitment to multiple process improvement project on the highest level.

The participants were asked to explicitly position the company they're working in at one of the levels offered by CCMI maturity model. The results are shown in Figure 3.

Figure 3: Levels of CMMI process maturity of companies in Serbia

It is interesting to note that most companies' processes are at Levels 1 to 3 of process maturity, where most of the respondents have placed their processes at Level 2 (34,1%). None of the respondents placed its company's processes on Level 4, and only 12,2% of the companies have their processes at the highest level of process maturity. Other answers to the questions concerning process maturity are in accordance to these results. The percentage of the respondents that said that processes in their company are frequently documented is 63,4%, while in 24,4% of cases processes are always documented. Processes are never monitored and measured in 14,6% of cases, frequently in 46,4%, and always in 39%. As much as 70,7% of respondents answered that the support provided by automated software applications is in accordance with company's processes. Only 2,4% of the respondents stated that process improvement initiatives are always being able to identify and remove problems and inconsistencies, while 82,9% stated that problems are frequently solved by process improvement initiatives. Most of the companies have spent up to 500000€ on process analysis, improvement and management in previous year (48,8% have spent 0-50000€, 41,5% have spent 50000-500000€), while only 9,8% of the companies have spent more than 500000€ in previous year. Most of the companies don't have formal group for process management (39%), or have formal process management group located within their executive management (24,4%).

Main drivers behind business process change initiatives identified among companies operating in Serbia are given in table 1.

Table 1: Main drivers behind business process change initiatives

Main drivers behind business process change initiatives	No. of companies
Business process architecture development	24
Onetime events (reorganization/mergers/acquisitions)	4
QMS certification	0
Risk management	6
Need for customer satisfaction improvement	24
Need for managing IT resources (ERP/CRM)	10
Business partner's requirements	8

When it comes to process initiatives that companies have undertaken so far, the results are given in table 2 (multiple answers were allowed)

Table 2: Process initiatives that companies have undertaken so far

Business process initiatives undertaken so far	No. of companies
Business process architecture development	17
Business process measurement system development	24
Process change coordination within company	16
Process management coordination within company	23
Process managers training for process analysis/redesign	11
Core processes redesign	7
Six Sigma improvement projects	2
Lean improvement projects	5
Continuous process improvement projects/KAIZEN	8
Process automation projects	14

When it comes to challenges and resistances encountered while trying to broaden business process initiatives, the results are given in table 3 (multiple answers were allowed)

Table 3: Challenges and resistances encountered while trying to broaden business process initiatives

Challenges encountered	No. of companies
Lack of interest within top management	8
Management requires ROI that is not achievable	2
Multiple process change projects require same resources	11
Previous process improvement projects were unsuccessful	0
Management doesn't want to invest in process change projects at this time	11
Something else	17

Chi-square test was used in order to test whether interdependence between the basic parameters of the company (business field, size, ownership structure, ...) and process management practice in companies in Serbia exists. It is interesting to note that ($X^2=6.889$, $df=2$, $p=0.032$) manufacturing companies are mostly focused on incremental process improvement initiatives. Companies that have spent less than 500000€ on process change initiatives in previous year are usually engaging external consultants for training their managers in process design and analyses. As far as the existence of formal process management goes, it can be concluded that companies that do not have formal group for process management often encounter problems with managing multiple process change project ($X^2=6.555$, $df=1$, $p=0.01$), which is the main reason why process change initiatives in these companies fail. The chi-square test did not reveal any significant differences between the size and ownership structure on one side, and process management practices conducted in companies in Serbia.

5. DISCUSSION

It is interesting to note that the majority of respondents are functional/department managers. This can be attributed to the fact that business process management related issues are relatively new to companies operating in Serbia, and business process awareness is not at the desirable level. That is why majority of companies assign functional/department managers to deal with process management issues. The understanding of term “Business process management” is similar to the one that leading world companies have (Harmon, 2007), as majority of them considers business process management to be a top-down methodology designed to organize, manage, and measure the organization, based on the organization’s core processes. Having in mind business conditions in Serbia as a transitioning country and world economy, it is understandable that all of the participating companies have showed some form of interest in business process management initiatives, since most companies are pressured to improve their competitive performance and customer satisfaction, and cut costs wherever possible. The analysis of process improvement initiative’s main drivers backs up this conclusion, since the need for improving existing/creating new products in order to maintain competitive advantage and the need to improve customer satisfaction are identified as main two drivers for process improvement.

Processes of over 60% of the companies operating in Serbia are at Levels 1 or 2 of CMMI process maturity model. Besides that, none of the participating companies have their processes at Level 4 of the model, and only 12,2% of the companies have their processes at Level 5 of the model. These results are not in accordance with the results of leading world companies (most of the world’s companies are at Level 3 of the model) (Harmon, 2007). This can also be attributed to the fact that business process management concepts are relatively new to Serbian companies.

Chi-square test has shown that manufacturing companies are mostly focused on incremental process improvement initiatives. This is not unusual since most of methodologies for continuous improvement (Kaizen, Lean, Six Sigma, etc.) were developed in manufacturing environments.

It can be concluded that companies that do not have formal group for process management often encounter problems with managing multiple process change project, which is the main reason why process change initiatives in these companies fail. This can be attributed to the fact that the absence of formal group for process management can lead to the lack of coordination between multiple process change projects, because responsibility is not clearly defined.

6. CONCLUSION

Business conditions in Serbia (the transition, low employment and productivity) dictate the need for companies to constantly improve ways of doing business. One approach that offers significant opportunities for business improvement is Business Process Management. Considering the results obtained from research, it can be concluded that BPM is a relatively new concept for enterprises in Serbia. Although it is a new concept, it can be seen that there is interest by companies to improve business processes, and that there is plenty of room to improve the understanding and application of business process management concepts, as the business process maturity of companies operating in Serbia is lower the process maturity of leading global companies. It is encouraging that Serbian companies understand the need to promote concurrent market position, as seen from analysis of main drivers for improving business processes. Functional organization is still the dominant form of organization of business systems in Serbia and it is necessary to make additional efforts in order to successfully make their transformation into process oriented company. The first step in this path could be the formation of formal group to manage processes, whose main task would be to coordinate the various business process improvement projects. It would also be good to strengthen business – academia connections, as the research shows that companies don’t have a clear picture of Business Process Management.

Abstract: Supply Chain Risk Management (SCRM) has a dominant place in active and successful management of business processes. Trends such as globalization, lean processes and the geographical concentration of production have made supply chain networks more efficient, but have also changed their risk profile. Supply chain management is exposed to various risks like earthquakes, economic crises, SARS, strikes, terrorist attacks etc., which can repeatedly disrupt the supply chain operations. Integration of risk management is crucial for the success of the process and it should be incorporated in the functioning of the organization. The goal of this paper is to present risks which are present within a supply chain, as well as different approaches in SCRM, steps to be taken and application in practice.

Keywords: supply chain, risk management, turbulence, disruption, risk

1. INTRODUCTION

Because of the competition in global markets, manufacturing companies are under increasing pressure to define supply chain management as key priority in order to reduce costs and risks. In the eighties of last century a more intensive approach in studying supply chain management had begun. Many companies now organize their supply chains in compliance with previously established settings in which they are trying to work closely with their suppliers and customers. The definition of SCM given by The Global Supply Chain Forum (2012) is the following: "Supply chain management is the integration of key business processes from end-user through original suppliers that provides products, services, and information that add value for customers and other stakeholders".

In supply chain functioning companies are exposed to risks individually as well as the whole supply process with its participants. Over the last ten years, earthquakes, economic crises, SARS, strikes, terrorist attacks have disrupted supply chain operations repeatedly. Supply chain disruptions can have significant impact on a firm's short-term performance. For example, Ericsson lost 400 million Euros after their supplier's semiconductor plant caught on fire in 2000, and Apple lost many customer orders during a supply shortage of DRAM chips after an earthquake hit Taiwan in 1999 (Tang, 2006). From fluctuations in fuel costs to the uncertain politics and economies of countries from which raw materials and component products are sourced, disruptions and delays of supply chain flows threaten the profitability of every firm competing in today's global business environment (Ueltschy et al., 2009).

Disruptions in the supply chain can have long term negative effects on performance of companies as special on its financial aspects. Many researchers have developed different models and strategies for SCRM in order to overcome the disruptions within the supply chain and their consequences. Risk Management is a management style based on assessing the potential likelihood and impact that could be caused to a business if key (strategic) risks are not controlled and mitigated.

The main objective of this paper is to present fields of supply chain risk management processes with emphasis on reasons of their importance of the company and all included companies of supply chain. The aim is to depict the types and effects of risks that affect the functioning of the supply chain, as well as their increased influence in the last decade that have led the company to deal with them, evaluate them and bring added value to shareholders.

2. SUPPLY CHAIN RISK

Risk management is a rapidly developing discipline and there are many and varied views and descriptions of what risk management involves, how it should be conducted and what it is for. Risk management is a central part of any organisation's strategic management. It is the process whereby organisations methodically address the risks attaching to their activities with the goal of achieving sustained benefit within each activity and across the portfolio of all activities (THEIRM, 2002).

Strengthening the supply chain in new market conditions on national as well as global level caused changes in the risk portfolio of the majority of companies. Next to "traditional" risks which every company is facing, new risks often emerge as a result of close cooperation between companies. Understanding supply risk requires much more than evaluating suppliers' financial conditions. Risk factors come in many shapes - operational, managerial, geographic and more (Lawton, 2009).

The majority of firms in this study do not currently have formal definitions for supply risk. However, each of the respondents from those firms had strong conceptions of what supply risk means to their organizations and they provided definitions of supply risk by their sources and outcomes. The sources of supply risk were described in terms of individual supplier failures and supplier market characteristics. Respondents conceptualized the outcomes of supply risk by the inability to meet customer requirements and threats to customer life and safety (Zsidisin, 2003).

Supply chain risk is exacerbated by the never-ending push to improve operating efficiency and reduce costs. Although trends such as lean manufacturing, just-in-time inventory, outsourcing and supplier consolidation have yielded compelling business benefits, they have also introduced new kinds of supply chain risk and reduced the margin for error without providing appropriate counter-balancing to help mitigate risk (Marchese et al., 2012).

The sources of supply risk tend to arise from individual supplier failures and from market factors. The individual supplier failures that define the scope of supply risk were the inability to handle demand fluctuations, quality problems at supplier plants, and the inability to stay in pace with technological changes. In addition, supply risk was understood in terms of supplier market characteristics. Market characteristics include sole sources (such as suppliers having a patent) and market capacity constraints (Zsidisin, 2003).

Before companies can devise effective means of reducing supply-chain risks, managers must first understand the universe of risk categories as well as the events and conditions that drive them (see Table 1). Then, armed with clear, specific knowledge about these crucial risks, companies can proceed to select and tailor mitigation strategies, which are likely to be most effective.

Table 1: Supply chain risk and their Drivers

Category of risk	Drivers of risk
Disruptions	<ul style="list-style-type: none"> • <i>Natural disaster</i> • <i>Labor dispute</i> • <i>Supplier bankruptcy</i> • <i>War and terrorism</i> • <i>Dependency on a single source of supply as well as the capacity and responsiveness of alternative suppliers</i>
Delays	<ul style="list-style-type: none"> • <i>High capacity utilization at supply source</i> • <i>Inflexibility of supply source</i> • <i>Poor quality or yield at supply source</i> • <i>Excessive handling due to border crossings or to change in transportation modes</i>
Systems	<ul style="list-style-type: none"> • <i>Information infrastructure breakdown</i> • <i>System integration or extensive systems networking</i> • <i>E-commerce</i>

Forecast	<ul style="list-style-type: none"> • <i>Inaccurate forecasts due to long lead times, seasonality, product variety, short life cycles, small customer base</i> • <i>"Bullwhip effect" or information distortion due to sales promotions, incentives, lack of supply-chain visibility and exaggeration of demand in times of product shortage</i>
Intellectual Property	<ul style="list-style-type: none"> • <i>Vertical integration of supply chain</i> • <i>Global outsourcing and markets</i>
Procurement	<ul style="list-style-type: none"> • <i>Exchange rate risk</i> • <i>Percentage of a key component or raw material procured from a single source</i> • <i>Industry wide capacity utilization</i> • <i>Long-term versus short-term contracts</i>
Receivables	<ul style="list-style-type: none"> • <i>Number of customers</i> • <i>Financial strength of customers</i>
Inventory	<ul style="list-style-type: none"> • <i>Rate of product obsolescence</i> • <i>Inventory holding cost</i> • <i>Product value</i> • <i>Demand and supply uncertainty</i>
Capacity	<ul style="list-style-type: none"> • <i>Cost of capacity</i> • <i>Capacity flexibility</i>

Source: Chopra, S. & Sodhi, M. S., (2004)

The combinations of various drivers presented in Table 1 may lead to jeopardizing the functioning of supply chain. Moreover, it may also lead to increasing the risk portfolio of every company in the supply chain. If certain internal risks of one company are not noticed or do not hold importance for it, the possibility of influencing other partners in the chain is open leading to increase the risk portfolio of every company in the chain. However, companies are often not aware of risk of other companies' risks within the chain since they are out of their reach and in many cases not visible.

According to the World Economic Forum (2012) research it is determined that risks which have proven to be more significant for the supply chain are natural disasters (59%), conflict and political unrests (46%) and sudden demand shocks (44%) which are hard and almost impossible to control. After the Deloitte Consulting LLP research a conclusion was drawn that despite the tsunami's widespread impact on global supply chains, most companies are not fundamentally changing how they manage supply chain risks. Meanwhile, supply chain risks appear to be rising, driven by a variety of internal and external forces – especially globalization, which is increasing supply chain complexity and amplifying the impact of disruptions (Marchese et al., 2012).

3. SUPPLY CHAIN RISK MANAGEMENT

According to Wildemann (2006) the majority of the investigated companies expected an increased importance of risk management in the future for all areas considered. In this context Supply Chain Risk Management (SCRM) is defined as a concept of Supply Chain Management, which contains all strategies and measures, all knowledge, all institutions, all processes and all technologies, which can be used on the technical, personal and organisational level to reduce supply chain risk (Kersten et al., 2006). SCRM is very important given the new economic and industrial environment in which firms currently work (Lavastre et al., 2011). SCRM is the management discipline which combines risk management with SCM. According to Paulson (2004) supply chain risk management (SCRM) is the intersection of supply chain management and risk management (RM) and has the intention to help organizations handle the uncertainties and risks in the supply chain as it can be seen on Figure 1.

Figure 1: The intersection of supply chain management and risk management

The main connection between SCRM and RM is the overall objective with the task to help organizations understand and assess risks and take certain measures in order to decrease errors and keep business successful. The difference is that SCRM focuses on risks within the supply chain, i.e. successes and failures of the whole chain while RM is dealing with individual risks of a company. It is of utmost importance that the whole organisation is familiar with the significance of SCRM. Senior management should approve SCRM and it is necessary that organisational structures are prepared for risk management.

According to Aberdeen group (2006) survey 82% of companies are concerned about supply chain resiliency, just 11% are actively managing this risk. This action gap is one of the greatest weaknesses of current corporate global supply chain strategies. It threatens the continuity of a company's business and sets the stage for gross margin erosion due to under-managed supply chain uncertainty and risk. An emerging set of technologies and solution providers are helping companies better assess risk and create contingency plans.

Supply chain risk management has follows the same principals as risk management on the company level. The steps to be taken are presented in Figure 2.

Figure 2: Risk management steps

Every process in the company needs a separate approach regarding risk management. In addition, before the next step in risk management is taken the company needs to harmonize its activities on every level because many risks can be transferred through the supply chain and it is not possible to include every risk if we are focused on one level of the chain. The previously mentioned steps are simple and logical and they support clear decision making in order to keep risk at an acceptable level. In practice, following these basic steps can cause many difficulties in risk management. Some risks are caused due to lack of understanding the business environment and the actors in organisations who may be unpredictable, complicated or not visible enough. Most risk management systems are designated to fail because the process is implemented according to these steps without taking into account the reality. Once risks have been identified, the necessary next step is to analyse each risk individually and to determine its potential consequences (Blome & Schoenherr, 2011).

A successful supply chain risk management program requires characteristics of a newly structured approach:

- A comprehensive supply chain risk profile,
- Established risk tolerances by type of risk, supplier, commodity, etc.,
- A clear understanding of the true cost (direct plus indirect) of supply chain risk events,
- Leading key risk indicators (KRIs) along with risk scoring models that give “early warning” to potential trouble,
- Pre-defined management responses corresponding to increased levels of supplier risk,
- Risk-based pricing and performance analysis to support improved risk response development,
- Alignment of individual incentives to risk-based decisions,
- A focus on early intervention rather than crisis management (www.pwc.com, 2009)

The McKinsey Quarterly (2006) found that the actions company currently use to minimize the potential effect or detrimental events of supply chain risks include performance contracts with suppliers or service providers (54%); alerting customers well ahead of time to potential concerns (38%); redundant suppliers/product design (37%); transferring price increases to customers (35%); vertical integration (29%); currency hedges, e.g., foreign exchange (25%); insurance (20%); commodity hedges, e.g., options, collars, forward buys (15%); and other (9%). In addition, according to the Aberdeen Group (2006) survey similar results were obtained. Increase in the flexibility of the supply chain, introduction of alternative supply chains and better analyses of suppliers’ activities have proven to be most important.

To improve supply chain risk management, companies are focusing on different strategies

- increasing logistics and supply agility by ensuring alternate suppliers, carriers, route,
- improving visibility and automation of supply chain activity (Aberdeen Group, 2006),
- increase responsiveness (Sunil Chopra and ManMohan S. Sodhi, 2004)

Assessment of supply chain risk may lead to destabilization of supply chain performances and may trigger domino effects such as ballooning inventory levels, longer customer lead times that threaten sales competitiveness, or even unjustified spending of resources which go over budget due to shorter transportation time and usage of more expensive secondary transporters. By decreasing the number of catastrophic events and daily risk of the supply chain, a company may achieve greater speed and reliable supply chain on a daily basis as well as creating more stable and effective business environment.

4. CONCLUSION

Today risk management is one of the most important activities within the supply chain which has become significant due to an increasingly complex and connected business environment. Risk management should be a continuous and developing process which runs throughout the organisation’s strategy and the implementation of that strategy (THEIRM, 2002).

Companies which were lucky not to be hit by different catastrophes which took place in the last ten years must not be silent observers but they should use experiences of others for planning answers and activities in the supply chains and be prepared for new catastrophes.

Since more companies have outsourced production on distant locations the number of subjects in the supply chain has increased so did the complexity of the system and risks. A few years back managers were mostly dealing with reducing costs, price deviations and inventory management. Today, supply continuity is the main business driver. Organisations now acknowledge that disruptions in the supply chain have great impact over performance of companies and they are necessary tools and measure to for overcoming negative effects. It is necessary to exchange experiences between different subjects of the supply chain which also have a high level of awareness of SCRM. In this paper some useful methods for SCRM were presented which in practice have to be adjusted to circumstances, i.e. the company itself, subjects in the supply chain and business environment.

³University of Belgrade, Faculty of Organizational Sciences, Undergraduate, juro26@yahoo.com

Abstract: *The main purpose of the paper is to analyze the organizational level and quality of the services of public transport in Belgrade, shown through the identified quality indicators and their trends. For the third consecutive year, first-year students from the Faculty of Organizational Sciences in Belgrade are conducting scientific research, as practical implementation of the subject Production Systems. The main objective of the project is to train students for practical work in the field of engineering management business approach. The method used in this research for gathering data is the method of current observations. Our findings show that certain trends of quality indicators have been present over the past 3 years. Those that are good should be further improved, and those that are not good should be changed in order to improve the current situation in the public transport system. For that reason, a proposal of measures that could improve the quality of these services is given in the discussion part. The aim of this research was to see the actual state of public transport in Belgrade from an objective standpoint and suggest actions for its future improvement. This project shows how valuable students' research can be, and also how data gathered in this kind of research could prove to be beneficial for numerous organizations, and in this particular case, for the organizations that provide public transportation services in Belgrade.*

Key words: *Quality indicators, trend of indicators, proposals for improvement*

1. INTRODUCTION

Quality of the service involves a comparison of expectations and performance, and it is an indicator of how well a delivered service matches the customer expectations (Lewis and Booms, 1983.). Furthermore, since the Public Transportation company in Belgrade (in further text: PT) provides the service of public transportation, the organizational level is directly derived from the quality of its services. In this case, quality of the services was measured using the method of current observation. The method as well as the complete research is explained further in the next chapter.

The main task was to find and present possible trends of the identified indicators of the quality of services during three years of this research. Intersection and further analysis of noted trends are made based on that. Additionally, specific measures that could improve the quality of service, and by that the organizational level of PT, are proposed.

One of the main objectives of this project is to train the students for practical work in the field of engineering management business approach through identifying and data gathering, calculating and analyzing the indicators of PT's quality of service. For that reason, this paper also represents the synthesis of the work and study of all 1650 students who participated in the project. On the other hand, the cooperation between the Belgrade University and the domestic economy is at a very low level. Taking this into account as well as benefits which successful cooperation could bring to both sides, it is not difficult to conclude that this area has great potential. Therefore, another aim of this paper is to emphasize this potential of the communication and possible cooperation (in this case specifically, between FOS and PT).

The next chapter explains the research methodology and subsequently the findings of the research through appropriate charts. A discussion chapter is based on the findings and it represents the most

important part of this paper, since it gives an analytical overview of the gathered data. Finally, a short resume of this paper is given at the end as a conclusion.

2. RESEARCH METHODOLOGY

First-year students of the Faculty of Organizational Sciences in Belgrade are conducting a scientific research for the third consecutive year as a practical implementation of the subject Production Systems.

The method used in this research for data gathering is the method of current observations. A modified method of current observations in this paper will be based on the monitoring of specific indicators (Radojković, 2010). The method itself will be similar to the original method, since it will be based on observing time and noting certain characteristics which indicate the quality PT's services. Each characteristic will be included in the paper, i.e. on the monitoring list. The monitoring list is defined precisely and it measures and evaluates the following indicators of the quality of the services: labeling of the vehicle, punctuality of departure, the waiting time of vehicles, ride comfort, driver behavior towards passengers, hygiene of the vehicles and possible failures; these indicators are explained further in the following text.

Good labeling of the vehicle means that at least the number and the appropriate direction of the public transportation vehicle are posted on the front window as well as near every door. The punctuality of departure is measured by comparing the planned (given by the official driving schedule) and the actual time of the departure of a vehicle. This is measured only on the initial stations, where the driving schedule is explicit. The waiting time of the vehicles is the time measured with an accurate clock, from the moment when the observer arrives at a stop to the moment when he or she enters the vehicle. Ride comfort is evaluated at the moment of entering the vehicle and it has three levels: everyone has a seat, there is room for standing or the vehicle is crowded. Drivers' attitude towards passengers is evaluated through two parameters. One is the driver's will to wait for the passengers who are running for the bus (waits or does not wait), and the other is how driver is closing the door (carefully or not carefully). Hygiene of the vehicles is evaluated by looking for dust or other kind of dirt inside the vehicles or on its windows (clean or unclean). Possible failures are the vehicle's failures that occurred during the regular public transportation usage. The findings of these indicators are shown in the next chapter.

The subject of the research is measuring the organizational level and the services quality of the public transportation in Belgrade, and by that, the work of an organization – PT which brings together all the companies that provide services of public transportation in Belgrade. In the first phase, data for further analysis is collected and students form teams of three to six people, where every team member is required to use the services of PT. When using the public transportation, the student (researcher) is obliged to enter the correct and appropriate information in his/her monitor list for the public transportation line currently being used. This phase is the data gathering phase.

In the second phase, every team writes a research paper with an analytical overview based on the data collected in first phase. Later, all monitor lists are gathered and merged, and based on the complete data for the selected year a final research paper is written, which is the synthesis of every team's research papers.

The statistics of the data gathering phase is shown in the following table:

Table 1: Statistics of the data gathering phase

Year and period	Monitor lists entries	Number of covered lines	Number of students	Number of teams
2009; 09.03-22.03.	16707	158	473	113
2010; 22.03-11.04.	22537	139	636	159
2011; 14.03-03.04.	28584	142	551	146

3. FINDINGS

Diagrams showing the trend of indicators through the last three years of our research are listed below, followed by a brief analysis.

In the period between 2009 and 2011, **labeling** indicators varied between 12,42% of bad-marked vehicles, to almost 30% in 2010. Modern trolleybuses of PT improved percentage of well-marked vehicles during the year of 2011 only 8.85% vehicles from Dorcol garage were inappropriately marked.

Table 2: Labelling

	LABELLING	
	Good	Bad
2009.	87.58%	12.42%
2010.	70.90%	29.10%
2011.	77.86%	22.14%

Figure 1: Labelling

The average **waiting time** during the three years of our research is around three minutes, which is acceptable and in line with some European capitals such as Budapest or Bratislava.

When talking about the **punctuality of departure**, it is noted the highest number of vehicles departing on time was measured in 2010, more precisely 78.59% of them. Data from the year 2011 indicate that the ratio between timely departures and those that were late is 2:1. This aspect needs to be changed, since records show that during the previous years there was almost 10% more departures which were on time.

Table 2: Punctuality of departure

	PUNCTUALITY OF DEPARTURE	
	Late	On time
2009.	23.98%	76.02%
2010.	21.41%	78.59%
2011.	30.19%	69.81%

Figure 2: Punctuality of departure

Results obtained by measuring this indicator show that **hygiene of the vehicles** needs to be improved. An interesting fact is that in 2010 the trolleybuses had the highest percentage of unclean vehicles - 51.50%, while in 2011 they were the cleanest of all vehicles with only 17.59% of unclean vehicles. This progress shows that PT in Belgrade is constantly trying to raise the level of its services. Nota bene is that users of the public transport are partially responsible for this state and that adequate measures need to be taken in order to educate and influence them.

Table 3: Hygiene of the vehicles

	HYGIENE OF THE VEHICLES	
	Clean	Unclean
2009	61.60%	38.40%
2010	57.43%	42.57%
2011	60.89%	39.11%

Figure 3: Hygiene of the vehicles

Throughout the research period, data regarding **the ride comfort** have not drastically changed. In 2011, the buses were the most crowded, 26.53%. During the same year, the best situation was in trolleybuses where everyone had a seat in 53.13% of the cases

Table 4: Ride comfort

	RIDE COMFORT		
	Everyone has a seat	There is room for standing	Crowded
2009	35.60%	41.68%	22.72%
2010	37.19%	42.40%	20.40%
2011	33.10%	43.45%	23.66%

Figure 4: Ride comfort

During our research, we came to the conclusion that the **drivers' attitude towards passengers** is quite good. Many of them are willing to wait for the passengers who have missed the bus. When talking about the percentage of drivers who carefully close the door, the situation is quite similar. It is important to note that the number of drivers who pay attention to passengers is constantly decreasing. This could particularly cause problems to disabled persons, the elderly and parents with children. For these reasons, some measures should be taken in order to stop this trend, since the safety of the passengers should come first.

Table 5: Drivers' attitude towards passengers

	DRIVERS' ATTITUDE TOWARDS PASSENGERS			
	Waiting for the passengers that are running		Carefully closes the door	
	Yes	No	Yes	No
2009	89.60%	10.40%	92.76%	7.24%
2010	85.99%	14.01%	92.68%	7.32%
2011	83.34%	16.66%	90.03%	9.97%

Figure 5: Drivers' attitude towards passengers

4. DISCUSSION

This list of the proposed measures represents a synthesis of a three-year research. Implementation of the BusPlus system resulted in some significant changes. Smart cards, digital boards with the exact time of departure etc. are some of the changes proposed by previous generations that participated in the research. This is just another indicator which proves that students of the Faculty of Organizational Sciences and the employees of the PT in Belgrade think in the same direction. This fact can form a basis for future cooperation between these two institutions.

The results stated in the previous section show that certain trends of indicators exist. Those that are good should be further improved, and those that are not should be changed in order to improve the current situation in public transport system.

Number of well-marked vehicles declined in the period between 2009 and 2010, but marked a growth afterwards, in 2011. This came as a result of introducing new vehicles into the public transport system, i.e. new trolleybuses. This trend can be continued with much smaller investments. Bearing in mind that labeling of the vehicles is very important, especially to foreigners using the transport system, it is necessary for it to be on the highest level. Despite the fact that some vehicles already have **digital boards**, some drivers do not update them on regular bases, so this must be appealed to. On the other hand, problem with older vehicles can be solved by printing directions and the line number on cardboard. This is a very cheap and simple solution and we think that it should be introduced since, according to the last measures, 22.14% of vehicles were inappropriately marked or completely unmarked.

Control of hygiene is one of the most important issues when talking about measures that need to be taken, since the health of thousands of citizens depends on it. Hygiene of the vehicles is an indicator with a trend of growth in the last three years and it need to be continued. Our proposal is to employ of persons who would be in charge of controlling the hygiene of the vehicles before they leave the garage. We are well aware that this may be expensive, but the same issue could be dealt with by expanding the work duties of the drivers.

As it is mentioned earlier, the number of courteous drivers is constantly decreasing. **Education of drivers** about possible problems which could occur due to their carelessness should partially solve this problem.

Information about the consequences of the activities of the PT could easily be obtained through necessary feedback from the clients/customers. **Introducing a special phone line for customer complaints** would make problems more transparent and solved faster.

Regarding our previous suggestion, we believe that **sanctions for badly behaved drivers** would be the next logical step, and that this would give a good example that bad and unmannered behaviour will not be tolerated. Progressive punishment should be considered and taking actions that range from pointing to

bad behaviour, warning the driver, to suspending them and even firing in extreme circumstances in order to maintain the image and the high quality of service in the Public Transport Company.

Another extremely important indicator showing a decline in the past 3 years is punctuality of departure from starting stations. Considering the fact that Belgrade is one of the larger business centres of the Eastern Europe, this is unacceptable because time and time management play an important role in lives of the majority of the people in Belgrade. The big problems are that the vehicles are stuck in traffic or delayed due to construction works on roads and they cannot be on time on their starting stations and are therefore unable to admit passengers at a specified time. Another problem is drivers who not consistent with the given driving plan, and those drivers should be treated as the drivers mentioned in the previous passage. A measure that needs to be taken in order to make this work is introducing a monitoring system, a system of tracking the location of vehicles via GPS and updating the **digital boards on initial stations** (something that is being introduced right now and we welcome the change).

It is no secret that the PT has issues with charging their customers – making people buy tickets. Everyday purchases of tickets from all of the customers of the Company would significantly reduce the need for subventions (if not completely eliminate it). We hope that the sales will increase with the introduction of the new BusPlus system and new ways of controlling the tickets (not wearing fluorescent vests is a step in the right direction). Before the results are visible, our suggestion is to provide a **ticket that would last a full day**, and cost approximately 3 Euro for the employed and 2 Euro for citizens with privileged status (university students, high school students, the unemployed etc.). This could also be a good way of encouraging tourists and people that are not staying in Belgrade a long time to buy tickets and contribute to the quality of services of the Company by increasing its budget.

Another important facet to note is that the passengers also influence the quality of service; therefore our proposition is to organize different **events and projects** in order to create a stronger bond between the PT and the people who use its services. Through such actions, we hope to encourage people to treat the PT and its vehicles with more respect and to raise the quality of this service significantly if they try.

4. CONCLUSION

The project which lies in the core of this research (assessing the organizational level and the quality of services of the PT in Belgrade) is designed as an opportunity for the youngest students of the Faculty of organizational sciences to apply theory in practice during the semester of attending the classes in Production Systems. Three years since its start – it has become a very serious project.

By participating in the project, the PT would have the benefit of influencing the way research is conducted and give suggestions for new parameters that could be marked in the future. Students-researches would gather the required data that could help the company complete its own reports and in return they would get precious experience of working in a team, gain practical skills in the field of engineering management of business systems, and they could feel that their work is making an impact which is very important for their motivation in future ventures. If this cooperation does occur, every citizen of Belgrade would greatly benefit from it through the upgraded quality of services of the public transport.

The aim of this research was not to point to the flaws of the PT or to criticize their work, but to see the actual state of the public transport in Belgrade from an objective standpoint and suggest actions for improvement in the future.

The data put forward is a clear indicator that the PT has worked over the past three years on maintaining the quality of its services. Considering the planned changes that are currently underway (e.g. introducing the new line of trams or the new ticket system) and the innovations that have been announced, we expect improvement in the markers for the following years and continual growth and impact of the company.

Another important note is that through events and certain actions, the Company could cooperate with the citizens of Belgrade on increasing the awareness of importance and the impact of their actions when using the services of this company. This company is important for many people living in Belgrade (and the vicinity) therefore better behaviour and a more understanding from the everyday traveler would significantly help the company, that will most certainly know how to repay it.

PUBLIC TRANSPORT KEY PERFORMANCE ANALYSIS IN RUSH HOURS

Milica Vučić¹, Adam Kovač²

¹University of Belgrade, Faculty of Organizational Sciences, Undergraduate, mima_1001@hotmail.com

²University of Belgrade, Faculty of Organizational Sciences, Undergraduate, adamzp7@gmail.com

Abstract: *The paper is aimed at presenting and analysing ride comfort of public transportation in Belgrade with a focus on ride comfort during the morning and the afternoon rush hours. First-year students of the Faculty of Organizational Sciences have been gathering data for three years, from 2009 to 2011, and the paper is designed to show trends of the ride comfort indicator during these three years, to propose measures that can be taken to improve it, and to show the potential that this kind of research has. The method of current observations was used for gathering data in the first phase of our research, which were later analysed through the remaining 2 phases. The data and the conclusions made could be of use to the Public Transport of Belgrade, with one of the key conclusions being that the afternoon rush hour is a period of day when ride comfort is at its lowest and the majority of efforts should be focused on improving it.*

Key words: *ride comfort, afternoon rush hour, morning rush hour, proposals for improvement, trend*

1. INTRODUCTION

Students of the first year of Faculty of Organizational Sciences in Belgrade, for the third consecutive year, are performing a scientific research, as a practical application of the subject "Production Systems". The subject of the research is measuring the level of organization and quality of the services of public transportation in Belgrade, and by that, a work of an organization called Public Transport "Belgrade" that brings together all the companies that provide services of public transportation in Belgrade.

Quality of the service involves a comparison of expectations with performance and it is a measure of how well a delivered service matches the customers' expectations. Furthermore, since the PT "Belgrade" provides the service of public transportation, the level of organization, is directly derived from the quality of its services. In this case, quality of the services was measured using the method of current observation and more about that method and the complete research as well, is explained in the next chapter.

In this paper, focus is on the one aspect of the quality of the services - ride comfort. This identified indicator is probably the most important, from the customers' aspect, in these case passengers of PT. In addition to other indicators that are measured and analyzed, the largest number of users at the peak, ride comfort has been selected as the key performance of public transport services.

One of the main objectives of this project is the training of the students for practical work in the field of engineering management business approach, through the identification and data gathering, calculation and analysis of the service quality's indicators of PT. On the other hand, the cooperation between the Belgrade University and the domestic economy is at a very low level. Taking into account that, as well as benefits, that successful cooperation could bring to both sides, it is not difficult to conclude that great potential lies in this area. For this reason, another goal of this paper is to point out that potential of the communication and eventual cooperation (in this case specifically, between FOS and PT).

The next chapter research methodology will be explained and after that, findings of the research will be presented, through appropriate charts. Based on the findings, a discussion chapter is made and it represents the most important part of this paper, because it gives the analytical review of the gathered data. As a conclusion, short resume of this paper is given in the end.

2. RESEARCH METHODOLOGY

The actual research is conducted since 2009 and it should be noted that participation in the research is not required, but due to certain awards and benefits that it brings, many students decide to take that step. In the first phase, data for further analysis is collected and in it, students form teams from three to six people, where every team member is required to use the services of PT. When using the public transportation, student (researcher) is obliged to enter the correct and appropriate information in his monitor list, for the public transportation line currently being used. Method used in this case is the method of current observations. This phase is called data gathering phase.

Modified method of current observations in this paper will be based on the monitoring of specific indicators (Radojković, 2010). Method by itself will be similar to the basic method, because it will be based on time observing and notifying certain appearances and characteristics that represents the quality of the services of PT. Each appearance will be put on the paper, i.e. on the recording list. Recording list is defined precisely and it measures and evaluates the following indicators of the quality of the services: representation of the vehicle, the accuracy of vehicle starting with the initial station, the waiting time of vehicles, ride comfort, driver behavior towards passengers, cleanliness of vehicles and possible failures.

Focusing on ride comfort during the morning rush hour from 07h to 09h and afternoon rush hour from 13h to 17h; findings, along with the detailed analysis, followed by appropriate charts, are given. The quality of the ride comfort, is measured as concentration of passengers in the public transportation's vehicles and it is embodied in three levels:

1. Everyone can sit- the highest level of the ride comfort
2. There is a room for standing - intermediate level of the ride comfort
3. It is crowded- the lowest level of the ride comfort

It should be pointed out that ride comfort is evaluated by the students (researchers) in the moment of entering the vehicle.

However it should be noted that data for this indicator is very sensitive in the case of major traffic jams and should be taken with a grain of salt. This is because in the monitoring period, especially in 2009 and 2010, there were major construction works on roads and unexpected situations (such as strikes, visits of foreign officials...) that would create traffic collapses, which distort the real picture of the ride comfort indicator.

Statistics of the appropriate data gathered for the need of this paper is given in the next table:

Year and period	Number of monitor list's entries			Lines covered	Number of teams
	Morning rush hour	Afternoon rush hour	Total		
2009; 09.03 - 22.03.	1786	5289	7075	114	113
2010; 22.03 - 11.04.	2606	9138	11744	139	159
2011; 14.03 - 03.04.	2343	10195	12538	135	146

3. FINDINGS

We wanted to analyze each segment (Everyone can sit, there is room for standing and its crowded) of our marker - Ride comfort, and compare how they changed through the three years of research that we conducted. The next three graphs that are created with a purpose to compare the values of morning rush hour with the afternoon rush hour, and to compare them individually to the average values we have calculated from the entire research – overall comfort.

The Figure 1 below is showing data for the "Everyone can sit" marker from all three years of research, comparing the morning rush hour, afternoon rush hour and overall comfort side by side. This marker is referring to a case of ride comfort when the vehicle is the least crowded and every person can sit.

Figure 1

The Figure 2 on the next page is showing data for the “There is room for standing” marker from all three years of research, comparing the morning rush hour, afternoon rush hour and overall comfort side by side. This marker is referring to a case of ride comfort when the vehicle is moderately crowded, not everyone can sit, but people don’t feel uncomfortable standing.

Figure 2

The Figure 3 below is showing data for the marker – “It’s crowded” from all three years of research, comparing the morning rush hour, afternoon rush hour and overall comfort side by side. This marker is referring to a case of ride comfort when the vehicle is the most crowded, people aren’t comfortable during the ride because of the number of people that are around them, and it is also difficult to get in and out of the vehicle.

Figure 3

The Figure 4 below is showing data for the morning rush hour ride comfort with all three years included side by side listing the average percentage for each of the markers – everyone can sit; there is room for standing; it’s crowded.

Figure 4

The Figure 5 below is showing data for the afternoon rush hour ride comfort with all three years included side by side listing the average percentage for each of the markers – everyone can sit; there is room for standing; it's crowded.

Figure 5

4. DISCUSSION

This section shows the research results and their analysis. Also, it contains a section with proposed set of measures for solving problems of crowded vehicles and comfort in rush hour, as well as examples of European cities where these measures are successfully implemented.

Looking at the Figure 1 for the first segment some trends was noticed:

- Average difference in percentages- 6,43% in favor of the morning rush hour over afternoon rush hour comfort, when looking at this marker which is representing the desired way to travel in PT
- Year when the Everyone can sit marker was at its peak is 2010, and the service was the best considering ride comfort.
- Average difference between the values of comfort in the morning rush hour and overall comfort is 2.45% - the values of morning rush hour are affecting the average comfort in a negative way but, the difference is showing a decreasing / positive trend over the years (3.6% was the difference in 2009, 2.9% in 2010 and most recently in 2011 the difference was only 0.9%).
- Average difference between the values of comfort in the afternoon rush hour and overall comfort is 9.03% – the values of afternoon rush hour are affecting the average comfort in an extremely negative way but, the difference is showing a decreasing / positive trend over the years (10.1% was the difference in 2009, 9.1% in 2010 and most recently in 2011 the difference was 7.4%).

Looking at the segment of Everyone can sit, the morning rush hour values do impact the overall values of comfort, but not in as much as the values during the afternoon rush hour (this is not just about

percentages which ratio is almost 1 to 4, but also about the number of observations – there are a lot more observations in the afternoon period, roughly about 3 times more over the three years).

The marker “There is room for standing” is shown in Figure 2 and is related to the state where not everyone can sit in a vehicle, but people feel comfortable even while standing, and the reasons for invading other people personal space are few and this occurrence is rare.

Trends that are noticed while analyzing this data:

- Average difference between comfort in the morning and the afternoon rush hour is 2.8%, considering this marker, with the morning rush hour being the better of the two – again.
- In the 2011 - the year with the highest percentage for this marker (with a rising trend), but it is not considered as a “winner” simply because the nature of this marker is to be between the desirable and the undesirable marker, hence its increase must be interpreted in correlation with the changes that happen to the other two markers - no clear conclusion.
- Comparing the morning rush hour comfort and the overall comfort it can be seen that there is very little difference between them, and until we analyze the third marker – It’s crowded we can only suspect that the ride comfort isn’t impacted by the morning rush hour as much as it would be expected.
- Average difference in percentages between the afternoon rush hour and overall comfort is 2.37%.

This marker is a mediator between two extremes – “Everyone can sit” and “It’s crowded”. Making this marker a part of research was needed as another possibility / choice, when the students are undecided, and it shows that in more than 40% of cases people even thought they can’t all sit, they don’t have to think about hurting someone if they try to move, or feel claustrophobic.

The Figure 3 is showing the percent of vehicles that were crowded, and even though its subjective it usually refers to situations in which a man doesn’t have freedom of movement inside of a vehicle and only the lucky few have the chance to sit down.

Taking a look at this graph here is a draw of several conclusions:

- Average difference between comfort in the morning and the afternoon rush hour is 3.43%, considering this marker, with the morning rush hour once again being the better of the two.
- It was implied that the year 2010 might have been the year in which the comfort was at its highest level of the three while analyzing the first graph, and this assumption is confirmed.
- Looking only at the overall comfort and the comfort during the morning rush hour it can be seen that there is a peak in 2009, but the values are getting closer in the last two years, further raising suspicion that the comfort in the morning rush hour is striving for the overall values, and as such being less different (less worse) than any other time of day (excluding the afternoon rush hour). This is hinting that the increase of number of vehicles in the morning rush hour isn’t as needed as in the afternoon.
- Another big difference between the overall comfort and the comfort during the afternoon rush hour - 6.6%, and again a negative impact of the afternoon rush hour time interval on the rest of the day.

Differences between rush hour and overall data were expected however there has been an odd trend that we noticed. The morning rush hour is offering very similar ride comfort to the ride comfort overall – it is showing few deviations. On the other hand ride comfort in the afternoon rush hour is evidently worse than overall ride comfort and we feel that it should be the main focus of measures that we are suggesting.

Based on the analyses of daily use of services of PT, a set of measures has been given that should improve efficiency, driving comfort during the afternoon rush hour.

Also it should be noted that earlier this year Bus Plus system was introduced, with a numerous innovations such as smart cards, monitoring systems, digital panel for the exact time of arrival and more that have contributed to improving the overall quality of the services of PTC. The introduction of these innovations is not covered by this paper, but some of our ideas (proposed measures for improving service quality) are coincide with the introduced Bus Plus benefits. This is the clear sign, that the students who have participated in this project think in the same direction as the management of PTC, which could prove to be the good basis for future cooperation.

In addition to these measures implemented, it is important to point out that vehicle hygiene should be improved to a higher level. Therefore, controllers of cleanliness should be appointed. As for the jams and the need to increase the number of vehicles, based on statistical data on the level of use of certain lines, PT started increasing the number of vehicles. Recently announced was the increase of number of vehicles on 9 lines, one of them being 33 which was observed as a crowded line in 44% of cases during the afternoon rush hour in 2011, and 31% during the morning rush hour. The PT added vehicles to this line based on data they received from the Bus Plus system. This line was problematic and it deserved more buses on it, however from our data we can see that there is one line that has been neglected – line 50 with around 50% of cases during rush hours being noted down as crowded in the year 2011. This an example that shows the potential for practical use of the data the students gathered.

The following set of measures have been proposed:

Considering that the metro transports a large number of passengers in a relatively short time, building one in Belgrade would reduce the number of vehicles on the streets during morning and afternoon rush hours and achieve the desired traffic relief. It is very important to establish an integrated system of metro-tram-bus in order to reduce time used for transport. As for the passengers, they would reach their destination faster and a lot cheaper considering the price of fuel today. The ecological component of electricity is very important – the use of electricity as fuel instead of the exhaust of the harmful ozone from vehicles. An excellent example is Paris with 12 million inhabitants, where the daily subway transports 4.5 million passengers.

Transportation across the rivers Sava and Danube was briefly present in year 2008. This form of transport should continue to be used by building the stations that are close to more important places in the city and activating the regular lines with an acceptable transport price. This type of transport links Zemun, Borča, Čukarica and Novi Beograd. The main aim of this transport is partial reduction of traffic jams on the streets and reviving the rivers that attract tourism. This kind of transport is very common worldwide. Cities like Amsterdam, Bangkok, Cape Town, Chicago, Dubai, Copenhagen, Hamburg, Istanbul, and especially London all boast with this kind of transportation. In London, this system is particularly developed and there has been an increase from the year 2000 until year 2009, from 2 to 5 million passengers on board. Further promotional campaign would help bring this form of transport into focus as a better alternative.

Increasing public awareness of the utility of BGVOZ, and as a major boost to usage of this kind of transport should be a higher frequency of departures, this way lessening the time of travelling compared to trams and buses.

BGBIKE is an idea that has been around for some time now and it would be structured as an organized network of bike rent. Bicycle rental stations would be placed on all frequent places in the city, covering the entire city. It is necessary to build and mark cycling routes and provide parking space. The goal is to reduce the number of vehicles on the streets, maintain the health of citizens and environment protection. Payment could be organized on a daily or monthly basis or per hour. In many cities around the world this type of transportation is applied and widely used: Barcelona, Amsterdam, Vienna, London, and Paris. We can take Copenhagen as an example, where 35% of the population rides bicycles to work or school, and when it comes to the citizens of Copenhagen the percentage goes up to 50%. People opt for this form of transportation mostly because it is healthier and cheaper.

To improve the vehicle fleet of PT- First of all, it is necessary to remove old buses, trolley buses and trams from service because they are slow and uncomfortable, and their breakdowns can often create traffic jams.

It is proposed that during traffic jams, PT supplies additional buses from the garage in order to accelerate the transport of individuals who are excluded from the traffic. It would be desirable that apart from the line 15, some other lines be supplied with popular double deck buses, primarily lengthy lines and crowded ones.

Building of a large capacity garage with parking spaces for cars. A significant number of drivers in jams is seeking for a parking place, a number of which exists particularly in the old part of Belgrade.

In Europe. Some other measures in addition to those above we would like to see introduced by the PT: CMS (COMFORT MEASURING SYSTEM). A Comfort Measuring System for Public Transportation Systems exploits the GPS and G-sensor of modern smart phones to measure the comfort level of vehicle rides. Then, it mashes up the sensed data (e.g. locations, acceleration, and time) with the authorized data (e.g. bus trajectories, and vehicle properties) of the public transportation system, and provides a detailed comfort statistics as a value added service. A CMS, called TPE-CMS is used to evaluate the public bus transportation service in Taipei City and it is applied in 4.028 buses and 287 routes. The CMS system can be deployed in any city, as long as there are participants volunteering and there are authorized transportation data available.

BRT (Bus Rapid Transit). BRT is a term applied to a variety of public transportation systems using buses to provide faster, more efficient service than an ordinary bus line. The goal of these systems is to approach the service quality of rail transit, while still enjoying the cost savings and flexibility of Bus Transit. The BRT is used in America, Europe, and Australia.

Implementation of the ISO 2631 standard which regulates vibration and comfort during the ride and the European standards EN 13 816, whose aim is to promote the approach to the improvement of quality of transport, focusing on customer needs, since driving comfort is one of the most important determinants of quality.

Different regulatory strategies to limit the movement of cars in a given time and space and using public transport in order to reduce traffic jams.

Investments in safety and security of passengers.

The most important thing to note is the fact that an improved city public transport is a prerequisite of achieving greater energy efficiency and provide better accessibility, as well as systematic monitoring of the behavior and needs of travelers for greater traveler satisfaction.

The key goal of the proposed measures is for PT to become fast, frequent and reliable and to achieve ride comfort for passengers at affordable prices with some reference to the environment. Implementation of these measures would achieve the desired relief in rush hours and uniform distribution of transport. This would increase the ride comfort of passengers, as well as raise the protection of the environment to a higher level.

CONCLUSION

Many of the measures that were proposed during the three period of research have so far been implemented thanks to the officials of public transport who showed great understanding for the needs and complaints of their users. Those measures were: replacement of outdated vehicles with new vehicles, improvement of bus stations and the introduction of monitoring systems in vehicles that includes a system for monitoring vehicles which compared to international standards is one of the most important for solving traffic jam and electronic payment system cards.

Three years of data for ride comfort have been analyzed from two rush hours and compared between them and the overall data. One of the most important conclusions is that actually the afternoon rush hour is a considerably bigger problem than its morning counterpart. Therefore new measures should be targeted to decrease the number of crowded vehicles in the afternoon rush hour by encouraging people to use alternative means of transportation such as trains - BGVOZ, reinstating the river bus, or investing in metro or bicycle-rent stations considering we have a developed bicycle track infrastructure in some parts of the city. Another suggestion is to increase the percentage of vehicles that operate in the afternoon rush hour if the percentage isn't already a hundred. An obvious solution that is being gradually implemented - increasing the number of vehicles that PT has at its disposal. Cooperation with students of Faculty of organizational sciences with PT would be of great benefit to both sides considering the data that this kind of research can provide, the money it can save for PT, and the feedback that PT can offer to the faculty, not to forget the experience the students acquire working on a project of this scale.

²PE PTT Communications Serbia

Abstract: *This paper is focused on measuring the process and development of synergistic effects of joint networks on the provision of postal services and other public services, state and local governments. Individual contribution of each participant in a synergistic chain, in terms of quality, time, network costs (i.e. efficiency and effectiveness of the network) were measured. The aim of this paper is to indicate a new approach in determining possibilities of achieving synergistic effects of partnerships between the public postal operators, state and other dominant economic entities in the RS in order to improve overall business performance and contribute to the progress of a wider social community. In the preparation of this paper, as well as in our previous studies, we used concepts of marketing management in businesses which bring focus of all key business activities on users and successfully manage relationships with them, Key Account Management (KAM), the modern concepts of the Theory of solving inventive tasks (TRIZ) and methods of fuzzy logic. The results are clearly presented and indicate the need to achieve long term synergistic effects of the activity of various participants in order to meet the need and demand for a universal postal service (hereinafter UPS) and other services of wider social and economic importance.*

Keywords: Synergy, network, post office, local government, key customers, UPS, business performance

1. INTRODUCTION

The Post of Serbia, as the oldest and only public postal operator (hereinafter referred to as PPO), provider of UPS² in the postal services market in the Republic of Serbia (RS), successfully responds to new business challenges and the need for the traditional company to develop into a successful business system, which, integrated into/with worldwide postal flows, contributes to the overall national development. Under conditions of rapid changes in business environment, deregulation and liberalization of the postal market, the postal services are required to adjust urgently to the market, redefine their own mission, vision, goals and develop modern strategies contributing to the provision of fast and efficient response to customers' request - both through enforcement of existing innovative services and new services based on informational technologies. Having chosen the marketing business orientation which puts their customers in the center of all key business activities, that is, providing their customers with customized services, the postal system opts to commercialize the postal service, committing themselves to the long term business success, stability and development of the system and personnel, while creating joint value for customers, the postal system and society as a whole (Ožegovic, 2005). Business network of Post of Serbia is the largest infrastructure and logistic network in RS. Postal network consists of postal network units (post offices) and other resources used by UPS provider in the performance of postal services. Post offices provide their access services of great significance to citizens and economy, especially in rural and underdeveloped areas. The post offices provide over 400 different types of services which contribute to development of businesses and gives service and support to vulnerable strata of the population (retired people, socially endangered). Post offices contribute greatly to the development of local communities, particularly their role in conducting postal operations and financial transactions³ (Kujacic, Sarac: 2011). Results of the research represent that postal units' managers and the Post's brand identity enjoy an exceptional level of public confidence. With the purpose of complex understanding of the development level of postal market in the RS and neighboring countries, the tables set forth represent the following: Table 1. Size of national market of postal services in the RS; Table 2. Comparative data/Comparison of PPO with other neighboring countries.

¹ This paper resulted from research project funded by the Ministry of Education and Science of the Republic of Serbia, under the name of "Reengineering the operator network of the universal postal service, with the organizational synergy of governmental and economic resources" (TR36040).

² According to Law on Postal Services (2005, 2011), UPS is a service of public interest, and represents a group of postal services which are constantly conducted on the RS territory under equal conditions for all customers, within the prescribed quality and under reasonable prices.

³ Results of the 2011 survey, on the sample of a thousand examinees, represent that postal-financial services have a key role in answering the citizen needs throughout the RS.

Table 1. Size of national market of postal services in the RS (year 2008)

Market segment	Volume (millions of items)	Volume represented in % (per services)	Income (mil. EUR)	Gross income represented in %
Basic(postal) services	302,374	63,06	86,83	42,58
Financial services	134,67	28,15	60,87	29,85
Other services	42,167	8,79	56,21	27,57
Total	479,508	100,00	203,91	100

Table 2. Comparison of the postal market development in the RS and neighboring countries

Country	km ²	Population (millions)	Item per citizen	Letters/km ²	Number of PPO's	Area in km ² / PPO	Average number of citizens /IPO
Austria	83.858	8.361	577	57,544	1.912	43.86	4.388,73

Key parameters and goals in the standards of quality of postal services, in both domestic and international postal traffic which a provider of the UPS in the RS has to execute are represented in the table 3. The results of measuring the quality of transfer deadlines in the Post of Serbia in the year 2010, according to J+3 and J+4 indicators are: J+3(63,5% OUTGOING, 71,2 % INCOMING); J+5 (95,5% OUTGOING, 94,3% INCOMING). The following represents the aforementioned.

Table 3. The aim of quality – time of transfer in the RS

Domestic traffic		International traffic	
Letter	Package	Aeroplane i high priority registered items - Europe	UPU
90% - 2 days	85% - 2 days	85% - 3 days(J+3 speed indicator)	65% - D+5
98,5% - 4 days	95% - 4 days	97 % - 5 days (J+5 reliability indicator)	
99,5% - 7 days	99% - 7 days		

The deadlines don't include the day of the receipt, days when the PPO's not working or delivering, and state holidays.

The criteria for opening postal network units and setting up mailboxes are regulated by Te Republic Agency for Postal Services. Provider of the UPS in the RS is obliged to follow these criteria, i.e. table 4 and 5.

Table 4. The Criteria for opening a postal unit in the RS

Number of households	Distance
> 1300	> 2 km to administrative border to the nearest PO
> 1300	> 5 km of group of settlements to the nearest PO
3000-12000	> 2 km to the new PO, per 3000 households
12000-36000	> 1,5 km to the new PO, per 4000 households
36000-100000	> 1,25 km to the new PO, per 6000 households
> 100000	> 1 km to the new PO, per 7500 households

Source:www.rapus.rs

Table 5. Criteria for setting up of mailboxes

Population	Remark/comment
> 1000	rural area
< 1000	more than average unregistered items a day
< 200000	one per 5000 inhabitants
> 200000	one per 10000 inhabitants

Source: www.rapus.rs

In rural areas and in some less developed urban areas, post offices play a key role in maintaining and contribution to improving of local communities. They regularly provide support and advice to endangered social groups. This socially important role of post offices - in addition to their responsibilities for the execution of services in the field of the UPS, and commercial functions outside the scope of services of the UPS – is highlighted by many local communities throughout the RS.

2. MODERN MANAGEMENT CONCEPTS AND INNOVATION OF THE POSTAL NETWORK AND SERVICES

Postal network, like the other distributive logistics industry is trying to adapt to business environment which is changing rapidly, but to also encourage the developmental processes (Ozegović, 2010). Customers expect a

high standard in the quality of service, highly professional staff and modern facilities in which those services are provided. Technology and communications and other modern trends in the market bring completely new ways of doing business and lead to further transformation of lifestyles and user preferences.

The network came to increasingly rely on a relatively small number of courses of business that bring the highest revenue. The results of previous studies show that the Post has to optimize the potential of the network, creating opportunities for new business directions and cooperation with local government and industry, as well as through the development of: joint cooperation in the exploitation of the postal network; information society and electronic commerce, postal and local infrastructure as the basis of other economic activities (Kujacic et al,2011). Many post offices in rural areas face a decline in traditional lines of business and show signs of unsatisfactory business performance and investments which last for years. The situation is similar with other public enterprises and institutions which operate their activities in rural areas. The consequences of decline in traditional lines of business will be more serious in the future due to the inevitable intertwining of urban and rural network, while new business lines could replace most, if not all of the lost revenue. Generally speaking, there is no discrepancy between the commercial objectives of the Post and the social role of the postal unit in urban areas. The modernization of the network will be of use to the local communities by creating a modernized post office with redefined services, i.e. with better services to fit with the customers' needs and expectations. Restrictions in postal commercial freedom in urban areas, could pose an obstacle to a substantial modernization and development of modern business strategies that are more than necessary for the postal network and the postal system as a whole (e.g. relationship with strategically important customers).

2.1. Resources and network accessibility

Providing spatial, personal, financial and temporal availability of PPO network (Serbian Post Office), does not allow the Post its full economic independence. It was noted that the postal network does not provide equal access to all areas of the RS. In some administrative districts more than 7,000 people come to one unit of the postal network. Delivery to a large number of households is not performed daily. Delivery to a wider delivery area is done 2-3 times a week, while to an even broader area only once a week (Table 6).

Table 6. PPO delivery area in the RS (2011)

Type of delivery area	Population coverage by type of delivery	Estimated distribution of items on delivery areas (from - to)	
NARROW	68%	80%	92%
WIDE	21%	15%	6%
WIDEST	11%	5%	2%

Source: Statistical data of the Post of Serbia, www.posta.rs

In Vojvodina, on average, every town has a post office, while in some regions of the RS one post office covers 10 towns or villages. It has to be emphasized that along with the work of postal mail delivery services, other instances, such as municipal governments, local governments, businesses and public companies engage their employees for the same purpose. Table 7 represents data for 16 municipalities (268 populated areas) from different regions of the RS, which were part of a survey in year 2011. In these municipalities 143 couriers are permanently employed. The average monthly number of items which are delivered solely by local communities and offices in these areas, compared to the number of items delivered by post, range from 10 % to 20%.Exception to this average happens during the months when delivery of large quantities of items takes place. Such items are: voting invitation, utility bills (periodically in small towns), etc. In period of increase in volume of shipments generated by local communities, local administration,public enterprises and other economic entities,additional manpower is hired for delivery of their shipments (usually through youth services cooperations).

Table 7. Information about delivery services in 16 municipalities in the RS

Towns /area	Local Community – LC				Local Community Offices - LCO			
	Number of deliverymen in LC	Number of employees in LC	Number of items delivered through the Post of Serbia (monthly)	Number of self delivered items (monthly)	Number of deliverymen in LCO	Number of employees in LCO	Number of items delivered through the Post of Serbia (monthly)	Number of self delivered items (monthly)
268 /16	89	205	26713	2421	54	162	13515	2085

Based on statistical data of the Post of Serbia (www.posta.rs) we were able to partially determine present efficiency of the postal network. Some relevant data is missing to determine efficiency (operating income and expenditures). Conclusions drawn from the results of the study are based on the recording conducted in the period from 01.01.2011. to 31.12.2011. Large number of delivery post offices is located in rural areas. The results of these studies have shown that a large number of mail delivery has several times more items in the final stages of delivery than in the receiving phase, indicating the need for allocation of income, based on the application of cost accounting systems.

2.2. Evaluation of the effectiveness and the possibility of innovation of PPO network and services

In the absence of available data, we have conducted a comprehensive research survey related to measuring and forecasting the efficiency and effectiveness of the PPO network and other networks of general interest, as well as their synergy effects which made the research much more complex. In order to make this research more efficient and effective, its presentation needs to be simplified. In order to select optimal solutions for the synergy of resources and services of the post office with the state, local governments as well as the businesses (which were set up by the state and others), public companies and other major participants, we have chosen to apply modern concepts and methodology that includes: fuzzy logic, TRIZ and the modern concept KAM. Input values set for the set model are: cost effectiveness, availability and productivity of the observed mode of organization of postal activity, network and services in a defined area. The term of cost effectiveness entails the relationship between achieved output and total expenses incurred in its realization. In order to determine cost effectiveness of postal network units providing services to its customers, it is important to accurately define the income which is generated in the observed unit, based on the performed activities during the phases of transfer of items. **Availability** as an input entry is very important parameter in our studies⁴. The term availability implies that the PPO connects all populated areas in the country as to provide its services to all customers, both in domestic and international postal traffic. **Productivity** as a parameter has been introduced to determine the "real value" of output produced per unit of time. This method, which has enabled the inventive approach in creating alternative solutions in synergy of resources, networks and services, is known as **TRIZ**. Application of TRIZ made a major break through in the selection of alternative solutions for the delegation of resources of state governments, local governments, the Post and other participants in the synergetic chain (Sarac, et.al, 2011). Using the principles of the TRIZ, system characteristics and the matrix of contradiction we have come to the new, innovative solutions, which have not been exploited yet.

2.2.1. Forecasting the need and demand for the UPS

Forecasting the demand for postal services – especially letter post, has always been one of the major preoccupations of postal administrations around the world. Given that it is an essential element of strategic planning, it is essential to evaluate the factors that have a decisive impact on the operations of postal operators. According to research conducted at the Universal Postal Union - UPU, the greatest impact on the volume of postal services impose economic factors (45%), followed by postal (24%), social (21%) and technology (10%). According to the UPU, by using certain econometric models, an increase of 1% BDP can influence the increase in the volume of letter post services between 0.8% and 1%. Observing the period of the past 6 years, even in the market of the postal services in the RS, this rule was confirmed where the ratio is even higher in favor of postal services growth (1.06%).

2.2.2. Expected development of competitive relations in the market of postal services in the RS

In the market of postal services in the RS, the competition which is becoming more and more intense has been noticed, especially in the most profitable parts of this market. Competition in the market consists of more than 200 businesses that annually perform more than 320 million of services. In line with the current trends in the global market primarily related to the process of deregulation, controlled and gradual liberalization of the postal market, the changing needs of users of postal services, as well as the need to stimulate the competition, growth in number of participants in the market of postal services is expected in the RS. Under new market conditions which include a precise definition of the status of each of the participants in the market of postal services, the Post of Serbia is positioned as the PPO which includes universal access to basic services for the entire country. On the other hand, as the market situation is becoming more intense and uncertain, the Post has to take its position through intense innovation of existing and by introducing new

⁴In addition to territorial availability, in subsequent research we will include a personal availability as an input.

commercial services in accordance with the need and demand. Thus, become both a national leader and regional leader in the contemporary market of postal services. Some of the results of market research and the analysis of competition indicate that an intense development of competition on one hand, and the size of market segment covered by select group of business users on the other, impose the need for key activities planned directly at strategically important business users with the possibility to achieve synergetic effect through development and maintenance of long-term profitable business relationships. *The development of modern strategic multi-phase business concept and strategy for key account management in the postal services companies, governmental bodies and local government can provide the opportunity for the long-term business prosperity while simultaneously contributing to the development of the society as a whole.*

2.2.3. Marketing business orientation and business performance as a framework for realization of synergistic effects of partnership

Traditional business concepts give way to modern concepts which are focused on customers and managing the relationships with them, which directly contribute to the improvement of company's business performance. Marketing business orientation is one of the major research topics in the field of marketing management in the past ten years. In order to stay on dynamic market, modern companies have to develop strategies that can ensure the survival, growth and development. In that sense, the companies are developing business relations with suppliers and distributors, investors, customers and other key players in the market. Studies conducted in recent years point out the factors which favour the efficiency of certain approaches to relationship marketing. Studies conducted in recent years indicate factors that favour the efficiency of relationship marketing approach. This shift towards relationship marketing brings new management philosophy – **KAM**, as one of the most important strategic marketing management trends in the last few decades (Conlon, Napolitano, Pusateri, 1997). This modern business concept represents strategy, philosophy, discipline and commitment of modern companies. It can be said that the strategy of key accounts management represents a way for successful development and maintenance of long term profitable relations with key customers. Philosophy focuses on achieving a satisfactory growth level of profitability of key customers and company. Discipline is largely focused on differentiated advantage over the competition, while the requirement for the modern companies involving management of the key users comes down to devotion to this management by the company which represents one of the key factors to its success. (Ožegović, 2010).

2.2.4. Key Account management and processes of identification, selection and categorization of key customers in specified areas

Moving the focus from individual transactions to relationships and Relationship Marketing (RM) and acceptance of customer heterogeneity with respect of the values given to the company, it resulted in emphasizing joint importance of marketing theory and practice. The two key changes have contributed to the rapid development of relationship marketing (RM) importance which is based on modern business concept of KAM. In contemporary business concept of key account management, studies have verified existence of a seller's need for greater investment in key customers and delivering values that meet and exceed their needs and expectations, while having the mutual benefit. In order to implement the project TR 36040, survey has been conducted from April 1st to May 31st 2011. Research in attitudes of business users (primarily municipalities, local communities and legal persons which are the founders- communal organizations) in terms of quality, competitiveness of the postal services used, cost of service and delivered value ratio and the overall satisfaction level in doing business with the Post, has been conducted in the selected area covered by 8 municipalities in Vojvodina. Nevertheless, our goal was to answer the underlying question whether they would recommend the Post to its clients, as the expression of highest level of trust and commitment to the relationship where the customer becomes an advocate of the service providing company. The results of the research and analyzed factors that have a significant impact on the key account management are given in the following review, Figures 1a, 1b, 1c, 1d, 1e.

Figure 1a. Quality assessment of postal services

Figure 1b. Postal services price to quality ratio

Figure 1c. Level of customers being informed

Figure 1b. Quality assessment of postal services

Figure 1d. Presentation of a research of customer satisfaction in cooperating with the Post

According to research conducted for needs of this paper it can be concluded that about 30% of the total volume of postal services is conducted in underdeveloped areas, mostly rural areas where enforcement of Postal Services requires higher costs. For such reasons, organizational types of postal network and the postal services itself are generally unprofitable in rural areas (Ozegovic, 2010), indicating the need for applying modern organizational models of association of related business areas, establishing and developing long term business partnerships that generate synergistic effects both for companies involved in the process of exchange and the community as a whole. As a method for this type of analysis, we have developed a model of customer value. The development of this model reflects the clear intention of managers of modern enterprises to build, maintain and promote good and lasting relations with their most important customers. The emphasis is on profitability of long term business relationship, but not on the optimal revenue, i.e. profit per individual transaction. For these reasons it is very important that in the postal traffic, KAM is treated as a process of building long term strategic partnership relations that result in synergetic effects, rather than the responsibility for sales. The proposal of strategic multi-phase model of KAM in the postal traffic, also known as "PostAIM" (Ozegovic, 2010) will be presented through a simulation of one of its parts related to the segmentation and categorization of customers and the possibility of its practical application in the selected company, the Post of Serbia. In terms of purposeful use of postal services, three basic segments of consumers can be extracted: State, social and other public institutions; Legal person; Individuals (citizens).

A preliminary categorization of customers in the selected area could be carried out by customer classification into A, B and C category by using the known Pareto 80/20 rule. In determination of criteria of identification, selection and categorization of strategically important customers, key customers, that is customer value for

the selected company, we have used the following criteria: profitability of key customer, share in revenue from sales, attractiveness. In formulating the model for segmentation and categorization of customers, we started from the fact that the value delivered to key customer is critical for the KAM (Pardo et al., 2006). The proposed model "PostPPA" – a basic model for calculating the value of customer (V_k) as a basis for segmentation of customers in postal services companies, can be represented with the following (Ozegovic, 2010)5:

$$V_k = \sum_{i=1}^n t_i \cdot p_i \quad (1)$$

where the following stand for:

t_i – weight of i th element;

p_i – coefficient (calculated, estimated value).

$$V_k = t_{up} \cdot pup + t_{pfk} \cdot ppfk + t_{pak} \cdot ppak \quad (2)$$

where the following stand for:

V_k – coefficient of the customer value;

t_{up} – weight coefficient of customer participation in total income;

pup – share % in total income;

t_{pfk} – weight coefficient of customer profitability;

$ppfk$ – customer profitability %;

t_{pak} – weight coefficient of the estimated customer attractiveness;

$ppak$ – % of estimated customer attractiveness;

$$\text{Vector of weight coefficients for } t \text{ is: } t = (0,3 \quad 0,5 \quad 0,2) \quad (3)$$

$$V_k = 0,3 \cdot pup + 0,5 \cdot ppfk + 0,2 \cdot ppak \quad (4).$$

The entire segmentation process and customer selection has to be repeated at least once a year and more often if necessary.

2.2.5. Portfolio and analysis of key customers

The goal of business segmentation involves identifying homogeneous market segments with similar needs, desires and characteristics, which indicated an increase in the importance of analysis of the customer's dynamic portfolio. On the basis of performed segmentation of business customers according to the value from the PPO perspective and strategically important customers of postal services, the following key segments to which identified key customers belong can be observed: state institutions, Telecommunications and information technologies, Financial organizations and banks, Communal organizations, Organizations for traffic and trade, Publishers and book distributors.

Value of key customer	High	1 2 4 20	18 10 3 14	8 13
	Medium	5 15 7 9	11 6 16	24 18
	Low	12 17 19 21	3 23	22 25
		High	Medium	Low

PPO synergistic business opportunities with key customers

Figure 2. Display of key customer portfolio matrix of Serbian Post6

On the basis of the results of this research, we can conclude that the successful implementation of key account management represents a strategy of long term profit that requires adding of value to relationships with potential key customers in order to create mutual long term interest, synergistic effects. Also, that that segment of the state administration7, local government and legal entities, become significantly involved in realized number of services and the PPO income (out of 25 identified potential key customers that used the "PostPPA" model, through the mentioned research it has been found that they generate about 79 % of income from the sale of the PPO; 7 potential key customers belong to the given segment). Information obtained in this analysis allow management to focus more on

5Testing of the application of the general model of customer value, PostPPA was conducted at the Post Office of Serbia, but the same is applicable further and beyond, especially in the service sector.

6Basic data of the 25 identified potential key customers in the Post of Serbia are represented numerically in the form of ordinal numbers previously generated from the table

7Bold in quadrants in matrix portfolio

achieving accumulated value of the portfolio, rather than the values derived from individual relationships (Ožegović, 2010).

The present imbalance in operating results and investments in these strategically important customers suggests the need to allocate available resources and divert investment on buyers, who have decisive impact on overall business effectiveness, developing long term partnerships with them, as well as the realization of synergistic effects of partnership, which represents the basis of modern strategic key account management concept. With such balanced inter-organizational relation of values, key customers should not be identified with "the larger buyer", who can over time be transferred into a group of key customer through planned management activities. Potential key customers in the Post of Serbia are strategic partners with whom long term synergy effects are achieved and the success is mutually shared.

3. SYNERGY EFFECT OF STRATEGIC PARTNERSHIP

Review and analysis of opportunities to achieve synergetic effects, in accordance with objectives of this paper, between the bodies of state and local government and the PPO will focus on local, less developed and rural areas of our country. Synergistic effects between the PPO and bodies of local governments can primarily be achieved in the form of creating a joint offer to citizens and potential users, as well as joint appearance. This new form of cooperation does not only entail the specified joint appearance, but also regular exchange of business information on potential joint customers. Prescribing the form, manner and form of exchange of business information is not available in advance because this way of establishing cooperation is a dynamic process and requires mutual respect and trust (the so called "open book" operating system), as well as prescribing the organizational forms of positioning a multifunctional team consisting of participants of both organizations. Realization of new forms of business cooperation through partnerships of the PPO with bodies of state and local authorities contributes to the success of achieving long-lasting forms of partnerships and the benefits in many areas. In establishing these new forms of business cooperation on the local and other markets, the focus of synergetic effects can primarily be seen in the following mutual long term interests, moreover benefits: a) creating high value of joint bids, b) ensuring a higher degree of utilization of available potential and resources of participants in the exchange, c) by sharing the brand (in a way that is of mutual interest), d) creating common products and/or services - integrated solutions in the service of citizens and businesses, e) strategic partnership to introduce new technologies, f) temporarily using postal/public administration bodies and local government at the onset of a particular market segment or at a meeting of general interest, g) joint use of sales and distribution network, h) savings achieved by using shared corporate office or by renting them, j) savings in hiring of employees (during the substitute of the temporarily absent employee of one or the other). Government authorities, local government and local communal organizations by occasionally hiring postman who according to the results of the research enjoys high reputation and trust, being easily recognized due to the uniform, can raise the level of achieved efficiency and effectiveness through mutual exchange of knowledge and experience regarding the usage of available resources and customer attitudes, etc. It can be concluded that the synergistic effects of partnerships in a selected area of business activity can be achieved efficiently and effectively and contribute to the stimulation and advancement of both state and local government and the PPO, as well as other legal persons founded by those state and local governments.

Synergy, as the effect of collective action exists⁸ if the condition is met:

$$NSV(A+B) > NSV(A) + NSV(B) \quad (5)$$

Where:

NSV(A+B) – current net worth of combined corporate asset of enterprise A and enterprise B

NSV(A) – current net worth of corporate asset of enterprise A

NSV(B) - current net worth of corporate asset of enterprise B

Sources of synergy are economies of scale, learning, risk management and cost-sharing, joint action against third parties, reduced costs of entering into new markets. Strategic analysis, selection and categorization of customers based on their value, that is, users of services, contributes to the successful management of their portfolio.

4. CONCLUSION

The aim of this paper is to indicate to one new approach in determining the possibilities of achieving synergistic effects of partnerships between the operators of the UPS, PPO, state and other dominant economic entities in the RS in order to improve overall business performance and contribution to the

⁸ According to: www.ekof.bg.ac.rs/SM_Glava_17

advancement the wider of social community. Based on the results of the conducted research, it can be concluded that profitable establishment of the aforementioned long term profitable business relations and partnerships in surveyed aspects primarily in connection with rationalization and optimal utilization of available resources, can produce synergistic effects. In addition to the significant and positive relationship in business cooperation between the PPO and the state and other major entities in the RS, for it to be improved after the development of models of strategic segmentation, classification and categorization of both the market of postal services and users of the UPS its implementation and monitoring, that is, complex model of management of long-term profitable partnerships, it is necessary to develop modern multifunctional models for segmentation, categorization and relationship management even with other medium and small state and business entities in this area of business. By doing this, systematic solutions could be improved and encouraged so as to contribute to continuous improvement of business performances and synergy effects between businesses entities involved in the chain of value as well as to give rise to the development and improvement of the society as a whole. The results of this paper represent interesting and useful theoretical, managerial and practical implications which can contribute greatly to the creation of effects of synergetic partnerships in developing countries, such as our own, the RS.

REMUNERATION SYSTEMS AS AN ELEMENT OF CORPORATE GOVERNANCE IN FINANCIAL CRISIS

Milanka Jelovac

Faculty of Economics, University of Belgrade, PhD student, milankajelovac@gmail.com

Abstract: *This paper discusses the problem of creating proper remuneration systems in order to improve corporate governance and business performances. To meet the challenges of the financial crisis, boards must change the way they work. Four aspects of corporate governance require attention: remuneration systems, risk management, boards performance and the exercise of shareholder rights. The main reason for writing this paper is an incentive to solve the long standing issue of remuneration systems. Pay for performance is a difficult concept in practice. Incentives at lower levels increased risk taking partly due to their failure to adjust bonuses for risks incurred. The OECD Principles hold boards directly responsible for managers' remuneration and advocate full transparency, so it must be emphasized that boards should have direct responsibility for remuneration systems. The systems must be in line with long-term objectives of the company, but it is easy to say, and hard to do. This paper represents a theoretical approach to the steps that a company must take to ensure that remuneration is established through as explicit governance process in which the roles and responsibilities of those involved are clearly defined and separated. Additionally, the importance of shareholders' role is emphasized in order to raise their awareness. In the modern era this paper can be an incentive for paying attention to intangible assets, motivation and improving business performances.*

Keywords: *remuneration systems, incentive packages, corporate governance, crisis, business performances, compensation*

1. INTRODUCTION

In modern times, when knowledge management has an undisputable role in every single area of doing and being, proper organization management, with the minimal volume of errors, is expected from everyone who lead the company and who are engaged to manage it. It is obvious that this is possible if the link between the ones who manage (managers) and the ones who own (owners) the company is direct, functional and unbreakable.

Corporate governance can be defined as a process in which managers professionally manage equity and owners tend to control them in order to ensure that managers take actions which lead to maximizing owners' wealth. Proper corporate governance means the respect of interests of all parties in the company which opens up other issues that exist in the relation manager-owner.

Remuneration systems represent an important element of corporate governance and one way for increasing the efficiency of corporate governance and business performance improving. Incentive mechanisms designing must ensure linking interests of managers and owners, decrease agency costs and increase benefits for owners. In that way, these mechanisms improve total quality management of the company. Linking owners' and managers' interests is a sensitive problem on which the company's strategy success frequently depends on and which raises serious issues on adequate compensation schemes choice and on measuring performances.

Corporate governance weaknesses are found in remuneration systems, risk management, board practices and the exercise of shareholder rights. These issues had played an important role in the development of the financial crisis. OECD Principles of Corporate Governance provided a good basis to adequately address the key concerns that have been raised and that there was no urgent need for them to be revised. It is extremely important to encourage and support the implementation of already agreed to international and national standards, including the OECD Principles of Corporate Governance.

In order to examine the issues of compensation systems in detail, this paper will firstly discuss the role of corporate governance in a modern company, compensation packages, their structure and their influence on corporate governance. Afterwards, in the second part of the paper, the role of proper corporate governance will be discussed as well as the choice of a proper compensation system in crisis.

2. REMUNERATION SYSTEMS – AN IMPORTANT ELEMENT OF CORPORATE GOVERNANCE

In order to define the place and the significance of remuneration systems in the frame of corporate governance, it is necessary to define the term of corporate governance. Corporate governance is a mechanism for aligning principals' and agents' interests and incentives. Corporate governance seeks to reconcile the relationships among the directors, board members, managers, stockholders and the outside financial community of analysts, bondholders, and other creditors by clearly assigning responsibilities, measuring performance and rewarding or penalizing managers in line with their impact on the company's long-term value creation.

Understanding the executive compensation package and its role in the modern company requires a basic understanding of corporate governance. Nowadays, the ownership and management functions are separated. This separation can arise from two situations. Firstly, there are individuals with pre-existing businesses who either do not have the desire or skills required to manage the business. In the second, there are individuals with good ideas or products that may not have the funds necessary to bring those products to market or sustain themselves through the start-up period and thus must seek outside investors. Effective coordination of executive compensation with the corporate governance function: rules, monitoring, and other incentives promoting effective relationships among important constituencies, has an important role in the company. Managers' compensation and corporate governance are linked and substantial effort and costs are required to better align incentives and reduce opportunism of all corporate stakeholders – top executives, board chairs and members, stockholders, debt holders and the financial community.

In the modern company, ownership and management are separated. This separation of the ownership and management functions can lead to conflicts. For example, although the owners are concerned with the maximization of the value of their stake in the company, the executives are concerned with the maximization of their own wealth and minimizing their effort. The mechanisms for controlling the conflicts that arise from the separation of the ownership and control of the company include monitoring by large shareholders and the board of directors, equity ownership by managers, market for corporate control, managerial labour market and compensation contracts that provide incentives to increase shareholder value. Monitoring by the board of directors has its limitations. Most directors have limited investment in the companies on whose board they sit and director's incentives also may not be aligned with those of shareholders. One reason the board cannot review every decision is the limited amount of time they have to spend on corporate matters, especially if the company is not their primary employer.

2.1. Designing remuneration schemes

Designing the remuneration schemes has the goal to minimize agency costs towards improving business performances. An important segment of corporate governance is the alignment among the managers' and owners' interests in order to decrease the possibility of high quality managers leaving when sector is in the decreasing phase or the possibility of managers at the pressure passing to other organizations (Đuričin, Janošević & Kaličanin, 2010).

As principals (owners, shareholders) have the major impact on value creating, it is crucially important to design such a remuneration system which will motivate managers to act in order to increase the company value. Hence, beside the short-term effects, it is really important to take into account also the long-term effects and objectives, because only in that way the gap between short-term and long-term can be bridged. Short-term goals are necessary, but not enough for total improving of business performances.

Remuneration systems have been varying through time. The system which has been in practise for years was based on managers being paid for their position, and not for their performance. Before 1980 managers and directors had been paid for a position, and their earnings represented the fixed cost for company. In period 1980-1990 compensations were linked to performances and earnings of managers and directors were considered as a variable cost. After 2000 the major part of manager earnings had an investment character.

Designing proper systems of remuneration considers defining the measures of performances and their relation with the company objectives (Đuričin et al., 2010). During the act of compensation schemes designing, some issues must be considered (Balsam, 2001):

- The package offer must be attractive;
- The manager must be encouraged to act according to company goals and objectives, which means increasing shareholder value and minimizing the costs to shareholders;
- By receiving proper compensations managers must be provided with the incentives to remain with the company.

Properly designed remuneration system represents a powerful tool of corporate governance. This tool directs managers and other employees behaving in the direction of continuous business performances improving and value creating. If we take into account that creating value is the basis for efficient corporate organization and high agency costs seriously endanger organization goals, it becomes clear that developing different remuneration systems, which link managers' and shareholder' interests, represent the strategically important issue.

It is extremely important to offer managers something that will be the reason for aligning their interests with the interests of owners. With this in mind, it will be rational to create such a governance system which would equalise managers' and owners' goals. In this respect, upon proper incentive system designing the care must be taken about potential users and costs. Using a particular plan requires considering of all outcomes in advance. Despite serious challenges in setting proper compensation systems, almost all greater organizations developed different compensation systems in order to minimize the consequences of the agency problem.

Four key objectives of incentive system implementation are usually emphasized (Malinić, 2008):

- Linking managers' and shareholders' interests which means giving compensation which will motivate managers to make strategic and operative decisions, as well as maximizing the shareholders' wealth;
- Achieving the proper wealth level, in the terms of setting manager awards to link the changes in managers' and owners' wealth;
- Minimising risk of quality managers leaving, even when they receive better offer when the industry is in the phase of lower productivity and recession;
- Maintaining shareholder costs at reasonable level.

Compensation system designing can be observed from different perspectives, from the aspect of setting the relationship between the compensation and performances, from the aspect of paying awards (in cash, stocks, options), from the aspect of the compensation system role in achieving the short-term and long-term objectives, etc.

The pay of chief executive officers has been rising rapidly since the early 1990s. In the early 1990s performance-related pay became more widespread. It is not only in the US that the problem is seen as politically if not economically acute. Executive compensation has become a major issue in Australia, Sweden, Germany, Switzerland, the Netherlands and France. In the EU, median CEO total remuneration (salary plus bonus) has risen at an average annual rate of around 14 per cent in the period 2004-2007 with particularly high rates in the UK, France, Germany and Switzerland.

2.2. Structure of remuneration packages

The structure of remuneration packages can differentiate in various situations, sectors, conditions and businesses, but packages usually consist of several main elements. It is important to emphasize that remuneration packages should be created in order to enable and motivate managers to focus on long-term performances. Incentive packages are one way to motivate managers.

The major components of the compensation package are the following:

- Main salary,
- Bonus,
- Stock options and grants,
- Pensions and benefits.

It must be emphasized that every component of the compensation package impacts the company's cash flows, both directly via the actual payment and indirectly via the company tax returns, so it must be taken into

account (Balsam, 2001). The compensation structure has evolved (Figure 1) during the twenty year period 1989-2009. Also, we can see the data from 2009 about chief executive officer's compensation (salary, bonus, stock gains and other compensation), average age, tenure and ownership. Remuneration packages structure varies across the companies and sectors, but increasing significance of long-term incentives has become evident.

Figure 5: Historical CEO compensation (Forbes, 2009)

Salaries are observed in the compensation packages across time, industry and corporate size, whereas other components of the compensation package have become more prevalent over the time and vary by industry and with the size of the company. Salary is the most basic part of the compensation package. It is fixed in amount, although it is variable in the sense that it can be renegotiated. An individual can get raises for good performance or get a pay cut for poor performance. Although salary needs to be competitive, because it is only one component of the compensation package, it need not always be greater than the salaries offered by competitors.

Bonuses are considered to be a variable component of the compensation package. The payment can be subjective or based upon objective criteria. It can be based upon one or more of the following performance measures: earnings, stock price, market share or customer satisfaction.

Stock-based components of compensation have two categories: stock options and stock grants. Although the value of both is based upon stock price performance after the date of grant, the payoffs and risks are different. Stock options allow their holder to purchase one or more shares of stock at a fixed price over a fixed period of time. Stock grants differ from stock options in that they have no exercise price.

The compensation can be deferred when an employee performs services in one period and receives payment in a subsequent period. The future payment can be in cash, stock, or benefits. Pension is deferred compensation in cash. Stock-based compensation granted in the current period can be considered deferred, as while the options or shares are granted in the current period, the executive does not have full rights to them until they vest in some future period. Furthermore with options, if the exercise price is greater than or equal to the market price at the date of grant, executives will not be taxed at least until the options are exercised.

As it was said earlier, remuneration structures vary in complexity. For example, in Finland, Sweden, Austria and the United Kingdom the fixed basic fee represents over 75% of the total fee. Companies in other countries added other layers of fees: the most common are attendance fees, variable fees based on company performance, basic fees for committee membership and chairmanship, and committee attendance fees. The proportion of the fixed remuneration (fixed basic and fixed committee fees) is on average 83% of the total remuneration. In Denmark, Sweden, Switzerland, Italy, Netherlands and the United Kingdom, fixed remuneration represents over 90% of the total. Remuneration is over 40% variable in France (based on attendance fees) and Germany (based on company performance). The remuneration of the chairmen and members of the audit, remuneration and nomination committees has remained stable since 2007 (Heidrick & Struggles, 2009).

3. THE CRISIS

Almost everyone is familiar with the causes of the global financial crisis which struck the whole world in 2008. Its consequences are present till today.

The financial crisis has raised a new order that has to be understood fully and accepted widely. The changes happening today are structural, truly transformative and will affect every company in every sector across the world. The financial crisis represents a challenge to policy makers that can be compared with the challenges that followed the collapse of Enron, WorldCom, Parmalat and by the Asian financial crisis of 1997 (OECD, 2009).

Corporate governance policy makers cannot stay beside the debate which raises questions about the relative role of legally binding, corporate governance requirements and their enforcement as opposed to principles-based, flexible instruments. These turbulent times demand greater focus on board effectiveness. While adherence to strong rules on corporate governance remains essential, the world economic crisis has introduced a need for discipline rarely seen over the last decade. The OECD Principles hold boards directly responsible for executive remuneration and advocate full transparency.

3.1. Remuneration systems are linked with the crisis

The governance of remuneration systems is the postulate of business performances improving. The financial crisis has raised new aspects of the compensation issue. Executives have had quite large equity share in their companies. They faced significant potential downside risks which should have restricted their risk appetite. The remuneration structure as a whole led to risk taking strategies since the executives faced expected losses on the downside and their basic cash compensation was high. It should be noted that in the face of public anger, a number of executives have voluntarily renounced their bonuses.

According to previous, there are four areas of corporate governance linked to recent failures of financial crisis:

- Remuneration systems;
- Risk management;
- The performance of boards;
- The exercise of shareholder rights.

These four areas are also closely related: if remuneration has been excessive and not structured properly, it can be considered that the boards have allowed this state of affairs to occur. The test of whether companies have effective corporate governance has, rightly or wrongly, become increasingly related to judgements about remuneration issues.

According to the problems that the crisis has raised, the awareness about the importance of compensation systems was revealed through the formation of remuneration committees. When we talk about committees in Europe, the average number has stabilized to three per company according to results from 2009 (Figure 2).

Figure 6: Average number of board committees (Heidrick & Struggles, 2009)

The remuneration committee is the second most common committee, found in 89% of companies. There has been little change in this over the years, but audit committees still continue to be more independent than remuneration committees.

The ratio of chief executive officer to average worker pay has widened rapidly. The issue had arisen even before the financial crisis, which has only served to make it more acute. The manifestation of the issue is not the same everywhere and at all times. In a number of countries, golden handshakes, even when a failed manager leaves a company, have been a source of concern.

Pay for performance as a concept has generally been supported by shareholders, but cases where the performance criteria have been extremely weak or subject to frequent revision are well documented. Most common has been the tendency to link bonuses and pay to targets that really have little to do with managers' performance such as the level of company's share price, and not the relative position of the company. Generally speaking, compensation is upwardly flexible, but there is little downside risk. This habit led to turbulences.

3.2. Remuneration system governance in crisis

The OECD Principles of corporate governance state doubtless that responsibility for remuneration systems is with the board. The importance of the Principles must be emphasized because they call for transparency, board responsibility and shareholder engagement.

The practical challenge is how to improve their position related with management. Just stating that remuneration systems should align incentives with the long-term interests of the company may not be enough and additional guidance is useful. In effort to align remuneration with the long-term interests of the company and its shareholders, it is important for the board to disclose specific mechanisms that link compensation to the long run interests of the company. The company must take steps to ensure that remuneration is established through the explicit governance process in which the roles and responsibilities of those who are involved, including consultants and risk managers, are clearly defined and separated. In a number of jurisdictions, it is considered good practice to give a significant role to non-executive independent board members in the process. Their remuneration should be decided through a transparent process that is disclosed in the remuneration report to shareholders. Depending on the characteristics of the company, remuneration systems that should be a focus of the board oversight need to be considered broadly and not just focused on the chief executive officer and board members.

The governance of compensation systems has very often failed because managers had too much influence over the level and conditions for performance based remuneration with boards which was unable or incapable of exercising objective judgement. In many cases it is striking how the link between performance and remuneration is very weak or difficult to establish. The use of company stock price as a single measure, for example, does not allow to benchmark company specific performance against an industry or market average (OECD, 2009). Also, the remuneration schemes are often overly complicated. They tend to be

asymmetric with limited downside risk thereby encouraging excessive risk taking. The goal needs to be remuneration systems that encourage long-term performance improving and this will require instruments to reward managers once the performance has been realised.

Defining the structure of remuneration schemes is a key aspect of corporate governance and companies need flexibility to adjust systems to their own circumstances. The balance between the fixed and variable components of remuneration packages should be carefully considered at company level, and the regulatory framework should not induce a shift towards excessive fixed remuneration components. Theories about the determinants of managers' and directors' remuneration differ widely, but the two major approaches are both relevant. One approach is to view remuneration as the result of efficient contracts. In this view, regulatory and other policy measures should focus on transparency so that shareholders and boards strike an efficient contract. The other approach which is more of a positive rather than a normative theory takes the view that management is able to exercise bargaining power and asymmetrical information to negotiate remuneration systems that are sub-optimal from the view point of corporate governance.

Performance measures should be related to the strategic objectives of the company and the time frame used to measure performance specified. The set of measures must be created to monitor accounting and other reporting practices that suggest weaknesses in corporate governance, not providing multi-period compensation packages, monitoring managers and financial analyst relationships, establishing an independent compensation committee composed of board members without managers participation, analysis of compensation packages with alternative scenarios and expected outcomes, limiting to certain top executives the grant of options and deferred stock, and with these, make every effort to establish true estimates of costs to the company and their impact on the managers and company value.

It is important for boards to first set the strategic goals of the company and its associated risk appetite. They are then in a position to establish compensation structure that meets a small number of performance metrics based on these goals. An explicit governance process needs to be established that will also define the role and duties of compensation consultants who are increasingly important. Good practice is for the process, remuneration structure and performance to be made transparent through some form of remuneration report. There also needs to be a possibility for shareholders to express their views about remuneration policy.

Where remuneration consultants are hired to advice on remuneration contracts and conditions, it is good practice for them to be engaged by the board with a key role for independent board members who are thus independent of management. Their role, including other work for the company, should be disclosed in a remuneration report. Boards need to ensure their continued independence by prohibiting or limiting the contemporaneous provision of other remuneration services and by requiring them to adhere to a code of conduct.

The boards have to decide and disclose, in their efforts to align remuneration with the long-term interests of the company and its shareholders, specific mechanisms that link compensation to the long run interests of the company such as multi-year performance based vesting conditions, deferred compensation, claw-backs and adjustment for risk. Performance measures should be related to the strategic objectives of the company and the time frame used to measure performance specified (OECD, 2010).

Boards and shareholders often look at a chief executive's annual compensation plan to determine whether the company is offering the right incentives to increase shareholder value. But few consider how does the compensation that the chief executive officer received over the years in the form of stock and stock options influence managerial decision making. In order to avoid unintended consequences, the authorities could find it important to review and understand how the tax system might constrain or influence the development by companies of remuneration systems based on long-term company performance.

It is useful for the board to understand the dollar amount that the managers can earn for the company. Boards are sometimes faced with the problem of what to say to shareholders when the managers receive very large pay-outs. Many boards will likely find that the pay-out amounts for various levels of stock price targets are much different than they expected, often encouraging too much or too little risk.

It must be highlighted that few boards look at how the chief executive's total wealth invested in the company changes as stock prices fluctuate, but they could and they should. The attention must be paid to evaluating how risk structures and incentives of managers' pay packages are aligned with the company's strategy. Ensuring effective measurement and monitoring of the value added by management is complex and costly

but it is essential for protecting stakeholders and increasing long-term total enterprise value of the company. It means that remuneration systems are the essential issue for performance management of the company.

4. CONCLUSION

Turbulent times have revealed new issues that emerged under circumstances that the crisis has brought. There is a growing awareness that the remuneration system designing is the major challenge which requires the commitment of a dedicated and expert group of directors.

Building a structure of responsibility and accountability is essential to address issues around managers' compensation. Greater transparency is necessary to broader stakeholder trust. Companies should also put in place a system that identifies potential conflicts of interests and implements countervailing measures.

As a critical component of corporate governance, compensation systems must constantly strive to align the incentives of managers with shareholders. As the value added by management is difficult and costly to measure, monitor and verify, this is a complex and critical challenge.

Finally, for main issues must be repeated: setting adequate measures, improving transparency, shareholders' role and boards' responsibilities. Companies should be able to set proper measures and to explain the main characteristics of their performance related remuneration systems in concise, transparent and non-technical terms. This should include the total cost of the systems, performance criteria and how the remuneration is adjusted for related risks. The role of shareholders is also very important so it should be considered good practice that remuneration policies are submitted to the annual meeting to shareholder approval in order to increase awareness and attention. Boards have been struggling for centuries to represent their shareholders effectively. There is no doubt that the crises lead to further evolution in the corporate governance practices of boards. In the meantime, boards must work hard in order to find mechanisms that link managers' compensation with the long-term interests of the company.

IMPORTANCE OF ORGANISATIONAL CHANGES AND LEADERSHIP IN CONTEMPORARY ENVIRONMENT

Saša Ćirić¹, Zorica Stojičić - Đerić²

¹Tigar AD, sasa.ciric@tigar.com

²Bortravel DOO, marketingbor@gmail.com

Abstract: *This document presents the importance of organising business activities in companies and making business more efficient and effective. This paper also aims to show how important it is to create and lead changes and be innovative in leading. This research will show the necessity of changes in organizational structures of modern companies according to complex and fast changes on the market with strong links to leadership-oriented management.*

Keywords: *leadership, changes, business activities, management, leader*

1. INTRODUCTION

In the era of globalisation and multinational companies, where market competition is large and aggressive, in order to survive and ensure a good placement of its products or services on a market, a company, be it large or small, has to follow and adjust to changes on the market. Today, companies need people, leaders and managers, capable of ensuring the company's survival on the market, as well as its progress with proactive exchange with the surroundings, external and internal alike.

Leadership creates a strategic vision, provides direction and orientation to activities, initiates and manages changes and motivates employees to follow it, because changes also imply changes in the enterprise structure, but also modifications in the employees' behaviour.

The basic hypotheses from which this research proceeds as follows:

- In order to subsist on a market and ensure good marketing of its products, a modern enterprise has to follow changes in the external environment.
- For maintaining an organisation's vitality, an enterprise requires top management with leadership capabilities, which observes changes in the external environment on time and follows them with constant, innovative changes in the enterprise.
- Good enterprise organisation implies leadership at different levels of enterprise structure.
- Enterprise transformation process, which implies changes in the organisation and functioning of an enterprise, requires leadership, which creates, initiates and manages such changes, whether major or minor; successful transformations are often insufficiently clear and demand sacrifices, creativity and innovations, and cannot happen without a convincing leadership.

2. ENTERPRISE AND MODERN ENVIRONMENT

"A company is a living organism. We can compare it to a tree that grows, develops and bears fruit. Fruits are products and services, and the aim is to have them as many as possible. Visible on every tree are its trunk, branches and fruits (or company's material and financial resources), which are nurtured and promoted, talked about and reported on. All we can see comes from roots, which are actually, the intellectual capital. There can be no healthy fruit without healthy and strong roots, which draw their strength from the soil, i.e. knowledge of the human resource potentials, in the first place." (1)

An enterprise is a social being – a group of people who carry out different activities in order to achieve a goal, i.e. make profit. An enterprise is at the same time a state (enterprise structure) and process (set of all activities). In the age of market economy globalisation, where competition is intensive and quick, in order to successfully carry out its business activities, an enterprise has to adjust to the market changes and not just follow them, but also to anticipate and adequately react to them. Adjustment of an enterprise's business operations to market changes has to be done through an adequate combination of strategic (major) and incremental (modest) changes. An analysis of the environment (which consists of all the individuals, organisations and institutions, as well as of all economic, political, legal, technological, socio-cultural and other factors which have an actual or potential impact on an enterprise's business results) is extremely

important for the business of an enterprise, adoption of strategic decisions and direction of its business activities. An analysis of the environment provides insight into its present state and, at the same time, anticipates its potential changes. (2)

In today's world the pace of these changes is rather fast and the competition strong and aggressive. Today's enterprises are faced daily with great risks on the one side, and great possibilities, on the other. It is necessary to strike a balance between risks and possibilities, which is only possible if enterprises follow technological trends and the global economy demands.

Survival of an enterprise and its progress under modern conditions, exclusively depend on the enterprise's capacity to adapt its production programme, technology and product quality to demands of the modern market. Competitively oriented enterprise is the one capable of offering on the market a good-quality product under more favourable conditions than its competition. A product is not produced just to be sold, but also to meet the consumers' expectations and wishes. Today, that is very hard to achieve, because competition is getting larger by the day. Enterprises have to transform into leadership enterprises that will achieve differential advantage on the global market. Such enterprise orientation imposes greater requests for itself, raising new challenges along the way. Accepting the risk will undoubtedly lead to greater success and better performance. (3)

In order to make profit, it is necessary to follow modern trends in science and technology development, IT achievements and modern management information system. Better knowledge of all IT categories enables better communications on the world market and favourable results in the international economy. Political surroundings are very important, especially as regards the adoption of important strategic decisions. State regulations and the country's political system condition synergic effect of all environment's factors on the development of business systems and successful survival of enterprises in turbulent surroundings. A successful and modern enterprise has to adapt to modern business trends. These modern trends imply:

- maximum profits and minimum costs,
- compromise (successful cooperation between employers and employees),
- information technologies (management information systems),
- good and stable state regulations and political system.

The most successful enterprises in global economy become those which initiate activities based on knowledge created in the enterprise. That's the know – how, expertise, as well as the organisation's development concept which learns by securing its survival and improvement of overall business results.

The major weakness of an enterprise as an economic organisation is its inability to change. Each organisation must have sufficient stability to continue to function well and, at the same time, prevent it from becoming static.

By satisfying the basic economic principles an enterprise can achieve positive business results. However, that's not sufficient for further future of enterprises in turbulent surroundings. World globalisation and dynamic environment force many enterprises to learn so as to adapt to unstable world market. Competency of an enterprise is its trade mark in the business world. Incompetent enterprises very soon go under because they did not manage to carry out transformation on time and adapt their organisational structure and strategy to market developments. Knowing its competition is exceptionally important for an enterprise. Therefore, it is necessary to follow what the competition is doing and always be one step ahead of it. No.1 enterprise in the business world is the one that accepted on time modern concepts of doing business and adapted its business operations to current developments in the environment. (4)

3. GLOBALISATION AND THE NECESSITY OF ORGANISATIONAL CHANGE

The globalisation process, a 21st century phenomenon, essentially relates to the growth of trade and investments in international business and to the integrated world economy. According to Punnett (2004) the globalisation concept is based on a number of relatively simple premises.

- Technological developments have increased to high levels and thus enabled the ease and speed of international communications and travel.
- Increased and easy communications and trade have made the world smaller.

- A smaller world means that people are more aware of events outside of their home country, and travel more to other countries.
- Increased awareness and travel result in a better understanding of foreign opportunities.
- A better understanding of foreign opportunities leads to increased international trade and investment.
- The increased international trade and investments lead to greater integration of the world economy.

Today, managers must be conscious that markets, supplies, investors, partners, and competitors are everywhere in the world. Successful businesses will take the risks and use opportunities wherever they are and will be prepared for downfalls. Successful managers, in their environments, need to understand the similarities and differences across national boundaries, in order to utilize the opportunities and be aware of potential business downfalls.

Business globalisation is easily recognised through a network of many brands and services all over the world. For example, Japanese electronics and car industries are distributed everywhere – in Asia, Europe, North America, while on the other side, the American cars, entertainment, financial services are present in Asia, Europe and North America. Most companies became multinational and transnational, practically meaning that they have their base in their home countries, but do business all over the world. For example, the French Michelin is based in France, and its factories – production plants are in many countries (Serbia, Rumania, China, Thailand,...), American Coca – Cola also (factories in France, Belgium,...), the highest percentage of Japanese Honda cars are produced in the USA, and such are many more examples of world known manufacturers. (5)

In order to achieve its objectives an enterprise has to clearly define its mission and vision, to define its objectives and adopt such organisational structure that will facilitate the implementation of set goals. Leadership is also necessary at all levels.

Organisational structure of enterprises is mostly a hierarchy concept of coordinating entities which cooperate and contribute to the achievement of the set objective. Organisational structure allows division of responsibilities to functions and entities, within branches, sectors, groups and individuals. In an organisational structure individuals can be employed for a definite and indefinite time period, which is defined under a contract. An efficient organisational structure should facilitate the operational relationship between different entities in the organisation and can improve work efficiency of organisational units. The organisational structure of an enterprise should be such so as to enable process control and monitoring, up to product delivery. It should be such so as to harmonise all requests and optimise the process itself. The organisations should enable application of individual capabilities with a view to achieving high flexibility and creativity. With the expansion of business, the chain of requests is increasing and the control expanding. If the organisation doesn't change, after a longer period of time its flexibility and creativity will decrease. Therefore, it is necessary to change the organisational structure from time to time, so as to make recovery possible. (6)

Problems with which the enterprises are faced lately can hardly be successfully resolved without successful organisations, and organisations cannot be successful without efficient leadership. The enterprise can obtain all other resources it lacks (technology, capital, etc.) through larger or smaller efforts. However, enterprises lacking leadership have limited chance to face the problems brought about by globalisation of the world market. Lacking leadership, enterprises continue to do what they have been doing for years in the way they have been doing it. They continue to improve the existing routines and existing business orientation.

In the business world, leadership is undoubtedly the most important activity and function in the collective work. The right man in the right position and at the right time can make miracles. Leaders, who are generally also managers, can be easily recognised in a business environment. Every leader's style implies a style of conduct and methods of performing the job. Some styles may be accepted by his associates, whereas others might be considered inappropriate. The style is a result of leader's philosophy, personality and experience.

It should be emphasised here that capability of an enterprise to face the changes basically depends on two leadership qualities. The first is the ability to timely spot and understand the changes in the external environment and the second is the capacity to procure and use the resources, and expertise, and to adequately react to changes. Leadership is a process which includes the movement of the organisation's members from the present state to the future, new state. (7)

Cooperation of the top management and mid-level management in an enterprise represents an essential factor in initiating and implementing strategic changes, especially major, transformational changes. "The less a strategy can be imitated, the more durable the source of competitive advantage." (8)

4. IMPLEMENTING ORGANISATIONAL CHANGES AND LEADERSHIP (A CASE STUDY)

Apart from the usual changes on the market, enterprises today are faced with the crisis, which is assessed as the largest global crisis since the world economic crash in 1929. From our country's perspective, the international crisis has only intensified the effects of national and regional crisis we have been facing for over one decade. The crisis always makes business significantly harder. Proactive response to it, while the negative effects are still on, can only be great work on system maintenance and intensive preparations, through development processes, modernisation and reconstruction, for that which comes after.

This crisis too has shown, in its crudest form, through the collapse of world business and financial empires, that what companies once were is no longer a guarantee of their survival and further development. Only those prepared to adequately change survive.

Company Tigar AD (shareholding company)

Under the conditions of a crisis many different business decisions have been made in Tigar so as not to bring the implementation of strategic objectives at risk. In the previous period a complex restructuring process was carried out in Tigar, which was considered the right one to enable sustainable development of the business system over the long-term. That implied being equipped with capacities, technologies, as well as higher productivity and better product quality compared to the competition. All these are greater and smaller innovative changes which a corporation made or is making so as to subsist and develop.

Tigar made a plan of successive investments for the 2007-2011 period. A year after the investment programme follows a period of development and industrialisation, and only then starts the period of commercialisation in which the return of investments will be ensured.

Experts point out that in the current crisis, the threatened liquidity is a test of sorts of the strength of the economy in general and of the company individually. And in order to ensure a reliable inflow of money from the market it has to provide products and services that meet the market requirements. However, it is first necessary to invest, commit money, whereafter it will successively return into the system. During the restructuring period, business results are always lower, needs for cash higher and investors and banks more cautious in making decisions, because they should finance some future results. In the case of Tigar the situation is particularly complex, because the entire system has been under restructuring for a couple of years now.

Tigar is a brand recognised on the national and international plane, and analysing the practice of large companies, Tigar's management came to a conclusion that in addition to corporate brand, the company needs to own other brands too, which it would develop on its own or take over, buying brands that have already proven themselves and are recognised on the market. Applying this practice, Tigar introduced brands Maniera (fashion shoes), Brolly (children's shoes), Bottega (rubber and Italian shoe shops), Stop & Drive (service network), and it bought famous foreign brands Hunter (rubber footwear) and Bilgutex (recycled rubber products).

Intensive development of new products for new markets and buyers, as well as the expansion of the product mix for the existing customers was the first priority after investments in capacities, good-quality equipment and continuous employee training and education were completed. In one year Tigar Americas managed to win a good position on the market of Canada. Partnership was made with STC firm in the most expensive part of production – protective footwear for extensive purposes. Miner and forest boots have already been commercialised, through a number of deliveries. Several new prototypes have been mastered, which are to be commercialised soon.

By acquiring the Century brand, which is present and known all over Europe, Tigar has secured an even better position in further winning this demanding market. It is very important that together with the brand, the unique dipping technology was also obtained. It ensures the absolute impermeability of footwear to any type of external fluids, liquids and other aggressive substances.

The company also carried out the modernisation of its retail network. When Tigar started marketing fashion footwear from the Maniera programme, a question of the sales channels arose. By opening Bottega shops, with the full programme of footwear for all seasons, Tigar opened its doors to a loyal customer. Since shoes from collections Maniera and Brolly are of seasonal character, an adequate programme had to be found, which would be a counterpart to these brands by its quality and, at the same time, interesting for the desired target group of potential customers. With the opening of Bottega shops conditions have been created for clear differentiation of Tigar's points of sale from others and the retails network was improved.

In 2009 Tigar continued the development of the largest national service network Stop & Drive, which fully follows the modern trends. Apart from opening new service centres in towns all over Serbia, great importance was attached to the modernisation of the existing facilities, as well as good-quality training of employees.

With the aim of expanding further the production and its market share on the national and international markets, Tigar Technical Tyres acquired a production programme of the Danish firm Bilgutex. This purchase included transfer of equipment, production technology, technical certifications and certificates for Bilgusafe products – children playgrounds tiles, Bilguland – sand pool fences, Bilgubollards – road margin poles, Bilgubuffers – buffers and Bilgulane – rubber mats. The transfer included taking over of commercial contracts, which enable not only the production, but also the marketing of these brands, which are already well positioned on the North European market.

Tigar Technical Tyres mastered the production of sport floorings from recycled rubber, which have long-life cycle in exploitation and do not require special maintenance. Products from recycled rubber for traffic and road signalisation have also been mastered.

The Footwear Factory was modernised with the acquisition of new technologies and product lines, as well as automatisisation of the existing process lines. Apart from introducing the mentioned innovative changes, Tigar also reconstructed some of the existing production lines, and also carried out the regular annual overhaul of factories.

Production costs and prices of final product have been reduced with the introduction of cheaper materials and alternative suppliers. Increasing energy efficiency, which includes numerous economic, ecological, social and other social responsibility components, including environmental protection, represents the key to business success and important competitive edge of companies committed to sustainable development. Experiences from European Union member countries show that ecologically aware companies can reduce energy costs up to 20%, without major investment, whereas thus achieved savings directly increase profits.

Within the activities aimed at promoting energy efficiency and reducing business costs, the Corporation Tigar adopted Energy and Water Saving Programme. Monitoring the consumption of resources is an on-going process in Tigar, with careful recording and analysing of gathered information on the water and energy use. Based on set consumption targets, further measures and actions are being taken so as to permanently promote the energy efficiency. Tigar regularly records the consumption of fuel gas and coal, energy and water consumption, as well as share of energy in the cost of finished products. Follow-up of these parameters and implementation of specific corrective measures contribute to the reduced wasting of raw materials, better product quality and preventive maintenance, improved financial planning of production and control of production processes, as well as intensified environmental protection.

Tigar was one of the first companies in the country to recognise the importance of long-term connections with foreign partners. The strategic partnership process, which lasted thirty years in the tyre programme with the American manufacturer B.F. Goodrich, started back in 1974, with the signing of the Contract on Business-Technical Cooperation, and then of the Joint Venture Contract in 1978. Takeover of B.F. Goodrich by Michelin Group in early 1990's marked the beginning of the globalisation process in the tyre production in world organisations and intensive concentration of production, research and development potentials with the leading manufacturers. The rising market demands, fierce competition, general regulations regarding quality, security, safety and environmental protection, complexity of access to markets of production materials, spare parts and equipment during the 90's, conditioned the linking of medium and small producers with the big ones, which started including in their programmes third and second-line products. Producers from Central and Eastern Europe and Far East also started to develop intensively, for most part, after joining major tyre systems. Due to the country's status, Tigar had no conditions for quicker development and investments and Michelin Group, as legal successor of B.F. Goodrich, became Tigar's partner within joint investments in the

tyre programme. In December 2001, a new Joint Venture Contract was signed with Michelin, under which strategic cooperation has been continued and a joint venture enterprise formed. (9)

Formation of a joint enterprise enabled tyre programme to modernise production capacities, ensure much better financing conditions, better quality access to markets of materials and equipment, employee training, better national and international positioning, growth of production, changes in the structure of product mix, growth of sales, particularly exports and capability to respond to sharp market requests. During 2007 it became clear that further successful development of the joint enterprise would be solely possible through the process of complete integration with the Michelin Group, since otherwise there was an actual danger for it to stagnate, which would have forceful adverse effects not only on the joint enterprise, but also on Tigar as a whole. Having in mind the interests of the joint enterprise on the one hand, and interests of enterprises under control ownership of Tigar AD on the other, definition of the most favourable strategy for a way out was launched, which would primarily secure the capital for the development of other programmes, good-quality commercial and service cooperation, as well as save jobs. That was all in the interest of owners, because it created foundations for long-term good-quality preservation of their investments. In 2009, Michelin Group became the sole owner of Tigar Tyres.

Fully taking into account the real effects of partnership it could be rightfully said that two respectable business systems have been developed through this process - Tigar AD and Tigar Tyres, which is important not only for the employees and owners, but also for the local community and country as a whole. Through this process Michelin showed that, although being one of the strongest multinational companies, it's not a company that merely pursues its own interests in individual countries, but is ready to render its full development contribution to partnership relations. Through this process, Tigar AD, for its part, implemented a unique project in Serbia, as the plant has not been closed down, not worker lost his job and the ownership structure was regularly changed on the Stock Exchange in line with the valid world trends. In addition, a strategic partner was included, who gradually fully integrated Tigar Tyres into its business system, full cooperation with the international financial institutions was achieved and all other programmes underwent or are in process of intensive modernisation and restructuring so as to position themselves in the best possible way on the domestic and world markets..

During these transformations, apart from permanent investments in the equipment and technology, constant investments were made in knowledge, which is one of the basic features of the company's business policy.

Tigar's strategy is that which gives the company the competitive edge, provides direction, builds the brand reputation, sets objectives, creates superior performance, defines market position and creates a unique offered business value. All basic programmes within the Corporation have been conceived so as to have or achieve the leading position, or to be among the leaders on the competitive market.

5. CONCLUSION

Globalisation, rising competition, large number of strong companies, which come from new world economic powers, such as China, India and Korea, admission of new states into the European Union and strengthening of their firms, limited raw materials and energy resources, have all defined the broad business environment in the last years. Deep disturbances in world finances and key changes on the international plane have directly affected business operations of many national and international companies.

On the other side, on the national level evident are major changes brought about by preparations for the integration in the European Union. The market is becoming ever more open. With the reduction of customs rates and other duties on imported goods, they become more competitive compared to national products. Prices of food and energy grow and foreign investors are withdrawing from the national capital market, with constantly present threat of rising inflation and sudden changes in the exchange rate.

The survival of an enterprise and its progress under contemporary conditions depend exclusively on the enterprise's ability to adapt its production programme, technology and product quality to the demands of the modern market. Competition oriented enterprise is the enterprise which can offer on the market a good-quality product.

Survival of an enterprise and its progress under modern conditions, exclusively depend on the enterprise's capacity to adapt its production programme, technology and product quality to demands of the modern market. Competitively oriented enterprise is the one capable of offering on the market a good-quality product

under more favourable conditions than its competition. A product is not produced just to be sold, but also to meet the consumers' expectations and wishes. Today, that is very hard to achieve, because competition is getting larger by the day. Enterprises have to transform into leadership enterprises that will achieve differential advantage on the global market. Such enterprise orientation imposes greater requests for itself, raising new challenges along the way. Accepting the risk will undoubtedly lead to greater success and better performance.

In order to make profit, it is necessary to follow modern trends in science and technology development, IT achievements and modern management information system.

In the global economy, the most successful enterprises become those which initiate activities based on knowledge created in the enterprise. That's the know – how, expertise, as well as the organisation's development concept which learns by securing its survival and improvement of overall business results.

In the context of today's global and national situation and state on the capital market, only those companies will survive which anticipate and understand changes occurring in their national, but also world surroundings, and which are ready to change by following these changes. Those are companies headed by the top management with strong leadership characteristics. Without strong leadership a company cannot survive and develop further under modern conditions of doing business. It is the responsibility of leaders at all levels, from CEOs to lowest-ranking managers, to help employees recognise and understand the necessity of changes and accept new ways of performing jobs.

In the world characterised by global competition, diversity, sharp technological changes and political turmoil, discontinuous organisational change is imposed as a determinant of organisational adjustment. Companies that can initiate and implement discontinuous organisational change gain competitive edge. Although not all changes are successful, the fact remains that inertia is a certain road to failure. Top management is of most crucial importance for initiating and implementing changes in the organisation. A charismatic leader is of vital significance for managing important changes in the system. Charismatic leaders provide vision, direction and energy.

However, charisma in itself is not enough for making crucial changes. Also required is good organisation, which includes tasks, responsibilities and stimulation of employees. Since many companies are large and complex, it is necessary to include managers at all levels in such systems for successful implementation of changes.

Successful implementation of changes is not based only on the strengths of persons implementing them – each of these personalities has to be capable of making teams, systems, procedures, of bringing in his energy so that the vision can be successfully achieved.

Even with highly inspirational leaders it is not simple to fully implement the plan. Changes require time. In the course of changes mistakes happen, environment changes, many key people leave. Irrespective of all these turbulences and complexity of change, the executive team has to develop ability to adapt to new conditions and, which is very important, must learn from mistakes, but also success too.

Just like an organisation cannot remain stable in the changing environment, the management has to be flexible. The ability of the executive team to continuously learn and be flexible is a measure of a successful proactive management process of the organisational changes of an enterprise.

REVIEW OF THE ORGANIZATIONAL AMBIDEXTERITY: LESSONS FOR MANAGERS AND OTHER PRACTITIONERS

Ivan Stefanović¹, Dragan Milošević²

¹NIS a.d. Novi Sad, ivan.stefanovic@nis.rs

² High School for Business Economics and Entrepreneurship, dmilosevic@ikomline.net

Abstract: *The reason for writing a review on organizational ambidexterity can be found in the necessity to establish a unified theoretical framework from a flood of papers being published on this topic in the last fifteen years. This growing body of knowledge deserves to be reviewed and systematized, which is why the authors survey, classify and synthesize different theoretical concepts and empirical studies that examine the nature of organizational ambidexterity. The paper starts by explaining the reasons for achieving and sustaining organizational ambidexterity, i.e. the need for ambidextrous organizations in the contemporary environment is explained. The paper continues by providing an insight into a delicate balance between differentiation and integration as the prime mechanisms for fostering organizational ambidexterity. Finally, it ends with practical guidelines on the manner in which organizational ambidexterity may be achieved. This paper is useful for academics as a solid foundation upon which other theoretical and empirical contributions ought to be built. On the other hand, it is also useful for managers and other practitioners in terms of specific guidelines for achieving and maintaining organizational ambidexterity.*

Key words: *Organizational ambidexterity, Ambidextrous organizations, Exploitation, Exploration, Continuity, Change.*

1. INTRODUCTION

Business environment today may be seen as discontinuous because the mapping from firm actions to performance outcomes changes frequently, profoundly, and in ways that are difficult to predict (cf. Siggelkow & Rivkin, 2005; Stefanović, Prokić & Vujović, 2012). Contemporary organizations are facing the unpredictable and more complex environment than ever before, which is why organizations ought to pay attention to a much larger number of variables in the environment and their dynamics than was the case earlier (Stefanović, Prokić & Vujović, 2012). Rise in complexity of the environment calls for an increase in search diversity of the organization, while rise in dynamics of the environment calls for an increase in its speed. Thus, in an environmental setting characterized by both turbulence and complexity, a firm must balance speed and search in order to achieve and retain its viability (Siggelkow & Rivkin, 2005).

For a firm to be successful in the contemporary environment, it must maintain continuity of its on-going operations, while fostering innovations and change at the same time. It is now well known that the archetypal tension between continuity and change might be better understood in terms of relational, synergistic tendencies rather than conflicting, incompatible forces that must be resolved one way or the other (Graetz & Smith, 2008). Continuity and change come together when stability, hierarchy, specialization, formalization and centralization are coupled with attributes such as speed, flexibility and responsiveness (Graetz & Smith, 2008). As Brown and Eisenhardt (1998) have noted, organizations will secure their existence only if they maintain a balance between flexibility and stability, because too many changes may create chaos in organizations if continuity is not taken into account, whereas the opposite could lead to inertia (Levinthal & March, 1993). In other words, due to the changes in their environment, organizations must learn how to do these and others seemingly opposite things at the same time. Therefore, organizations need to strive to become dualistic entities (Pettigrew & Fenton, 2000).

If one takes a closer look at organizations, he will notice that they are characterized by dualities or paradoxes, such as: efficiency and innovation, integration and differentiation, control and freedom, centralization and decentralization, and competition and co-operation (Child & McGrath, 2001). In order to remain successful over long periods, organizations, as well as their managers, must become ambidextrous (Tushman & O'Reilly, 1996). Organizational ambidexterity, the term first used in this context by Duncan (1976), represents a firm's capability to manage the tensions between simultaneous, yet contradictory processes (Duncan, 1976). In general, the concept of organizational ambidexterity has been used to "describe a variety of distinctions in organization behaviour and outcomes" (Simsek, 2009, p. 599). More specifically, it has been used to depict an organization's ability to simultaneously work on two different things,

such as: exploration and exploitation, efficiency and flexibility, incremental and radical innovation or alignment and adaptability.

In order to define the organizational ambidexterity more precisely, one must incorporate the level of observation, i.e. whether the object of observation is a group of organizations, a single organization, a specific group within an organization, or perhaps an individual. Some studies indicate that ambidexterity is rooted in individual's ability to explore and exploit. Thus, organizational mechanisms may be required to enable ambidexterity at the individual level (Raisch et al., 2009). On the other hand, the majority of studies regard ambidexterity as a set of mechanisms enabling exploration and exploitation activities simultaneously. In this sense, organizational ambidexterity ought to be regarded primarily as an organization-level construct that manifests itself in the organization's balance of high levels of exploitation and exploration, efficiency and flexibility, incremental and radical innovation, as well as alignment and adaptability. In other words, ambidextrous organizations are the ones that are fully capable in attaining a high level of innovation, flexibility and effectiveness, without losing the benefits of stability, routinization and efficiency (Simsek, 2009). Even though organizational ambidexterity gained significant attention in recent years, it remains poorly understood phenomenon (Simsek, 2009). For example, scholars and practitioners agree on the importance of balance between exploration and exploitation, but "there is considerably less clarity on how this balance can be achieved" (Gupta et al., 2006, p. 697), which is why numerous authors are trying to build a more comprehensive framework (e.g. Andriopoulos & Lewis, 2009; He & Wong, 2004; Jansen et al., 2006; O'Reilly & Tushman, 2011; Simsek, 2009).

The purpose of this paper is to synthesize various theoretical and empirical contributions on organizational ambidexterity in order to build a more comprehensive theoretical framework and to provide guidelines for managers and other practitioners on how to build ambidextrous organizations.

2. THE NEED FOR AMBIDEXTROUS ORGANIZATIONS

Knowledge intensive businesses, such as design and engineering services, advanced electronic, biotechnology, software design, healthcare, consulting, etc., feed upon a continuous cycle of innovation (Miles et al., 1997). For this kind of business, it is necessary to simultaneously achieve high level of exploration, resulting in viable innovations, as well as a high level of exploitation, i.e. high level of performance in on-going day-to-day operations. Therefore, exploration of the future and exploitation of the past is a necessity (Lewin & Volberda, 1999).

The exploration-exploitation trade-off is a well known subject (Schumpeter, 1934; March, 1991). Exploration can be defined by terms such as: search, variation, experimentation, and discovery, while exploitation includes: efficiency, refinement, selection, and implementation (March, 1991). The basic trait of exploitation is the refinement and extension of existing competences and technologies. Thus, these are steps taken into relatively known future with predictable returns. On the other hand, the essence of exploration is experimentation with new alternatives and probes into unknown future. The returns are usually uncertain and distant (March, 1991). Neither one alternative for itself is a good choice for an organization. A delicate balance between exploration and exploitation must be obtained in order to achieve long-term survival and development of an organization. A firm must "engage in enough exploitation to ensure the organization's current viability and to engage in enough exploration to ensure future viability" (Levinthal & March, 1993, p. 105).

Tushman and O'Reilly (1996) noted that an ambidextrous firm that is capable of operating simultaneously to explore and exploit is likely to achieve superior performance than firms emphasizing one at the expense of the other. These firms are able to simultaneously pursue both incremental and discontinuous innovation. On the other hand, they argued that in reality, few firms may succeed in managing exploration and exploitation at the same time, because these notions assume fundamentally different logics and require different strategies and structures, and the resulting tension is difficult to reconcile. But this is not all. To be ambidextrous, organizations have to reconcile these internal tensions with the conflicting demands in their task environments (Raisch & Birkinshaw, 2008), which makes this issue even more complicated.

Nevertheless, the tension between exploitation and exploration may be viewed as the problem of a firm's choice: whether it ought to continuously adapt to existing environmental demands, thus fostering structural inertia and reducing its capacity to adapt to future environmental demands (Hannan & Freeman, 1984) or experiment with new alternatives, thus reducing the speed at which existing competencies are improved (March, 1991). This particular problem may be resolved by finding an adequate balance that matches the

existing environmental and organizational context. Thus, the central organizing challenge has become the ability to develop systems that thrive in paradox, providing both efficiency and innovation along with a centralized vision and decentralized power (Child & McGrath, 2001). "The real test of leadership, then, is to be able to compete successfully by both increasing the alignment or fit among strategy, structure, culture, and processes, while simultaneously preparing for the inevitable revolutions required by discontinuous environmental change. This requires organizational and management skills to compete in a mature market (where cost, efficiency, and incremental innovation are key) and to develop new products and services (where radical innovation, speed, and flexibility are critical). A focus on either one of these skill sets is conceptually easy. Unfortunately, focusing on only one guarantees short-term success but long-term failure. Managers need to be able to do both at the same time, that is, they need to be ambidextrous." (Tushman & O'Reilly, 1996, p. 11)

3. ENABLING ORGANIZATIONAL AMBIDEXTERITY: THE BALANCE BETWEEN DIFFERENTIATION AND INTEGRATION

Differentiating and integrating are two opposing, yet complementary processes needed in order to achieve ambidexterity. These processes enable one another. Differentiation refers to the separation of explorative and exploitative activities into distinct organizational units, while integration represents the mechanisms that enable organizations to address exploitative and explorative activities within the same organizational unit (Raisch et al., 2009). "Differentiating pulls apart the existing product and innovation by focusing on how they differ from one another. Integrating, in contrast, reinforces and makes mindful possible synergies between these products... It is the engagement in both of these cognitive processes that leads to... balanced decision making." (Smith & Tushman, 2005, p. 529)

In order to achieve equilibrium, firms must match structural differentiation and integration to key contingencies (Lawrence & Lorsch, 1967). They need to balance differentiation to adapt rapidly with integration to achieve efficiency (Westerman, McFarlan & Iansiti, 2006). Thus, blending integration and differentiation is very important for ambidextrous organizations. Integration tactics accentuate the importance of both poles of exploitation-exploration tension, while differentiation helps maximize the distinct benefits of these opposing poles by clearly focusing actions on them (Andriopoulos & Lewis, 2009). Cao, Gedajlovic and Zhang (2009) have shown that ambidexterity is fostered by close interrelations between existing and new knowledge. They argue that synergistic effect can be achieved by allowing existing resources to be more fully employed to acquire new capabilities, while at the same time permitting new knowledge to be more fully integrated into the existing pool of resources. Structural differentiation and integration play a crucial role in a firm's ability to pursue exploratory and exploitative innovation concurrently, even though these two types of innovation require fundamentally different and inconsistent architectures and competencies that create paradoxical challenges (Jansen et al., 2009). Andriopoulos and Lewis (2009) showed that the simultaneous use of both integration and differentiation approaches to managing paradoxes of innovation demonstrate managerial creativity. Raisch et al (2009) have noted that integration and differentiation are complementary mechanisms for achieving organizational effectiveness. The natural tension between these opposing forces requires ongoing managerial attention, which is why the managerial task is to determine the right degree of differentiation and integration.

Perhaps the main question is whether the same organizational unit or even an individual will assume the different roles (e.g. exploration and exploitation) or different organizational units/individuals will assume responsibilities for different roles. This kind of analysis on the group level has been provided by Smith and Tushman (2005). They argue that two fundamentally different types of top management teams are able to execute balanced decision making: leadercentric and teamcentric. In leadercentric teams, the leader integrates the contradictory agendas of the team members, whereas in teamcentric teams, the teams themselves integrate the contradictory agendas.

In order to achieve ambidexterity, firms have a myriad of options available. Different organizational solutions may substitute for each other to yield a functionally equivalent effect (Gresov & Drazin, 1997). In this sense, architectural and contextual ambidexterity will be depicted in this paper as different options leading to the same goal. The theory of architectural ambidexterity emphasizes dual structures and strategies, i.e. differentiating efforts to focus on either exploitative or exploratory innovation (Gupta et al., 2006). These segregated efforts rely on: (1) spatial separation that parses work into distinct units, (2) temporal separation in order to utilize the same unit but at different times for either exploitation or exploration, and (3) parallel structures in which two kind of structures exist at the same time, switching people back and forth between them (Puranam et al., 2006; Raisch & Birkinshaw, 2008). On the other hand, the theory of contextual

ambidexterity proposes behavioral and social means of integrating exploitation and exploration (Birkinshaw & Gibson, 2004), i.e. a carefully selected set of systems and processes that collectively define organizational members' behavioural context (Simsek, 2009). Thus, contextual ambidexterity may be perceived as "the behavioral capacity to simultaneously demonstrate alignment and adaptability across an entire business unit" (Gibson & Birkinshaw, 2004, p. 209). This behavioral view posits organizational ambidexterity as a function of high performance context in which individuals are embedded. In this case, managers are responsible for creating a context that enables employees to use their own judgment on dividing their time between exploration and exploitation (Birkinshaw & Gibson, 2004; Eisenhardt, Furr & Bingham, 2010), but ultimately, ambidexterity is rooted in individual's ability to explore and exploit (Raisch & Birkinshaw, 2008). This context is characterized by a combination of stretch, discipline, support and trust to facilitate organizational ambidexterity (Gibson & Birkinshaw, 2004). Ambidextrous organizations are supported by a common vision and by supportive leaders who both encourage the culture and know enough to allow appropriate variations to occur across organizational units (Tushman & O'Reilly, 1996). Raisch et al (2009) have noted that managers can exhibit to different degrees personal ambidexterity by engaging both in exploitation and exploration activities. The variance in the degree of personal ambidexterity stems from both personal characteristics and organizational contexts faced by the manager.

Nevertheless, both architectural and contextual ambidexterity have some pitfalls that need to be addressed. For example, while strict structural separation is likely to result in sharp interfaces, ambiguous priorities, and a lack of common orientation, contextual ambidexterity shifts the problem of balancing flexibility and efficiency from the level of organizational to the individual level. It is doubtful that members of an organization can deliver what the organization as a whole fails to do (Schreyögg & Sydow, 2010). On the other hand, even though architectural and contextual ambidexterity have been implicitly conceptualized as alternative solutions, there are complementarities between them (Raisch & Birkinshaw, 2008; Tushman & O'Reilly, 1996). An ambidextrous organization may be characterized by structural separation, clear strategic intent, an overarching vision and values, and an aligned senior team with the ability to manage trade-offs (O'Reilly & Tushman, 2007). In the remainder of this paper, the focus will be solely on architectural ambidexterity, i.e. on spatial separation and parallel structures (in brief), while there will be no discussion regarding the temporal separation. In the opinion of authors, organizational unit that either exploits or explores does not reflect the nature of ambidexterity. Integration mechanisms for achieving ambidexterity will be depicted as well.

3.1. SPATIAL SEPARATION

There is significant difference between structures designed for efficiency and those forged for innovations. For example, Burns and Stalker (1961) emphasized the difference between mechanistic and organic structures. While mechanistic structures are created for efficiency and stability, organic structures are made for effectiveness and adaptability. Nevertheless, contemporary organizations require both types of structures: organic to create innovations and mechanistic to implement and deploy them (Duncan, 1976), which means that these two completely different structure must blend in one in order for a firm to be successful. In other words, ambidextrous organizations must reconcile opposite tensions and inconsistent demands, such as demands of exploration and exploitation, by building internally inconsistent architecture within an organization. This inconsistent architecture retains the benefits of experimentation and variability, along with the benefits of exploitation and efficiency. It allows for uncoupling the variance-decreasing units and activities from those organizational units where variation is critical. Exploratory units are usually small and decentralized, with loose cultures and processes, while exploitation units are larger and more centralized, with tight cultures and processes (Benner & Tushman, 2003; Tushman & O'Reilly, 1996).

Tushman and O'Reilly (1996) have noted that organizational ambidexterity may be achieved when one or more business units in the organization focus on exploiting and one or more on exploring. This kind of structural differentiation, which is the product of subdivision of organizational tasks into different units (Lawrence & Lorsch, 1967), protects ongoing operations in exploitative units from interfering with processes and competencies being developed in exploratory units (Jansen et al., 2009). It allows very different frames to coexist in the firm, while not requiring different cognitive frames to coexist within individuals. The only frame integration that does occur within individuals is at the corporate level, where they need to engage different frames without the risk of creating operating inconsistencies (Gilbert, 2006). In other words, these differentiated autonomous business units ought to be strategically integrated through a senior executive's vision, while having limited tactical integration between themselves (Tushman & O'Reilly, 1997). Managers can highlight different goals and measures at different times. In this way, they can encourage more exploration or more exploitation, by emphasizing different aspects of performance, i.e. by operating several different performance measurement systems and by altering the degree to which these systems overlap or

diverge (Anderson, 1999). Usually, structurally differentiated units move from a primary orientation on exploration toward a more ambidextrous or even exploitative orientation over time.

Nevertheless, there are only a few options at disposal for a firm that wants to engage both in exploration and exploitation. It may differentiate its structure, i.e., adopt decentralized structure in terms of more or less independent internal division or a free-standing subsidiary. In contrast, a firm may adopt centralized structure and integrate its existing and innovative activities through fine-tuning and incremental changes or higher-dimensional, systemic reconfigurations (Siggelkow & Levinthal, 2003).

Westerman, McFralan and Iansiti (2006) suggested three options for achieving exploitation and exploration simultaneously: (1) separate-early, (2) integrate-early, and (3) wait-then-transform. Each of these options has its positive and negative implications on performance. The firms ought to choose the mode that best fits their strategic context and capabilities.

Separate-early approach strongly differentiates exploratory units and minimizes their interdependencies with exploitative ones. This option structurally optimizes for uncertainty, meaning that innovating unit can engage in rapid variation to respond to uncertainty, free from the existing limitations and boundaries in existing units. At the same time, this option suboptimizes interdependence. It cannot fully exploit benefits resulting from valuable interdependencies. Separate-early is well fit for variation early in the life cycle, but it becomes less fit later, requiring a transition to more integrated form. "This adaptation mode appears well suited for highly uncertain innovations or for firms where senior management cannot devote attention to coordinating interdependencies early in the life cycle. However, senior management involvement is still required to both set limits on early local search processes and to manage the transition to an integrated form." (Westerman, McFralan & Iansiti, 2006, p. 236)

Integrate-early is an opposite choice. It optimizes interdependence, while suboptimizing uncertainty. This approach is usually more efficient than the previous one because it makes use of existing resources in operating units. "However, it can be slower to act than the separate-early mode because it requires extensive effort to manage interdependencies early in the life cycle (although this coordination effort decreases over time)" (Westerman, McFralan & Iansiti, 2006, p. 237). Firms that do not lack strong integrative capabilities or the ones that can devote sufficient senior management attention to coordination early in the life cycle, would seem appropriate for this mode.

Wait-then-transform is the mode that avoids managing conflicting contingencies early in the life cycle. In other words, the firm must have enough slack resources to outwait uncertainty. After uncertainty passes, the firm optimizes for interdependence (Westerman, McFralan & Iansiti, 2006).

For firms that experience a large shift in their environment, a temporary decentralized response might be more appropriate than either a fully centralized response or a long-term decentralized structure. In this situation, firms may change their organizational structure from the aspect of balance between centralization and decentralization, both immediately after environmental change toward decentralization and after a period of initial exploration, back to a higher level of centralization, which can take place even though the environment is not changing. The benefit of temporary decentralization arises from its ability to sufficiently dislodge a firm from its prevailing practice so that the firm escapes its current development trajectory (Siggelkow & Levinthal, 2003). In order to reap the benefits from higher-dimensional changes affected by large environment shifts, a firm requires mechanisms for stability and coordination, i.e. a firm must employ organizational features that both push the firm toward exploration and pull it toward stability. In this manner, exploration and exploitation are not achieved simultaneously, but rather sequentially by adopting different organizational structures (Rivkin & Siggelkow, 2003). Furthermore, Siggelkow and Levinthal (2003) argue that in environments that experience a high frequency of large shifts, firms ought to repeat the process of going back and forth between exploration and exploitation. "As a result, firms might cycle through different organizational structures, pulsating back and forth between decentralization, to ignite new search, and centralization, to increase coordination." (Siggelkow & Levinthal, 2003, p. 665)

3.2. PARALLEL STRUCTURES

The difference between permanent and temporary organization can be explained using several criteria, but perhaps the most important one concerns the nature of the work to be done. In this sense, temporary organization is focused on a task, i.e. on action, while a permanent organization emphasizes goals and recurrent goal revisions, which primarily provide foci for decision-making (Lundin & Söderholm, 1995).

In order to achieve ambidexterity, some organizations are using parallel structures, i.e. they allow people to switch back and forth between two or more types of structures, depending on the requirements of their current task (Bahrami, 1992; Raisch & Birkinshaw, 2008; McDonough & Leifer, 1983). A good example of ambidextrous organizations using parallel structures is provided by Bahrami (1992), who describes some of the organizations operating in the Silicon Valley as “structured and yet chaotic... between stability on the one hand, and flexibility on the other” (p. 39). She argued that these organizations consist of two components. “The first component is a substrate of the formal structure which only periodically undergoes major transformation. This provides a formal mechanism for grouping skills, clustering activities, and assigning reporting relationships, as well as a base unit, which gives many employees an anchor of stability. However, due to inertial forces, these bedrock structures cannot be changed as frequently as may be warranted by internal and external changes. Many firms compensate for the relative inflexibility of the bedrock structure by using overlays of temporary project teams and multi-functional groups whose members are drawn from various operating units. These enable a firm to focus on critical assignments without causing major disruptions” (p. 39). Another example of dualistic structures in terms of employees moving back and forth between a bureaucratic structure for routine tasks and an organic structure for nonroutine tasks is provided by Adler, Goldoftas and Levine (1999). They have described how production workers switch between the two tasks supported by “parallel” organizational structures, such as quality circles.

Thus, these dualistic arrangements depicted here enable organizations to create a relatively stable setting within which people and resources can be effectively deployed in a flexible manner. Two structures coexist in order to ensure efficiency and flexibility at the same time. Parallel structures therefore allow competing demands for exploration and exploitation to be addressed within a single organizational unit (Gibson & Birkinshaw, 2004).

3.3. INTEGRATION

Firms that compete in environments characterized by high levels of complexity and dynamism require a higher level of division of labour in order to monitor many rapidly changing sectors of the environment. This leads to greater differences within the top management team regarding formality of structure, interpersonal orientation, and time orientation (Lawrence & Lorsch, 1967). Such divergence in perspectives makes consensus on the strategic direction of the firm difficult. Thus, Lawrence and Lorsch (1967) showed that increased differentiation necessitates an increased use of integrating structure to achieve high levels of performance. In less differentiated firms basic integrating structures such as managerial hierarchy of authority, rules and operating procedures, and informal integration by managers outside official channels may suffice, whereas in more highly differentiated firms, complex mechanisms may be necessary.

In organizations in which ambidexterity is achieved through spatial separation, integration may occur in form of loosely coupled organizational units. In this form explorative units are strongly buffered against exploitative units (Leonard-Barton, 1995; Levinthal, 1997). On the other hand, integration may occur even in form that combines both tight and loose coupling (Tushman & O'Reilly, 1997). In this kind of ambidextrous organizations, explorative and exploitative units are physically and culturally separated from one another and have different incentive systems, as well as management teams. Integration across units is achieved through coordination at the senior management level and a strong, widely shared organizational culture (O'Reilly & Tushman, 2004).

Jansen et al. (2009) examined the manner in which formal and informal senior team integration mechanisms, such as contingency rewards and social integration, as well as formal and informal organizational integration mechanisms, i.e. cross-functional interfaces and connectedness, mediate the relationship between structural differentiation and ambidexterity. They discovered that differentiation has positive effects on ambidextrous organizations. This effect is indirect, operating through both informal senior team integration and formal organizational integration mechanisms, such as liaison personnel and teams. The results of this research for senior team integration mechanisms showed that senior team contingency rewards, i.e. the formal component of senior team integration mechanisms, do not contribute to the achievement of ambidexterity. On the other side, senior team social integration fully mediates the relationship between structural differentiation and ambidexterity, and Jansen et al. (2009) concluded that structural differentiation is only detrimental to informal social relations at lower levels of hierarchy. This is why ambidextrous organizations need to resolve conflicting tensions between the members of senior teams, and to integrate diverse knowledge sources, which are located across exploratory and exploitative units (Smith & Tushman, 2005; Jansen et al., 2009). As for the organizational integration mechanisms concerns, regarding the formal

component of integration, Jansen et al. (2009) found that cross-functional interfaces are effective integrative mechanisms in structurally differentiated ambidextrous organizations. These interfaces have a mediating effect regarding the discussion of the hierarchical level at which integration between exploratory and exploitative efforts needs to happen. Gilbert (2006) argued that cross-functional interfaces are very important because of their ability to facilitate flows of knowledge between exploitative and exploratory units. Jansen et al. (2009) showed that, regarding informal social relations within organization, connectedness, viewed as the overall pattern of a firm's social network in terms of density, directly contributes to achieving ambidexterity, but it does not mediate the relationship between structural differentiation and ambidexterity. They stated that it becomes more difficult to develop and maintain informal social relationships between organizational members working in differentiated exploitative and exploratory units. Thus, according to them, connectedness (i.e. dense social relations) and its specific features, such as discipline, trust and support, directly affect the achievement of contextual ambidexterity.

Thus, informal integration mechanisms provided by senior management teams ought to be expanded by incorporating lower-level cross-functional liaisons (Gilbert, 2006; Jansen et al., 2009). Ambidextrous organizations need to incorporate more formal organizational integration mechanisms (i.e. cross-functional interfaces) at lower levels of hierarchy, because organizational members at these levels face high differentiation, but low level of interdependency, which requires more formal integration. On the other hand, at the higher hierarchical levels, ambidextrous organizations need to foster informal social integration among senior team members. At these levels, managers also face high differentiation as well as high dependency, which require frequent adjustments and more informal means of integration (Jansen et al., 2009).

4. CONCLUSION

Organizational ambidexterity gradually becomes a necessary condition for all firms that are trying to achieve long-term viability and prosperity in the discontinuous environment. However, this task is not an easy one. In order to become ambidextrous, organizations must learn how to achieve superior performance both in explorative activities, resulting in viable innovations, as well as in exploitative ones, resulting in high level of performance in on-going day-to-day operations.

The development of ambidextrous organizations would certainly be helpful for numerous firms in developing countries trying to achieve at least similar competitive positions as their counterparts in developed countries. In this way, they would have a chance to outperform those rivals that are still focused on being the best either in exploitation or in exploration. Therefore, gaining sufficient amount of knowledge regarding this issue is one of the most important tasks for the managers leading organizations, especially in developing countries, which is why the lessons presented in this paper are primarily dedicated to them.

This paper provides a profound insight into the concept of organizational ambidexterity. Authors are hoping that it will present a solid foundation upon which other authors can continue to build theoretical framework regarding ambidextrous organizations. On the other hand, authors are also hoping that this paper may present a set of guidelines for further empirical research on this subject, as well as for managers and other practitioners on how to build ambidextrous organizations. Only thorough understanding of the nature of ambidextrous organizations and the manner in which they ought to be built will enable scholars and practitioners to jointly put additional effort in order to enhance the probability of contemporary organizations to thrive in the age of discontinuity.

² NIS a.d. Novi Sad, srdjan.simic@nis.rs

³ NIS a.d. Novi Sad, dejan.ikonov@nis.rs

Abstract: *This paper depicts the intended reorganization of a department in a large company operating in Serbia. If this pilot project proves successful, it will be spread throughout the major part of this company. The aim of the reorganization in stake is to make a shift in this department: from a vertically structured into a horizontally oriented, process-driven one. This kind of reorganization has been insufficiently documented within companies operating in Serbia. It means that managers in these companies cannot expect to have any kind of guidelines when starting these endeavours. Therefore, authors are hoping that this paper will present a solid foundation upon which the body of knowledge relevant to practitioners in Serbia will be built. The reason for writing this paper is to share some thoughts on this kind of reorganization and extract experiences from a discussion hopefully to be initiated on this issue, in order to come up with coherent conclusions that would be helpful for all organizations in Serbia trying to achieve a higher level of competitiveness through the adoption of a process-oriented perspective.*

Key words: *functional organization, horizontal organization, decentralization, reorganization, hierarchy, process.*

1. INTRODUCTION

The world of organizations is subjected to the increased pace of constant changes within the environment, thus making the global organizational landscape a very hostile place. Some organizational forms presumably fail to flourish in these environmental circumstances while other forms successfully compete with them for essential resources (Hannan & Freeman, 1977). In order to make organizations sensitive and responsive to the relevant shifts in its environment, a major change in the concept of organizing must occur, i.e. the focus of organizations needs to be placed on their core processes and the manner in which they create value for the customers. Thus, vertical bureaucracies, i.e. functionally organized firms, ought to be transformed into the horizontal corporations, focused on its core processes. These organizations represent dynamic and strategically planned networks of self-programmed, self-directed units based on decentralization (Castells, 1996).

However, this is not an easy task. Adopting process perspective within an organization represents a major shift in organizational structure and culture (Davenport, 1994). In this paper, authors are depicting the complexities of such endeavour. The paper illustrates an intended reorganization of one department in a large company operating in Serbia. The aim of this reorganization is to increase overall effectiveness and efficiency of the department in stake. In order to achieve this objective, a shift from the classical functional, vertically integrated organizational structure into the process-oriented, horizontal one, must be made.

2. THEORETICAL BACKGROUND

In a functional organization (sometimes called the “unitary form” or “U-form”), all the activities pertaining to a particular function are organized into departments (Harris & Raviv, 2002). The functional form is structured around inputs required to perform the tasks of the organization (Hax & Majluf, 1981), and the primary building block of performance is the individual and his or her job (Ostroff & Smith, 1992). Functional organization uses a centrally coordinated, vertically integrated structure to manage employees in highly specialized jobs and is well-suited to single-business strategies (Miles et al., 1997; Miles et al., 2009). Thus, this form is more predominant in organizations having single or dominant products (Hax & Majluf, 1981). Its crucial advantage is functional excellence. “A functional organization tends to develop highly qualified technical skills and a climate conducive to technical excellence and high efficiency. It provides a ‘critical mass’ for the career advancement of its professionals. But its inherent stress on specialization pushes the decision-making process upwards, because only at the top do we find the confluence of all inputs required for a final decision” (Hax & Majluf, 1981, p. 421).

On the other hand, it is well known that the functional organization was a dominant organizational form in the era of standardization (Miles et al., 1997). However, contemporary organizations are facing the unpredictable and more complex environment than ever before (cf. Stefanović, Prokić & Vujović, 2012). In order to achieve long-term viability, organizations must develop a system of organizational response to any relevant change in the environment in real time (Ansoff & Antoniou, 2005). Taking this general shift in the organizational environment into account, one would argue that the main disadvantages of the functional organization are coordination and flexibility, i.e. the ability to quickly respond to all significant shifts in its environment. Bureaucracy, who is regarded as one of the main traits of functional organizations, is slow to adapt when a change is necessary because signals for change need to filter their way to decision makers and back again to those entrusted with execution (Child & McGrath, 2001). Taking this into account, Ostroff and Smith (1992) have noted that “because so many of today’s competitive demands appear to call even more on coordination than on functional excellence, it is no surprise that vertical organizations have a hard time responding to this kind of challenges...” (p. 150). Therefore, a different kind of organizing is necessary for a firm in order to thrive in the contemporary environment.

Since the beginning of the 90’s numerous academics and practitioners have come to realize that the opportunity for firms to become more agile and responsive to the environmental stimuli lies in adopting a different kind of perspective on the issues of management and organization. They discovered that the focus on the core processes within organization instead of the tasks and hierarchy will much likely produce significant improvements of the overall results. “A process is simply a structured set of activities designed to produce a specified output for a particular customer or market. It has a beginning, an end, and clearly identified inputs and outputs. A process is... a structure for action, for how work is done... [Business] processes are therefore the structure by which an organization does what is necessary to produce value for its customers” (Davenport, 1994, pp. 134-135). In other words, business processes are the driving force of any organization (Hammer & Champy, 1993).

Taking a process perspective implies adopting the customers point of view (Davenport, 1994). “In this alternative form of organization, work is primarily structured around a small number of business processes or work flows, which link the activities of employees to the needs and capabilities of suppliers and customers in a way that improves the performance of all three...” (Ostroff & Smith, 1992, p. 151). This is why the implementation of the process approach in organization is likely to yield certain benefits in terms of the overall performance but it is very important that there are reasonable expectations for success that will be fulfilled (Davenport & Stoddard, 1994).

Ostroff and Smith (1992) argue that, in order to make a transformation from vertically structured, functional organization, into a horizontally structured, process-oriented organization, a firm must take these steps: (1) organize around processes, not tasks; (2) flatten hierarchy by minimizing the subdivision of work flows and non-value-added activities; (3) assign ownership of processes and process performance; (4) link performance objectives and evaluation to customer satisfaction; (5) make teams, not individuals, the principal building blocks of organization performance and design; (6) combine managerial and non-managerial activities as often as possible; (7) treat multiple competencies as the rule, not the exception; (8) inform and train people on a “just-in-time to perform” basis, not on a “need to know” basis; (9) maximize supplier and customer contact; and (10) reward individual skill development and team performance, not just individual performance.

The benefits of the transformation from the vertical functional organization into the horizontal process-oriented one may be seen through the achievement of higher level of a firm performance. Firm performance indicates the quality of the firm’s continuous co-alignment with the environment (Chakravarthy, 1986). Thus, the process-oriented organization ought to develop a performance model of its operations that relates process performance, and the customer satisfaction level resulting from it (Davenport, 1994). Process performance represents a degree of stakeholder satisfaction, which is why process performance measurement ought to be focused on those individuals who have an interest in the business process. In order to develop this stakeholder-driven performance measurement system, stakeholders of the process have to be identified and their process-relevant goals clarified. Each group of stakeholders needs to be represented by an aspect or dimension of performance (Kuong, 2000).

Kuong (2000) suggested an approach to compose a holistic process performance measurement system (PPMS) comprised of the following steps: (1) eliciting appropriate process performance indicators (using a generic set of performance and picking up the right ones, which is a less expensive and less time consuming approach, or starting from scratch, which is a more effective approach, because the indicators will be tailored

according to the specific needs of the processes within an organization); (2) determining targeted values for each indicator (input can be derived from: scanning the market, asking stakeholders, benchmarking, simulation and experiments, or research institutions); (3) developing methods to gather data (data sources, methods and instruments have to be defined in order to gather the necessary data); and (4) creating an information system that manages collected data (the gathered data have to be compared against target values and historical values, information regarding the performance gap has to be acquired, and the results must be disseminated to the process participants).

Another important issue, which cannot be viewed separately from the issue of reorganizing from the vertical to horizontal organization, is achieving an appropriate balance between centralization and decentralization. On one hand, an organizational structure is perceived as decentralized when decision making has been disaggregated into a number of organizational units, each making its own decisions (Siggelkow & Levinthal, 2003). Therefore, decentralization represents the transfer of decision-making authority and resources to lower levels of the organization: from the top management level down the hierarchy. It promotes internal and external organizational flexibility that is required for firms to respond speedily and appropriately to market signals (Hill, Martin & Harris, 2000). At corporate level, decentralization involves assigning responsibilities to semi-independent operating units and reduces the role of the corporate core to a minimum (Kay, 1993). The most radical form of decentralization is so-called “marketization”, either the contracting-out to external suppliers of activities previously performed in-house, or the creation of internal quasi-markets among semi-independent units within the firm (Hill, Martin & Harris, 2000). On the other hand, an organizational structure is perceived as centralized when decisions are made only at the level of the firm as a whole or one specific organizational unit (Siggelkow & Levinthal, 2003). Centralization is the tightest means of coordinating decision making in organizations, but the rationale for decentralization stems from the fact that: (1) many decisions cannot be understood at one center or in one brain; (2) it allows the organization to respond quickly to local conditions; and (3) it is a stimulus for motivation of employees (Mintzberg, 1979).

Numerous researches have been conducted on the topic of centralization versus decentralization. For example, Vancil (1978) empirically examined around 300 companies and concluded there is a strong tendency to decentralize functions that are closer to the customer. Tushman and O'Reilly (1996) have argued that an important part of the solution of very successful firms such as: ABB (Asea Brown Boveri), Johnson & Johnson and Hewlett-Packard, is massive decentralization of decision making, but with consistency attained through individual accountability, information sharing, and strong financial control, as well as a common overall culture. In this vein, Hill, Martin and Harris (2000) have stated that “one needs to distinguish between the different types of decision affected by decentralization. There is a broad distinction between financial and strategic issues, on the one hand, and operational issues on the other. Decentralization may be implemented on ‘tight-loose’ principles. Financial and strategic issues may be centralized while the others are decentralized” (p. 566). However, they have shown that patterns of centralization/decentralization are sensitive to historical contexts, particularly to initial starting points. With different initial conditions, the trajectories of development may reasonably be expected to differ.

Three empirically confirmed hypotheses seem to be very useful here. *The first one* is that centralization is negatively associated with effectiveness in turbulent environment (e.g., Child 1984; Randolph & Dess, 1984). “Turbulent environments require organizations to act frequently and quickly and this in turn requires that information about the environment be processed rapidly. Since each level in a hierarchy creates a delay in the vertical movement of information, and assuming that lower-level units are dealing with the turbulent environment, it follows that organizational actions should be selected by the lower-level units and with the involvement of as few upper hierarchical levels as possible” (Huber, Miller & Glick, 1990, p. 13). *The second one* considers the relationship between centralization and effectiveness regarding the size of an organization. It states that centralization is negatively associated with effectiveness in large organizations (e.g., Child, 1975; Daft, 1992). Regarding this hypothesis, Huber, Miller and Glick (1990) stated that “because communication distortions and delays increase as the number of organizational levels between message senders and message receivers increases, decision making is more effective if decision makers are organizationally near those with relevant information (presumably lower-level members) and if decision makers are organizationally near those who carry out decision-maker directives (presumably lower-level members)” (p. 14). And finally, *the third hypothesis* depicts the implications of centralization on efficiency and effectiveness (productivity). It is hypothesized that “centralization is more positively related to efficiency than it is to productivity” (Huber, Miller & Glick, 1990, p. 15).

Thus, two issues are of prime importance for this paper: (1) the particular manner in which the classical functional, vertically integrated organizational structure may be reorganized into the process-oriented,

horizontal one, and (2) achieving an appropriate balance between centralization and decentralization along the way. In this vein, Keidel (1990) argues that the search for balance between control (centralization) and autonomy (decentralization) needs to be complemented with cooperation (teamwork), which is a fundamental trait of horizontal organizations.

It should be noted here that moving toward process-oriented organization is not a universal solution that needs to be adopted by every firm. On the other hand, not even the most process-oriented firms have created an entirely process-based organizations, because there is still a need for specialized functions (Davenport, 1994). Each firm must seek its own unique balance between the vertical and horizontal features needed to deliver an appropriate level of performance (Ostroff & Smith, 1992), as well as its own balance between centralization and decentralization.

3. REORGANIZING A LARGE COMPANY IN SERBIA

The focus of this paper is on a large company operating in Serbia and employing more than 9.000 people. The name of the company and its industry are confidential and will not be revealed. This company is a vertically integrated system that encompasses the whole process of creating value: from the raw material production to the sales of final products directly to the customers through its own distribution network. The company consists of four sequentially related semi-autonomous divisions in terms of producing value for the customer with clear boundaries between them. On the other hand, the headquarters of the company consists of a number of functions (e.g. finances, legal and corporate, strategy and investments, etc.), which provide support to the semi-autonomous divisions. These functions are very influential within divisions. Most of them have their own functionally subordinated organizational units within each division. People employed in these organizational units are subordinated through the line of hierarchy to the executive director of the division they work in, but are also functionally subordinated to the function in which scope of work they operate. Thus, this company is characterized by specific line-function relations. In this vein, it may be concluded that its model of organizing is somewhere between the classical functional organization and classical divisionalized form.

Within this company, the processes usually follow existing boundaries of organizational structure and authority. The only exception is functionally subordinated organizational units within divisions already mentioned. The process owners in these units are located in the headquarters, i.e. the functions and departments within them. In other words, functions are in charge for the manner in which the work within these units will be done, while line managers in divisions determine what will be done. Nevertheless, processes should not be determined by the existing organizational structure, but rather represent the basis for organizational structure design. In this way, a process may cut across business functions, geography, product groups, or even the boundaries of a single organization (Davenport, 1994). On the other hand, frequent miscommunication and duplication of work in the company in state is the sign of not having the proper coordination mechanisms in place. Coordination mechanisms are design tools that are used in addition to a firm's hierarchical reporting arrangements to increase coordination, communication and decision making across organizational boundaries (Brown, 1999; Daft, 1992; Galbraith, 1994).

The scope of the intended reorganization is not the overall company, but rather one department (we will refer to it as Organizational Optimization Department or OOD) that provides support to the whole company in terms of organization design, business processes, and integrated management systems. The organizational structure of OOD is presented in the Figure 1. This department consists of three sectors within the headquarters, and four functionally subordinated sectors out of which each operates in one of the four divisions already mentioned (shown by the dotted lines in Figure 1). Each of the three sectors operating in the headquarters is in charge for one domain of work, namely: organization design, business processes and integrated management systems. They develop know-how within their domain of work and define standards according to which the job ought to be done within the headquarters, where they provide their services to the other functions and departments, as well as within divisions by the functionally subordinated sectors in charge. On the other hand, sectors operating in divisions are in charge for all of these work domains. They need to implement the know how and standards provided by all three sectors from the headquarters. Sectors in divisions are physically dispersed on several locations, which means that some form of decentralization regarding the actual operations is required, but simultaneously a high degree of centralization regarding the know-how and methodological issues exists at the level of headquarters, which ought to result in a uniform quality of services provided to all divisions, as well as the headquarters. Thus, the role of the headquarters is to facilitate operations and make them go faster and better, which is why the staff in headquarters ought to possess only the expertise that the field wants and needs (Tushman & O'Reilly, 1996).

The aim of OOD reorganization is to increase overall effectiveness and efficiency of its processes in terms of the increase in quality of outputs (viewed from the client standpoint, i.e. divisions, as well as functions in the headquarters) and reduction of its cycle time and resources engaged. In order to achieve radical improvements in terms of effectiveness and efficiency of its work, it has been realized that the focus of the reorganization must be on the processes. Some analyses and numerous discussions lead to the conclusion that the process perspective ought to be adopted and OOD needs to be reorganized in a manner that will facilitate its processes. Another issue seemed very important: whether existing line-function relations need to stay in place or functionally subordinated units need to be entirely incorporated within the OOD. Thus, the comparative analysis has been done and its results are presented in the Table 1 and Table 2.

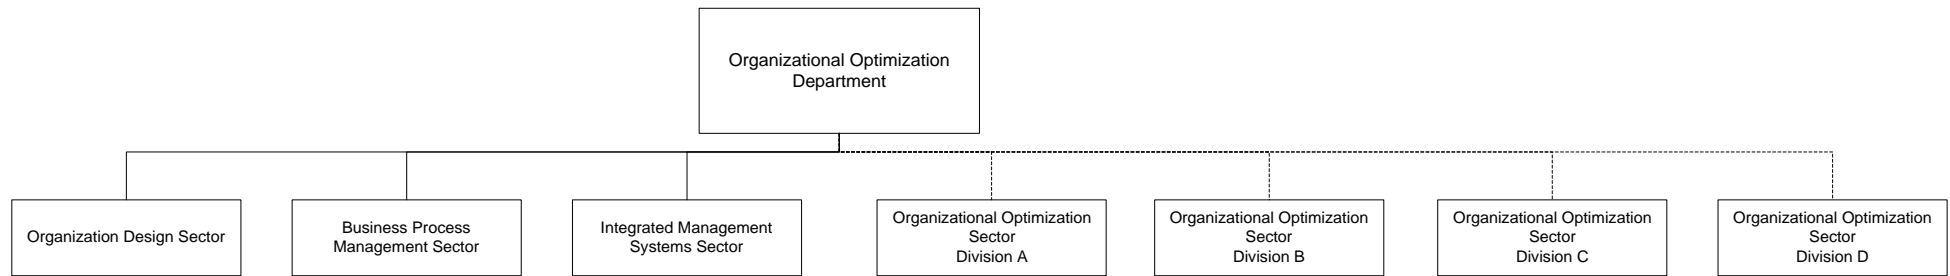

Figure 1: Current organizational structure

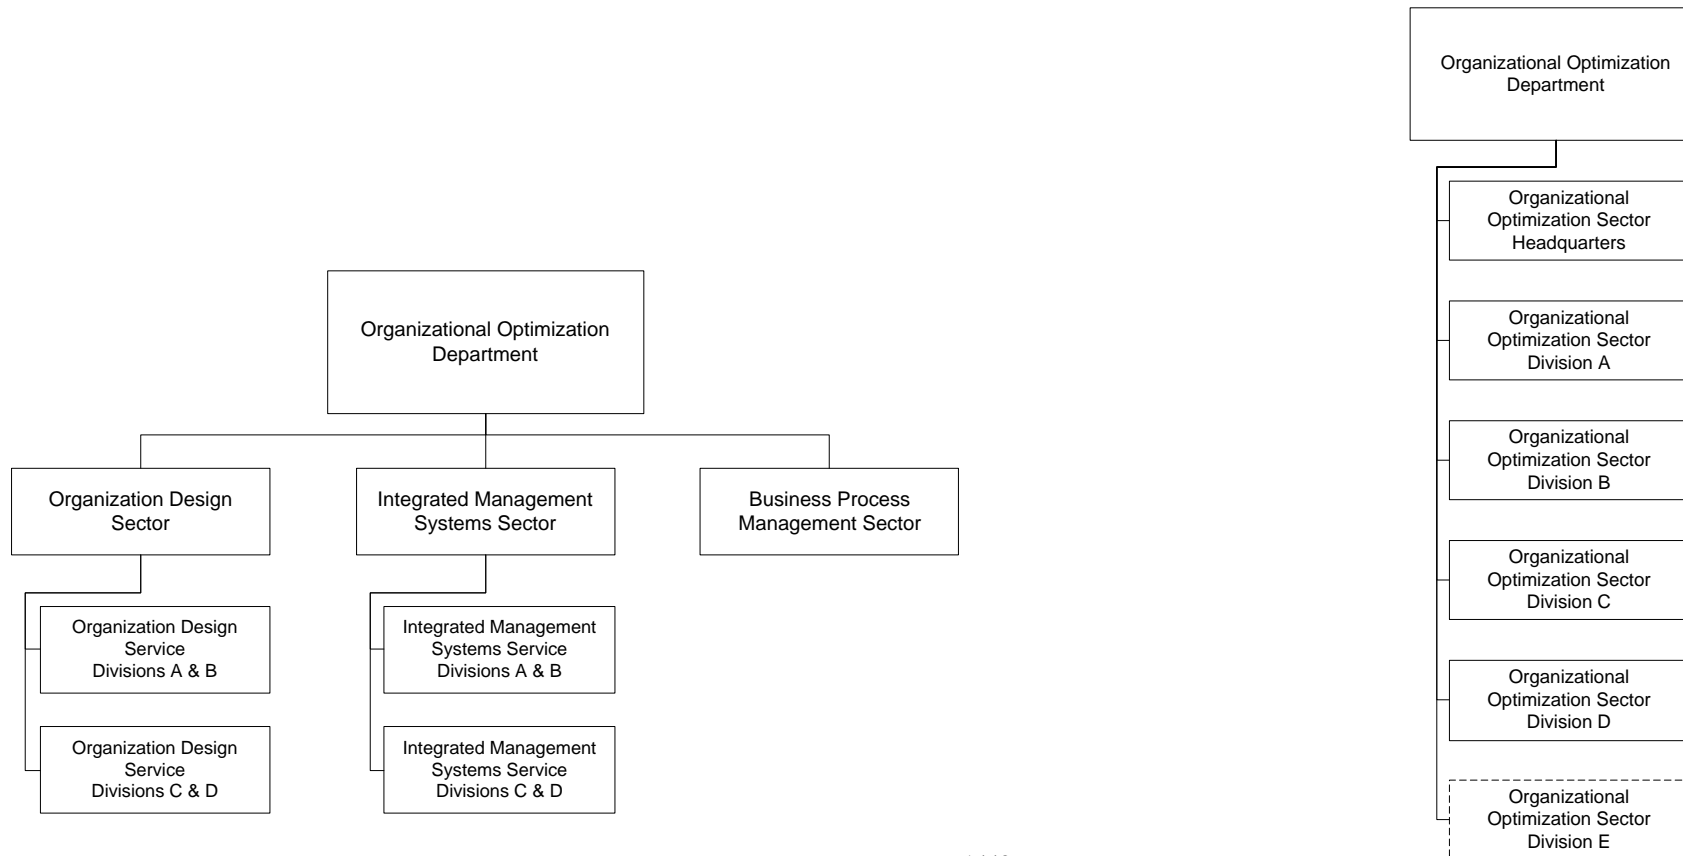

Figure 2: Proposed organizational structure in the 1st phase

Figure 3: Proposed organizational structure in the 2nd phase

Table 1: Functional vs. Process Organization

Organizational Issues	Functional Organization	Process Organization
The number of levels of hierarchy	Tall organization; more levels of hierarchy	Flat organization; less levels of hierarchy
Span of control	Narrow	Wide
Importance of Coordination Mechanisms	<ol style="list-style-type: none"> 1. Standardization of work 2. Direct supervision 3. Standardization of output 4. Mutual adjustment 5. Standardization of skills 	<ol style="list-style-type: none"> 1. Standardization of work 2. Standardization of output 3. Mutual adjustment 4. Direct supervision 5. Standardization of skills
Degree of specialization	Employees as specialists	Employees as universalists
Departmentalization Criteria	Knowledge and skills	Work-flow interdependencies
Level of Centralization	High centralization	Low centralization
Process Boundaries	Process is fragmented by the functional sylos	Process brakes the functional sylos
Process Owner	Line manager	Manager accountable for customer satisfaction
Performance Measurement and Reward System	Vertically defined; line manager determines the reward	Horizontally defined; customer determines the reward

Table 2: OOD Director as Line vs. Functional Manager

Organizational Issues	OOD Director as a Line Manager	OOD Director as a Functional Manager
Unity of Command Principle	Obedied (one manager)	Violated (two managers)
Unity of Direction Principle	Obedied (goals are decomposed on several subgoals down the hierarchy)	Violated sometimes (due to the overlap of the goals of the line and functional manager that may be in collision)
Process Owner	Line manager	Line and functional manager (each within its domain of authority)
Performance Measurement and Reward System	Vertically defined; line manager determines the reward	Vertically defined; both line and functional manager determine the reward
Conflict Risk	Low	High
Knowledge Transfer between the Headquarters and Divisions	High	Low
The Possibility of Process-approach Implementation	High	Low
The Possibility of Work Duplication	Low	High

The source: Authors

The results of these analyses show unambiguous need to conduct the radical organizational shift from the vertically established hierarchy to the more flexible, horizontally oriented department focused on its processes and the value they create. In order to achieve this shift, the process perspective must be adopted, which means that divisions and other functions within the headquarters ought to be perceived as clients instead of partners, as it was the case until now. Therefore, a number of things need to change in order to facilitate this shift. One of the first things to change is the performance measurement system, as well as the reward system, because these two are inextricably intertwined. New performance measurement system needs to implement horizontal KPIs that will follow the processes indicating its performances until the delivery of services to the clients (divisions and functions) where it would measure the satisfaction of the clients with the service provided, i.e. in which degree does the services provided to the client facilitate its own operations and business results. These horizontal KPIs ought to complement the existing vertical KPIs, not to replace them. As for the reward system concerns, it must be related to KPIs and to the level of competencies achieved by the process team and each individual within it. In process-based organizations "information and training get provided just-in-time – on a 'need to perform', not a 'need to know' basis. Career paths follow work flows: advancement goes to people who master multiple jobs, team skills, and

continuous improvement. Compensation rewards both individual skill development and team performance" (Ostroff & Smith, 1992, pp. 151-152). In this vein, Davenport (1994) argues that managers and other individual contributors should be evaluated and compensated on the basis of their contribution to cross-functional processes. On the other hand, two major obstacles for achieving this organizational change are identified. The first one is concerned with unevenly distributed competencies between sectors. The competence base is located within the headquarters, which means that their transfer has left out. In other words, the first task on this route of reorganization is to make nivelation of competencies, i.e. that all employees within OOD possess similar level of competencies in their scope of work. The other one concerns the resistance of certain groups of employees that is expected once the plans for reorganization are being communicated. Therefore, the reorganization ought to be conducted in two phases. Organization structure that will result from the first phase ought to achieve competencies nivelation, after which the second phase ought to result in a horizontal, client driven, process organization.

The first phase of the intended reorganization will result in a taller hierarchy, accompanied by a high degree of centralization in order to make the existing processes uniform and more efficient. It is well known that hierarchy represents the formal coordinating mechanism that aims to minimize the deficiencies that have resulted from the division of labor. In the functional organization, it ties together business units, functions, departments and even individual tasks, thus providing the unity of efforts for achieving identified goals (Ostroff & Smith, 1992). In this phase employees ought to be routinely moved across units to ensure the development of personal relationships and greater interunit cooperation (Dess et al., 1995), as well as similar level of competencies. It is planned that this phase, in which functionally subordinated sectors will be renamed into sections and transferred from divisions into OOD, lasts between a year and a year and a half. The people working in these four sectors will be evenly distributed between the new sections directly subordinated to the Organization Design Sector and Integrated Management System Sector (according to their knowledge and previous experience) in order to obtain all the competencies required within this domain of work, while all of them will be trained by the Business Process Management Sector because this domain of work is equally important to all employees in OOD. However, employees from divisions A and B will be put into the same section because the divisions they came from have a lot of similarities regarding the nature of operations being performed. The same will happen with employees from divisions C and D. The result of the first phase of reorganization is represented in Figure 2. *The second phase* of reorganization will be characterized by a high degree of decentralization and focus on the process teams in order to achieve the highest level of responsiveness to the client's needs. The sections will become sectors again out of which each one will be in charge for one client, i.e. division. At this moment, employees will possess a satisfactory level of competencies. Thus, they will be returned into their own sectors comprising a true process teams. Each team organized around the process will need to take the front-line, problem solving initiative required to meet its overall objectives. The team members will be cross-trained so that they can perform each of the tasks necessary to the entire process, i.e. they will possess complementary skills. "For most employees in most organizations, the cutting edge standard of specialized task expertise is illusory. Whether they are front-line workers or executive vice presidents, most people contribute more to the customer satisfaction by understanding, even if at a moderate level, a large number of the tasks required to produce satisfaction than by being extraordinarily good at only a few" (Ostroff & Smith, 1992, p. 162). The result of the second phase of reorganization is exhibited in Figure 3. Division E, which is represented by the dotted lines indicates that each new division established will be accompanied by the new sector.

One of the benefits of transforming an organization from the vertical to the horizontal one is the flattening of hierarchy, which results in the cost reduction and increase of the flexibility. This is not obvious in the reorganization just described, because the focus is on one department only, but will be more evident when the reorganization spreads on the larger part of the company. "The way to flatten hierarchy is to combine related but formerly fragmented tasks, eliminate activities that do not add value or contribute to the achievement of performance objectives (unnecessary inspection, for example), and reduce as far as possible the number of activity areas into which each core process is divided" (Ostroff & Smith, 1992, p. 157). Very often managers developed in rigid hierarchies find it difficult to make the transition to the more democratic, participative style that teamwork requires (Dess et al., 1995), which must be taken into consideration before the reorganization starts.

4. CONCLUSION

The shift from the vertically structured, rigid hierarchy to the horizontal, process oriented company armed with the speed and flexibility is not a matter of possibility, but rather of necessity, if the company wants to achieve long term success and thrive in the complex and dynamic environment such as the one we live in.

As Ostroff and Smith (1992) noted: "Enough companies have moved away from their vertical past, at least in part, to convince any responsible managerial jury that significant performance gains do follow the shift to a horizontal organization" (p. 167).

The intended reorganization depicted in this paper ought to be regarded as a pilot project. If it proves successful in terms of the expected results, it will be spread on a number of other departments throughout the company. The experience gained from this project will be very useful for other endeavors similar to this one, not only for the company in stake, but for the others as well if it is to be communicated with them. Only radical organizational changes aimed to alter the very core of organizational architecture, such as this one, will foster the increase of competitiveness of numerous enterprises in Serbia that are currently struggling for its very existence.

EXTENDING HOLDING AS AN INSTITUTIONAL MODEL TO THE PUBLIC SECTOR

Abstract: *In most cities the public sector directly affects the lives of all residents, so these public companies are among priorities for city authorities. In order to improve public services, many city governments have performed the restructuring of the public sector and formed holding organizations of public companies. This paper will show the examples of several European cities, where holding is the current organizational form in the public sector. Special focus will be on the possibility of implementing this approach in the city of Belgrade. These examples contain concrete methods, which lead to improved control and handling of the whole system, reduction in management costs and overheads, and eventually, to a better quality of public services. Having in mind the success of implemented institutional solutions in the examples shown in this paper, we may conclude that forming a holding of public companies is one of possibilities for the future development of the public sector in the city of Belgrade.*

Keywords: *holding, public sector, restructuring, organizational structure, reorganization, network organization*

1. INTRODUCTION

Main characteristics of modern business, such as rapid changes, new business models, development of ICT, and many others, generate the demand for usage of advanced organizational models. Since public sector is very important for local community, many authors discussed which organizational form of public companies is the most suitable, not only to provide most efficient services to the residents, but also to reduce the expenses and use the city budget optimally. Many of these authors mention different network organizational models in this context. The advantages of network models, in both public and private companies, are significant. They include improvements in learning system, better allocation of resources, more efficient planning, easier dealing with complex problems, identifying the key values and, in the very end, increased quality of products and services (Jaško, Jaško & Čudanov, 2010). These models are all based on specialization. It means that every organization should identify its primary activity (or primary activities), which is the main cause of their existence, and then focus on it. This basic activity is called core business. Organizational concept like this is necessarily followed by cooperation with other organizations, in order to complete the value chain, so the customers can receive full service. There are many ways for every organization to eliminate all the activities that are not part of its core business. Outsourcing is one of them. Having completed this, the process of developing a network model can be started (Popović, Jaško & Prokić, 2010). Network consists of main company and network members, which are specialized for different functions.

One reason for forming a network is reducing of transaction costs in companies where market relations are frequent and of high value. Transaction costs are expenses of products' transaction across the border of organizational system or one of its parts (Dulanović & Jaško, 2007). This leads to infusion of hierarchical elements into market exchange (Zenger & Hestrelly, 1997), which is also known as quasi internalization (Sydow, 1999). Analysing transaction costs, management of the company may decide to form a network organization with its intensive partners, in order to be more profitable. Increased relationships formalization and business processes standardization will definitely reduce the expenses.

Another approach considers releasing some of the functions that were previously part of company's business. This is known as infusion of market management into hierarchy (Zenger & Hestrelly, 1997). One of the goals of internal functions outsourcing is their motivation to become an equal player on free market and to do business at market principles. This process is followed by creation of profit centres.

In first scenario, an external network of independent organizations is created. There are two types of these organizations. More stable solution is called strategic network structure, while less stable one is known as virtual organization, whose main characteristic is high level of flexibility. Stable network structure is formed when a company decides to focus on those activities that represent its best performance, which is in most cases core business, while others are released to external organizations. This may be great concept for

organizing supporting functions in large companies, such as maintenance or security. These activities are usually not part of core business in large companies, so idea is to hire specialized firms, in order to significantly reduce costs.

In second one, an internal or modular network organization is formed. It is usually holding or concern. Internal network organization means that all the parties are under the same ownership. Its main characteristic is that every entity is large enough to do the business independently and to interact not only with other members of the network, but also with the third parties on the market. Independent organizational entities are specialized for certain activities. They are controlled by Mother Company, so they become dependent companies within it (Dulanović & Jaško, 2007). Therefore it is clear that holding is an institutional form of internal network.

Holding is the term that stands for society (Mother Company) that controls other societies (Daughter Company, branch) through shares ownership (Dulanović & Jaško, 2009). This control considers the influence that holding company has on branches' business, while they remain independent formally. General opinion is that the main benefit of holding organization is on fiscal plan, tax reduction actually. However, the main advantage is holding's control of every branch, especially of their financial management (Vasiljević, 2009). When it comes to competency and responsibility, level of this control can move from simple checking of business results to active involvement in company's functioning. Branches access the financial markets through holding company. For large transactions approval from holding is needed. Besides that, all the investments that Daughter Companies make are strictly controlled by Mother Company. On the other hand, holding company usually leaves its entities large space for doing core business, industrial or commercial, at will. Nevertheless, holding can always direct its branches, perform some common activities such as marketing, public relations, research and development, human resources, accounting or legal services. It may also own their patents and licenses ([Charvériat](#), [Gouthière](#), [Bardet](#) & [Beetschen](#), 1991).

Public sector holdings first appeared in the beginning of 20th century in energetic, when large number of small producers in some countries in USA formed holding companies. However, this approach led to the monopoly in certain industries, so it was forbidden by the law very soon (Public Utility Holding Company Act of 1935). Still, this law did not forbid forming a holding of city companies, since they belong to different industries, so this does not cause the monopoly. This brought to new model of public sector organization in some cities. The energetic companies mentioned before were public, but were not owned by state or city. They were profit-oriented, which is the main reason why their unification was not allowed, since it would harm the residents. Purpose of existence of public sector is to satisfy public needs. However, local public companies should not be considered as non-efficient monopoly organizations (Hall, 1998). All over the world we can find examples of successful public companies that are owned by the city, but also do their business on regional markets. One of them is water company 100% owned by the city of Berlin, which was one of the key partners during water supply privatization in Budapest.

One of the main reasons for forming a holding of public companies is the increase in costs in public sector. During 1990s complete reform of public sector was conducted in Italy. It was caused by expenses and many cities formed public holdings then. Parts of these holdings were later sold, which led to the public-private partnerships. In Genoa, for example, city holding was formed in 1995 (Azienda Mediterraneo del Gaz and Acqua- AMGA), and already in 1996 49% of shares were sold to private investors. Similar examples can be found in Germany, in Frankfurt and Mannheim (Hall, 1998).

This paper will analyse public holdings in four European cities: Győr, Milano, Ljubljana and Vienna. Each city is of different size and has many specific characteristics. Nevertheless, holding solution was implemented successfully in public sector in every one of them, which proves the universality of this concept.

2. GYŐR, HUNGARY

In 2007, city authorities in Győr, city in northwest of Hungary, decided to form a holding of public sector, in order to create a city owned company that will manage city assets professionally. Together with that, this company should manage and control other independent public companies, achieving better efficiency then previously. Organizational structure of Győr holding is shown on Figure 1 (Szabo, 2008).

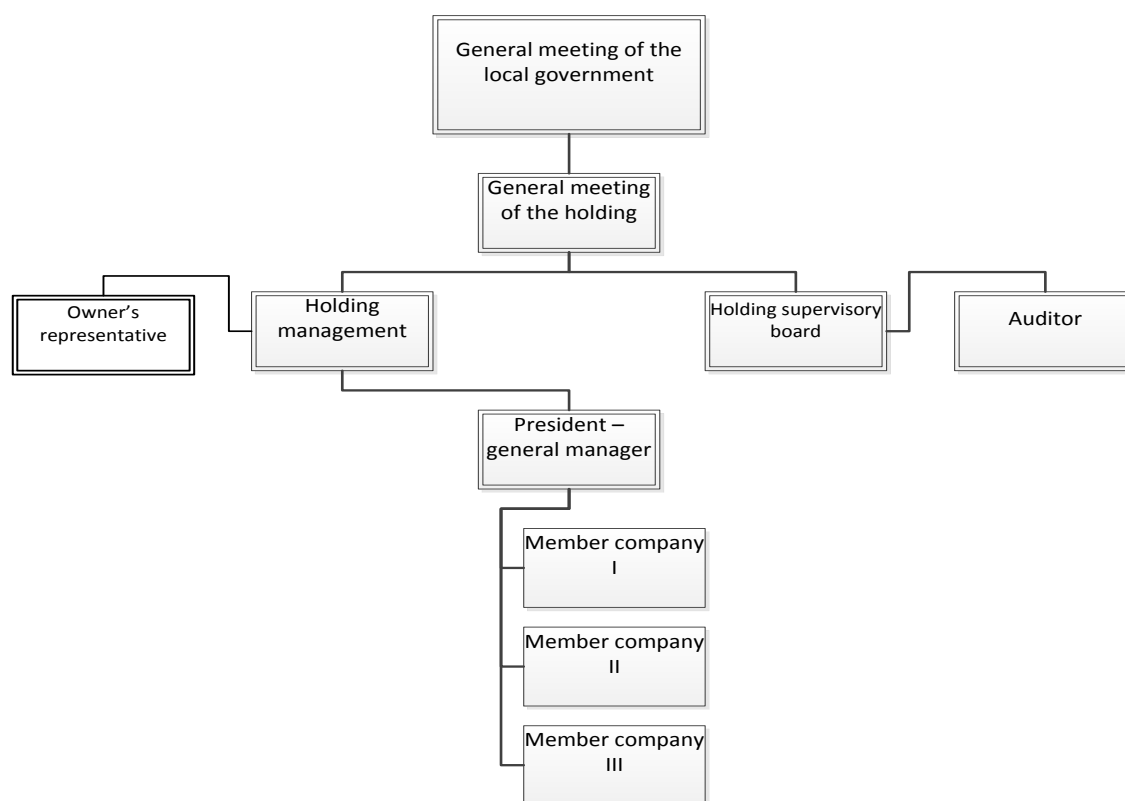

Figure 7: Organizational structure of municipal holding company, Győr, Hungary

Since one of the goals was better control of public companies, a supervisory board was formed. The idea was to introduce professional management into public services, which would consist of professional managers, instead of leading party members. However, if we look at the Figure 1, we can notice that city authorities still had the possibility to place their representative in the board, which allowed them to keep immediate insight and control. This problem of non-professional managers in public companies, such as in Győr, is also very present in Serbia, even in Belgrade. Increased control leads towards more transparent activities, which can reduce constant pressure that public puts on city authorities when it comes to public sector business results.

On the other hand, since there is no centralized organizational unit which could help in achieving economies of scale, so the increase in public companies efficiency can be questioned. Strategic decisions are made on the top level, which means that holding managers' task is to define goals for all public companies, plan and coordinate their work, approve operational plans and budgets, secure and allocate financial resources, manage the investments etc. Forming this strategic holding releases the managers of Daughter Companies from strategic tasks, which allows them to be completely focused on their core business and responsible for its efficiency.

Most cities commit large part of their budget to public sector. One of the most important goals of Győr holding was to reduce this financial pressure that existed. Common financial management is maybe the most important characteristic of holding company. This was implemented in Győr. Common liquidity control and investments optimization led to certain savings when holding was formed (Szabo, 2008). Besides that, holding's position on financial market is much better than any of the independent companies ever had. Before the restructuring, each company could raise loan at different interest rate, depending on their business results, size, activity risk etc. However, holding is now able to get credits at more affordable terms, and allocate the money in accordance with city strategy. Taking loans from commercial banks is just one of self-financing concepts that holding management wanted to implement, in order to reduce dependence on the city budget. Another one considers sort of internal bank, whose task is to manage holding's free resources. This would open the possibility for companies to get credit from some other member of the holding, at more affordable interest rate than any commercial bank could offer.

Implementation of organizational structure on Figure 1 reduced the management costs. Each public company used to have its own steering committee, while now only one board exists in holding. This approach could lead to huge savings in city of Belgrade, since 25 public and public communal companies now do their business separately. Certain savings are also possible during procurement, although there is no independent organizational unit for these activities on top level (Szabo, 2008). Procurement of goods and services of large values should be done for every holding member together, while companies would get certain specific items, when necessary. Besides all this, network organization of public sector enables wide spectrum of internal services that companies can provide to each other. They can be charged at market prices or transfer prices, depending on strategic decision of holding board when it comes to profit allocation, since all the resources remain in holding.

Cornerstone of all changes is development of integrated information system, which will increase the efficiency and control level in public companies. Changes in organizational structure are followed by technological improvements (Todorović, Čudanov & Komazec, 2012). It also supports decision making process. This should be followed by integration of financial and accounting activities, with standardization of planning and reporting. Integrated system allows more reliable measurement of companies' performance that not only increases the quality of decision making, but also brings more transparency in business.

3. LJUBLJANA, SLOVENIA

Public holding Ljubljana was founded in 1994, and today consists only from four companies. "Energetika Ljubljana" is company that provides heating services to residents, while "Vodovod i kanalizacija" is responsible for water supply. Another member is city transportation company "Ljubljanski potnički promet" (LPP). Fourth public entity, "Snaga" company, provides the maintenance of green areas, sanitation and garbage management.

One of its characteristics is that it also has other sources of financing, in addition to its core business, which was mentioned before. Reason for this is the fact that holding members are able to offer their services on free market, so they can compete with private companies. For example, LPP is authorized to provide technical reviews, so besides processing its own vehicles, it also offers this service to other parties. Anyone can do technical review and complete vehicle registration process here. Many public companies in Belgrade, considering work experience and expertise of the employees, could be extremely competitive on free market in certain fields.

If we compare the activities in public holding Ljubljana and those in Belgrade public sector, we can conclude several things. Public holding Ljubljana has significantly less coverage than all public companies in Belgrade. City size cannot be taken as an argument in this case, since certain public services simply need to be provided, despite the number of residents or area size. Some services that are in Belgrade provided by public sector, in Ljubljana are outsourced to private companies, due to economic reasons, since they are able to do more quality job, with less expenses. The model present in Ljubljana, which turned out to be rather efficient in many cities, could be implemented in city of Belgrade, by forming a public holding and then privatize some of its parts.

4. MILANO, ITALY

As part of already mentioned public sector reform in Italy, public holdings were formed in many cities. Besides the activities that are usually under the control of cities, such as heating, water supply or public transportation, city of Milano also manages sports objects, cultural manifestations and food supply of schools and kindergartens. Before the holding was formed, city of Milano provided the services directly or via some agencies that it owned 100%, so called "aziende municipalizzate". Reform goal was to implement modern management principles in public companies' functioning. City of Milano today manages all the mentioned activities using certain instruments, joint stock companies that form the holding, which is owned by the city. Private companies are also included in public sector, through partial ownership of some holding entities.

A very complex set of control instruments was formed, in order to control the activities of public companies, holding members. Besides increased level of control, another goal of this system is to secure the city demands in terms of quality and quantity of the services provided. Relationship between city of Milano and city holding is shown on Figure 2 (Longo & Cristofoli, 2008).

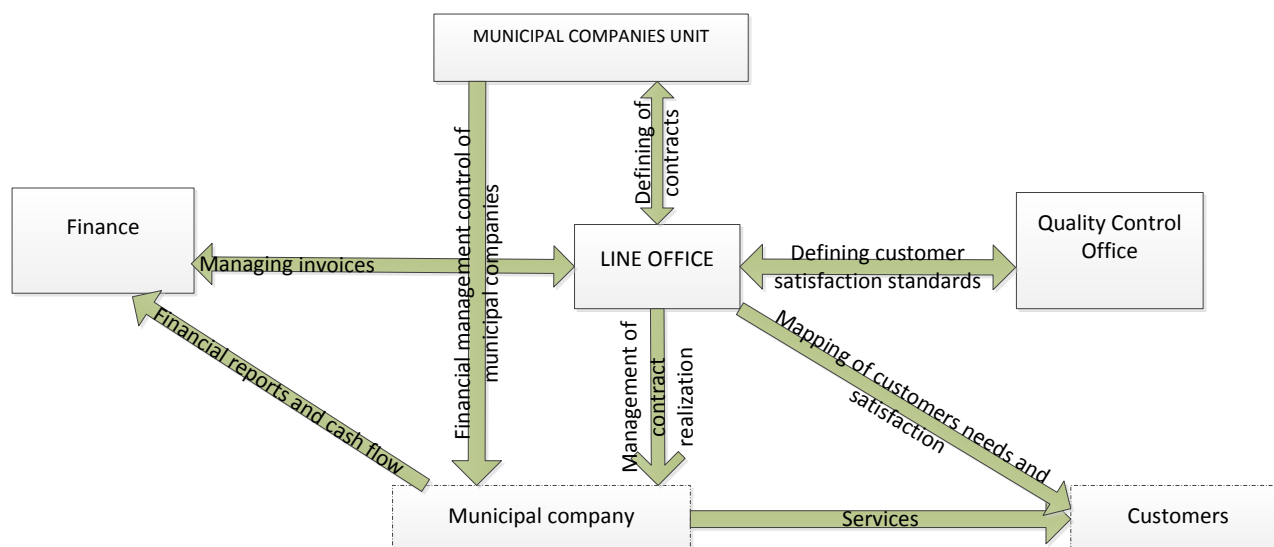

Figure 8: Set of control instruments for activities of municipal companies

Figure 2 shows the system that enables adequate control level of activities of public companies to city authorities, and focus on residents as end users. Finance department and Line office are part of the same mechanism. While Line office manages contracting between city of Milano and public holding, Finance department controls the financial transactions of public companies that form the holding (Longo & Cristofoli, 2008). These two units represent the financial connection between the city and holding. First step is to define the contract between the city and city holding (purchaser-provider contract), where all the demands, in terms of quality and quantity of services, are clearly specified. Another point is the price that city will pay after the service is provided. This contracting is done by different organizational units, specialized for certain services, grouped in Line Office. Another task of Line Office experts is to follow the execution of these contracts and to, in cooperation with Finance department, approve the payment of services. Part of the job that these two units perform can be compared to the activities that City secretariat for public and public communal companies conducts in Belgrade. However, Finance department also controls financial reports of all public companies that are members of city holding in Milano. It is authorized for financial management of the holding, especially for the investments.

One of main characteristics of city holding in Milano, that makes it different from most other similar models, is the existence of separate quality management organizational unit. Purpose of quality management concept in public sector is to identify resident's needs and to define the way to satisfy those needs. Quality management department in Milano holding performs the researches in order to determine the level of satisfaction with the public services among the residents. End product of this research should be clear standards, that city holding must fulfil. These defined standards, in cooperation with Line Office, are implemented into contracts. If some holding entity does not satisfy them when providing the service, Line Office will stop the payment for that service.

City of Milano achieves its ownership rights through steering committee, which consists of the representatives of current city government. This is the top level of holding management and the lowest hierarchical level where politics play key role.

We may conclude that the most important characteristics of city holding in Milano are: increased control of public companies, control and steering organizational units that consist of experts and professional managers and clear focus on end users, city residents. For city of Belgrade it would be very useful if one quality management department for all public companies was introduced, in order to determine the level of residents' satisfaction with their work and to see what they expect from public sector. Holding as institutional model would enable implementation of certain control instruments, as mentioned before, which would further put pressure on public companies to provide more quality services to residents.

5. VIENNA, AUSTRIA

City holding in Vienna is an antipode to city holdings that provide small number of services (Győr, Ljubljana). Currently, it is 100% owned by city of Vienna and it consists of 75 small and large companies, which are involved in different jobs. Founded in 1974, it represents one of the first city holdings in this part of Europe. Vienna holding connected two concepts that are usually considered to be antagonistic. First one is satisfying the needs of Vienna residents, and the second one is gaining profit and providing other services besides the public ones. Share owned by the city of Vienna has been changing since then, during the last decade of 20th century Bank Austria owned significant stake, but since 2001 the city has been the only owner.

The question that appears is whether it is good solution when the city owns complete portfolio, while doing business in so many different areas. In Vienna, this approach turned out to be successful, since profitability was achieved without additional taxes or other expenses for the residents. On the other hand, according to the researches done by Mercer consulting company, Vienna was the world number one city in the quality of living in years 2010 and 2011. Cities were ranked according to 39 different criteria, divided into 10 categories, where only one is the quality of public services, which are usually controlled by city government, no matter what the organizational form is. Nevertheless, city holding definitely has large influence through its 75 companies on different spheres of residents' lives, which positively affects the living quality in Vienna. Of course, it is just one of the factors, since general economic situation in Austria must not be leftover when calculating this indicator.

One of the main characteristics of Vienna holding, that may be very useful for further development of Belgrade, are partnerships between public sector and private companies. The partnerships tend to share risks and profits and the aim is to reach synergy effects, implying the possibility to create competitive advantages (Weiermair, Peters & Frehse, 2008). In many areas of business, Vienna holding forms partnerships with private companies, which provides added value for the residents, with small financial investments. The most common form of partnership is the situation when private company, after financing the building of some object, has the right to use it until it recovers the investment and gain certain profit, after which that object becomes the ownership of the holding. The example of partnerships between private and public companies in Vienna is Central Danube Region GmbH, the company for cooperation with other cities on central Danube and infrastructure development in this region. Another one is the reconstructing of the house where famous Austrian composer Wolfgang Amadeus Mozart lived. Both projects were done in cooperation with Raiffeisen Bank in Austria.

Organizational structure of this group is shown on Figure 3.

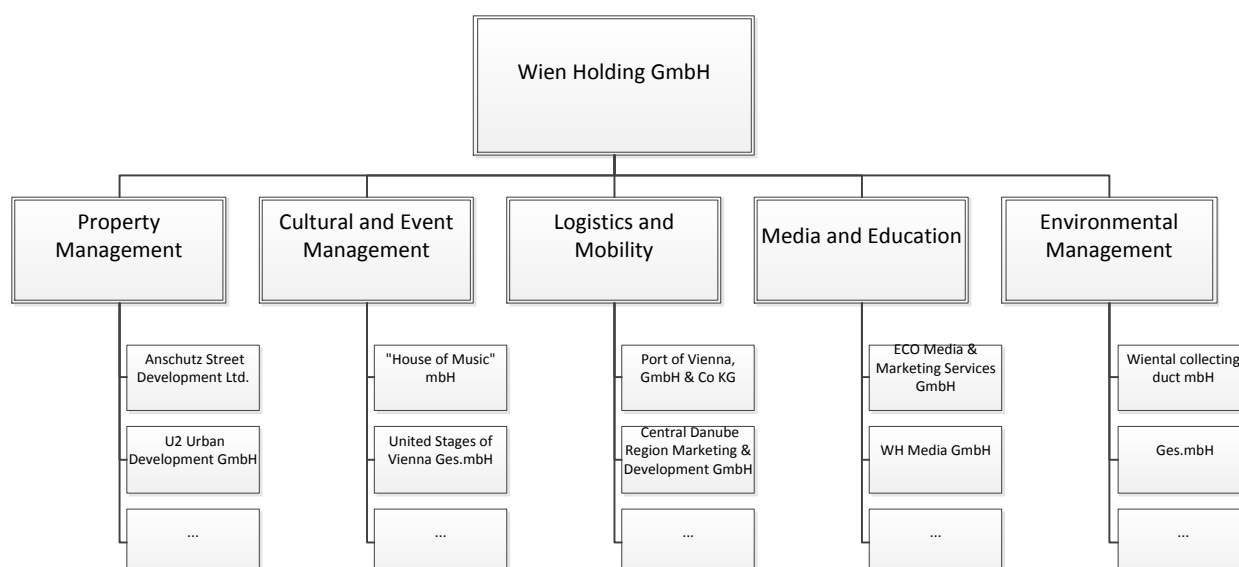

Figure 9: Organizational structure of Wien City Holding

Members of this holding are classified into five clusters, in order to achieve more efficient control of large number of companies.

6. CONCLUSION

Concrete examples that were described in this paper show why authorities in the city of Belgrade should consider forming holding institutional model of public companies, in order to improve global functionality of public sector. During period of crisis and difficult economic situation, city government should tend to decrease the expenses of public and public communal companies, which would reduce the pressure on the city budget, so the funds could be used to reach other goals, such as infrastructure development, cultural development, social protection improvement etc. Holding company, as shown in all the examples in this paper, would reduce management costs and overheads, since more than 20 steering committees (Krivokapić & Čudanov, 2010) would be replaced with only one board, through which external stakeholders could make an impact. Such organizational model enables the introduction of professional managers in public companies, followed by forming of certain control instruments, as in Győr. Costs reduction can also be achieved through economies of scale, especially when it comes to procurement. City of Belgrade, considering the size of complete needs of public sector, could demand from certain foreign suppliers to organize the local production, which can lead to industrial development of city and whole country. On the other hand, position of city holding on financial market would be much stronger than any public company currently has individually. This would definitely generate savings when it comes to interest rate when taking loans, but also through liquidity and indebtedness management.

City of Belgrade, by forming the holding of public sector, would advance the handling of public companies. There are two base elements that lead to these improvements. First one is integrated information system, which provides the support for decision making process. Second is adjusted financial and accounting system, which would enable comparison of public companies. Better control increases the business transparency of public sector, which is one of the main expectations of Belgrade residents.

Milano example can be used, too. Certain organizational units, which would focus on residents and their needs, should be formed. Their task would be to define the quality and quantity of services that public companies, holding members, should satisfy. They should also be responsible for decision making, when it comes to payments. This would put pressure on city companies to do better job.

As we can notice, if holding institutional model is implemented in city of Belgrade, certain disadvantages that currently exist in public sector will be overcome. Future researches in this area should determine the feasibility of this concept in Belgrade.

Abstract: *A modern business environment has caused significant changes in the public sector functioning in cities worldwide. In order to provide more quality services for its residents, city authorities started to abandon traditional models of public sector organization and tried to find a better way to connect public companies. Many cities turned to modern types of organizational structure, such as networks, using mostly holding as an institutional model of the public sector organization. Through the analysis of performance, structural and functional analyses of public companies owned by the city of Belgrade, this paper will identify the disadvantages of the current organizational model of the public sector in Belgrade, determine a possibility of establishing a holding, and point out the improvements that the implementation of this solution could bring to public companies. Since the analysis has shown a number of potential benefits for both public companies and city residents, future research should focus on the legal aspect of establishing a city holding in Belgrade.*

Keywords: *holding, network, organizational structure, restructuring, public sector, public company, Belgrade*

1. INTRODUCTION

During last 30 years many significant changes have been occurring in term of public services provided by local governments, in both developed and developing countries. These changes are stimulated by demands for public sector modernization. The ideas that dominate in all the attempts of reforming are decentralization, liberalization and partnerships with between public and private companies (Garcia & Marcou, 2003). Many theorists considered the contracting out concept, which includes privatization and deals with private companies, as a way to increase the efficiency of public sector, since the efficiency is one of the main problems of services provided by public companies.

However, some authors do not consider local public companies as the organizations that are necessarily non-efficient (Hall, 1998). This point of view has been proved in certain empirical researches (Boardman & Vining, 1989). This encouraged the authorities in many cities to try to improve the organizational model of public sector, which led to the signing of contracts with private companies, forming of partnerships between public and private companies and privatization. Considering the needs for public companies coordination, holding potentially presents the most efficient model for public sector organization. It is a type of network organization that implies the existence of the society that controls other societies through the shares ownership (Dulanović & Jaško, 2009). Network organization, through better coordination, increases the efficiency of resources allocation, brings more flexibility, enables organizational learning, improves planning process and upgrades the quality of services (Jaško, Jaško & Čudanov, 2010).

In many cities these advantages have been recognized as the possibility to gain benefits both for residents and public companies, which led to the restructuring of public sectors into holdings. Public sector reform during 1990s introduced holding solutions to many cities in Italy. Parts of these holdings were later sold to private companies, but in most situations cities remained major owners (Garrone, Grilli & Rousseau, 2010). Decision whether to sell part of public holding to some private company or not is based on transaction cost analysis, which plays very important role in this process (Warner & Hefetz, 2008). These costs represent the expenses of products' transaction across the border of organizational system or one of its parts (Dulanović & Jaško, 2007). Sometimes it is more profitable to concede certain functions to external subject. Holding should be released from all the activities that other companies are able to process more efficiently and more quality, and then different types of inter-organizational relationships ought to be established with those companies (Popović, Jaško & Prokić, 2010). The fact that the ownership of city holdings can be mixed, partially private actually, is their very important characteristic, since this is the intermediate step towards completing the process of privatization (Schmitz, 2000). Of course, certain legislation must be voted first, as happened in Italy (Bognetti & Robotti, 2007).

In this paper we analyzed the organization of public sector in Belgrade and identified major disadvantages of current model. We showed that introducing holding as institutional model could lead to significant improvements, when it comes to management, coordination and control. Special focus was on the benefits that this solution could bring to public companies, in terms of reduced costs and overheads, and to residents, in terms of upgraded quality of public services and increased business transparency in public sector. All the data used in the following analysis were gathered by the project team from Faculty of Organizational Sciences, during the work on project "Analysis of organization of public and public communal companies in the city of Belgrade".

2. ANALYSIS OF PERFORMANCE

Performance of total public sector in Belgrade was analysed using the Porter's value chain, which includes clear differentiation of core business and supporting activities (Jaško, Krivokapić & Čudanov, 2010). This tool enables the standardization of the activities performed in different public companies and the comparison of their performance, so the summary recommendations can be made for public sector in global. Having performed this analysis, we came to the following conclusions:

- Total number of full-time employees in all public companies in Belgrade is 18.806
- Total reserves in public sector are 1.819 employees
- Supporting activities are performed by 26,5% of employees, the reserves are 679 people
- Core business occupies 76,5% of total number of employees, including the reserves of 1.140 people
- Largest reserves are discovered in inbound logistics function, that is the part of core business, and their amount is 664 employees

However, in order to better understand the situation and notice the divergence that exists among public companies in Belgrade, we have to analyse total number of employees and their performance for every company individually, in order to determine the reserves in each part of the public sector. The results are presented in Table 1.

Table 1: Individual performance analysis of public companies in Belgrade

N o	Public company	Number of employees	Average performance	Reserves (in N° of employees)
1.	JKP "Beograd put"	1.346	97,80%	30
2.	GSP "Beograd"	6.631	89,17%	718
3.	JKP "Pogrebne usluge"	480	89,45%	51
4.	JKP "Beogradske elektrane"	2.260	88,28%	265
5.	JKP "Gradska čistoća"	1.782	93,85%	110
6.	JKP "BVK"	2.686	90,14%	265
7.	JKP "Gradske pijace"	240	85,09%	36
8.	JKP "Zelelnilo Beograd"	1.270	91,91%	103
9.	JKP "Parking servis"	687	94,24%	40
10.	JP "Gradsko stambeno"	165	92,56%	12
11.	JKP "Infostan"	151	75,27%	37
12.	Direkcija za građevinsko zemljište i izgradnju grada Beograda	325	86,34%	44
13.	JUP "Urbanistički zavod Beograd"	141	87,99%	17
14.	JRP "Studio B"	232	89,35%	25
15.	"Arena Beograd" d.o.o.	46	84,86%	7
1	JP "Sava centar"	141	75,98%	34

6.				
1 7.	JP "Beogradvode"	128	89,52%	13
1 8.	Turistička organizacija Beograda	33	85,84%	5
1 9.	JP "Ada Ciganlija"	30	92,39%	2
2 0.	JP "Beogradska tvrđava"	16	85,12%	2
2 1.	JP "Hipodrom Beograd"	16	78,54%	3
TOTAL IN BELGRADE PUBLIC SECTOR:		18.806	90,33%	1.819

Observation of these results leads us to the following conclusions:

- There is no public company in Belgrade that is without any reserves in term of number of employees
- Largest absolute amount of reserves (670 employees) is present in GSP "Beograd", which is expected since this is the public company with largest total number of employees
- Highest average performance is noticed in JKP "Beograd put", due to large number of employees in core business and the fact that their productivity is on a very high level

3. STRUCTURAL ANALYSIS

Since all the public companies in Belgrade are independent subjects, the analysis of their organizational structures needs to be done separately. Current type of organizational structure in every company is shown in Table 2.

Table 2: Types of organizational models in public companies in Belgrade

Nº	Public company	Type of organizational structure
1.	JKP "Beograd put"	Functional
2.	GSP "Beograd"	Divisional
3.	JKP "Pogrebne usluge"	Functional
4.	JKP "Beogradske elektrane"	Functional
5.	JKP "Gradska čistoća"	Functional
6.	JKP "BVK"	Functional
7.	JKP "Gradske pijace"	Functional
8.	JKP "Zelee nilo Beograd"	Functional
9.	JKP "Parking servis"	Functional
10.	JP "Gradsko stambeno"	Functional
11.	JKP "Infostan"	Functional
12.	Direkcija za građevinsko zemljište i izgradnju grada Beograda	Functional
13.	JUP "Urbanistički zavod Beograd"	Functional
14.	JRP "Studio B"	Functional
15.	"Arena Beograd" d.o.o.	Functional
16.	JP "Sava centar"	Functional
17.	JP "Beogradvode"	Functional
18.	Turistička organizacija Beograda	Functional
19.	JP "Ada Ciganlija"	Unknown
20.	JP "Beogradska tvrđava"	Functional
21.	JP "Hipodrom Beograd"	Functional

Functional model of organizational structure is identified in almost all public companies in Belgrade. Only in GSP "Beograd" we can find divisional type of organizational structure. Large disadvantage of functional

model of organizational structure is its tendency to generalize the efficiency and contribution of different parts of structure to total business success of the company (Hansen & Mouritsen, 2006). This problem may occur even during successful time, not to mention periods of crisis, when much larger damage may be caused. Side effect that was described can easily be identified in every public company. It can be overcome by introducing network type of organizational structure to public sector in the city of Belgrade, with holding as institutional model.

Currently, level of cooperation between public companies is very low. Although they are allowed to hire each other for certain tasks without announcing a tender, very often this right is not used. The main reason is lack of coordination, caused by the large number of governing bodies in Belgrade public sector. Actually, each public company has its own steering committee, and some of them consist of more than ten people. This usually leads to the situation that the public company which is supposed to perform certain task for another public company usually has no resources available at that moment. In that case, some private company needs to be hired, at higher price, so the costs are increased. And if this happens often, in every public company, total expenses of public sector are much higher than they could be if network organization model was implemented.

4. FUNCTIONAL ANALYSIS USING CORE/NON-CORE CRITERIUM

Due to current institutional model, public companies in Belgrade operate as individual subjects and perform their tasks independently, under strategic governance of city authorities. As a consequence, most of them have formed certain non-core units in their organizational structure, whose purpose is to provide necessary activities of support. The problem is that these functions cannot be used optimally, which generates the reserves that were mentioned before. Volume of their work is very small, so they are not occupied all the time, but the current model of business organization does not allow them to serve other companies owned by the city of Belgrade.

Functional analysis provides the number of core and non-core organizational units in every public company in Belgrade. The results are presented in Table 3.

Table 3: Number of core and non-core organizational units in Belgrade public companies

N°	Public company	Number of organizational units on top hierarchical level	
		Core	Non-core
1.	JKP "Beograd put"	6	1
2.	GSP "Beograd"	27	9
3.	JKP "Pogrebne usluge"	11	8
4.	JKP "Beogradske elektrane"	6	4
5.	JKP "Gradska čistoća"	15	3
6.	JKP "BVK"	18	10
7.	JKP "Gradske pijace"	1	5
8.	JKP "Zelee nilo Beograd"	5	1
9.	JKP "Parking servis"	2	1
10.	JP "Gradsko stambeno"	1	2
11.	JKP "Infostan"	2	1
12.	Direkcija za građevinsko zemljište i izgradnju grada Beograda	5	3
13.	JUP "Urbanistički zavod Beograd"	3	0
14.	JRP "Studio B"	3	0
15.	"Arena Beograd" d.o.o.	3	0
16.	JP "Sava centar"	3	2
17.	JP "Beogradvode"	9	4
18.	Turistička organizacija Beograda	3	2

19.	JP "Ada Ciganlija"	Unknown	Unknown
20.	JP "Beogradska tvrđava"	1	2
21.	JP "Hipodrom Beograd"	1	2

In most public companies in Belgrade some functions are not the part of core business. Certain of those non-core functions, such as marketing, finance, accounting, security, objects maintenance, human resources or general and legal affairs are often the same in several companies, which means that forming a holding as network organizational model could enable the unification of these functions in order to serve the complete holding. This would increase the level of coordination, facilitate the control and significantly reduce the costs and overheads.

5. ANALYSIS OF MANAGEMENT AND CONTROL

As we mentioned before, due to the existence of many steering committees, the unity of direction which is one of the main principles of management, does not exist in Belgrade public sector. This also causes certain overheads that could be significantly reduced if holding institutional model was introduced. All the disadvantages that were identified would be eliminated by forming unique board at the head of the city holding, that would deal with strategic decisions on the top level, while operational activities would remain in the companies. The board should consist of the members of all public companies and representatives of the city authorities.

In order to get insight into current management and control system in public sector, we analyzed the control range in public companies. This parameter compares the number of managers and executors. Control range in certain public companies in Belgrade may seem to be appropriate. However, even the average number is near the optimal value, some organizational units may demand certain changes. Control range may and should differ on different hierarchical levels. That is the reason why this parameter was analysed in every public company separately and why every organizational unit was taken into account. The results are shown in Table 4.

Table 4: Control range in public companies in Belgrade

N°	Public company	Control range		
		Total	Minimal	Maximal
1.	JKP "Beograd put"	10,86	3	40,83
2.	GSP "Beograd"	19,59	1,33	168,35
3.	JKP "Pogrebne usluge"	5,96	2	20
4.	JKP "Beogradske elektrane"	8,46	1,25	11,6
5.	JKP "Gradska čistoća"	7,50	3,45	24
6.	JKP "BVK"	4,32	1,25	24,75
7.	JKP "Gradske pijace"	4,60	3,28	28
8.	JKP "Zelee nilo Beograd"	12,66	4,62	18,78
9.	JKP "Parking servis"	7,38	4,67	19,33
10.	JP "Gradsko stambeno"	6,22	6	7,75
11.	JKP "Infostan"	4,92	2,5	15
12.	Direkcija za građevinsko zemljište i izgradnju grada Beograda	5,71	0,2	10,5
13.	JUP "Urbanistički zavod Beograd"	4,38	3,5	7,75
14.	JRP "Studio B"	8,44	3,6	12,67
15.	"Arena Beograd" d.o.o.	3,18	2,67	5
16.	JP "Sava centar"	4,72	3,57	15
17.	JP "Beogradvode"	8,71	0,8	28
18.	Turistička organizacija Beograda	2,30	0,5	4
19.	JP "Ada Ciganlija"	2,33	/	/
20.	JP "Beogradska tvrđava"	4	/	/
21.	JP "Hipodrom Beograd"	4	/	/

The analysis showed that there is a lot of space for improvements in this area. If we use the process model as the base for the improvements of organizational structure (Komazec, Todorović & Jevtić, 2012), we can find in some companies certain organizational units that should be integrated. This would not only reduce the costs of management by decreasing the number of managers, but also improve the control range and upgrade the unity of command, which is another important principle of management. And if we remember that the functional analysis showed that certain functions should be serving more than one company, we can conclude that implementation of holding institutional model would affect positively on control range and the unity of command by reducing the number of managers.

6. CONCLUSION

The analysis of public companies' performance using the Porter's value chain as a tool identified certain reserves in almost every public company in Belgrade. The largest reserves can be found in GSP "Beograd", JKP "Beogradske elektrane", JKP "Gradska čistoća", JKP "Beogradski vodovod i kanalizacija" and JKP "Zeletinlo Beograd". Although this can be explained by large number of employees in these companies, the reserves are significant and their optimization would increase the business efficiency. Even if the performance of certain companies is near maximum, they generate large expenses on global level, since complete public sector in Belgrade is financed from the city budget and should not be observed as a group of independent companies, but as a single entity.

Structural analysis identified functional model as the most common type of organizational structure in Belgrade public companies. Its tendency to generalize the contribution of different functions is very present, and can be overcome by introducing holding solution to the public sector. This would also improve the coordination, which is on a very low level at this moment. Main cause of bad coordination is the existence of many steering committees, one in each public company. Unique board for whole holding, including the representatives of all public companies, would definitely solve this problem.

Functional analysis identified the existence of certain non-core organizational units in most public companies. It also showed that many of these non-core functions are common for different companies. The implementation of network model of organizational structure could increase the efficiency of public sector. Same non-core functions from different companies could be integrated in order to form unique departments that will serve the complete holding. That would increase the level of control and significantly reduce the overheads in Belgrade public sector.

Finally, the analysis of management and control shows that reorganization could lead to the decrease in management costs, since several functions would serve all the members of the network. This would cause the integration of some organizational units in public sector, which would reduce the number of managers. It would also upgrade the control range and improve unity of command and unity of direction, two very important principles of management.

All these results prove that introducing holding institutional model to public sector in the city of Belgrade would bring significant improvements, in terms of organization, efficiency, control, direction, coordination and cost reduction. As the consequence, the quality of services that public companies provide would be upgraded, so the residents would also benefit. Since this approach already achieved good results in many cities worldwide, Vienna, Ljubljana and Milano are just some of the examples, there is no reason why city authorities should not consider the implementation of holding solution as one of the alternatives for future development of the city of Belgrade.

CRISIS PREVENTION AND CRISIS MANAGEMENT MODEL

Stefan Marković

Faculty of Organizational Sciences stefan_kv_87@yahoo.com

Abstract: *This paper focuses on crisis prevention as an integral part of successful crisis management. The paper explores scholarship regarding the basic concepts of crisis management. A new crisis prevention and management model will be presented afterwards. This new model consists of four Balanced Scorecard perspectives and five main organizational crisis. The model is made in matrix form, and relevance for every Balanced Scorecard perspective and organizational crisis is determined by assigning the proper number of points, or coefficient to them.*

The goal of the model is to determine key indicators for an organization which will then be used for overall business observation and prediction of potential crisis. Using this model and defined key indicators, organizations can conduct effective crisis management in order to overcome the crisis. The model also ranks the key indicators in order to distinguish the most important ones, so that the organization can react to the most urgent issues and handle them before the crisis strike. The way the model is used and its practical application will be shown on the example of a transportation company.

Keywords: *crisis, crisis management, crisis prevention, Balanced Scorecard, crisis prevention and crisis management model*

1. INTRODUCTION

Since 1960's when the phrase crisis management was first used to describe well known Cuban crisis, its meaning and area of application have extended to almost every sphere of everyday life, especially in business. Crisis management is the main field of research of many scholars and practitioners. Since the world economy is faced with a great recession in the last few years, crisis management and its practices are now in need more than ever before.

Organizational crisis are not something unknown and new in the world of business, but it seems that even with the great amount of available book knowledge made in crisis prediction and crisis management is insignificant, or none. This is the main reason why this problem is in the center of this paper, and its goal is to change the way crises are seen by companies, and the way crises are handled. Having that in mind, this paper will be based on "Crisis prevention and crisis management model" which will be explained in detail through the rest of the paper. This model incorporates some well-known concepts of crisis management, and it can be easily adjusted for use in many different industries. The purpose of the model is to help organizations to predict potential crises and adequately prepare for them, but this model can also be used for managing a crisis that has already hit a company.

2. CRISIS AND CRISIS MANAGEMENT

In order to better understand the model it is necessary to always have in mind the basic concepts of crisis and crisis management. Definition of crisis which will be used here is probably the most used and known definition of crisis: "Contrary to popular belief, crisis may not be necessarily bad. It is merely characterized by a certain degree of risk or uncertainty" (Fink, 2000).

Crisis management can be defined as a number of functions or processes which goal is to identify, learn about and predict possible crisis, define procedures that will allow the organization to prevent the crisis or overcome it much easier than if it was unprepared, thus minimizing the consequences of crisis. Even though crisis management in theory seems relatively easy to implement, situation radically changes when you have to implement it in a concrete company. That's the reason why "Crisis prevention and crisis management model" will be presented as a possible solution to this problem.

This model utilizes key indicators defined by using Balanced Scorecard perspectives and five main organizational crisis. It is necessary to analyze entire company and its business processes, and to make predictions for every segment of company, which will force the company management to create a new view

of its company and help guide it to a right path. The goal is to define key indicators for each of the five main organizational crisis, and define proper actions to overcome the crisis.

The model focuses primarily on crisis prevention, because if the company predicts a crisis on time, resources and time at its disposal will enable the company to overcome the crisis much easier. If the company does not notice the early signs of the crisis and the crisis has already occurred, resources and time at its disposal are limited and it will be significantly more difficult to overcome the crisis. It is much easier to manage a crisis if the company is already prepared and knows what to expect, what the potential hazards are and what to change in order to avoid a crisis. That is why this model has great significance in the prediction of the crisis.

3. CRISIS PREVENTION AND CRISIS MANAGEMENT MODEL

The proper use of the model requires seeing a bigger picture of company, considering company internal and external environment, industry, suppliers, customers and other indicators depending of the company observed. It is clear that just observing financial indicators won't be enough to fully implement this model into crisis management of a certain company. Therefore, we'll need to implement indicators other than financial, in order to create an appropriate model for a company. These indicators can easily be adjusted to any industry.

As presented in Figure 1, model is a 5x4 matrix. Rows are reserved for main organizational crisis that can hit a company, and those are:

- Performance crisis; The examples of these crises are: reduced number of orders, sales scope decline, market share reduction.
- Identity crisis; The examples of these crises are: there are no plans for a period longer than 6 months, introduction of the program beyond the core competencies of the company, non-core programs show higher profitability than the core ones.
- Innovation crisis; The examples of these crises are: rare initiation of development projects, RD orientation to copying, increase in costs without RD results.
- Crisis of company management; The examples of these crises are: autocratic style of leadership, complete centralization of decision-making, the top executives are leaving the company, failures are justified by the objective circumstances.
- Work collective crisis; The examples of these crises are: conflict between management and staff, priority of individual goals over the collective ones, intergroup and interdepartmental rivalries.

Columns consist of 4 Balanced Scorecard perspectives (Kaplan & Norton, 1996):

- Financial perspective
- Customer perspective
- Internal perspective
- Innovation and learning perspective

Table 1: "Crisis prevention and crisis management model"

Crisis / Perspectives	Financial perspectives	Customer perspective	Internal perspective	Innovation and learning perspective
Performance crisis				
Identity crisis				
Innovation crisis				
Crisis of company management				
Work collective crisis				

The reason why Balanced Scorecard was used is because we can identify up to 25 key indicators by taking in consideration its four perspectives. These 25 key indicators are more than enough to predict crisis in time and identify possible solutions to overcome any issue. There is no use in keeping track of a large number of indicators since company may lose sight of what really is important. After identifying up to 25 key indicators using Balanced Scorecard, those indicators are then sorted to a belonging type of crisis.

This many indicators are quite enough for a company to prepare for crisis and predict it, and then with appropriate set of actions overcome it much easier.

Here are some basic rules of how to properly use this model:

Table 2: Determining the importance of crisis for a company

	Points
Performance crisis	
Identity crisis	
Innovation crisis	
Crisis of company management	
Work collective crisis	
Σ	100

It is necessary to assign points for each type of crisis, so that in total all points for crisis are worth 100 points. Points are assigned based on the importance of crisis for one company, and it is decided subjectively by company managers, or after taking in consideration opinion of the consultant.

Four perspectives from Balanced Scorecard are assigned with a weighted coefficients in total of 1.

Table 3: Assigning weighted coefficients to Balanced Scorecard perspectives

	Weighted coefficient
Financial perspective	
Customer perspective	
Internal perspective	
Innovation and learning perspective	
Σ	1

Weighted coefficients are assigned based on the importance of each perspective for one company, and it is decided subjectively by company managers, or after taking in consideration opinion of the consultant.

Another reason why the model is made in a matrix form is because it will be used as basis for AHP method to get the ranks for every key indicator. That doesn't mean that key indicator with the highest value is the only one that is important to a company. Once when the key indicators are determined, they are all of great importance to a company in the term of preventing the crisis. The reason why key indicators will be ranked is to group them, and then depending of the group they belong to, they will be monitored for progress. Those key indicators that have the biggest value will be assigned to the first group, and those indicators should be monitored on daily or weekly basis. Indicators from second and third group should be monitored on monthly basis, or every three months.

3.1. Basic rules of "Crisis prevention and crisis management model"

You have to comply with the three basic rules of "Crisis prevention and crisis management model" in order to create an appropriate model for a specific company.

The first rule refers to assigning points to organizational crisis. Each crisis can be assigned to maximum of 40 points. The reason for this rule is to prevent managers to overestimate one crisis, and ignore other crisis. For example, managers have a tendency to assign too many points to a performance crisis, thus ignoring other crisis, like for example work collective crisis.

The same reasoning is used for the second rule, which refers to assigning weighted coefficients to Balanced Scorecard perspectives. Each Balanced Scorecard perspective can be assigned to maximum of 0.35 coefficient.

These first two rules limit the number of points and coefficients that can be assigned to each crisis and perspective. Following those two rules managers are forced to think in different way, and they can't favour only one crisis or only one perspective. They need to see a bigger picture and be prepared for any kind of crisis in order to overcome any potential issue or crisis. They can't see a company just through a couple of

financial indicators or only through good relationships with customers. With limited amount of points and coefficients available, managers have to be extra careful and create a perfect balance of between crisis and perspectives, in order to create just the model they need for their company. Company is not just a bunch of numbers and reports or its properties, a company is made of people who work there, its customers who buy their products and satisfy their needs, and many others.

The third rule refers to assigning the minimal number of points and coefficients to crisis and perspectives. Each of the crisis and perspectives must be assigned with at least minimal number of points and coefficients, for crisis at least 10 points, and for perspectives at least 0,1 coefficients. This way managers have to think about the possible crisis that they haven't thought of before, and they can't say that for example, innovation crisis will never hit our company, or that innovation and learning perspective have no importance for us.

3.1. Advantages and disadvantages of the model

The first advantage of the model is that it requires from managers to see a bigger picture and to observe a company as a whole. Carefully identified key indicators allow the managers to observe every aspect of their business on daily, weekly or month basis.

Rules defined within the model force the managers to have a rather new view on their business. They will start thinking of the new crisis and issues that can occur of which they may not have thought before. This way they can gain a new insight of their business and make proper changes in order to prevent future crisis. "Crisis prevention and crisis management model" is very flexible model, meaning that it can be easily adjusted for use in any industry and for every company. Model provides the guidelines which properly followed allow the user to create a model for his company. However, because of its flexibility and its use in many industries, it has its disadvantages.

One of disadvantages is to determine wrong key indicators. If by any chance wrong key indicators are determined and observed, managers can be convinced that company is doing fine, while in reality it is not prepared for the upcoming crisis.

Other disadvantage is the obvious subjectivity of the model. Managers of the company assign points and coefficients according to their own opinion. This can be readjusted by asking for the opinion of the consultants.

4. PRACTICAL APPLICATION OF "CRISIS PREVENTION AND CRISIS MANAGEMENT MODEL"

Practical application of model will be presented using data from a transportation company. First, we'll show key indicators and how points and coefficients are assigned to specific crisis and perspectives. Afterwards, every aspect of the model will be explained in detail.

Table 4: Practical application of "Crisis prevention and crisis management model"

Crisis/Perspectives	Financial perspective 0,25	Customer perspective 0,2	Internal perspective 0,3	Innovation and learning perspective 0,25
Performance crisis 30	PCT0,045			
	PIT0,045			
	PintT0,045			
	PconT 0,045			
	PGT 0,045			
Identity crisis 15		PCD0,08		
		PA 0,05		
		NAC 0,07		
Innovation crisis 15			IBS 0,04	PET 0,03
			INIL0,04	LIC0,04
Crisis of company			PATR 0,08	ES 0,05

management 20	CNCE 0,025		VMS 0,06	KKE 0,05
			COU0,08	
Work collective crisis 20				PME 0,04
				EM0,04

Table 5: Legend of key indicators

KEY INDICATORS

PCT – Profit of city transport
PIT – Profit of intercity transport

PlntT – Profit of international transport
PConT – Profit of contracted transport
PGT – Profit of goods transport
CNCE – Core and Non Core expenses
PCD – Percentage of cancelled departures
PA – Percentage of accidents
NAC – Number of accidents with casualties
IBS – Investment in Bus station

INIL – Investment in new international line
PATR – Proper assignment of tasks and responsibilities
VMS – Vision, mission and strategy
COU – Control of organizational units
PET – Programs for employee training
LIC – Loss of intellectual capital
ES – Employee satisfaction
KKE – Keeping the key employees
PME – Personal motives of employees
EM – Employee motivation

After calculating the aggregated value for every key indicator and their ranking, they should be sorted into according groups. In this particular case, we will sort all of the indicators into three groups:

Key indicators rank	
1. PATR	1,6
2. COU	1,6
3. PCT	1,35
4. PIT	1,35
5. PlntT	1,35
6. PConT	1,35
7. PGT	1,35
8. PCD	1,2
9. VMS	1,2
10. NAC	1,05
11. EM	1,0
12. KKE	1,0
13. PME	0,8
14. EM	0,8
15. PA	0,75
16. IBS	0,6
17. LIC	0,6
18. INIL	0,6
19. CNCE	0,5
20. PET	0,45

I Group	
PATR	COU
PCT	PIT
PlntT	PConT
PGT	
II Group	
PCD	VMS
NAC	EM
KKE	PME
EM	PA
III Group	
IBS	LIC
INIL	CNCE
PET	

Figure 10: Ranks and groups of key indicators

Among these key indicators there are both quantitative and qualitative indicators. Even though it's easier just to observe quantitative data, it is not possible nor wise for the problem of crisis management to discard qualitative indicators and observe only the quantitative ones. As said before, a company is not just a bunch of numbers nor it is only its asset or machines, it is also made of people who work there and its customers. Company is a forever changing system.

Key indicators should be checked for progress on daily, weekly or monthly basis. Criteria used to assign key indicators to a specific group is their aggregated value which is calculated by multiplying points for a specific crisis and coefficients assigned to key indicator. Key indicators in the first group are the ones that managers need to track on the daily to weekly basis and that require imminent action. First group of indicators are the ones that relate to profit in organization units, but there are also two indicators regarding the crisis of company management. Those are proper assignment of tasks and responsibilities and control of organizational units.

The reason why these two indicators are within the first group is an obvious lack of proper assignment of tasks and responsibilities. There isn't any manager that can precisely tell what his tasks are and how his performance is measured. For example, there is no marketing division in company. There are no employees with the task of creating marketing promotions, or taking care of the company's image. Management is in a unique situation where everyone is doing everyone else's job, and no one is taking responsibility for the decisions made. Without the proper task assignment it is impossible to determine the responsibility for a single employee and the decisions made. Another problem is that organizational units have become organization for itself without any obligation to report to the top management, nor are they adequately controlled.

This shows how this model is finely tuned, and that not only financial indicators are the ones that should be observed if a company wants to be fully prepared for crisis. Those two non-financial indicators from the first group have the greatest aggregated value in the whole model. Having that in mind, the first task of the management would be to completely change the way company is runned and to assign proper tasks and responsibilities to every employee.

Second group of indicators are the ones like defining the vision, mission and strategy of the company, and the ones that refer to accidents involving the company's trucks and buses. There are also indicators related to employees, their satisfaction, motivation and personal motives.

Last but not least is the third group of indicators, consisting of investment indicators, core and non core expenses, loss of intellectual capital and employee training.

Defining the groups for indicators doesn't mean that there are some key indicators more important than the others. Ones determined, all of the key indicators are essential to a company in order to prevent and manage any crisis. Grouping the key indicators is to determine the urgency of reaction needed to handle the issues and manage the crisis. Indicators from the first group require urgent reaction from the company management in order for a company to survive. At the same time, other key indicators should be analyzed in order to create a better future for the company. In order to create a good and working "Crisis prevention and crisis management model" we must take in consideration every one of these 20 key indicators previously determined.

The goal of the model is to single out only the most important indicators in order to help accompany prepare itself for the upcoming crisis. Nevertheless, without defining the proper actions to improve those key indicator, this model would have no practical use. However, the task of designing and implementing just the right actions is simplified a lot by a fact that key indicators are already determined and managers only have to follow guidelines set by the key indicators.

5. CONCLUSION

This model emphasises the importance of crisis prevention, rather than managing the crisis. However, "Crisis prevention and crisis management model" can be used both for the purpose of crisis prevention and crisis management. This paper is focused on preventing crisis, because if crisis is foreseen there is more time to react and avoid the crisis or at least mitigate the effects of crisis.

"Crisis prevention and crisis management model" utilizes key indicators in a very simple, but effective way, and enables the company to be fully prepared for the upcoming crisis. This particular model which practical use was shown on the example of transformational company, can be easily adapted for use in the same industry. This model is not rigid, it is actually very flexible, and can be adapted for use in almost every industry.

Model can be enhanced in a way to determine key indicators for different industries, thus creating almost finished models that can be prepared for use with minimal adjustments. By accumulating that experience, a large database of models can be created that could be used both in education and for the needs of companies.

Abstract: *This paper describes basic characteristics of military organized systems and assumes that the crisis as a category is present in all spheres of human activity. Involvement of military organizational systems in dealing with various types of crisis is a reality that we follow in any crisis situation. In order to act in a crisis situation it is necessary to know the basic characteristics of a crisis and how to overcome and mitigate it. This paper is a result of experience in tackling various crises, and theoretical development in the sphere of crisis management. The way of crisis management is a good basis for further structuring in terms of successful implementation in the process of the practical resolving of various crisis situations along with the institutionalization of a unified approach to crisis management.*

Key words: *military organized, systems, crisis, phase of the crisis, management*

1. INTRODUCTION

Crisis management in military organized systems has broader context that includes entire spectrum of activities focused on the crisis: prevention before the crisis occurs, crisis management in a strict sense, gaining new experiences in the process of mastering the crisis. Activities related to the process of dealing with crisis are considered to be a crisis managing process and crisis resolving process. Crisis managing is carried out through different phases, which are characteristic of the crisis management process.

Before the crisis occurs, preventive actions are necessary, aimed at the acquisition of knowledge, which are the product scenic visions of development in the future or how the prediction of crisis appearance.

After the crisis occurs, despite the measures taken to prevent it, the focus on it's resolving. This includes activities aimed at alleviating the crisis and harm reduction. Experiences important to be extracted from the process of mastering the crisis include certain facts about the characteristics of the crisis and its real consequences. This particular part of the crisis related to the fundamental questions that concern the identification of the crisis, its force and effect, are crisis management in a strict sense.

From the broader context of crisis management, the last step is the reaction to the crisis. The main issue to be resolved relates to the further response actions. The focus is on the experiences and lessons learned from the crisis resolving process and on defining future actions of any military organized system despite its type and size.

The main element in comprehension and setting crisis under control should be a specific place and role of the organization (including any military organization, and organizational units). This is primarily conditioned on the environment and the stability of the environment in which the military organization exists, its competences and, finally, its identity in functioning in the specific task.

2. TERM AND CHARACTERISTICS OF MILITARY ORGANIZED SYSTEMS

The military organized systems include organisations basically defined by the structure in which particular business units or business processes are taken. It implies different hierarchical levels expressed by certain responsibilities in its functioning. It is very important from the point of military organized systems and their study, primarily because of that any military organization in any system, regardless of the level and structure include different objects that have some specific features, that are or may be of some interest. There are immediate links that directly cause changes in the whole system.

An important assumption in functioning of military organized systems is their guidance expressed through certain functions and processes that lead to achievement of goals. The objectives of the military organized systems are determined by a specified functions of the given system and its characteristics.

When discussing the characteristics of military organized systems, there are different criteria according to which features can be expressed. This paper expresses the view in terms of monitoring the status of management as an important element and an integral part of every military organized system. The essence of the approach, in the context of understanding military organized systems, is based on needs and concrete results in solving complex and practical problems.

Currently, what attracts the attention when it comes to military organized systems and researches in this field, is an approach to developing management skills and elements of commands and commanders who are directly related to the military organized systems in terms of their management. So, we are in the stage of development, when scientific researches, setting up certain theories in solving systemic problems in the area of military organized systems, especially in the field of crisis management should be considered equally.

If issues relating to military organized systems are looked more carefully, especially those issues regarding the importance of defence activities, it can be concluded that even though there are practical solutions in the sphere of operational management, there are no completed and comprehensive built systems of universal and comprehensive action to all levels, particularly in areas of crisis. This is the consequence of real circumstances that have arisen from the need for restructuring military organized systems and this process is still in process (Karovic, S. et al. Military management - scientific events of science and business management or defence science, SIMNOD, Belgrade, 2011.)

3. BASIC ELEMENTS OF CRISIS

Any crisis carries negative connotations. It is a term nowadays often used as a slang. It describes personal status or situation or general condition of the negative and undesirable (hazardous) consequences. However, taking into account often use of the above term, there is no comprehensive and conceptual content of the term, but there are many different situations that reflect the above term.

The modern concept of the term crisis is derived from the medical literature which indicates a dangerous state of health. This state cannot be recovered without permanent damage, external intervention or fundamental restructuring. Therefore, self-defence mechanisms are not enough for resolving a crisis. This characteristic, when it comes to social sciences, is used to explain and describe the crisis in the economic, political, social and cultural systems.

It is important to emphasize that the crisis means a condition that leads to the edge of survival of some organization, the state of vulnerability of its existence, environment in which it cannot act normally, which threatens its ability to survive, disables it in achieving goals, and, finally, affect the ability of future normal operation.

This process reflects the current tendency in the organization that can be used in processes realized in levels to reduce the risk (prevention) and increase the ability of an adequate response. The elements of the crisis, its general form is shown in Figure 1.

Figure 1: The general form of crisis

Through reviewing crisis and its expressions, and stages that manifest its actions, models of action at particular stages could be defined. Common characteristics of activities or processes carried out in a period previous to a crisis are defined by the type and circumstances in which it manifests. Action in the field of prevention includes activities which will ensure that an organization will be able to activate the next stage of the crisis can be successfully resist. Model of crisis management in a given circumstances, is based on measurements of real and objective analysis of form and threat degree and possible consequence of the interaction of different factors in this phase, which may have effects in the next crisis phase.

The Figure 1. shows that in certain crisis phases some specific elements could appear, which arise in a period previous to a crisis and build continuously while leading to its culmination and the highest point, no matter whether it is a crisis in the system or a crisis caused by the action of nature. However, it is important to distinguish between actions in a particular situation where there is no developed system that would fully meet all the criteria. There is a general attitude that, depending on the type of crisis, different resources will be engaged to act. It is impossible to define the specific model of action, because in the particular case prepared plans for a specific situation should be activated. This means that the plan is a model of action in a specific situation.

According to the views of modern armies, and especially NATO, approach or model for solving the crisis situation has elements shown in Figure 1. It is characterized by the existence of two distinct phases, divided by the culmination point, there are escalation phase and de-escalation of the crisis phase. This transition occurs in any definition of the process of crisis.

On "a stability period" diagram shows the form of crisis in which no violence or threats of priority objectives are present. There is a lack of potential tension between the conflicting parties.

- The diagram can be shifted up to the "disagreement" division - showing that a threat to priority goals is identified. It characterizes a warning on a possible crisis.
- The curve can culminate to the point of "confrontation", indicating the growth of violence on one or the other side in a crisis, showing that there is a crisis
- The curve shows that the crisis can grow up to a point when the situation turns into a conflict.

De-escalation phase of crisis is characterised by:

- Eventually the intensity of the crisis will subside by showing its course in the diagram. Curve shows a declination, in passing through a phase of decline of the conflicting parties may include the recognition that the threat of the priority objectives is in declination, does not mean that the crisis is over, it was brought into favourable condition. This form of crisis shows that the worst is over.
- Curve decreases to a relatively low-intensity diagram showing the stability of the "new" to the crisis may be higher or lower intensity than the original, shows the new "status quo" that is acceptable to all parties involved in the crisis.

4. CRISIS MANAGEMENT

From the point of crisis management considerations one should bear in mind the broader context that includes the entire spectrum of activities focused on the crisis: prevention before the onset of the crisis through crisis management in the narrower sense, in order to gain new experiences in the process of mastering the crisis. Activities related to the process of crisis management are considered to be a crisis or its mastering. Crisis management is carried out through different phases, which are characteristic for the process crisis management.

Before the crisis, it is necessary to have preventive action aimed at the acquisition of knowledge perspective, which are the products of scenery visions of development in the future or the model of prediction of the action.

After the crisis, despite the measures taken to prevent it, the focus has centred on its mastery. This does involve activities aimed at alleviating the crisis and harm reduction. The experiences that need to be extracted from the process of mastering the crisis include certain facts about the characteristics of the crisis and its real consequences. This particular part of the crisis related to the fundamental questions that concern the identification of the crisis, its force and effect, are crisis management in the narrower sense.

From the broader context of crisis management, the last step is the reaction to the crisis. The core issue to be resolved relates to further response actions. The focus is on the experiences and lessons from the crisis and the definition of the future courses of action in the organization of any type and size.

The main element in the knowledge and mastery of the crisis should be a specific place and role of the organization (including any military organization, and organizational units). This is primarily caused by the environment and the stability of the environment in which the military organization exists, its competence and, finally, its identity as a function of a specific task.

4.1. Crisis management in a broader sense

In particular crisis management through defined stages that manifest themselves in prevention activities identifying the crisis and respond to the crisis can be explained in more detail. In this sense it can be used, as pointed out by Osmanagić-Bedenik (2003). Two-dimensional matrix comprising five levels and five stages, with their emphasis on networking (Töpfer, 1999). Matrix ensures that at every level and every stage of investigating the antecedents and consequences of the crisis. The way research is presented in the following elements:

- The content-process level includes events that are in the process of crisis and directly related, or a moment of events,
- Information level has implications for early warning and knowledge as well as special forms of information provided by preventive action. Simultaneous realization of potential causes and consequences of the crisis and raises the question of collecting and sending information as a key segment
- The organizational level refers to the design of processes and structures, direction of the organization and shaping organizational units to master the crisis. The essence of the above refers to the level executives and direct holders of certain tasks and roles and
- The communication level refers to media information, associates, managers, owners and the general public of the crisis, its causes and the measures taken. Briefly define the issues related to information and content related to elements of who, when, how and what to inform?
- Psychological level includes attitudes, emotions, the degree of involvement, understanding, motivation and behaviour of all who are in contact with the crisis as the organization and outside the organization. The essential question of the levels above apply to the consequences of events and activities information on the persons directly or indirectly associated with the crisis.

Table 1: The matrix of crisis management process
(Osmanagic-Bedenik, N.: *Crisis as opportunity, school books, Zagreb, 2003.*)

Levels	Phases				
	Prevention	Early warning	Set crisis under control	rehabilitation (renewing)	Using the expiriance of the crisis
	As the crisis be prevented? ↓	As the upcoming crisis can be recognized? ↓	How can mitigate the consequences of the current crisis? ↓	How to reach the minimum positive level before the crisis? ↓	How to draw from the crisis overcome ↓ experience (used)?
contents	The moment of developments (What's going on?) →				
informations	Collection of information (Who collects and sends information?) →				
organizations	Holders of certain tasks (Who takes the roles and missions?) →				
communications	Who, when, and what informs? →				
psychology	What are the consequences of events, information and actions? →				

The final terms it can be stated that all the factors and stages are based on crisis management and they are universally applicable to all types of crises, such as natural, technological and social. Also, it is important to emphasize that when it comes to mastering the crisis, there are certain stages that can be formulated as:

- prevention, which is being taken and procedures to prevent the onset of the crisis and measures for its master,
- early warning, which includes symptoms (signals-indicators) of the occurrence of crises,
- setting crisis under control, including a system of measures taken to eliminate the negative effects caused by the action of the crisis and restore the original state and the functions that existed before the onset of the crisis and
- the adoption experiences of the crisis, primarily related to the lessons learned which were characteristic of the crisis period and its implementation in preventive action plans to reduce the risk of future onset of a crisis, or possibly build on indicators of the crisis.

These are important elements that one should bear in mind in relation to its crisis, and mastering. They are the key solutions crises.

4.2. Information Structure

Looking at the crisis from the point of mastery and the measures taken, it is necessary to understand and expand the area affected by the crisis in terms of process information. This applies primarily in the field of information if it is to manage the crisis in the way of a comprehensive system approach, which in this case, and it is an essential element, especially in the prevention phase, ie. preventive action. If we observe the phases of prevention, emphasis is given on a permanent progressive direction information, (Osmanagic-Bedenik, N.: Crisis as opportunity, school books, Zagreb, 2003.) from the bottom where the actual indicators and warnings, to the top, where the receiving information is, which is in some way connected with the flow of information within the organization. This is particularly specific to the military organization that has formalized the flow of information and strictly defined hierarchical structure that directly reflects the previously mentioned statement in terms of receiving information. With the advent of the crisis the direction of information flow can take different courses so that the process of mastering the so-called crisis occurs, star shaped or in a different direction which is basically an action activity.

Observing any organization, including the military, communication relations were established so as to allow a constant flow of information. The moment of occurrence is very important, as well as the aspect of preventing crisis because in this case the organizational process follows and prevents so-called bad news in the worst case, prevent rumours.

Hence the emergence of the crisis and the process of mastering the crisis include a rapid response that starts from the highest command levels, and ends with the lowest level that turns everything into action plans and practical actions to their goals of higher level tasks achieved.

From the point of considering communication networks and information flow, under the direction of movement, access is an important element of so-called progressive informational network, which essentially reflect the views of experts or other persons as the harbinger of the crisis, or sensors. Their main task is to accept the views of the above who can point out the occurrence of crises. His basic characteristic is openness and unidirectionality. However, it is not flexible in terms of applicability in the military organization, because of the strictly formalized relationships that characterize the military organization.

In contrast to progressive informational network, there is retrograde information network, which is based on a clearly structured and organization concept, which is characteristic of the military organization, where the flow of information takes place top down. The point is to master the crisis in the relationship that characterizes the relationship of subordination, ie. all information and orders are based on the commands, then from the top of the organization.

The command of a specific unit or organization that are outside the sphere of military organization, in a crisis situation, quickly analyze and assess the causes and consequences of the crisis and is taking concrete measures to master the crisis. The highest level of command decision-making is, in some cases the crisis staff. It should be noted, when the military organization is concerned, this is the command that is place-making and implementing individual measures.

As Osmanagic-Bedenik says, results and knowledge of crisis management process has five stages and five levels that can be displayed matrix flow, table 2. (Osmanagic-Bedenik, 2003). The matrix shows the process flow crisis that is basically the process of networking activities. The essential element that determines the

position of crisis management and its mastery is based on gaining experience from the crisis and overcome the constant study and implementation of such experiences in the appropriate emergency management plans.

In table 2, the flow is clearly evident, and interdependency of the activities that are important in terms of crisis management fields shaded in steps one to seven, then, from prevention to experience their full implementation, and coming up with new knowledge about the crisis.

It is important to emphasize that the initial initiation comes from the psychological point of view through the indicators and the feeling that something is "wrong" and thus produce a willingness to develop a crisis plan on the content level. In the next step, the attention is on early warning, therefore, the early discovery and early warning are the level of information where practical indicators and information are shaped. If we look deeper, we can conclude that the first two steps are essentially aimed at crisis prevention, and directed that a crisis does not occur at all. However, if a crisis occurs, ie. if the organization from "normal" moved in "emergency" situation, then all five levels in the third stage are activated.

The fourth step is to develop measures of crisis management, while in the fifth step, the emphasis is on communication and organizational fields emerging from the crisis.

Sixth step connects levels of mastering the crisis and use the experience of the crisis, while the seventh step is the emphasis in organizational communication areas out of the crisis.

Table 2: The matrix of the process flow of the crisis
(Osmanagic-Bedenik, N.: *Crisis as opportunity*, School books, Zagreb, 2003)

Levels	Phases				
	Prevention	Early warning	Set crisis under control	rehabilitation (renewing)	Using the experience of the crisis
contents		2	3		
informations	1			6	
organizations			4		7
communication				5	
psychology					

Direct connections and interactions of the individual phases and levels occur in a given time and space and represent a continuous relationship of mutual influence. The matrix of the process flow of the crisis highlights the dependence relationship of individual phases and stages of the process of crisis management (Osmanagic-Bedenik, 2003).

In essence, the process of crisis management is a constructive reasoning, decision making and action that is aimed to determine the future status and avoiding crises. If this is not possible, then it means mastering its success.

4.3. Crisis management in the narrower sense

If we take into account preceding paragraphs regarding crisis management, they emphasize the difference between crisis management in a broad sense, encompassing a wide range of activities of an organization focused on the crisis, and crisis management in the narrow sense which includes activities geared to action during the crisis, or for the period mastering the crisis. The process of crisis management in the narrower sense is shown in Table 3.

Table 3: Process of crisis management in the narrower sense (setting crisis under control)
(Osmanagic-Bedenik, N. *Crisis as opportunity*, School books, Zagreb, 2003.)

Display of crisis situation	Realisation of new concepts			
	phase 1: Appearance of crisis	phase 2: Beginnig of renewing	phase 3: Renewing	phase 4: Insurance new direction
<ul style="list-style-type: none"> • recognition of the symptoms of the crisis • search for help with field • hiring specialists to help 	<ul style="list-style-type: none"> • appointment of the crisis team • alignment of interests and activities of participants • The first factor analysis of the crisis • determination of the recovery team 	<ul style="list-style-type: none"> • commencement of the restoration team • analysis of the organization • preparation and presentation of the concept of restructuring • emergency measures 	<ul style="list-style-type: none"> • the introduction of structural change • implementation of measures for restructuring • implementation of control measures • Development of long-term conception of the organization 	<ul style="list-style-type: none"> • stabilization of the structure changes • usresredenost the key responsibilities • activation of additional features • achieve safe operation and functioning
	2-4 Weeks	1-2 Months	3-12 Months	2-3 Years

The picture is characteristic for the first phase of the recovery process engaging all resources that will ensure and facilitate operation of the organization in order to maintain key functions and relations. It is necessary to define priorities, external and internal accountability, and if necessary, enlist the help of the field, and some managers to assign certain powers. The priority work of the command in the military organization is aimed at restoring the basic functions of the organization and take concrete measures to eliminate organizational problems.

The second phase is characterized by the production of the basic concepts of restructuring based on the initial analysis of the situation in order to begin recovery.

The third phase is characterized by a concrete idea of strategic and operational restructuring of the organization. Activities are geared towards environmental action and are based on the activities and processes in a particular military organization to adapt its organizational structure. This phase, as seen in the previous picture, can take 1-2 months.

The last phase is characteristic for presupposes regeneration, determination of structural changes and concentration on core competences (responsibilities). It is based on a strategic dynamics which is preoriented towards the restoration and must be continued in order to avoid future crises.

It is know within the military practice, as well as based on analysis, and in this case, it is given its dimension. The basic and detailed analysis discover the real causes of the crisis. Only after understanding the causes of the crisis, it is possible to define measures that will lead organization (military) in a state of normal operation, and stable operation.

5. PHASES OF THE CRISIS MANAGEMENT

The process of crisis management, as previously noted, encompasses a wide range of activities that can show different stages. In a narrow sense, the crisis management activities include primarily during crisis or a period of mastering the crisis (turning point). The purpose of system management is much broader and includes all activities of preventive action, to master the crisis and reactive response, which is called crisis management in general.

The crisis is an essential part in the development of any organization, which also applies to military organizational systems, no matter what the level is, so it cannot simply be skipped. The success of coping with the crisis manifests itself in the length of time that passes through an organization and the consequences which remain at the organization after a crisis, if compared with the same organization take a factor of success as a category of successful or unsuccessful organizations. Effective organizational unit or organizational system, especially the military has been successful in terms of handling the crisis, especially if it has a "tool", ie. specific methods and instruments for the prevention, timely detection and mastering the crisis. It can be concluded that in such systems, organizational crises are rarely performed, and the consequences of shorter duration are less.

Finally, the crisis is a regular occurrence and common feature of any organizational system, particularly in terms of development of the organization. Practically, each stage in the development of the organization or its operation carries risks and requires a different type of management, a different strategy and governance.

The success of crisis management can be subsumed under the phase response elements, which essentially reflect the characteristics of the crisis. In this sense we can talk about the stages of crisis management which include:

- preventive action (prediction) to prevent the crisis,
- Identifying the crisis (if it is occurring, how to recognize it – indicators, the strength) and
- reactive crisis management, or mastery of a crisis (which is being done in order to master the crisis).

The main precondition of crisis management is timely observation or knowledge of hazards, and special attention is paid to the so-called warning signals - early warning systems that need to be sensitive to register the onset of the crisis. The crisis never occurs at once and suddenly, it starts slowly and becomes negative further on in all the prominent types.

If the intensity of the crisis is stronger, the meaning is clearer. Also, if the early warning signals are prominent, it is more difficult to "return" to a previous state or normal activity. The above mentioned statement certainly puts a priority responsibility to the unit commander, if it is a military organization, and management of the organization to build a collection of early warning signals or early warning, manifested in the data to the qualitative and quantitative scale on the occurrence of external and internal changes.

A particularly important segment belongs to the experience he needed to use as a lesson from the crisis. In crisis prevention, emphasis is given to the prediction capabilities, and the scenarios of future development directions. Therefore, prevention includes not only avoiding crises, but also applies to the preparation for the inevitable crisis and the crisis that simply cannot be avoided.

The central issue in this case, a contingency plan that defines all the activities required to master the crisis after its occurrence. When the crisis occurred, the focus is directed toward its mastery, including its moderation, harm reduction and recovery as a new beginning.

Bearing this in mind, the leadership of the organization, in this case referring to the military organization systems, commands are required to participate and address the main activities (actions) required for each stage of the process of crisis management.

6. CONCLUSION

The paper noted that the crisis is an integral part of our everyday life and crises that may be affected by all the organizations and the military organization systems. Among the factors in the monitoring and development of the crisis there are certain phases common to all types of crises. Universal for both the community and for the nature of the crisis. The subject of work are primarily social crises that have implications in the area of disturbed social relations with elements in a growing level of violence. The process of crisis management is a constructive reasoning, decision making and action that is aimed to determine the future status and avoiding crises. If this is not possible, then it means mastering its success.

Approach to crisis management systems in the military organization is facing views primarily broader and narrower approach dominated prevention and identification of the crisis. For crisis management in a broader sense identified by two-dimensional matrix of a matrix that includes five levels and five stages, with an emphasis on their networks. Matrix provides us with every level and every stage of investigating the antecedents and consequences of the crisis and is universally applicable to all types of crises.

The article also noted that successful crisis management is necessary for development of information structure. This applies primarily in the field of information if it is to manage the crisis in the way of a comprehensive system approach is an essential element, especially at the stage of crisis prevention. Information structure represents the connection between the management of the broad and narrow, especially the narrow sense includes activities geared to action during the crisis, or for the period of mastering the crisis.

Looking at crisis management in the narrower sense, given the identified phases of crisis management, which is known in military practice, in this case, gives its dimensions. The basic and detailed analysis discover the real causes of the crisis. Only after understanding the causes of the crisis, it is possible to define measures that will bring the military into a state of normal operation, and stable operation.

In particular that crisis management can involve a wide range of activities that are characteristic for each phase. Special measures relating to activities during the crisis belong to the sphere of inner control. However, to successfully master the crisis one requires a systematic approach that encompasses all the activities of preventive action, in order to master the crisis and reactive response, which is called crisis management in general.

NATIONAL QUALIFICATION FRAMEWORK AND SYSTEMATIZATION OF WORK PLACES

Branko Matic¹

¹Business College Valjevo, branko.matic@vipos.edu.rs

Abstract: *This paper discusses the impact of the National Qualification Framework (NQF) on Systematizations of Work Places (SWP) in companies and other organizations which do not comply with the framework. It takes into account the existence of the old system of marking degrees and names of professional titles. The paper presents analysis and comparison between old systems and NQF with the aim to determine similarities and differences. The NQF impact on SWP elements has been investigated too. The paper gives suggestions for making a SWP in compliance with new regulations and therefore could be useful for top managers, project organizations and human resource managers.*

Key words: *level of qualification, list of names, systematization, position, titles, occupations*

1. INTRODUCTION

National Qualification Framework of Serbia is adopted at the beginning of the year 2010. Beside the List of professional, academic and scientific names (LN) it should be the basic document for the redefinition of old and the making of new Systematization of Work Places in companies and other organizations. The redefinition has not been done yet in any organization because the responsible staff has not been familiar enough with the role of NQF and LN. The existence of the old system of marking degrees and professional titles aggravate the situation. Therefore it is necessary to define the relations between the old and new system and investigate the ways how to apply NQF in SWP.

2. SYSTEMATIZATION OF WORK PLACES

The basic document governing the operation of enterprises and other organizations is Regulation on organization and systematization of jobs. It is mandatory according to the Labour Law from 2005 and it defines the organizational units, the types of jobs, the type and level of education and special working requirements for that jobs. It therefore defines all elements related to the workplace and the conditions to be met by candidates. SWP is an organizational regulation of director that is used as basis for: planning, recruitment, recording and managing of employees, the rights arising from employment and calculation of earnings.

Labour Law speaks about "jobs" while the praxis uses "work places". Work place is the smallest technologically and organizationally completed unit within which a part of operation or production is performed. Within a work place one or several operations are performed. SWP is a list of places in a company which results from its organization. The list is adjusted to the organisational structure in a unique, unambiguous and uniform manner for the whole company in terms of the type and content of data defined by it. SWP is made as a table that contains data listed from 1 to 7 as shown in the table 1 below.

Table 1: Example of Systematization of Work Places

No. code	Title of work place	Nr of empl.	Education level	Education type	Expe-rience	Other requirements	Coeffi-cient
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
1.	Director	1	VII-1	Dipl. Ing. of work organization	5	English	6
2.	Head of accounting	1	VI-1	Economist	3	Computer skills	4

By making SWP the following rules have to be respected in order to define its elements:

(2) **Title of work place** - comes from the content of the work; the title defines employee's occupation. Here should be noted the difference between title (educational background) and occupation (the work performed by employee).

(4) **Education** (degree required for the workplace - type and level) - determined on the basis of professional consideration of the required knowledge, skills and ability to work at a workplace by appropriate choice of the existing type, direction and level of education provided by educational institutions of Serbia.

(6) **Other requirements** - additional knowledge and skills as a prerequisite for the job, e.g. knowledge of foreign languages, use of computer, safety at work course, driving licence and others.

For each work position from the SWP, a job description should be done (tasks, powers, responsibilities). The set of all descriptions makes an annex to the Systematization of Work Places.

3. QUALIFICATIONS - TITLES AND DEGREES

Before the Law on Higher Education passed in 2005, there were in Serbia job titles and degrees of education obtained by the University Law and High School Law. The titles and degrees were determined in the former Yugoslavia and during the political changes were just taken over. They are shown in the table below, (according to National Classification Framework of Serbia 2010)

Degree of education	Faculty/academy/university		College or applied studies		European Qualification Framework of Higher Education (Bologna process)	European Qualification Framework (levels)
VIII	Ph.D/doctorate				3. cycles	8
VII-2	Master of science/magister	Specialization			2. cycles	7
VII-1	II degree	graduate (diploma)			1. cycles	6
VI-2			Specialization	Study 3 years	short cycles	5
VI-1	I degree		Study 2 or 2,5 years			

Picture 1: Levels of education by 2005.

A characteristic of this system was the clarity in determining titles and level of education which derived from the type of educational institution and length of schooling. There was a unique approach to different professions; titles and degrees were in a logical order as in the following example: economist VI-1, degree of economy VII-1, magister degree in economics VII-2, doctor of economy VIII. (It is important to note that many study programmes were divided into different courses.) All diplomas obtained and issued before the accreditation of high school institutions include these, above mentioned titles. The large majority of graduates in Serbia have diplomas with these titles.

The previous titles were mainly in accordance with the degrees of European Classification Framework (EQF). The Doctor of Science VIII degree corresponds to the eighth level of EU, and all graduates VII-1 degree correspond to the 7th level of EU. There were discrepancies in the title of Magister of Science, which was in Serbia VII-2 degree and in the EU belongs to the 8th level. (It is interesting that in Croatia the Magister of Science was VIII degree.) There is another discrepancy with VI-1 degree which corresponds to EU 5th level. These two degrees (VI-1 and VII-2) do not exist anymore after 2005 neither in the Law on Higher Education nor in the accompanying legislation. However, these two and all aforementioned titles will be acquired and written in diplomas until the expire of legislative deadlines of the studies according to previous laws.

3.1 Records in the field of work

The title and degree of qualification is a data used in a various records in the field of work and particularly in the work of National Employment Service (NES). In 1998 in SR Yugoslavia was passed "Code List in the records of work" that contains "Code List of jobs and qualifications". (Gluvak, M. 1998) In the Code List of Jobs, occupations are divided according to two features:

- 1) according to complexity of work - categories I-VIII
- 2) according to similarity of fields - into 19 work fields within which 75 groups of professions are defined as shown in the table 2 (the field of work: Economy, Law and Administration)

Though the name of the document says The Code List of Jobs, it is in fact a Code List of professional titles. The same Code List (which is precisely explained by Gluvak, M. 1998) is still used nowadays in the unified information system of NES. In 2008 the Code List was harmonised with the List of Professional, Academic and Scientific Titles of National Council for

Table 2: Code of Titles-excerpt

XII Economy, Law and Administration
66. Managers and organisers
67. Economists
68. Lawyers
69. It specialists and statisticians
70. Human resources jobs
71. Administrators
72. Defence, Security, Protection jobs
73. Zanimanja osiguranja

Higher Education. In order to include new titles from the List, the Code List was amended with new codes for new titles in higher education (categories from VI to VIII). The new titles and their codes are entirely harmonised with the List. They are divided into five fields and several areas.

4. THE LEVELS OF HIGHER EDUCATION AND THE LIST OF PROFESSIONAL, ACADEMIC AND SCIENTIFIC TITLES

Law on Higher Education from 2005 united higher education in Serbia and brought significant changes in many aspects, especially in terms of professional titles. Aforementioned Law on Higher Education and accompanying regulations passed by National Council for Higher Education have changed fundamentally the previous qualifications (titles and degrees). The entirely new forms of higher education are introduced. Their titles are divided into three levels, shown in the Picture 2 (National Qualifications Framework of Serbia, 2010)

European Qualifications Framework levels	European Qualifications Framework on Higher Education (Bologna process)	Serbian National Qualifications Framework (SNQF)					
		Academic studies			Applied studies	ECTS	
8	3. cycle	Doctoral BA-3	Specialist BA-2b			180	480
7	2. cycle	Master BA-2a				120-60	300
					Specialist BC-2	240	
6	1. cycle	Bachelor 3y BA-1a	Bachelor 4y BA-1b	Integrated BA-2a	Medicine BA-2a	Bachelor BC-1	180-240

Picture 2: Levels of education by 2005.

A characteristic of this system is the existence of three levels of higher education adjusted to the three levels of EQF and to the first, second and third cycles of high education according to Bologna process - bachelor, master and doctoral studies. There is also compliance with ECTS. A new thing is that for the levels are defined alphanumeric numberings. So, the first level has got two marks for academic study BA-1a, BA-1b and one mark for applied study C-1. The second level has got one mark for academic studies BA-2a and one for applied studies BC-2. The third level has got two marks BA-3 and BA-2a. These marks have to be written in diplomas and supplement diplomas from 2012.

For these three levels, The List of Professional, Academic and Scientific Titles has been defined (Regulation on the list of professional, academic and scientific titles, 2010), adopted by National Council in 2007, changed and amended in 2010. The List defines: the field, the type of study, professional, academic and scientific titles, their abbreviations for each of the five fields within the system of higher education consisting of 48 fields:

- Field 1 - natural sciences and mathematics (8 areas),
- Field 2 - technical and technological sciences (16 areas),
- Field 3 - social and human sciences (16 areas),
- Field 4 - medical sciences (4 areas),
- Field 5 - art (4 areas).

The method of determining titles with academic studies is similar to the previous one, for example economist, graduate economist, master economist, specialist economist and doctor of science - in the field of economics. In the field management and business: manager, graduated manager, master manager, specialist manager and doctor of science. The new titles are: master and specialist, while the third level includes a somewhat different title.

With applied studies and levels, in front of titles is added the adjective "applied", for example applied economist, applied manager, and with level two is added the word "specialist", as specialist applied economist, specialist applied manager.

Abbreviations are defined for all titles of academic and applied studies, which is a novelty, because in the past they were used but they were not defined.

In the world there are a number of professional titles with the corresponding abbreviations that originate from English language and based on three levels: Bachelor, Master, Doctorate. The best known examples are: BA - Bachelor of Arts, BS - Bachelor of Science, MA - Master of Arts, MBA - Master of Business Administration. The review of all abbreviations can be found on the site www.all-acronyms.com/tag/academic_degree.

5. QUALIFICATIONS FRAMEWORK AND LEARNING OUTCOMES DESCRIPTORS

Higher education system is supplemented by Serbian National Qualifications Framework - SNQF, which was adopted by National Council for Higher Education on 23.04.2010. This document contains preamble, one table and two pictures. In the preamble objectives of SNQF are specified as follows: "integration of students into the labour market, preparation for life as active citizens in a democratic society, personal development throughout life, development and maintenance of a broad-based quality knowledge of the whole society". In order to achieve the objectives "SNQF defines what a student needs to know, what has to understand and what is he/she able to do on the basis of qualification he/she gained, it means SNQF defines what are learning outcomes expected of each qualification". Learning outcomes descriptions for two most common types of education: basic applied studies and graduate are given in the table 3.

Table 3: Learning outcomes descriptions SNQF (excerpts)

Type of education	Learning outcomes descriptions
BC-1:	<ul style="list-style-type: none"> to show knowledge in the field of study which is based on previous education and which enables for usage of specialized literature; to be able to apply knowledge and understanding in profession; to be able to pass on knowledge to other; to possess the ability to continue their studies;
BA-2a:	<ul style="list-style-type: none"> to show knowledge and understanding in the field of study which supports the knowledge acquired at undergraduate level and is the basis for the development of critical thinking and application of knowledge; to be able to apply knowledge to solve problems in new or unfamiliar environment in a broader or multidisciplinary areas within the educational-scientific-artistic field of study to have the ability to integrate knowledge, solve complex problems, to make judgments based on information available that contain reflections on social and ethical responsibilities associated with the application of their knowledge and judgments; to be able to clearly and unambiguously convey knowledge and way of reasoning to professional and general public; to possess ability to pursue studies in a manner which they will choose independently.

As you can see "SNQF defines only general learning outcomes. Apart from the outcomes, each specific program of study within higher education must meet specific requirements in relation to the scope of knowledge, skills and competencies appropriate for particular area, or educational-scientific field."

On 23.april 2008 the European Parliament adopted Recommendation C 111/1, with which was defined European Qualifications Framework - EQF. The European Framework in Annex II gives certain descriptors of learning outcomes for the three qualifying factors: knowledge, skills and competencies, as given in the table 4

Table 4: Descriptors defining levels in the European Qualifications Framework (EQF)

	Knowledge	Skills	Competence
Level 6 <i>The learning outcomes relevant to Level 6 are</i>	advanced knowledge of a field of work or study, involving a critical understanding of theories and principles	advanced skills, demonstrating mastery and innovation, required to solve complex and unpredictable problems in a specialised field of work or study	manage complex technical or professional activities or projects, taking responsibility for decisionmaking in unpredictable work or study contexts take responsibility for managing professional development of individuals and groups

Level 7 <i>The learning outcomes relevant to Level 7 are</i>	highly specialised knowledge, some of which is at the forefront of knowledge in a field of work or study, as the basis for original thinking and/or research critical awareness of knowledge issues in a field and at the interface between different fields	specialised problem-solving skills required in research and/or innovation in order to develop new knowledge and procedures and to integrate knowledge from different fields	manage and transform work or study contexts that are complex, unpredictable and require new strategic approaches take responsibility for contributing to professional knowledge and practice and/or for reviewing the strategic performance of teams
--	--	---	--

It is further said in Recommendation: "The development and recognition of citizens' knowledge, skills and competence are crucial for the development of individuals, competitiveness, employment and social cohesion in the Community. Such development and recognition should facilitate transnational mobility for workers and learners and contribute to meeting the requirements of supply and demand in the European labour market. Access to and participation in lifelong learning for all, including disadvantaged people, and the use of qualifications should therefore be promoted and improved at national and Community level." This shows that the EQF has primary importance for the European Union. Therefore, member states will accept instruments EQF, so that from 2012, all new diplomas of qualification, certificates and European documents issued by the competent institutions contain a clear reference, from the national qualifications systems to the corresponding EQF level.

The Recommendation includes the Annex III - Common Principles for Quality Assurance in Higher Education and Vocational Education and Training in the context of the European Qualifications Framework and Annex I with the definitions of terms used. Some important terms are defined as follows:

- **knowledge** means the outcome of the assimilation of information through learning. Knowledge is the body of facts, principles, theories and practices that is related to a field of work or study. Knowledge is described as theoretical and/or factual;
- **skills** means the ability to apply knowledge and use know-how to complete tasks and solve problems, skills are described as cognitive (involving the use of logical, intuitive and creative thinking) or practical (involving manual dexterity and the use of methods, materials, tools and instruments);
- **competence** means the proven ability to use knowledge, skills and personal, social and/or methodological abilities, in work or study situations and in professional and personal development. Competence is described in terms of responsibility and autonomy.

6. CLASSIFICATION OF OCCUPATIONS

Many countries that have developed their own national qualifications framework have adopted the national classification of occupations. In Serbia, this is not the case. (In SFRY there was a "unique nomenclature of occupations", which was never implemented, but was neglected although it was being made long and very professional.)

The situation worldwide is quite different. Many developed countries have a very well organised national classification of occupations. The model for this is since 1958, the International Standard Classification of Occupations (ISCO) from International Labour Organization (ILO). ISCO is an ILO classification structure for organizing information on labour and jobs. It is part of the international family of economic and social classifications of the United Nations. The current version, known as ISCO-08, was published in 2008 and is the fourth iteration. The ILO describes the purpose of the ISCO classification as: "a tool for organizing jobs into a clearly defined set of groups according to the tasks and duties undertaken in the job. It is intended for use in statistical applications and in a variety of client oriented applications. Client oriented applications include the matching of job seekers with job vacancies, the management of short or long term migration of workers between countries and the development of vocational training programmes and guidance."

The ISCO-08 divides jobs into 10 major groups. Each major group is further organized into sub-major, minor and unit (not shown) groups marked by four digit. Number of sub-major (subgroups) is given in parentheses in Table 5. Then follows a great number of minor, and at the end are the units 671 in the ISCO-08. The units are in fact specific occupations that are described in detail.

Table 5: Classification of occupations ILO and Canada

ISCO-08 from International Labour Organization	National Occupation Classification (NOC) of Canada
--	--

1 - <u>Managers</u> (4)	0 - Management occupations
2 - <u>Professionals</u> (6)	1 - Business, finance and administration occupations
3 - <u>Technicians</u> and associate professionals (5)	2 - Natural and applied sciences and related occupations
4 - Clerical support workers (4)	3 - Health occupations
5 - Service and sales workers (4)	4 - Occupations in education, law and social, community and government services
6 - Skilled agricultural, forestry and fishery workers (3)	5 - Occupations in art, culture, recreation and sport
7 - Craft and related trades workers (5)	6 - Sales and service occupations
8 - Plant and machine operators, and assemblers (3)	7 - Trades, transport and equipment operators and related occupations
9 - Elementary occupations (6)	8 - Natural resources, agriculture and related production occupation
0 - Armed forces occupations (3)	9 - Occupations in manufacturing and utilities

7. CRITICAL ANALYSIS OF SNQF AND THE LIST OF NAMES AND THEIR APPLICATION IN SWP

Most SWP (Systematization of Work Places) in companies and organizations in Serbia were made as described in Section 2. Better made SWP determine qualification in a way described in Section 3, in accordance with qualifications (titles and degrees) which were valid until adoption of the Lists of professional, academic and scientific titles in 2010. In many SWP, which were made worse, qualification is only defined the degree, which allows flexibility in recruitment for the work position. However, not specified kind of qualification, makes it impossible for any human resource planning, chaos in the labour market and disorient young people in deciding on the type of high-school education. Although, generally, the levels of education are similar to the levels of the EU, they are not harmonized, which can be a major problem in all the activities of cooperation and work with companies and organizations from the EU. Also, it can be a major obstacle to EU integration. The titles of qualifications and corresponding abbreviations existing prior to 2010 are completely incompatible with European and international academic degree. It is not any better with the titles and abbreviations from LN from 2010.

Bearer of SNQF, National Council for Higher Education, by establishing this document tried to provide a good basis and resolve these issues. Although it is stated in the preamble that "it is shown relationship of qualifications in education, and mobility between qualifications" it would not be concluded from the data given in Picture 1. It is necessary to define directly the relationship between the old and new degrees in higher education, particularly in connection with the detailed definition, once given as a "type of qualification". The relationship between old and new systems is shown in Table 6.

Table 6: Comparison of old and new systems of titles

O L D			N E W			
<i>degree</i>	<i>title</i>	<i>abbrev.</i>	<i>level</i>	<i>code</i>	<i>title</i>	<i>example of abbrev.</i>
VIII	Doctor	Dr	III	BA-3	Doctor	Dr
VII-2	Magistar	Mr		BA-2b	Specialist	Spec. manager
VII-2	Specialist	Spec.	II	BA-2a	Master	Mast. manager
VII-1	Faculty	Dipl.		BC-2	Applied specialist	Spec. appl. manager
VI-2	Program VI-2 degree	Spec.	I	BA-1b	Undergraduate 4 g.	Dipl. manag..
VI-1	College and I degree F	VŠ		BA1-a	Academic 3 g.	Manager
				BC-1	Applied	Applied manager

Only arranged in this way becomes clear what are potential problems related to professional titles. These problems come up when drafting a new SWP, because the old and new system are not harmonized. To overcome these problems the following rules should be used:

- a) the previous title "magister" no longer exists, and is not the same as the new "master" which is lower degree. It is the closest to a new specialist BA-2b;
- b) the previous title specialist is lower than a new specialist;
- c) the previous Faculty - Dipl. is higher than the new Bachelor of 3 years BA-1a;
- d) to the previous faculty which lasted 4 years corresponds basic academic 4 years study BA-1b;
- e) to the previous faculty - Dipl which lasted 5 years corresponds a new Master BA-2a;
- f) to the new basic academic 3 - year study does not correspond none of the old ones;
- g) to the old degree VI-2 does not correspond none of the new ones but it could be compared to applied specialist study BC-2;
- h) to the previous degree VI-1 does not correspond none of the old ones but it could be compared to applied BC-1.

The old SWP should be transformed and a new one should be done with new professional titles and codes. The aforementioned rules should be used in allocation of persons who previously acquired high and higher education as Annex to the document.

Table 7: Changes in systematization of work places

No. code	Title of work place	Nr of empl.	Qualification code	title	Expe-rience	Other requirements	Coeffi-cient
(1)	(2)	(3)	(4)		(5)	(6)	(7)
1.	Direcor	1	BA-1b	Dipl.manager	5	English	6
2.	Head of accounting	1	BC-1	Applied economist	3	Computer skills	4

A much larger problem will be to harmonise the new forms of education defined in SNQF (table 3) with the levels defined by the EQF descriptors (table 4). There is a significant difference between the levels defined uniquely by SNQF and EQF which provides descriptors structured as: knowledge, skills and competencies. This method of determining learning outcomes is much better and contributes to the usability of a qualifications framework and achieving the objectives of its adoption. This is especially true for the use of SWP for which is the SNQF practically useless. It is therefore urgently necessary to change its "learning outcomes descriptors" and harmonize with the way of determining descriptors for: knowledge, skills and competencies as in EQF.

Even if it were done quickly, which is realistic, because the EQF could be used, modified SNQF still would not be of much use for it as such is not operationally useful. On the basis of it should be made standard qualifications and occupational standards. The definitions of these two standards (according to Dželalija, M. 2009) indicate the nature of these documents, which allows for the development of operational use of SWP.

"Qualification Standard means the content and structure of certain qualifications, and includes all information required to determine the level, volume and profile of qualification, and data required for quality assurance and improvement of standards of qualification.

Occupational Standard is a list of tasks that an individual carries out and a list of competencies required for their successful performance."

Only after the establishment of these two standards can be accessed to the development of **National lists of qualifications of Serbia** which should replace The list of professional, academic and scientific qualifications. Then the **National List of Serbian occupation** should be made, modelled on the ISCO-08, which should replace the Code List of Occupations. By this, all required documents, which are important for the regulation of human work, will be completed. Only in this way can be established the relationship between higher education and employment in companies and other organisations. The key link in this relationship is SWP which, because of the errors in SNQF and the lack of these standards, cannot be shaped in the required way to ensure **employability** - "individual competitiveness in the labour market regarding the necessary competence to achieve initial employment, its retention or acquisition of new where necessary." (Dželalija, M. 2009)

8. CONCLUSION

The existing SWP are not in accordance with SNQF and LT in terms of the titles of work places - occupations and qualifications - and titles. List of Titles, issued by the National Council for Higher Education is in line with the Law on Higher Education but is essentially a reworked old system titles. The new master and

professional titles are added and abbreviations are defined. Titles are generally balanced and aligned with the levels of the Framework for Qualifications of the EU, but completely deviate from the usual academic titles in the world, which can be a problem for comparability purposes.

Adopted SNQF defines descriptors of learning outcomes that are appropriate for editing pass between the forms of higher education, but are inadequate for the needs of the SWP, as it does not define the knowledge, skills and competencies by level, in which SNQF significantly deviate from the EQF. Neither LT nor SNQF fully comply with international standard qualifications, so they are not a good foundation for the development of the National Classification of Occupations, which does not exist in Serbia.

Therefore the existing SWP can be harmonized with the Law on Higher Education, SNQF and LT only in terms of professional qualifications, so that their level will be described with literal numerical codes, and the type with abbreviation from SNQF. It is not possible to define the names of jobs - occupations in a new way until adoption of the National Classification of Occupations. Until then, all the activities of human resources managements and employability of highly educated persons will be inappropriate.

Abstract: *Objective of our paper is to present outline of the business model for research data repository. We have used data gathered from questionnaire distributed to universities in Balkan environment. Our findings are presented through descriptive statistics reports. Also, conclusions from analysis are fitted into a business model. Basic framework for it is provided by business model canvass of Osterwalder and Pigneur. Main result of our paper is analysis of user needs for research data repository and outline of self-sustainable business model, which could also find application in different milieus. Conclusion is that two-sided platform of researchers and companies with research needs is the best solution. It would be of interest for researchers due to easy access to research data, networking, collaboration and opportunities to earn additional resources. Limitation of our paper is level of detail in description. We hope that this model will find opportunity to be further elaborated and finally implemented in real environment.*

Keywords: *business model, organization, collaboration, research data, repository.*

1. INTRODUCTION

This paper presents business model outline for research data repository. Data repository would be valuable to researchers from Balkan area, having pressures to publish research in indexed journals. It would facilitate collaboration and ease the research process. It would be hosted on a website containing other Web 2.0 forms of interaction, like forums, wikis and basic social networking. Our plan is to develop self-sustainable business model for website in order to boost cooperation among researchers from Balkan area in the long term. Repository can also be used as pilot project for future projects which could cover larger scope than regional.

In brief, main idea is to use available funding from organizations such as CERGE as initial financial resource needed for development of site, and make it as economical as possible without significant loss of functionality, combining XML and folksonomies in order to use, classify and access research data. Data is planned to be uploaded by researchers, with free registration. Registered users could upload their research data, and access partial set of other research data, while advanced users would have accessible advanced search, more functionality and all research data. Research data would be ranked by other users, and according to those ranks, interaction level with other users and collaborative activities on forums users would be automatically ranked. Higher ranks mean higher accessibility of data, as well as advanced functionalities and search. This is basic outline of idea, while main part of this research paper is development of a business model according to canvas developed by Osterwalder and Pigneur (2010).

One of first strategic decisions in starting a new enterprise is development of sound business model. Business model can be understood as abstract representation of basic business logic (Osterwalder, 2001). It can be defined as architecture of a firm and its network of partners for creating, marketing and delivering value and relationship capital to one or several segments of customers in order to generate profitable and sustainable revenue streams (Dubosson-Torbay, Osterwalder and Pigneur 2002). Recent research shows following conclusions the business model is emerging as a new unit of analysis; business models emphasize a system-level, holistic approach to explaining how firms “do business”; firm activities play an important role in the various conceptualizations of business models that have been proposed; and business models seek to explain how value is created, not just how it is captured (Zott, Amit, Massa, 2011).

2. METHODS

For the purpose of this paper we have performed data gathering among teaching and research staff of universities in Balkan area, named “The content of the database on a new website in the Balkan area”. Overall we have gathered 38 responses from Romania, Serbia, Greece, Macedonia and other countries.

Analysis of questionnaire results was initially performed only on descriptive level for the purpose of this paper. Entire questionnaire is presented in following.

Identification and contact information for University (company, enterprise, institution etc.)			
Position / function in the university (company etc.)			
University (company etc.) address			
University (company etc.) phone			
University (company etc.) website:			
A. University (company etc.) profile*			
Code * 1 = complex; 2 = technical; 3 = human and socio-economic; 4 = medicine and pharmacy; 5 = agricultural and veterinary; 6 = arts, architecture and sports; 7 = military; 8 = other profile			
B. Key areas where students (employees) are trained**			
Code** 1 = general; 2 = natural sciences; 3 = humanities; 4 = theology; 5 = technical; 6 = social and political sciences; 7 = economics; 8 = arts; 9 = architecture and urban planning; 10 = physical culture; 11 = agricultural and forestry sciences; 12 = veterinary medicine; 13 = engineering sciences; 14 = military science and information; 15 = health; 16 = other areas.			
C. Are you interested in a new database or information website in the Balkan area?		YES	NO
D. Please specify the first three important domains of interest to include in this new website***			
Code*** 1 = demography; 2 = education; 3 = history; 4 = economics; 5 = tourism; 6 = culture; 7 = management; 8 = entrepreneurship; 9 = environment ; 10 = other (please specify)			
E. Please specify the form of collaborative activities and detail the specific way that you want to collaborate:			
F. What kind of information as result of cooperation do you want to get from this website?			
Code**** 1 = statistics; 2 = courses organized by the universities for company, enterprise, institution etc; 3 = equipment / software enterprise in education; 4 = applied research and development projects; 5 = new plans for education in universities or new topics in university curriculum, reflecting market demands; 6 = projects and partnerships in the company enterprise, institution ; 7 = international projects and partnerships. 8 = other (please specify)			
G. Please mark the type of collaboration based on the new website and its information:			
Code***** 1 = scientific research (contract research); 2 = consulting (contract services); 3 = project partners / project consortium (partnership agreement / consortium); 4 = rent space by the university or company (lease); 5 = sponsorship / mecenate (sponsorship contract in the company) 6 = other type (please specify)			
H. What level do you need to access information as result of this website?		National	Regional
I. What benefits do you expect from the information as a result of this new website?			
Code***** 1 = raising students' and employees' knowledge; 2 = increase teacher qualifications; 3 = curriculum changes; 4 = purchase of equipment and soft; 4 = research contracts; 5 = common research centres, incubators, technology transfer centres; 6 = adapting training offer; 7 = other result (please specify)			

2. BUSINESS MODEL PATTERN

Model of this enterprise will be simplified and presented in business model canvas, developed by Osterwalder and Pigneur (2010). This canvas has already been used in context of Web 2.0 science journal (Nüesch and Andrea 2011), development of internet based business in e-trade (Rajkov and Čudanov 2012) and genetic sequencing data analysis business (Čudanov, Krivokapić and Komazec 2012a; Čudanov, Krivokapić and Komazec 2012b). Main components of their canvas are:

- Customer Segments

- Value Propositions
- Channels
- Customer Relationships
- Revenue Streams
- Key Resources
- Key Activities
- Key Partnerships
- Cost Structure

Customer segments as first element of the model defines different groups of individual clients and organizations to whom cooperation should be aimed. Those groups generally enable existence of observed organizational system. Thus they deserve attention, and best way to apply it is to segment them into different groups. Following step is defining priority of each segment, and development of business model which will serve each segment. Group of customers can be observed as a segment when their needs require and justify certain proposition, when they are approached by different distribution channels, demand different kind of relations or have generally different profitability and wish to pay different segments of the value proposal (Dubosson-Torbay, Osterwalder and Pigneur 2002; Osterwalder and Pigneur 2010). Company can however focus toward one specific segment, and form a unique business model. An example of customer segment can be market niche, as smaller market parts with clients of the same characteristics or demands (Dalgic and Leeuw 1994).

Value proposal can be defined as package of products and services created for needs of customer segments. If proposed value is different from those existing in the market in order to differentiate organization from competition. Values created for customer segments basically attract their attention to organizational system. Value creation can be aided by novelty in business, product/service performance, adjustment to client needs, product design, brand and status organization has in public, price, cost reduction, risk reduction, accessibility, convenience and usability (Osterwalder and Pigneur 2010).

Distribution channels are a way to attract and communicate with customer segments. Those are “contact” points between company and clients. Through distribution channels company awakens customer awareness, help them to access value propositions, enables buying of products/services, delivers proposed values and post-sales support. Channels can be divided into direct and indirect, or partner and owned. Right mix of distribution channels provides efficient satisfaction of user needs.

Customer relationships define relationships between organization and market segments. Each segment should have defined relationships. Goals of are to attract new customers, retain existing one, or to increase “wallet share”, i.e. amount of sales toward the customer, and in that goal relations can be personal assistance, dedicated personal assistance, self-services, automated user services, different communities and co-creation of relationship (Osterwalder and Pigneur, 2010).

Revenue streams define amounts of cash that is generated from each customer segments. Question to which a company needs to give answer is: what value us each customer segment really willing to pay? Only after clear, realistic and correct answers to those questions can we propose viable business model. Transactions can be viewed in simplest as one-time payments and recurring payments, while Dubosson-Torbay, Osterwalder and Pigneur (2002) further classify revenues from asset sales, usage fees, subscription fees, renting/lending/leasing, licensing, brokerage fees and advertising.

Key resources can be described as most valuable physical, intellectual, human and financial assets related to functioning of organizations. Those are resources without which organization would not be able to create value proposition in a desired way.

Key activities are list of most important activities to be performed in order for model to function and for Companies need to apply those activities while creating values in dynamic markets, keep relations with customer segments, thus creating revenues. Porter defines most important activities as “core activities”, consisting of inbound logistics, operations, outbound logistics, marketing, sales and post-sale services (Porter and Miller 1985), while knowledge sharing, supply chain management and product development process activities are identified as most important in manufacturing industry context (Huang, Stewart and Chen 2008). Elaborate list of key activities is deeply dependent on the nature of the business, and even best categorizations cannot be fully utilizable for individual cases.

Key partnerships describe network of suppliers and partners who enable business model to function. Partnerships are foundations of activities and relationships within companies, which can help it to be differentiated in market through unique offer. Partnerships can be formed when partners recognize advantages of forming a new business model and economy of scale, in order to reduce risk or uncertainty or to ensure resources for successful operations. That can lead to virtual or network organizations, often associated with e-enterprises (Zhou, Peng, Li, Wang, Wu & Shao 2010). Osterwalder and Pigneur (2010) divide partnerships into: strategic alliances between non-competitors, strategic partnerships between competitors, joint ventures to develop new businesses and buyer-supplier relationships to assure reliable supplies.

Cost structure represents all the costs organization has incurred through developing and utilization of business model. If key resources, key activities and key partnerships are defined, it can be relatively easily estimated. While elaborating minimization of costs, it is very important to define business model in order to decide if company will aim to minimizing costs or maximizing the delivered value. In first case, company will try to minimize costs whenever possible, using value proposals of low prices, maximizing automation or utilization of external resources. Companies lead by high value on the contrary increase value, and can be usually recognized by higher amount of personal input, services and adoption. Cost structure is usually analyzed through fixed, variable costs, economies of scale and economies of scope (Osterwalder and Pigneur, 2010).

This canvass connects, and in a very understandable way shows elements of business model, which are main reasons for choosing it as a main background for research. If system is generally understood in its entirety, it can be important for obtaining good business results (Christopher, 2011). This canvass is also flexible enough to view organizational goals, clear out real value proposals as well as ways for its achievement. It is useful as a tool for translating idea into business plan and processes, and successful execution. Appliance of this canvass is very wide, ranging through all industries, from manufacturing to high-technology services, from basic operations to most innovative business. Application is also not limited by organizational size, from small to multinational organizations. One of main strengths of Osterwalder's and Pigneur's canvas is that it helps us prevent losing focus from the entirety of system towards details. It is thus very helpful for strategic planning and business development.

3. RESULTS

Gathered data was analysed by descriptive means at first, for the purpose of this paper. Out of 38 returned questionnaires 37 (97.37%) applicants have agreed that they are interested in a "new database or information website in the Balkan area". That justifies development of business model for research data repository, as it was dubbed in our paper. Following results are presented in order to depicture technical and business aspects of developed business model. First important part is university profile, given in Figure 11. We can see that complex and technical universities are dominant, ensuring multidisciplinary of research data that should be gathered in future repository. That implies open nature of key partners, which is presented in our business model.

Figure 11: University profiles

Next aspect analyses key area in which students are trained, and is similar to university profiles, and leads to similar directions for our business model, where first choice answers are presented in Figure 12.

Figure 12: Key areas where students are trained.

However, domains that would be desired for inclusion in this research data repository are rather biased towards education (27%), economics (13%), tourism (13%) and management (21%), suggesting rudimentary classification of data sets. Results are presented in Figure 13.

Figure 13: Domains of interest for research data

Next figure shows expected results from research data repository. Common conclusion is that cooperation is needed for any of desired outcomes, so it is a component that has to be included in the nature of business model. Desired outcomes are synthesized in value proposals of business model, and shown in Figure 14.

Figure 14: Expected outcomes of new data repository

4. BUSINESS MODEL

On the basis of questionnaire feedback and analysis results our business model was developed. One of the basic reasons for development of business model for this enterprise is increasing reliability and chances of success. Lack of business models was especially observed during dot.com market crash, where lack of clear business strategy which would result in clear plans and business models is listed as reason for bankruptcy of those companies, along with external crises caused by external market crash (Hwang and Stewart, 2006). Internet based business has quite unsuccessful history of alignment of business systems and IT processes, and such alignment is one of the main success factors for IT investment performances. (Pajić, 2011). In order to ensure success of research data repository, it is important not only to satisfy technical aspects of programming the Web platform, but also to develop sustainable business model. Figure 15 shows draft business model for future research data repository.

Key partners Funding organizations (CERGE) Universities and research communities Companies with research demand	Key activities Platform maintenance	Value proposition Accessible research data Automated data combination for synergy Cooperation in curriculum development Access to research community	Customer relationships User communities Folksonomies Automated relations	Customer segments Research institutions Individual researchers Companies with research demands
	Key resources Web platform Image of reliability		Channels Web portal	
Cost Structure Costs of platform maintenace and development Cost of control against misuse			Revenue streams Fees for research demands Targeted advertizement	

Figure 15: Business model of research data repository

5. CONCLUSION

This paper presents business model for research data repository. Technical aspects, both software and functionality design is not elaborated in this paper. Main focus is on business aspect, with idea to develop self-sustainable model which could maintain its own existence and possibly spread to cover more than one region. In order to do that, we had to develop two-side platform, where main parties would be researchers, along with companies with research demands. In this model, website with research data repository would have main purpose to gather research community, providing value for companies in need of some research. Companies could on the other side provide their research demand along with related data and description. Also, companies demanding research could offer a fixed reward to all interested researchers, and pay it to best researcher/research team, or the researcher/team with first applicable results or solution. On the other hand, companies could demand research for free, if researchers are interested. Anyhow, companies must pay a nominal fee for posting research demand. That fee will be used to cover costs incurred by maintenance and future development of this platform, as well as control against misuse. Although such costs are not expected to be high, some amount of revenue is necessary in order to maintain website. That revenue can also be supplemented by targeted advertisements. All that completes model which is initially to be funded by donation. Our paper gives only the basic outline of the model due to text length restrictions. Details in all categories, like financial, technical, market or processes can be a topic for some of our future articles.

THE ADJUSTMENT OF ORGANIZATIONAL FORMS TOWARDS BETTER HIGH-TECH PROJECT PORFOLIO'S PERFORMANCE

Laslo Zohar

SCE – Shamoon College of Engineering, zohar@sce.ac.il

Abstract: *Project managers support the idea that successful projects occur when the resources necessary for their work are obtained. Functional managers support the idea that resources should be made available based on the overall needs of the organization. In fact, organizations are much more complex entities as different project groups compete for scarce resources. One successful project may divert essential resources from other projects and thereby prevent the organization from achieving an overall successful performance. Thus, in contrast to the customary emphasis on the needs of individual projects when thinking about matrix forms, effective implementation calls for an 'optimized' equilibrium between the satisfaction goals of the different organizational units. The paper introduces some insights into the implementation of matrix forms in high-tech project portfolios where uncertainty, ambiguity, and complexity are looming.*

Keywords: *matrix forms, project portfolio, flow of resources, purchase policy, setting priorities, low-tech environment, system dynamics model*

1. INTRODUCTION

The matrix structure has become the popular organizational framework for managing the development of new products and services (Perham, 1970) and the primary organizational means for maintaining an efficient flow of resources in project portfolios. This structure operates through a two-dimensional system of control: a project line chain of command and a functional chain of command (Lawrence et al., 1982). Within the matrix, each chain of command keeps its traditional role and takes responsibility for goals as in the two earlier hierarchical forms of organization (Lawrence & Lorsch, 1967). Project managers retain responsibility for developing products, while functional managers concentrate on the organization's capability to make use of up-to-date technical knowledge. In order to complete a job, functional managers must address different objectives and priorities than project managers. The different objectives are based on functional managers' focus on long-term effectiveness, while project managers concentrate on more immediate accomplishments (Allen et al., 1988; Project Management Institute, 1997). The matrix organization attempts to combine the advantages of functional structures with product-oriented structures so as to create synergism by a shared responsibility between project and functional management. A balance between these often opposing forces in an organization was presumed to lead to an optimum balance between product completion and technical excellence (Katz & Allen, 1985). In matrix organizations, both lateral and hierarchical dimensions of matrices depend on one another and neither stands alone (Joyce, 1985). Organizations using matrix structures were expected to keep up with new technologies while obtaining savings in a more efficient assignment of human and physical resources.

Important issues that loom high in the management of R&D projects are those of uncertainty, ambiguity, and complexity (Pich et al., 2002). To survive, high-tech companies must cope with the effects these issues may produce. Burton & Obel (1998) recommend the matrix configuration for high uncertainty environments, because matrix management allows for a greater ease in loaning an employee to another project without making the change permanent. In any event, it is easier to accomplish work objectives in an organizational structure such as matrix, where task loads are shifting rapidly between departments.

While the matrix enjoyed widespread popularity in the 1970s, discord about the effectiveness of the concept surfaced in the 1980s. Shortcomings in the matrix form of organization became evident as functional and project managers were found to compete detrimentally for organizational resources (Peters & Waterman, 1984). Project managers seek to obtain resources to meet any unanticipated circumstance by either expanding existing capacities or contracting for services from external suppliers. In contrast, functional managers oppose indiscriminate accumulation of assets by a project; they usually reject attempts to outsource work because of possible underemployment of firm personnel. A project portfolio adds another set of disagreements when project managers compete against each other for the allocation of scarce resources (Platje et al., 1994; Payne, 1995). Moore (1977) argued that the flow of resources is

the basic force that identifies the dynamic nature of a system and Thamhain & Wilemon (1974) found that high intensity conflicts revolve around items such as scheduling, priorities, and manpower.

Critics of the matrix, however, describe an inherent propensity for conflict among managers, which substantially limits its effectiveness. Although conflicts may actually encourage more effective information exchange that can improve decision making (Stasser & Titus, 1985), this positive effect breaks down quickly when conflict becomes more intense (De Dreu & Weingart, 2003). Larson & Gobeli (1987) argued that even when conflict in the matrix was kept to a low level, shared decision making caused slow reaction times and made it difficult to evaluate responsibility. Moreover, the strife reduces job satisfaction for functional managers (Turner et al., 1998) and results in contradictory policies that lead to a misallocation of resources and reductions in organizational effectiveness (Martin, 1994; Cardullo, 1996). However, high intensity conflicts and an unbalanced power of influence are the most substantive failures of matrix implementation (Davis & Lawrence, 1977). High-tech companies, however, must survive in a dynamic environment and the matrix retains its popularity as the solution for rapidly changing marketplaces and technologies (Grinnell & Apple, 1975).

This paper surveys research carried out over a decade in which implementations of matrix forms seeking improved project portfolio performance have been investigated. This research has introduced new paradigms for matrix implementations due to the increased complexity of projects, especially those relative to uncertainty. A system dynamics model was developed and implemented for such complex high-tech environment, a milieu with high uncertainty in meeting project deadlines and with intensive competition over scarce resources.

2. THE LOW-TECH CASE

The first category in organizational classification is the low-tech case—an environment not involving scarce resources of unique specialization. Total shared resource capacity is not a constraint, because a shortage of internal resources can be reinforced through the import of external capacities that can be provided by subcontractors in a fairly rapid response time. In this environment the matrix forms can be classified into the following fundamental types (Laslo & Goldberg, 2008):

1. Project matrix, so-called 'profit and cost centres'.
2. Functional matrix, so-called 'megaproject'.

In project matrix forms power is given to project managers. The common configuration of these matrix forms is based on the following basic principles:

1. The project manager has full control over a project budget and is authorized to take independent make-buy decisions.
2. The functional unit manager allocates resource capacity without discrimination among projects (the same price, no project preferences, or project priorities).

The second principle is relevant for a high-tech case but not for a low-tech case, because in the latter environment each project manager is permitted to achieve full satisfaction of needed resources from external sources (outsourcing).

In functional matrix forms power is given to functional managers. The functional managers do not allocate resources to the projects, but rather, the resources are directly allocated to project activities, taking their criticality into consideration. The common configuration of these matrix forms is based on the following basic principles:

1. The functional manager allocates resources according to present or future internal capacity, and agrees to take external buy decisions only when this does not threaten the future employment of organizational resources.
2. The functional manager allocates internal resource capacity without discrimination (the same price, no preferences or priorities).

In the low-tech case, the principle of allocating internal resource capacity without discrimination is common to both project matrix and functional matrix forms; the difference between these fundamental forms derives only from the 'make internally' or 'buy externally' policy (see Table 1).

Table 1. Fundamental matrix forms associated with the low tech case

Make-buy Policy	Matrix Form
Full satisfaction of projects' needs	Project matrix form
Partial satisfaction of projects' needs	Functional matrix form

It is clear that project managers will prefer a matrix form where they have full control of the budget and where they are authorized to take independent make-buy decisions. Project matrix forms provide freedom to obtain all resources seen as needed to implement programs.

For the functional manager, the project matrix forms can be seen as a disaster. These matrix forms prevent reasonable planning for future employment of the organization's capacities. Functional managers seek functional matrix forms so they can control when and how projects are given additional resources, often on the basis of outsourcing.

The different preferences of the matrix forms in a low-tech environment are shown in Table 2.

Table 2. The low-tech case: Preferences of matrix forms

Matrix Form From the Aspect of ...	Project Matrix Form	Functional Matrix Form
The project manager (P)	The best matrix form	The worst matrix form
The functional manager (F)	The worst matrix form	The best matrix form

The traditional description of confrontations occurring within a matrix organization is shown in Figure 1.

Figure 1. The low-tech case: 1 front of confrontation

The implementation of a project matrix by an organization is never acceptable to functional managers (F) who pursue functional matrix forms. This aspiration by functional managers will be opposed by a coalition of project managers (P) involved with both favoured and unfavoured projects. In contrast, functional managers will do everything to prevent moves to a project matrix form.

This confrontation is intrinsic to the nature of the managerial positions. Davis & Lawrence (1978) suggest that because power struggles occur when managers share authority, organizations should seek ways to prevent conflict from reaching destructive heights.

3. THE HIGH-TECH CASE

Laslo & Goldberg (2008) consider the high-tech case as one where organizational technological specialization causes difficulties in achieving additional resource capacities in a rapid response time, although reinforcement by external capacities is legitimate. The allocated capacities of scarce resources

are constraints that determine progress in the implementation of a project. In this environment the matrix forms can be classified into three fundamental types:

- Project matrix.
- Balanced matrix, so-called 'directed priorities policy'.
- Functional matrix.

Project matrices are the same in both the high-tech and low-tech environments. Moreover, the basic principles of these matrix forms remain the same. In contrast to the low-tech situation, however, in the high-tech situation, resource allocation without discrimination becomes a real decision alternative. When the organization maintains a monopoly over scarce resources, it would have difficulty supplementing those resources through external purchase. In both low-tech and high-tech environments, functional matrix forms are based on the same principles. The balanced matrix form is unique to the high-tech environment. Where scarce resources are involved, an organization's readiness and ability to purchase those resources externally cannot satisfy the resource needs of the projects—external resource unavailability trumps both readiness and ability to pay. Limited capacities must be shared somehow between favoured and unfavoured projects.

In the balanced matrix form, greater power goes to favoured project managers and to functional managers who deal with unfavoured project managers. The configuration of these matrix forms is based on two principles:

1. The functional manager allocates organizational resource capacity according to directed priorities - usually to the favoured projects, while unfavoured projects have to manage with the remaining resources.
2. The make-buy policy is usually differential and determined by a project's priority.

With the virtual impossibility of a differential make-buy policy because of an inability to obtain further scarce resources, instead of two fundamental matrix forms involving differential project treatment, we define only one fundamental form. So, the high-tech case can be described through three fundamental matrix forms based on two dimensions: the make-buy policy and the priority policy (see Table 3).

Table 3. Fundamental matrix forms associated with the high-tech case

Priority Policy Make-buy Policy	Equal Treatment to All Projects (without priorities)	Different Treatment to Each Project (directed priorities)
Full satisfaction of projects' needs	Project matrix form	Balanced matrix form
Partial satisfaction of projects' needs	Functional matrix form	

A two dimensional definition of fundamental resource policies in the high-tech environment brings about a consideration of more complicated decision preferences (see Table 4).

Table 4. The high tech case: Preferences of matrix forms

Matrix Form From the Aspect of ...	Project Matrix Form	Balanced Matrix Form	Functional Matrix Form
The favoured project manager (H)	A fair matrix form	The best matrix form	The worst matrix form
The unfavoured project manager (L)	The best matrix form	The worst matrix form	A fair matrix form
The functional manager (F)	The worst matrix form	A fair matrix form	The best matrix form

In this case, competition between projects on resource allocations, especially concerning scarce resources, breaks the traditional coalition between project managers, and brings about unexpected agreement between functional managers and project managers.

In a high-tech situation, scarce resource capacities are constraints. These constraints reduce the attractiveness of project matrix forms among managers of favoured projects. A project matrix form offers unlimited resource capacities for normal resources, but competition occurs for scarce resources with unfavoured projects. A balanced matrix form creates an option for favoured projects to obtain scarce

resources. Therefore a balanced matrix form should be the preferred choice for favoured project managers. A functional matrix form, on the other hand, means favoured projects face a rationing of resources, and gives favoured project managers a good reason to reject such a matrix form.

Project matrix forms are the favourite matrix form for managers of unfavoured projects. This matrix form guarantees them a share of all resources, in contrast to a balanced matrix form that leaves unfavoured projects with a low probability of receiving scarce resources and could lead to their failure. Despite the fact that functional matrix forms also aim at rationing resources, unfavoured projects prefer them over balanced matrix forms, because they have a better chance of receiving resources.

The functional managers' objective, because it is directed at the optimized use of available resources, makes the functional matrix a most attractive matrix form. For the same reason, functional managers reject the project matrix, a form that prevents resource allocation planning. A balanced matrix form, however, can be a compromise for functional managers. Project managers, however, disagree on the worth of a balanced matrix form, because favoured projects are not limited by the need to allocate resources to internal development, while unfavoured projects, most of which are internal ventures, face difficulties as resources are pulled from them to be given to the favoured, mostly sponsored, projects.

According to Laslo & Goldberg (2008), the high-tech environment derives three confrontations within the matrix organization as shown in Figure 2.

Figure 2: The high-tech case: 3 fronts of confrontation

All project managers resist functional matrix forms. When favoured project managers (H) seek a project matrix form, they are able to build a coalition with the unfavoured project managers (L) against the functional managers. But if favoured project managers try to improve their position even further by adopting a balanced matrix form, functional managers and unfavoured project managers may cooperate to oppose this move.

Functional managers, on the other hand, will do everything they can to prevent project matrix forms. When they attempt to achieve full control over buy decisions through a functional matrix form, however, the traditional coalition between the favoured and the unfavoured project managers oppose them. But if functional managers are ready to compromise, they can achieve an agreement with the favoured project managers on the adoption of a balanced matrix form, a step that will be opposed by unfavoured project managers.

Balanced matrix forms are the preferred policies for favoured projects, but a disaster for unfavoured projects. Managers of unfavoured projects can partner with functional managers if they agree to improve their position by moving toward the functional matrix form, a step that will be opposed by favoured project managers. The efforts of unfavoured project managers to go farther, and to obtain a project matrix form, will be confronted by an unexpected coalition of favoured project managers and functional managers.

4. THE SYSTEM DYNAMICS MODEL OF A PROJECT PORTFOLIO'S FLOW OF RESOURCES

A model describing a dynamic flow of resources in a project portfolio can be used to evaluate the impact of alternative matrix forms on the performances of the project portfolio, of its functional units, and of each of its individual projects. Under uncertainty, these expected performances are difficult to investigate empirically because all the variables are an integral part of a complex organizational system where it would be impossible to obtain an adequate variety of situations. A simulation allows a limitless number of comparisons, where a real organization would resist intervention because of its possible consequences. Hence, many more variables are controlled than would be possible in a study of real organizations.

Forrester's 'system dynamics' theory provides a means to understand the payoff outcomes of each player's actions in such a complex and uncertain system (Forrester, 1980). What makes using system dynamics different from other approaches to studying systems is the use of feedback loops. In its simplest sense, system dynamics focuses on information that is transmitted and returned throughout the progress of a process, and the system behaviours over time that result from those flows. The feedback loops create the nonlinearity found so frequently in complex dynamic problems. Running 'what if?' simulations to test certain matrix forms on such a model enables us to study reinforcing processes—feedback flows that generate exponential growth or collapse—and balancing processes—feedback flows that help a system maintain stability.

The probability of a project meeting a scheduled due date within a fixed budget cannot be estimated for R&D projects because of uncertainty about the resources and time needed to complete any one activity, as well as the extent to which freed resources can be used to expedite the work of other activities. In such a situation, giving full satisfaction to all assumed project requirements at the first stage of a project may actually bring about delays due to an inability to meet unexpected and unmet resource requirements at later stages because of constrained budget conditions. In contrast, projects with only partial satisfaction of requirements may, under crisis conditions, obtain additional resources in order to prevent delays. The system dynamics model as shown in Figure 3 enables the prediction of the matrix forms outcomes.

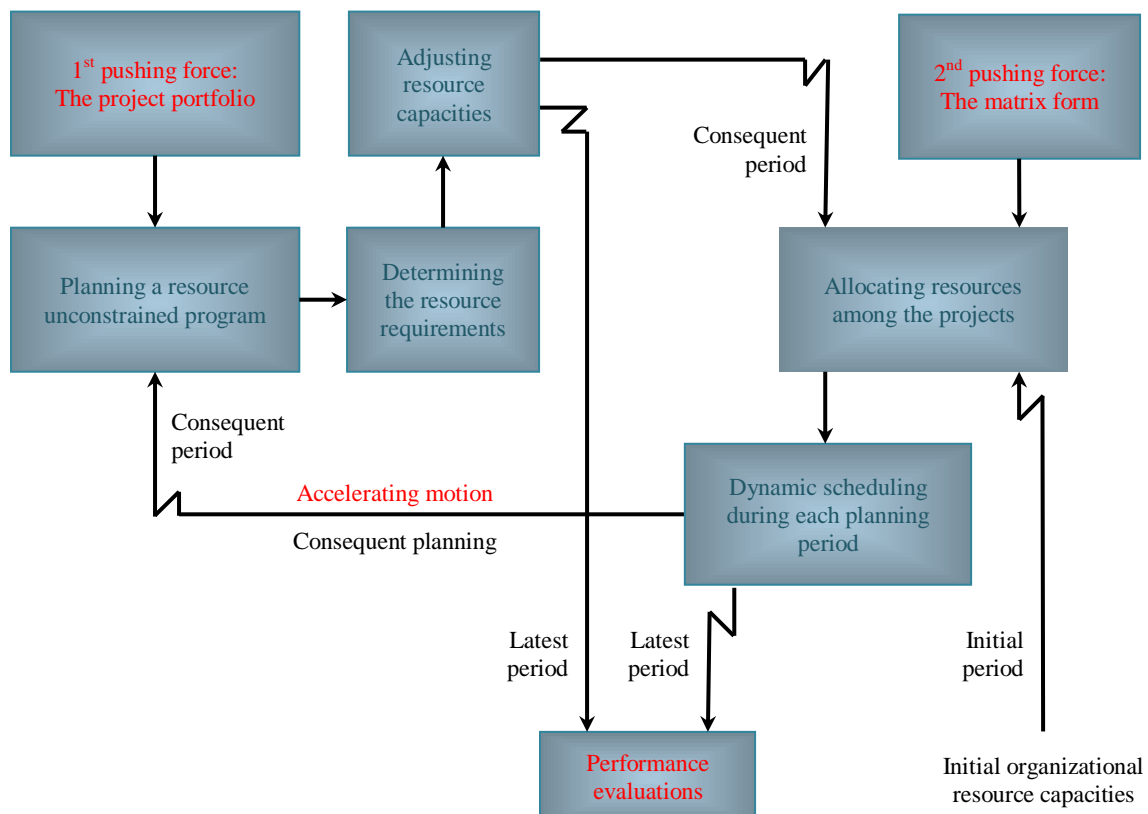

Figure 3: The system dynamics model of project portfolio's flow of resources

The first pushing force in this model is the project portfolio. The probability of project programs meeting timetables and not exceeding allocated budgets was found to be influenced by three characteristics: first, the need by projects for scarce resources; second, the extent to which activities needed personnel from different functional areas; and third, the degree of uncertainty regarding the time necessary to complete activities. Each of these three characteristics can be used as an indicator of the project portfolio's technological status. A high level of each characteristic indicates a technological environment, but also indicates a complicated scheduling process and instability of the flow of resources within the project portfolio. By applying binary attributes (low or high) to each characteristic, eight possible combinations define eight different project portfolio patterns from which projects can be sampled. These sampled projects enable us to investigate the performances of the different matrix forms within eight project portfolios with various typologies.

The second pushing force in this model is the matrix form. Assuming a 'homo economicus' model, system dynamics feedback loops for alternative matrix forms provide the following possible results: 1) the feedback loops might not contribute new information that could influence decisions regarding favourite matrix form, 2) the feedback loops might reveal that a preferred matrix form is not as advantageous as previously thought and therefore leads to neutrality, and 3) the impact of the feedback loops might even demonstrate that a previous position was wrong and reverse a participant's position about which matrix form to favour.

An objective function composed of one or more of a large number of objectives can be chosen for performance evaluations of the project portfolio, each of its projects, and each of its functional units. For the analysis of the impact of matrix forms on these performances, the following objectives were selected by Laslo & Goldberg (2001): 1) reduction of delay penalties, 2) of direct labour costs, 3) of idle labour costs, 4) of manpower expansion expenses, and 5) of losses from unnecessary outsourcing.

5. INSIGHTS PROVIDED BY THE IMPLEMENTATION OF THE SYSTEMS DYNAMIC MODEL

5.1. Adjusting the matrix form to organizational objectives

The readiness to change organizational structures is particularly important in an environment characterized by rapid changes in the nature of the competition, while at the same time offering new technological advantages. Upper management may choose to centralize decision making and provide greater resources to particular projects, give control over budget decisions to functional managers, or provide more freedom to individual projects to make use of similar resource allocations (Kim & Burton, 2002). In order to optimize matrix performance, the distribution of power among project and functional managers, which is reflected by the different matrix forms, must be changed continuously in line with the project portfolio's characteristics and objectives. The aim of the study of Laslo & Goldberg (2001) was to find when organizational and market conditions necessitate increases or reductions in the influence of project managers, i.e., conversion of the matrix form, in order to reach improved performance of the project portfolio and/or its units. The implementation of the system dynamics model provided simulated results from which we can draw the following conclusions:

- For the objective of reducing delay penalties as the level of all three project portfolio's characteristics increase from an initial level, it is necessary to increase the influence of project managers (converting functional matrix form into balanced form, or, balanced matrix form into project form). Similarly, decreases from initial levels of the characteristics encourage a decrease in the influence of project managers (converting project matrix form into balanced form, or balanced matrix form into functional form).
- For the objective of reducing favoured projects' labour direct cost, idle labour cost and total labour cost, the need by projects for scarce resources changes in the influence of project managers are not required, as the extent to which activities needed personnel from different functional areas increases from an initial level it is necessary to increase the influence of project managers (converting functional matrix form into balanced form, or, balanced matrix form into project form) and vice versa, and as the degree of uncertainty regarding the time necessary to complete activities increases from an initial level it is necessary to decrease the influence of project managers and vice versa.

- For the objective of reducing unfavoured projects' labour direct cost the need by projects for scarce resources and the degree of uncertainty regarding the time necessary to complete activities changes in the influence of project managers are not required, but as the extent to which activities needed personnel from different functional areas increases from an initial level it is necessary to decrease the influence of project managers and vice versa.
- For the objectives of reducing manpower expansion expenses and losses from unnecessary outsourcing changes in the influence of project managers are not required.

5.2. Looking for a consensus about the project portfolio's matrix form

Conflicts believed to be unavoidable are assumed to reduce the effective performance of matrix structures because project managers and functional managers struggle for greater control over the allocation of organizational resources. As a consequence, organizations do not unite around one matrix form and fail to adopt one of the matrix forms as a preferred organizational structure. A difficulty of predicting the full consequences of each matrix form in a dynamic environment has become a serious complicating factor in attempted pre-accepted formation. Disagreement among managers over matrix forms, however, may turn out to be unrealistic as the attainment of a favoured matrix form may actually reduce their performance. Laslo & Goldberg (2008) examined the possibility of unnecessary and unrealistic conflicts in the context of the favoured matrix form by calculating the expected net benefit to be obtained by each participant for each matrix form as they relate to various project portfolio's characteristics and objectives. The implementation of the system dynamics model provided simulated results from which we can draw the following conclusions:

- Consensus on the functional matrix form can be attained only when both favoured and unfavoured project managers' objective is the reduction of the direct labour costs (we should pay attention that in any case the functional managers' objectives are reductions of the idle labour costs, the manpower expansion expenses, and the losses from unnecessary outsourcing). Such consensus is attainable in each project portfolio pattern where the extent to which activities needed personnel from different functional areas is high, in an additional pattern where this characteristic is low, the need by projects for scarce resources is high and the degree of uncertainty regarding the time necessary to complete activities is low.
- Reduction of the number of conflicts in the context of matrix form can mostly be achieved in the other scenarios if the participants will be aware that some of the conflicts are in fact unrealistic, but in these scenarios consensus on the preferred matrix form seems to be unattainable.

5.3. Looking for an additional implementation of the balanced matrix form

Hendrix et al. (1998) found that a multi-project situation causes problems in the allocation of scarce resources, such as personnel, to a diversified project portfolio. They suggest flexible resource planning to take into account the availability of scarce resources. Laslo (2010) investigated the implementation of this suggestion in information technology project portfolios, where such resources are available, but very expensive. The idea of the integrated matrix form is implementation of a project matrix form on non-scarce resources and a functional matrix on scarce resources. For this purpose a sophisticated resource planning and scheduling search algorithm was developed. The simulated results of the integrated matrix form implementation, in comparison with those of the project matrix form implementation, showed the following:

- For the objective of reducing delay penalties the integrated matrix form seems to be significantly superior.
- For the objective of reducing total idle labour costs the integrated matrix form seems to be significantly superior.
- For the objective of reducing manpower expansion expenses the integrated matrix form seems to be significantly superior in the context of scarce resources but inferior in the context of non-scarce resources.

- For the objective of reducing losses from unnecessary outsourcing the integrated matrix form seems to be significantly inferior.

6. SUMMARY

Irrespective of the findings in the context of the matrix forms and their implementations in project portfolios, a simulation can never be the reality—it can only reflect it. These studies assumed 'homo economicus' participants and a management policy directed at the improvement of the project portfolio's performance. 'Noises' such as friendship or antagonism among participants may change the results. Nevertheless, these studies provide evidence for the problematic nature of assumptions about behaviours and conflicts in matrix structures, and call for further research.

Abstract: *The success of strategic project management is highly dependent on the definition and implementation of the project strategy and an adequate measurement of project success. The aim of the paper is to analyze the specifics of the project strategy and measuring project success in the execution of strategic projects. The paper explains the concept of strategic project management through the comparison of project management and strategic project management. Specificities of project strategy are observed through main project strategy elements: business perspective, objectives, product/service definition, competitive advantage, success and failure criteria, project definition and strategic focus. The project strategic success measurement is analyzed through project efficiency, benefit to the customer, benefit for the organization and preparing for the future.*

Key words: *project management, strategic project management, project strategy, project success, measurement of project success*

1. INTRODUCTION

The relevant research has shown (The Standish Group Reports, 2009) that a large number of organizations do not achieve the set goals in the execution of their projects, among them, the completion of the project in the predicted time period, within the budget and the agreed quality; on the other hand, a more serious problem seems that many of them fail to achieve business goals, while it is a commonplace that the desired results fail to be achieved in either group. The majority of organizations strive to improve the execution of their projects in a traditional way, e.g., through the employees' education, the work process improvement, introducing software support, etc. The focus upon these elements only results in a limitation as to how much the effectiveness and the efficiency of the project execution can be improved, especially from the aspect of the organization's achieving its goals. In order that a higher competitive advantage be achieved, the real improvements have to be closely linked to the strategic aspect of project management.

The development of the project management concept is today directed to the strategic aspects, hence project management now is approached in a way different from that in the past. This new attitude is related to the understanding of project management as part of the company's strategic activities (Williams & Parr, 2004). The relation between the project and the strategic managements is a logic one, however, the dilemmas and problems as to how they should be related are still present. This calls for a development of appropriate guides on the methods in which the organizations can harmonize the projects with strategies, as well as make the project managers and the project teams responsible not only for bringing a project to an end, but for ensuring that the project should achieve the organizational objectives for the purpose of which it was started.

2. STRATEGIC MANAGEMENT AND STRATEGIC PROJECT MANAGEMENT

The relationship between the strategic and the strategic project managements can be presented by way of a management pyramid (Figure 1.) that is especially present in the project oriented organizations. Looking from the top down, the top of the pyramid provides for the directions of an aggregate project and program management – the strategic management. It is on this level that the organization defines the comprehensive bases of its existence and business activities. Here the vision, the mission, the principles, the organizational goals and the strategic plan are defined. Through strategic planning the company and

* The paper is a result of research within the framework of Project No.179081, named: "Researching contemporary tendencies of strategic management using specialized management disciplines in function of competitiveness of Serbian economy", which is supported by the Ministry of Education and Science of the Republic of Serbia

the individual business units define their path of action and identify the key objectives to be achieved. The strategic direction of a company is a basis for the selection of projects, such as the research projects, the new products and services development, the information technologies implementation projects, the business operations improvement projects, etc.

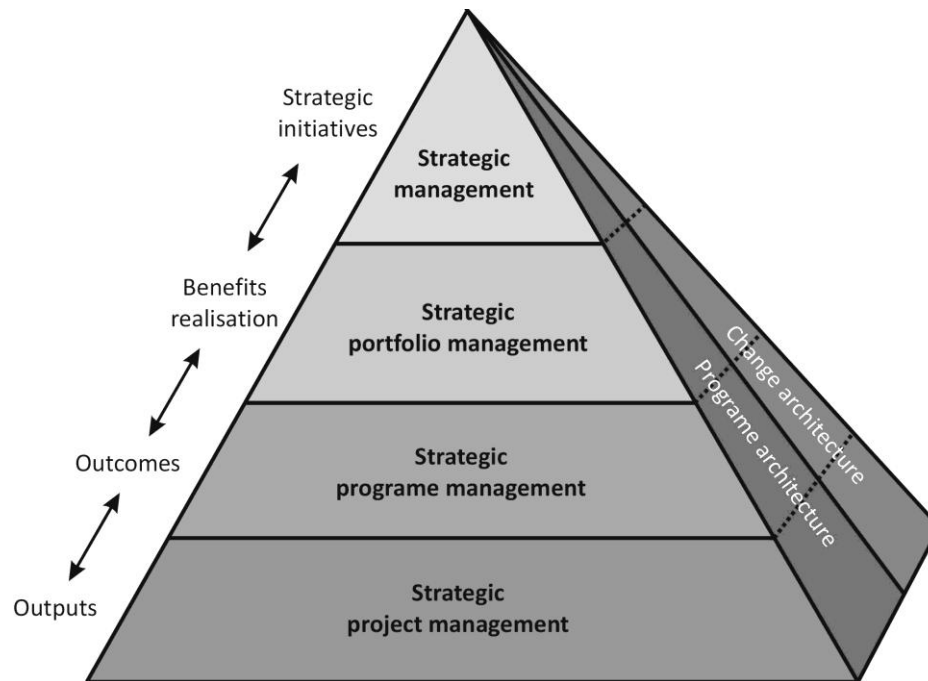

Figure 1. The relationship between the strategic and the project managements in the organization (Williams & Parr, 2004; modified)

The strategic portfolio management allows for the translation of organizational strategic goals into the programs and projects. On defining the strategic direction, it is necessary that the programs and the projects be selected and that the resources be allocated. The project and program selection includes the identification of opportunities, the estimate of organizational fitting, the cost analysis, the risk and benefit analysis, the portfolio forming and selection. The success of the project portfolio depends on the organizational readiness and support in the strategic portfolio management.

The majority of portfolio decisions are burdened by a time horizon, by a serious uncertainty and by a large number of variables that affect any program and any project. The most commonly used tools in the development of the business model to predict the potential value of the project are the impact diagram, the sensitivity analysis or the decision tree. A well defined decision process is the basis for developing an effective portfolio strategy. Defining a quality decision to be implemented in, e.g., research and development, where the result will not be fully known in years, is no easy task.

On passing the portfolio selection process each program and project is appointed an appropriate significance in relation to the organization as well as in relation to other programs and projects. The problem in the portfolio management, however, arises when the projects selected do not show a clear connection or a relation with the company's strategy. Generally, all the projects to be executed should be in accord with the strategy and philosophy of the organizational work and business activities. It is often that certain projects that are under way in the organization are not subjected to the portfolio selection process, but represent a group of projects that are realized independently of the portfolio, but still consume the limited resources of the company.

The project linking should be operationalized at the strategic management level. The links on this level, although rather complicated sometimes, are the key to a successful multiproject management in the organization. Each new project in the domain of processes, products or services should be interlinked with the previous programs and projects, or the programs and projects that are currently under way. Regardless of the extent to which the projects are autonomous as regards one another, on the company

level they are not independent. Their interrelation is evident in the disposal of the limited organizational resources, to the mutual aims, to the activities such as supplies, that are generally carried out for a number of projects. The projects that are conducted independently of the project portfolios are generally smaller projects with daily planning and priority identification. They are started as a response to certain urgent organizational needs, the reason being most commonly in relation to a certain risk and its consequences or to taking a certain opportunity.

The program and project management occupy the lowest levels. In the modern perception of the project oriented organization, we are dealing with strategic program management and strategic project management. The strategic program and project management are defined on the basis of the realization, by the stages and the activities related to the multiproject management in the organization.

All the elements of the pyramid must be synchronized towards a successful implementation of a multiproject management in the organization. The organization has to establish an unbiased mechanism in monitoring the programs and projects: measurement of returns on investments of an individual project/program, measuring a number of projects/programs within a project portfolio and a continual adjusting to the overall objectives of the organization. It is of great importance that there is a prior agreement as to an unbiased priority identifying. It is only after the company has defined its overall objectives and the project investment strategy that an optimal group of projects or a project mix can be created for the implementation of the company's strategy and achievement of organizational goals.

The strategic portfolio management, the strategic program management and strategic project management are shown to represent different levels of management in an organization. These forms of management vary in size and in the contents of management, however, they make a whole of the multiproject management in the organization. The program architecture comprises the establishment of mechanisms which serve to provide the program and project teams with a support throughout the procedures, methods and techniques necessary for them to be efficient in work. The change architecture focuses upon the human factor the change brings. It can be defined as a process of change strategy creation and implementation.

3. STRATEGIC PROJECT MANAGEMENT

The previous research that connected the strategic management and the program/project management was directed towards the elaboration of portfolio management. The research comprised the aspects of portfolio management such as the project selection, priority identification, harmonizing the projects within the portfolio, adjusting the project to the project strategy, strategic resource management and improving the strategic management of the functional areas and projects of the organization (Cooper, Edgett and Kleinschmidt, 1998; Dinsmore, 1999; Dye and Pennypacker, 1999; Petrović, 2003). The latest research, however, relates to adjusting the strategy on the project and the program levels of activities and creating an integrated adapted approach of program and project management to a business strategy (Cleland, 1999; Morris and Jamison, 2004; Shenhar, Milošević, Dvir and Thamhain, 2007).

The strategic project management is a new approach in project management, focused upon creating competitive advantage for the organization in the project execution. This approach is especially relevant for strategic projects initiated in order to create the company's future, all kinds of research and development projects among them. However, it is not related to this group of projects only.

The organizations of today can no longer leave the strategy in the care of the top managers, and leave the operational realization to be carried out by project managers. The projects will increasingly have to be managed as strategic activities. To realize these changes, the project managers and the project teams must have a formal planning and execution framework in accordance with the strategic approach. Table 1. presents the difference between the classic project management and the strategic project management.

Table 1. Project management and strategic project management (Shenhar, Milošević, Dvir, & Thamhain, 2007, modified)

	Project management	Strategic project management
Basic Paradigm	Projects are a collection of activities that need to be executed on time, budget, and requirements	Projects are strategic organizational processes that are initiated to achieve business goals

Focus	Efficiency	Effectiveness and efficiency
Perspective	Operational	Strategic and operational
Manager's Role	Getting the job done – on time, within budget, according to specifications	Getting the business results Winning in the market place
Project Management style	One size fits all	Adjustment approach
Project definition	Project scope, what needs to be done?	Product, competitive advantage, strategy, scope
Planning	Activities, schedule, budget	End results, success dimensions, activities
Project Reviews	Progress, status, milestones, budget	Customer needs, strategy, success dimensions, status
Human Side	Teams, conflict resolution	Meaning, motivation

4. PROJECT STRATEGY

The basic organizational goal is the added value creation for its stakeholders. The most important stakeholders are its owners, then people who work in the organization, and finally the clients and the customers who purchase the goods or the services from a certain organization. A successful organization creates value for each of the groups. The value creation for each of the groups of stakeholders is also a means of value creation for other groups that find their interest in the business operations.

The strategy is the basic guide of the overall value creation that is central to the organizational existence. The most important function of the strategy as part of the planned process is to develop a collective mind and transfer knowledge to managers that will be responsible for the strategy implementation. The project managers have to introduce the strategic project management in order to reproduce the strategic process within their projects and ensure that the project results be in accord with the strategy. The business strategy should provide for the key orientation of the project and is a foundation for the decision making in the course of the program and project realization.

The understanding of strategy as a management process and the role of the project manager in the process is related to the understanding of the difference between the business strategy or a strategic direction/path and the strategy that is executed or the obligatory strategy. The defined strategy means the attitude of the top management as to what an organization should do and what it will be doing. The strategy that is being executed is the one the organization really implements. They differ in that the middle level managers and the project managers have to translate the defined strategy into action. In this way certain elements are lost, however, others are gained in the process itself. There is always a gap between a defined strategy and the strategy that is executed, however, when the strategy process functions well, both strategies will help the company follow a consistent and successful path.

Bringing the strategic management and the project management into accord is a two-way process, where the adopted organizational business strategy affects the selection, preparation and execution of the project. On the other hand, the project execution has a feedback impact upon the organizational strategy. Every project may have its own specific strategy and that is the strategy that is being implemented. The project strategy is the method in which the project is planned to achieve the set objectives and business results.

The project strategy should have the following defined elements (Shenhar, et al., 2007, modified):

- Business perspective/background – The business perspective defines the reasons and the motivation for the project realization. Here, it is necessary that the product/service users, their needs and demands be defined, as well as the method the project to solve them.
- Objective – Here, it is necessary that the end goal of the project be defined, that is, the business goal and the long-term benefit to be achieved by the project completion.
- Product/service definition – The product/service definition comprises the description of the product or the service, their functional or technical characteristics, implementation and application costs, reliability, maintenance, compatibility, etc.

- Competitive advantage/value – The reasons are described as to why one will be willing to pay for the product or the service, why the product/service is superior to the alternative products/services, etc. On the other hand, it is necessary that the value be defined from the part of the organization – the long-term benefits the organization will enjoy and the way the product/service adapt to the long-term strategic objectives.
- Success and failure criteria – The criteria on the basis of which the project will be assessed should be defined, but the project limitations and the main anticipated risks, too.
- Project definition – This section defines what is necessary to be done on the project, but also what should not be done. The project type may also be defined according to certain characteristics (novelty, complexity, technology, uncertainty), which in turn defines the approach to project management. The project definition includes the appointing of the project team and the project manager that will execute the project, the execution time horizon and the necessary resources.
- Strategic focus – This is the last section defined in the project strategy, nevertheless, it is its main part. It defines the manner in which the project is planned to achieve the set goals and achieve business results. The strategic focus will include the guide that will highlight to the project participants the activities and the approach by which the desired objective will be made a reality. The strategic focus comprises such elements as the position to be attained by the project execution, the guide to behaviour and decision making, the work policy and the development of the processes that will lead to the planned results.

5. THE PROJECT STRATEGIC SUCCESS MEASUREMENT

The project strategic success measurement is one step above the classic project success measurement. On the basis of the research conducted by Shenhar, Dvir, Levy and Maltz (2001) four dimensions of project success are proposed:

- Project efficiency – According to the authors of the research, this is a short-term value that measures the project efficiency as regards the time, budgeted and the project requirements. The results for this dimension of the project are readily obtainable, the measuring and getting the result being possible at any moment along the project execution. Although success in this project dimension may give good results and show that the project is well conducted and that the work on the project was efficient, this does not mean that the project will yield good long-term results and bring benefits for the organization.
- Benefit to the customer – The second dimension of the project success is related to the customer. This dimension stresses the customer's requirements and the manner in which their set demand is met. It also measures the customer satisfaction with the product or service through the customer's readiness to return for some other project or some future services.
- Benefit for the organization – The benefit for the organization that carried out the project is reflected through the profit, through the amount of sales realized or services given, through the market share and through similar business results. The benefits for the organization can, however, vary as regards the type of the project carried out. In case of internal projects, such as improvement of the organization or of the work process, the benefit can be reflected in the shortening of working hours, in the improved quality of procedures or other direct benefits. In addition to the direct benefits, it is necessary that the indirect benefits for the organization should be measured. These are not easy to measure, however, they may be very important, therefore they should not be neglected.
- Preparing the future – The fourth dimension refers to measuring the project contribution to the arrangements for the organizations and technology infrastructure for the future. Here we measure the development of new markets, ideas, innovation, products, services, skills, technologies, the attained organizational flexibility, that is, anything that can bring competitive advantage in the future.

The results of the first dimension of the project success can be obtained during the project execution or immediately upon the completion of the project. The second dimension gives results in a short-time period after the results of the project are delivered to the customers and a short time during which the product is used (e.g., a number of months from the moment the product is first used). The third dimension can most commonly be measured after a period of time when the service is given or the product is sold has elapsed

(e.g., one to two years), while the fourth dimension of the project strategic success is possible to measure only upon a longer period of time (e.g., upon two or five years).

6. CONCLUSION

Although the majority of project managers and project teams recognize the importance of the relation between the harmonization of the organizational strategy and achieving organizational goals, these elements are, unfortunately, taken into consideration only at the beginning, while later, in the course of the project execution, the focus is on the operative approach. It is for this reason that a strategic harmonization of the project should be carried out, and this can be achieved by implementing the hierarchical form of management, including the management levels such as strategic management, strategic portfolio management, strategic program management and strategic project management. A new concept in this hierarchical framework is the strategic program and project management, where the stress is on its strategic focus. In accordance with the strategic framework of project management the method of measuring the project success is defined. This is no longer one-dimensional, but comprises several dimensions of project success that have to be taken into consideration.

The prevailing way of thinking in project execution focuses mainly upon the operational aspect as well as upon achieving efficiency in the project realization. The project success is typically regarded through such categories as the completion of the project in the defined time, within the projected budget and the project requirements. This is how the project managers take their job, so they do not think they should be engaged in dealing with the project effectiveness, nor with achieving business results. On the other hand, however, the truth is that projects are started for the very purpose of achieving certain business results. The most important objective in the project execution is, from the point of view of the organization, to achieve business results. Therefore, both the project manager and the project management in general have to focus upon this and try to find the ways to ensure that the business results of the organization are achieved.

PROJECT PERFORMANCE MANAGEMENT USING IPMA PE MODEL¹

Vladimir Obradović¹, Dejan Petrović²

¹University of Belgrade, Faculty of Organizational Sciences, obradovicv@fon.bg.ac.rs

²University of Belgrade, Faculty of Organizational Sciences, dejanp@fon.bg.ac.rs

Abstract: *Performance management has evolved a long way in terms of functional and procedural definition. Still there are not widely used and standardized concepts. This paper will present insights and an approach to project performance management based on internationally used and accepted model. The paper is primarily based on secondary research, but also brings authors' expertise and experience with PE model application in terms of project performance management. Paper will not go into deep presentation and explanation of the model, but rather it's application possibilities. Main result of the paper is to provide readers with an overview of a useful model that could be used as a powerful project management performance based tool. For practitioners from various industries this paper will provide a roadmap to a new way of project based performance management. As for scholars, this paper will be a starting point for further research in the area of strategy-to-project performance management.*

Keywords: *project, performance, management, excellence, IPMA*

1. INTRODUCTION

Performance and management are terms very widely used. However, performance management is still not very clearly defined discipline. If we go through literature and practise, we will certainly find a lot of different approaches to performance management and performances per se. Even though it's one of the youngest management disciplines, performance management has travelled long way and evolved substantially. First, it was only connected to some of the functional areas of management, while later on it has spread all over the organization from top to bottom and vice versa. In process way it evolved from performance indicators setting, through their measurement to full application of performance management.

Nowadays, everything is project. If one wants to determine and manage the performance of an organization, it would be very difficult to do it without project performance management. We may go even further and say that in contemporary world there is no other way of performance management than one going through projects.

Regarding project performances, there are quite a few approaches. However, they differ in their philosophy and methodology, so it's very difficult to establish unified, widely spread approach. IPMA PE model offers a solid possibility of unified performance management tool usage. This tool could enable standardized project performance management and hence comparison and benchmarking all over the world, regarding size, complexity, industry, people involved and other characteristics of the project.

2. PERFORMANCE MANAGEMENT

There is great confusion about meaning of term performance management. If you try to Google it, you will get countless different meanings and explanations. The confusion starts with the usage of different acronyms: BPM – Business Performance Management, CPM – Corporation Performance Management, EPM – Enterprise Performance Management, etc. All these acronyms has the same meaning and mean one thing - performance management (Cokins, 2009).

The further confusion comes from the fact that many people see performance management too narrowly and apply it to individual functions or departments. In that way we get marketing performance management or IT performance management (Cokins, 2009).

Historically, performance management was seen as one employer process and was used by human recourse department Today it is widely accepted as a performance management of the organization as a whole (Cokins, 2009).

¹ Supported by Ministry of Education and Science of Republic of Serbia, project No. 179081

All this led to a paradox that recent performance management methodologies start with what performance management is not, instead of what performance management is (Cokins, 2009).

Most performance management definitions highlight the importance of having goals, objective and strategies clearly formulated at organizational and corporate level. Furthermore, the purpose of performance management is to archive organizational affectivity and to provide better results. The important aspect of performance management is developing strategies and their conversion into concrete action guidelines. Performance management is also about commitment and motivation for achieving company goals, and the communication plays important role in this process. Therefore, performance management is much ore than performance measurement (Verweire & Van Den Berghe, 2004). Performance assessment is not performance management, too. It is just one part of performance management. Performance management should be used as a meaningful tool that helps people and organizations to succeed (Bacal, 2012).

Some authors relate performance management to human resources function. Bacal defines performance management as continuous communication process between employer and its supervisor, with clear expectations and understanding about work that need to be done in the partnership. It represents a system with numerous components that need to be included into value creation in organization (Bacal, 2012).

Alternatively some say that business performances are measurements of growth and profitability of company through it's business endeavours and organizational and technical resources applications (Chen & Huang, 2012).

On the other hand, some others look at performance management much more widely. One of definitions is that performance management is a process that helps organization to formulate, implement and change its strategy in order to satisfy its stakeholders. In other words, it is comprehensive management process that shapes the road of continuous improvement through ensuring that everyone understands where organization stands and where it should be to satisfy shareholders needs (Verweire & Van Den Berghe, 2004).

One logically comes to a conclusion that performance management should deal with all manor functions in the organization, from strategic to operational level. Performance management is all about improvement, synchronised improvement in order to create value fro shareholders and owners. Performance management means converting plans into executions and solutions. It is a process of managing strategy of the organization (Cokins, 2009). The ultimate goal of performance management is to achieve sustainable organizational performance (Verweire & Van Den Berghe, 2004).

Performance management includes setting clear, common expectations and understanding about (Bacal, 2012):

- Essential function of work need to be done,
- Way in which the work of employees contribute to organizational goals,
- Concrete meaning of term “doing the job well”,
- Way in which employee and his supervisor work together to sustain, improve or upgrade current performances,
- Job performance measurement,
- Identification and elimination of barriers in achieving performances.

Performance management is not something that (Bacal, 2012):

- Managers do to employees,
- Force people to do better and harder,
- Is useful only when performances are bad,
- Is done by fulfilling forms ones in a year.

Performance management is beneficial for employees, management and organization and must be conducted in a collaborative and cooperative way. Performance management is a tool for precluding bad performances and for mutual work on performance improvement. Performance management is about talking and listening, learning and promoting (Bacal, 2012).

Potential benefits from performance management is in that performance management (Bacal, 2012):

- Reduces the need for managers to be involved in each activity,
- Saves time by helping employees to make decisions individually by providing them with necessary knowledge and understanding,
- Reduces misunderstandings about who is responsible for what, and thus saves time,
- Reduces frequency of situations in which manager do not have necessary information when he needs it,
- Reduces mistakes by identifying their causes,
- Increases involvement and motivation by providing context and meaning for employees,
- Provides feedback about work done,
- Provides feeling of empowerment to employees by giving them opportunity to make everyday decisions,
- Reveals ways of improving performances even when there is no current problem,
- Increases moral and productivity by providing understanding about how each job contributes to overall success.

Performance management is not a new methodology than everyone needs to learn; it tightly integrates business improvements and analytical methodologies that organizations are already familiar with. Performance management can be seen as an umbrella concept, since it integrates business and financial information into unique frame of support to planning and decision-making. This includes strategic mapping, balanced scorecard, cost management, budgeting, anticipating and planning. It inspires other key solutions such as supply chain management, risk management, human capital management systems, as lean management and Six Sigma. (Cokins, 2009)

Performance management is not compound of several unconnected parts that can be improved separately. It is a holistic model where all parts must be connected and combined in order to execute strategy of organization in meaningful and coherent way (Hope & Player, 2012).

Performance management includes (Hope & Player, 2012):

- Strategic planning,
- Value for shareholders and customers,
- Lean cost management,
- Performance measures,
- Performance evaluation.

Hope and Player connect performance management with strategy, but do not give the models of strategy execution. If we know that most successful way of strategy implementation is through various projects (Obradovic, Jovanovic, Petrovic, & Mihic, 2010), then the logical next step is certainly in the project performance direction.

3. PROJECT PERFORMANCE MANAGEMENT

If one wants to talk about project performance management, at the first place there is a need to establish what are project performances. They should be some sorts of measurement of project success. Project performance management significantly improves project success (Qureshi, Warraich, & Hijazi, 2009). Traditionally project is successful if it meets its objectives (in terms of quality), schedule and costs. These elements are often named project triangle. Atkinson (1999) named these three measures as the 'iron triangle'. It would be difficult and probably not accurate to prove that these criteria are not important, but it's more than clear to every project practitioner, that they are simply not enough.

Scholars and practitioners are seeking for more and more indicators of project success. Low and Chuan (2006) argue that the measure of project success can no longer be limited to the traditional indicators such as time, cost, and quality. Certain differentiations of success criteria are suggested by various authors trying to distinguish project success from project management success (Cookie-Davies, 2002) (Shenhar, 2004). This is very slippery area though. Could one have successful project management and unsuccessful project? This is very unlikely, because there is no good management if the result is bad. Vice versa is probably possible only by accident, so it also cannot be considered a rule.

Another interesting point in establishing project success criteria is a point of view. Who is entitled to state that the project (according to some criteria) was successful or not? Some authors vote for overall satisfaction of the project stakeholders (Bryde & Brown, 2005). Some point out internal factors such as project team (Belout & Gauvreau, 2004). Other authors point out the importance of client or customer satisfaction (Pinto & Slevin, 1988). Westerveld (2003) goes along with client's appreciation and project team appreciation, but expands the set with users, vendors (subcontractors) and other stakeholders, which gives strong resemblance with later definitions of Bryde and Brown .

4. IPMA PE MODEL

International Project Management Association (IPMA) is world's largest non-profit professional association of project practitioners. It started in 1965 as a discussion group of managers of international projects, previously known as "INTERNET". During time it grew into large international organization gathering more than 55 Member Associations from 54 countries worldwide. It defines the international principles of excellence in project management, representing the convictions and interests of project managers worldwide. IPMA brings together knowledge and experience and makes it accessible to the public (Obradovic, 2012).

As it's main objectives IPMA states:

- Development of a **standardised** understanding of project management
- Development of an **independent** field of knowledge
- Promotion of **competences** in project management in all fields of industry
- Promotion of an **international society** for project management

In order objectives to be reached numerous activities are performed throughout the year by thousands of IPMA individual and corporate members. One of the most growing endeavours within the organization is certainly annual IPMA Project Excellence Award that promotes best-managed projects in the world. IPMA PE Award:

- Annually awards project management prizes to project teams that achieve, and can prove, great feats in project management,
- Supports professional project management as a way to achieve greatness and
- Identifies projects that are qualified to be examples of excellent project management.

IPMA Project Excellence model was developed on well known EFQM model. Here are roots and history of PE model:

- **1980`s** – USA - Malcolm Baldrige Award TQM Award
- **1992** – Europe – EFQM Business Excellence Model, TQM European Foundation for Quality Management
- **1996** – Germany – GPM* EFQM Model re-designed to PEM
- **1997** – Germany GPM first Project Management Award for excellent Project Performance Project Excellence Model
- **2001** – IPMA First Training of IPMA PM Award Assessors
- **since 2002** – Presentations of IPMA International Project Excellence Award

Ever since 2002, international assessors, creating a baseline for best project management practice, are assessing projects all over the world. The assessments are performed in an unified way using PE model (Figure 1) which comprises of 9 criteria and 22 sub criteria. Each of sub criteria is enriched with lists of points of departure as informal guidelines in setting the assessment.

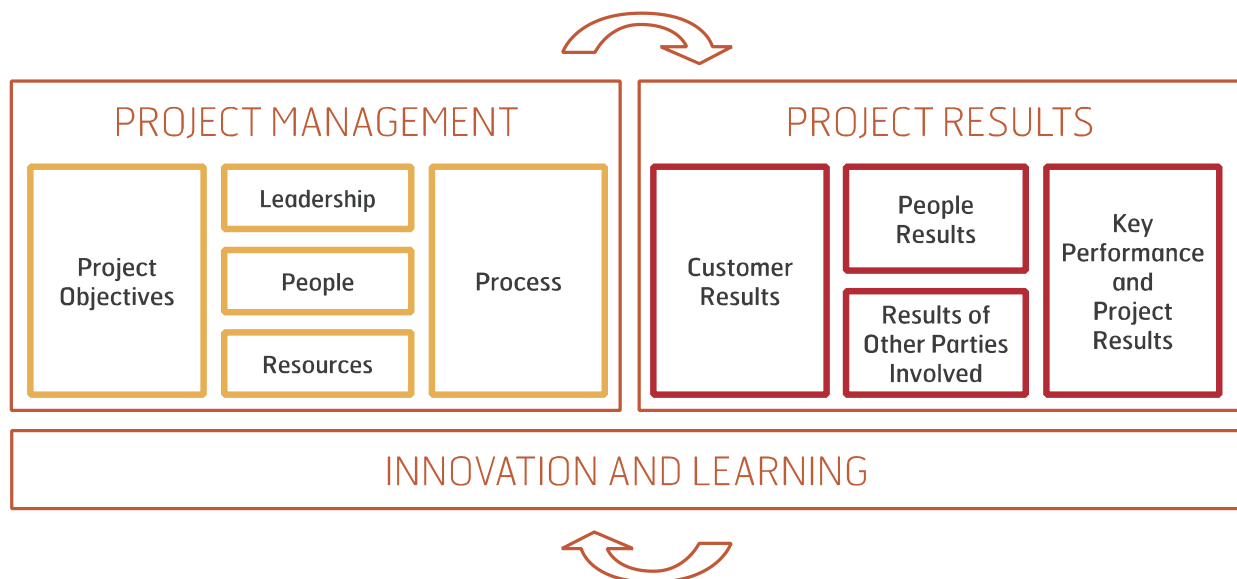

Figure 1. IPMA PE model

PE model looks into project performance taking into account two areas:

1. Project Management and
2. Project Results.

When measuring success of project management assessors take into account 5 criteria dealing mostly with how project was planned, steered and driven towards it's goal. The criteria taken into account here are: (setting of) project objectives, leadership, people, resources, and processes. A number of sub criteria are used to determine more specific measurements of given elements helping reaching common understanding of the criteria.

The second part of the model is dealing mostly with results. But as stated previously it is necessary to sort out the results and take into account various perspectives and perceptions. Results are measured from the point of view of: customer, people, other parties involved (various partners), and project itself (mostly technical outputs).

Most of people that are not familiar with the model in depth think of it as a tool used for a project 'beauty contest' and getting annual IPMA PE Award, However, benefits are far beyond that. Most important ones are:

- Project teams can **measure** where they stand on the way to great achievement.
- Teams work out their **strengths and improvement potential** of project work.
- Teams create possibilities for comparison with other project teams (**Project Benchmarking**).
- Organisations establish a **base for optimising** future project work.

At the beginning companies through independent assessment process tried to determine the performance of executed projects. But gaining an insight in the quality of the model, companies are nowadays using model from the day one in their project management in order to reach maximum efficiency but effectiveness also. They use it as a project management performance tool in order to plan, execute, control, and improve their projects. PE model is getting more and more used in the non-profit sector, where the competition and need for good project governance is also growing rapidly.

5. CONCLUSION

Various authors define performance management in various ways. Firstly, we must come to a common understanding what it is as a process. It is not setting of performance indicators nor it's pure measurement. It's far beyond.

Secondly, we must determine what are success measurement criteria. If, as in all management disciplines, the overall objective is gaining success, then we must know how to measure it. Definitions of

success and performance criteria go from purely human resources or financial aspects to overall strategic overviews. Surely success, hence the performance cannot be measured through one function but rather looking at a organizational business success as a whole. Therefore in organizational performance management we must go all the way from the strategic to operational level.

Having in mind that, one cannot talk about performance management, not taking into account performances of the projects as a primary tool for strategy implementation. Classic project management theories focus on hard components of every project: time, money and quality. Modern approaches, however, are trying to widen the horizons of project success elements. Today, focus is moving towards customer expectations and satisfaction, towards vendors, users and broader set of stakeholders. Some authors go even further saying that there is no successful project management without successful health and security management, or knowledge management within the project.

IPMA PE model, which is widely used, described in this paper, tries to embrace all modern approaches and to provide unique, yet unified way for measuring and managing project performances. It can be used as a tool for post project assessment, but more and more companies use it as a performance management approach which enables them to manage projects from strategic to operational level, from planning to closing phase, taking into account all relevant stakeholders and project functional areas. There is no contemporary performance management without project performance management.

Abstract: *Communication is a key success factor of any project. An increasing number of virtual projects creates a need for better communication and collaboration among team members. Traditional ways of communicating fail to meet most of the requirements of virtual project environment. Therefore, new technologies are implemented in a way that can support transition to a virtual environment. This paper considers the basic characteristics of virtual teams and virtual project management with special emphasis on the role of communication processes in virtual environments. Definitions and characteristics of virtual teams and recommendations for establishing effective virtual communication are discussed in the first part of the paper. After that, communication tools in a virtual environment are presented. The ending part of the paper offers the analysis of the role of communications in knowledge transfer in virtual teams. Based on extensive theoretical background of the paper, its results can serve as a basis for the empirical research, which focuses on Serbia's territory and provides insight into major trends in the considered area.*

Keywords: *Communication, virtual project management, virtual teams, transfer of knowledge in virtual environment*

1. INTRODUCTION

Virtual project management is recognized as a new discipline of project management, i.e., a new manner of managing a project that owes its evolution primarily to the Internet and various software tools that facilitate the project execution. Virtual project management has its specific features, though. Here the team members differ in the manner they work, in the culture and even in their expectations, due to the country, the city, or the continent they come from. Project managers often collaborate with people they have never had any previous experience in working with, hence their task is to learn about the specific characteristics of their employees and define an appropriate method of work as well as an appropriate organizational culture. Virtual project management makes it rather difficult to the manager to get to know the team members well, as these are spatially dispersed, therefore the task of the manager as a creator of an atmosphere is often far from easy, and may even be impossible to accomplish.

What the members of a virtual project team rely on in accomplishing their task is certainly the technology, as well as various software tools that are meant to meet the needs of the virtual project management. The main task of any tool is to ensure an unobstructed communication among the team members given their geographical distance from one another and the complications this may cause. The purpose of these tools is to ensure that the team members collaborate in a virtual environment which is the only place they meet. These tools should also ensure that project managers manage the project more easily, which includes resource management as well as monitoring the project execution, among other things.

2. VIRTUAL PROJECT TEAMS – DEFINITIONS AND MAJOR TRENDS

The concept of a virtual team is not easy to describe, partly because various theoreticians attached importance to various aspects of the team. Parker (1994) describes the team as a group of people with a high degree of autonomy directed towards achieving a certain goal or accomplishing a certain task. Katzenbach and Smith (1994) describe the team as a small group of people with complementary skills, committed to a certain goal and approach for which they are mutually accountable. Generally, virtual teams surpass the distances, the time zones and any organizational boundaries. Delisle et al. (2001) describe a virtual team as a set of members oriented to task accomplishment, acting as a temporary group, divided by geographical or in time. A majority of organizations take a project team, and therefore a

* The paper is a result of research within the framework of Project No.179081, named: "Researching contemporary tendencies of strategic management using specialized management disciplines in function of competitiveness of Serbian economy", which is supported by the Ministry of Education and Science of the Republic of Serbia

virtual project team, to be an executive part of the organization. This is especially characteristic of the organizations that adopted a project management approach.

Indications are that virtual project organizations will be the next level of organizational structure evolution. Mayer (1998) maintains that virtual organizations are models the companies will use in the future. Only several years later, this vision has become a reality for a large number of companies. A survey into project managers' salaries reveals that virtual teams and global projects surpass the boundaries of many a company, government or culture. The findings have shown that as many as 21% of respondents are engaged in the projects that include a number of countries, and that 15% of them work on projects including more than one continent (the Project Management Institute, 2001). One reason for this transformation is that customers, suppliers and employees are no longer located in the same city, but in different time zones and on different continents. It is fairly probable that in the next decade a majority of project managers will be engaged in virtual project teams for at least a part of their work time.

The culture of project management can be said to suffer important changes due to the development of virtual teams. It is interesting, however, that, while the virtual team concept is an important strategic tool for advanced organizations, little information is available on how this team should be maintained properly. The reasons a majority of companies decide in favour of a transition to virtual teams are the following:

- Financial (transport and property costs reduction);
- Human resources (finding the right person for the job regardless of the location he/she is, a balanced business and private life of the employed);
- Organizational (decentralized organization, regional representatives, innovation).

The trends contributing to an ever stronger demand for forming virtual teams are as follows (Goncalves, 2005., Stoehr, 2002):

- Globalization
- Strategic alliances
- Telecommunications
- Downsizing
- Trend of outsourcing

The above mentioned are strongly supported in the analyses conducted by Visitacion (2003) and the Cutter Consortium (2005) in which the following is given:

- 50% of new software projects are Web based;
- 20% of them are critical;
- 31% of an organization's IT budget is spent on Web projects; and
- 95% of these projects are to be accomplished "within a year."

A primary advantage of virtual teams is the selection of most educated and most adequate resources, as the project manager has access to a large database of resources. An additional advantage is in that the people at certain locations have access to sophisticated technologies required that the project is properly completed, not available at other locations. The result is that virtual teams allow for the engagement of adequate people and technologies, both at reasonable prices.

On the other hand, one weakness of virtual teams is that their members do not have so much chance to get promoted, due to a lack of informal communication with their seniors. A large number of problems in virtual teams result from the fact that the management does not have much trust in the team that is not under constant supervision. Certain people prefer personal contacts and will never feel confident and at ease working in a virtual team. Others are more flexible and are willing to work in a virtual team in order to improve and move on in their job.

According to Goncalves' research (2005), the basic tasks accomplished by virtual teams as a percentage of their participation in the project manager's working hours are as follows:

- Business relations and communication with clients (35%);
- Defining, planning and organization of the project (25%);
- Measuring progress and quality control (15%);
- Coordination and communication within the team (10%);
- Technical problems solving (10%); and
- Managing virtual working environment (5%).

The data show that the project manager pays considerably more attention to the communication with clients in comparison with the communication with team members and other stakeholders. This may lead to problems in communication, alienation among the team members, loss of team spirit and the synergy effect, which is one of the most important cohesive factors, regardless of the type of the team.

As well as any change in the organization, the implementation of virtual project management solutions brings, however, numerous challenges (Archibald, 2003). The first group of challenges refers to the capacity and competence of human resources in the organization to accept and implement the designed solutions, especially if these exceed the domain of their expertise (Burke, 2002, Gareis, 2003). A second group is related to fear, tradition or suppressed personal interests that may surface as a result of facing the change (Jovanovic et. al, 2007). A third group of challenges includes the work of virtual teams and discusses the problems in communication that result from dehumanization of work and alienation among the team members (Kimble, 2000; DeMarie, 2000; Ramachandran, 2005).

One of the biggest problems in virtual project management is the maturity of an organization to adopt and implement IT and e-PM solutions (Kloppenborg, 2002). Since project managers are professionals from various fields of expertise, often outside the IT sector, a clash may occur between the velocity in the development of e-PM support in the organization and the capacity of individuals to adopt and implement it in an adequate way (Petrovic et al., 2009). Therefore the importance of trainings in raising e-PM capacities of managers gains an ever increasing importance. The challenge is greater in that the technologies develop very fast, so it is possible that the acquired knowledge may become obsolete at an equally fast rate (Mihic, 2011).

3. ESTABLISHING EFFECTIVE VIRTUAL COMMUNICATION

Talking about the work of virtual teams, it is necessary to mention that communication among the team members becomes significantly aggravated, primarily due to physical distance characteristic of them. Since body language is part of everyday communication, the recipient of the message will not be in a position to understand it properly.

Birdwhistell claims that 65% of the meaning of a message is conveyed by non-verbal communication (Birdwhistell, 1970). Nowadays, certain authors maintain that this percentage is significantly higher. Fromkin and Rodman, for example, claim that as much as 90% of the meaning of a message is conveyed non-verbally (Fromkin and Rodman, 1983).

When a person reads an e-mail, they receive only a small part of the message they are to receive; consequently, chances are that misunderstanding among the team members may occur due to the very lack of personal interaction.

Similarly, informal communication is a major source of information. This type of communication is not present in virtual organizations. Members of the team do not have coffee together during the break, hence they cannot turn to their colleague to ask about his previous experience without using an e-mail or a telephone, which is far from being as efficient and as effective as in case of a traditional organization.

Research has shown that a small physical distance offer more opportunities to conduct communication (Allen, 1977), whereas long distance may endanger it. One research has found that people sitting at a distance of 40 metres from one another had a 5% chance to communicate, and only once a week. The percentage did not rise until the distance was reduced to 8 metres. It was then that the team members achieved a better collaboration and a better communication. This research highlights the challenges facing virtual teams in which personal communication is at best rare, and most often is impossible.

Similarly, fragmented communication may be rather harmful in virtual teams, primarily because classical communication generally relies upon non-verbal gestures which is most often absent in virtual teams (Guss, 1997).

Upon assembling a virtual team, the members of the team have to become aware that a standard interaction among people is rarely present in a virtual team (Table 1).

Table 1: Interpersonal interaction (✓-accessible, ×-mainly inaccessible)

	Traditional teams	Virtual teams
Data	✓	✓
Written procedures	✓	✓
Unwritten procedures	✓	×
Voice tonality	✓	×
Facial expressions	✓	×
Gestures	✓	×
Body language	✓	×
Social interaction	✓	×

This does not mean that people in a virtual team do not have personal contacts; it simply means that they find other, alternative methods of conducting communication. Characteristic of all teams is that a regular, i.e., traditional conversation will give a feeling of physical and emotional relationship among the team members. The members of a virtual team, however, need to communicate more frequently, in order that the people in the team should feel close, especially because a majority of interactions in a virtual team are not synchronized.

In other words, a face-to-face talk helps establish communication, since both parties in the conversation are in a position to offer feedback information as the conversation is under way. Furthermore, after the feedback information is analyzed, it is possible to introduce some changes if necessary. Literature reveals that words contribute to understanding a message by only 5%, the voice helps by 38%, whereas the facial expression is responsible for correct understanding by 55% (Meharabian, 1968).

Similarly, literature has it that the manner in which the message is sent is often more important than the content of the message itself. Hence, in order that a certain message is fully understood, it is necessary that the members of the team learn how to listen to their interlocutor actively. As regards the constraints of virtual teams, however, it is necessary that different methods of active listening should be developed.

While communication in classical conversation is generally controlled by the sender of the message, the communication in a virtual team is most frequently controlled by the recipient. This means that even if the message is sent, there is no guarantee that it is received. For example, when we telephone to a certain person, he/she may decide not to answer the phone, or to end the conversation in any moment he/she chooses. Similarly, if we send an e-mail to someone and we do not get the reply, we cannot be certain whether the reason for failing to get it is that this person has not received the message or that the person does not want to reply. In classical conversation it is really rare that the recipient of the message fails to hear the message, i.e., fails to answer.

In any type of conversation, especially in case of virtual teams, the recipient of the message has to accept the transfer of the message in order that he/she can read it at all. In this process of transfer certain complications, such as filtering of information or registering only certain portions of the message, may occur. Thus it is possible that certain members isolate themselves from the project team in that they will avoid supplying necessary information. On the other hand, some people believe that if they bombard others with information, they will contribute to the project's success, even if this information is not of great importance for the project. These are the people that focus upon the quantity, not the quality of communication.

Since communication in virtual teams is rather aggravated, the plans of communication and a certain sort of training would be of great help. The training should incorporate the following aspects:

- Use of important communication models and media
- Improving interpersonal communication skills
- Effective use of e-mails
- Methods for facilitating organization of meetings
- Importance of active listening
- Techniques for problem resolving in groups.

4. COMMUNICATION TOOLS IN VIRTUAL PROJECT MANAGEMENT

There are a number of tools that enable communication to be established when working in a virtual team. Some of these tools are the following: e-mail, forums, telephone, video conferences, chat, PM portals and face-to-face conversations. In addition to the listed tools of communication, there are fax, websites, instant messages, etc.

E-mail. As a communication tool, e-mail has several advantages, mainly due to its being non-synchronized by nature. On reading an e-mail, people have more time to think about how to reply, as well as about the contents of their message, especially if the message is sent in a foreign language. In such a case, they will have time to look into the dictionary and find the appropriate translation equivalents for certain words or phrases. The basic drawbacks of e-mail are the lack of verbal interaction among the team members and a slow feedback.

Forums. Their advantages are the same as in case of e-mail, and besides, the posts can be changed, some offer the opportunity of search, they are well structured, they offer the opportunity of revising the message and do not oblige anybody to reply to the posts. Similarly to e-mail, the major disadvantage is the lack of verbal interaction and a slow feedback.

Telephone. As a communication tool, telephone is mainly used in personal and direct communication. Its advantages are many in comparison with e-mail, when there is a need for a dialogue. Using the telephone as a communication tool may be difficult since during the conversation one has no knowledge of the interlocutor's visual signs, and besides, one may find it difficult to understand the interlocutor if he/she comes from a different speaking area.

Videoconferences. This type of communication may be effective in case of a number of people having a conversation. In comparison with the telephone, in videoconferencing everybody has an insight into what another one is saying. The drawback of this type of communication is that the transmission quality may be poor, which diminishes its usefulness and sometimes leads to frustrations. Videoconferences are mainly used when complex tasks, such as product development, are to be accomplished.

Chat. Chat is an informal type of communication, easy to use and useful in establishing better relations among the members of a virtual team. One advantage is also a prompt reply. On the other hand, there is a problem in using it, especially if people are slow in typing or do not have a full grasp of the communication language on a project.

Project management portals. The project management portals supply the centralization and coordination of project activities, which is a primary function of the Project Management Office. It is for this reason that in the last years the application of PM portals has been increasing in numerous companies that carry out various, complex and often geographically distant projects, i.e., possess a developed project organization, based on the implementation of the Project Management Office and on the application of temporary organizational structures (projects and programs) (Block, 2001).

Project management portals include Extranet or Intranet corporate portals. They represent developed user applications, completely integrated into the web environment. Their basic function is the centralization of all project information with an aim to work out and publish quality project documentation, project teams and their members' collaboration, sharing ideas and information related to the project, easier management and tracking of certain project aspects, such as risk, time, budget, resources etc.

The PM portal, integrated with scheduling applications, provides a powerful solution to the stakeholder's needs. Through a common interface, team members can submit reports on progress in a timely manner (accessible from anywhere that has Internet access), project managers can rapidly verify progress and update schedules, and all project participants can access the very latest status information in a controlled environment.

The basic advantages of virtual teams that coordinate their work via portals are the flexibility of access, the possibility of choice of the extent to which the stakeholders will be included into the work of the team, the creating the so-called knowledge tanks and establishing contacts going beyond the time and space limits. The disadvantages are generally reflected in the language and culture barriers (Jovanovic et. al, 2007). Problems related to words, accents or ways of expressing oneself are successfully solved by use

of electronic translators. These have proved to be a more efficient and less expensive means compared to language courses and training interpreters. The understanding of the message context is a much greater problem than knowledge of foreign languages. The dialogue between different cultural groups allows for mutual understanding, thereby coming to a consensus about a common frame of work that would be flexible enough to give credit to each member of the team.

Face-to-face conversation. This type of communication is considered to be a most powerful communication tool as it adds a personal note to a conversation. When we talk face-to-face with a person, we can clearly see our interlocutor's reaction to our words. It is also one way to establish closer personal relations. A possible disadvantage is that it may take a lot of time and money to have such a meeting or conversation.

5. COMMUNICATION AND TRANSFER OF KNOWLEDGE IN VIRTUAL TEAMS

The research on virtual teams conducted so far has mainly focused upon cross-functional virtual teams within one organization (Duarte and Tennant 1999; Johansen and O'Hara Devereaux, 1994) and are rather limited. These research works generally focused upon managing virtual teams in that the team members were motivated by their participation in management (Johansen and O'Hara Devereaux, 1994), then upon identifying an individual from the team with a group or the organization (Nemiro 2000), as well as upon building trust within the team (Javenpaa and Leidner, 1999).

Only a small portion of these research works deals with the exchange of knowledge within virtual teams, as well as with the type of knowledge that is exchanged, the manner in which the knowledge is shared and the effects that exchange has on the ultimate goals of the project.

The researches have shown that knowledge exchange within the team is significantly facilitated by an equal distribution of knowledge to all the team members, by having discussions on the existing knowledge and by not suppressing an informal knowledge exchange (Kraut, 1990). This research helped prove that an efficient communication via electronic media, collaboration and coordination are based on the fact that all the team members, at any point in time, have the knowledge necessary to understand the problem as well as the knowledge of the method of working in a virtual environment (Clark, 1996; Clark and Brennan, 1991, 1993; Davenport and Prusak, 1997; Krauss and Fussell 1990; Madhavan and Grover 1998; Marshal and Novick 1995).

In order that virtual teams should share mutual knowledge and understanding of the method(s) of work, it is necessary that the team members define the existing problems, norms and rules in advance. Very often, these rules and norms are known for the simple reason that those people worked together in the team before or that they worked in the same organization, production line, industry or field.

It frequently happens, however, that certain virtual teams lack this mutual knowledge because team members have never before worked together. In such cases it is necessary that this mutual knowledge be created. Some research have revealed that the best time for building a mutual knowledge tank is the period of initiating the project itself, when creativity is at its highest. This is the right moment to gather together all the team members so that they should exchange their ideas, experiences and knowledge; then responsibilities should be delegated and the members should start accomplishing their tasks (Johansen and O'Hara Devereaux, 1994). After the mutual knowledge has been created, each member of the team returns to their parent organizations in their respective countries, and they continue to collaborate using different communication tools.

Assembling the team and delegation of responsibilities and tasks among the members can be performed in case a certain task should be accomplished that has a limited range of possible solutions and an already well known decision making process. In case of an innovative type tasks, however, the methods used in creating mutual knowledge in routine tasks cannot be implemented. It is primarily because resolving the problem itself in routine tasks differs from that in innovative jobs. In case of creative tasks:

- Solutions require a synthesis of knowledge from specific fields;
- Solutions are found unpredictably (Safoutin and Thurston, 1993);
- Often the problems are not clearly defined, and are understood only when a solution has already been achieved;

- Task cannot be simply delegated to an individual, as all the team members contribute to the process in an unpredictable way (Hubka and Eder 1996).

Characteristics of innovative teams show that only one meeting of the members of a virtual team is insufficient to acquire mutual knowledge and understand the problems, processes or solutions. Frequently organized meetings in case of traditional teams allow for the development of new ideas and thus improve the mutual knowledge too. Too frequent meetings, however, may endanger the benefits the work in virtual team brings.

If the meetings of the virtual team should be held frequently, e.g., on a weekly basis, that would mean that the work is not so virtual after all. Hence certain authors maintain that decisions concerning highly innovative solutions have to be based on a virtual knowledge exchange, which largely differs from the traditional knowledge exchange in teams.

6. CONCLUSION AND FURTHER RESEARCH

An increasing number of companies embark on conducting projects in a virtual environment, as they become aware of the advantages such an approach offers. With a further development of technology, the communication in virtual teams will become both more effective and more efficient. Such an approach has broad prospects; in the near future an ever larger number of projects will be conducted employing virtual teams, and the importance of the persons managing the virtual communication will increase. Hence, the companies whose employees efficiently adapt to the dynamic development of modern technologies are certainly in an advanced position, therefore an increasing importance is expected to be assigned to education and trainings in the fields of communication management, virtual project management and project management software tools.

Theoretical analysis in this paper may lead to a conclusion that virtual teams will be the method in which the business will be conducted and projects will be executed in the future. It is through virtual teams that the best experts from all over the world can be engaged, which means that we need not be confined to only the best from our own region; also, the operations costs are significantly reduced, and, most important, the time required for the project to be completed is significantly shortened.

On the other hand, using virtual teams in work bears certain risks that are worth paying attention to and devoting enough time in order that they should be timely avoided. Here we primarily have in mind the members of the team that come from different cultures, the selection of communication technology, the language barriers and the method in which the knowledge is spread.

Fortunately, these shortcomings can be surpassed in that a competent person will be appointed to coordinate the team members and their communication. When the first problems in communication emerge, adequate measures have to be undertaken to resolve them. This is by no means an easy job, however, it is crucial in a successful execution of the project in a virtual environment. The person responsible for the coordination of the members and the communication among them has to be able to create such a relationship among the members that they all feel they are part of the team, that they work towards a common goal.

Further studies of these topics are related to empirical research that should analyze the major trends in the field of communication in virtual project management. Such research would be based on practice in Serbian organizations and have to analyze the key aspects of communication in the virtual environment, such as tools, procedures, ICT support, knowledge management, collaboration of project team members and management of cultural and sociological differences in the team. Thus an adequate basis for comparison will be created, and it will represent the baseline for organizations in improving the PM competences and establishing efficient human resource management in virtual teams.

Abstract: *This article analyses basic aspects and commitment of the project approach in building operational and functional capacities of the Serbian Armed Forces. The defence system and Serbian Armed Forces are very dynamic socio-technical systems that involve continuous transformation of elements of a strategic concept and doctrinal documents, legislation, organization, human and material resources, as well as ways of training commands and units. Therefore, planned and programmed implementation of defence preparations, through the building of operational and functional capacities is in the focus of experts and decision makers in the Ministry of Defence and Serbian Armed Forces...*

Keywords: *project approach, operational capabilities, defence system, Serbian Armed Forces²*

1. INTRODUCTION

Throughout history, the main achievements in the theory of management and organization are related to military activities. Since the existence of defence system and military, there was a need to manage such a complex and nationally important system. In the theoretical, doctrinal and practical regard approaches in management of operational capabilities building have changed and enriched with new knowledge and experiences.

Due to the nature and importance of the military organization, for a very long time new knowledge in the field of management, leadership and command were used as a basis for improving management processes in the domain of other state functions and in the domain of other activities. In complex social-technical systems, in recent history, there is growing need to develop and improve contents and activity areas of strategic management. Planning, as a function and process, is the most important content of strategic management, without which success in the domain of other functions is unthinkable. Necessary resources are defined by planning and programming of organizational changes, as a satisfactory compromise between the capacities of the state and operational needs.

Strategic management, as a concept already has clearly defined meaning, although there are different interpretations, as well as descriptions of relations of this concept to other lower categorical concepts. Some of these problems are of semantic nature, given that the various concepts are attributed to the same content, and vice versa, i.e. under the same term different contents are comprehended. Management could be defined as an activity aimed at achieving specific, predetermined goals.

Henri Fayol lined elements of management by a logical sequence of management functions, such as:³ planning, organizing, ordering, coordinating and controlling. He believed that all those functions are necessary, not only for successful conduct of business, but also in politics, religion, army and that they are universally applicable.

2. STRATEGIC PLANNING IN THE DEFENSE SYSTEM

Strategic planning which is supported by objective financing of costs and implemented through a programmed changes of system, in the process of harmonization of needs and possibilities, seems essential content of the strategic management of defence matters, including the reform process. In today's world of uncontrolled, rapid and difficult to predict changes of factors that determine the strategic defence planning, modernity and efficiency of strategic management are becoming increasingly important. In this sense, flexibility and adequate response in real time is coming increasingly to the fore.

²This paper presented some of the results of the research project: "Cost-effective source of new technologies and the concentration of defense through social changes and strategic orientations of Serbia in the 21st century (MNT III47029 RS)" funded by the Ministry of Education and Science of the Republic of Serbia.

³Henri Fayol as cited in Kootz, & Weinrich, 1988, Management, p.33.

From the standpoint of functional analysis, strategic management or strategic leadership⁴ of the defence system includes: strategic planning, commanding, organizing, coordination and control. So these are the basic control functions, which carry a strategic attribute, since they relate to the highest management body and essentially reflect to the whole system. Complex systems, especially the security and defence, need as more efficient strategic planning and leadership through guidance.

Often, one is automatically becoming a manager based on school degree and other qualifications, as well as taking a specific position in the organizational hierarchy, but for management needs much more than formal organizational position. Management generally, and effective management in particular, can never be completely learned up to the end. Special social conditions are necessary for management, as well as the essential skills of managers. Therefore, the phenomenon of leadership and success of leaders has always drawn the attention of not only scientists, but also the wider social public. Successful leaders emerge in different areas of life, starting from statesman, politicians, up to the generals.

At the time of modern civilization, technology and much more limited power of the individual to influence complex systems and processes, in the new conditions it is necessary to redefine the content and scope of the leadership concept. The leader is no longer the traditional leader, but the man in the shadow, which does not impose on co-workers from a position of formal authority, but build relationships with them as equal partners. From these relations in an organization depends its overall success.

3. OPERATIONAL CAPABILITIES FACTORS AS BACKGROUND OF THE PROJECT APPROACH

Strategic planning because of the significance of impact on the whole system and on other functions of strategic management is particularly important. Therefore, in theoretical and doctrinal areas of strategic planning, as well as in the realisation area of these functions, the national specificities are present. Thus, strategic planning is often referred as a way to manage changes, a method to allocate and create the future of the system envisaged in the context of environmental conditions, process or procedure for selecting the optimal path, a way of dealing with the situation and alike. All these approaches can be commented specifically from the aspect of scope and content of the term. Strategic planning can not be identified with any individually given content, but may be with the synthesis of all previously granted individual meanings. The whole content of the term "strategic planning" exhausts in the content of the basic function, which specifies for the highest level of management in the defence system.

Through strategic planning it is necessary to review and comprehensively analyse alternatives of the structural and functional system organization in terms of efficiency, effectiveness and economy. Because of the importance of strategic planning for the defence system, there are natural resistances to planned decisions that are prepared within that function. These resistances are generated from inside and outside the system, and often are coordinated. Their function is to prevent the adoption or implementation of strategic decisions. Strategic decisions are the result of strategic decision making, and therefore of strategic planning. According to Drucker, "Strategic planning does not deal with future decisions, but with the future of present decisions".⁵

Based on comparative analysis of the definitions of term of capabilities, there can be derived factors that determine them and the elements that meet the content of the term. Factors of capabilities are of external and internal character.⁶ Most important factors of capabilities are: doctrine, organization, cadres, armament and military equipment, training, education, infrastructure and interoperability. Each of these factors can be particularly operationalized and has a concrete expression for each combat system, through quantitative and qualitative properties. Their building can be programmed through a project approach for different periods of time.

⁴ At the present time, when more and more theoretical sources are used which contains the term "management", it is very difficult to restore the original term "leadership" in Serbian language. One can say that they are synonyms, because both terms have a foundation in management theory, respectively leadership theory.

⁵ Milosavljevic, 1999, Fundamentals of strategic management.

⁶ The factors are all of the active conditions, ie. all objects (things, processes, properties) which throughout their actions participate in producing a given phenomenon (regardless of whether they are necessary and sufficient). Markovic, 1981, Philosophical basis of science, p.639.

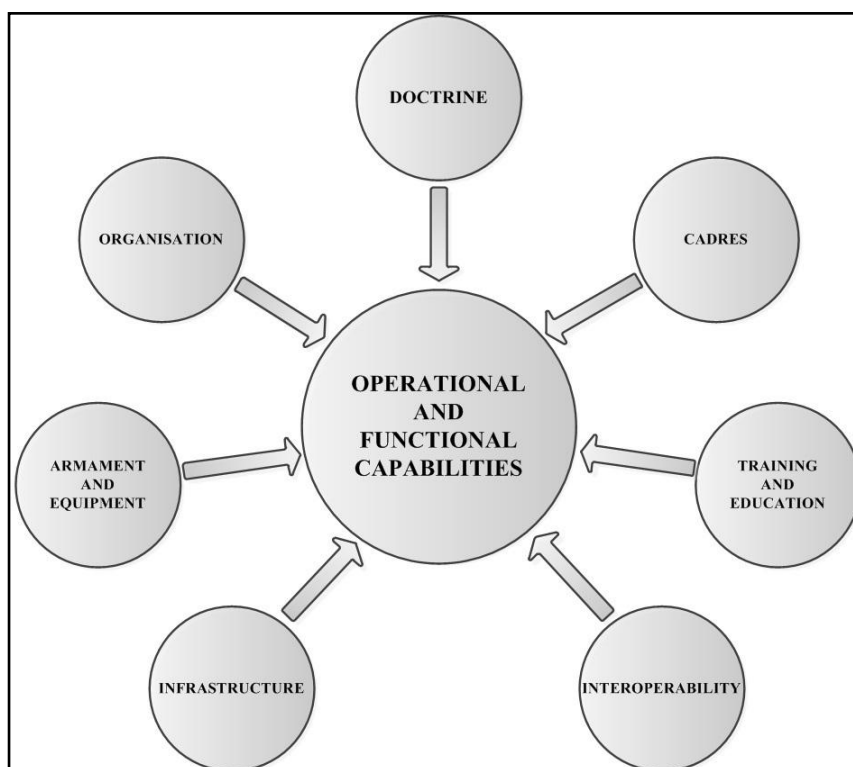

Figure 1: Operational and functional capabilities factors of the Serbian Armed Forces

Operational capabilities represent the ability of the army or its parts to achieve the desired effects in specified time and under the certain conditions and standards, through the conduct of operations. Operational capability, in relation to the criterion of belonging to the functions of combat operations, can be grouped into the following types: capability to command, capability to act and counteract and capability of security.

Individual types of operational capability should be analysed from the standpoint of factors that determine them, and evaluated and measured from the aspect of issues and elements that make their content.

4. MONITORING THE IMPLEMENTATION OF STRATEGIC DOCUMENTS, PLANS, PROGRAMS, PROJECTS

Monitoring the implementation of strategic documents, through the degree of realization of strategic objectives and issued strategic decisions is problem of every strategic management, particularly in complex, dynamic systems that are developing and acting in unpredictable strategic environment.

A representative example of such system is the military and defence system as a whole. The results of modern research confirm already acknowledged social regularity that many state institutions in the world, as well as managers of complex systems, leaders and commanders are satisfied with the adoption of a regulation, law, strategy or other act that regulates their activity, and that very little or insufficient attention is paid to their execution.

Experienced managers in particular emphasize that it is much easier to develop a solid strategic plan than to implement it and achieve the desired outcomes. The hardest part is the implementation of strategies and plans in large systems, which have great depth. What implementation strategies makes more difficult and time-demanding task than developing the strategy is a broad spectrum of management activities that should be taken care of, a wide range of methods, human resource management, persistence needed to launch and initiate various initiatives, a large number of complicated issues to solve, resistance to change that should be overcome, the difficulties in unifying the efforts of many different working groups in a compact functional unit.⁷

⁷ Thompson, Strickland III, & Gamble, 2008, Strategic management, p.317.

The research results confirmed that nearly 70-80 percent of the commitments in the strategies and other planning documents remain unfulfilled.⁸ This is particularly the case for the strategies and other general acts in which are defined strategic orientations, for whom does not appear institution explicitly responsible for implementation. So the strategies, when they are adopted, should be operationalized through action plans, plans, programs and projects, as well as to determine the mechanisms, instruments and techniques for the accurate measurement of achievement of the declared goals, objectives or strategic orientations.

Successful management of the implementation process of strategies, plans and programs require a series of continuous activities by managers, such as:

- monitoring changes in the strategic environment and their reflections on the strategies and plans;
- identification of problems and consideration of obstacles that are or may be found in the way of implementation of strategies, plans and programs;
- performing constructive pressure on the lower organizational levels to achieve good results;
- keeping the attention of the organization on need for operational execution and compliance with established deadlines;
- more exact measurement of the achievement level of stated objectives and execution of tasks;
- expression of an objective approach in rewarding and taking sanctions against responsible persons at all levels;
- implementing corrective actions to improve implementation of the strategy and achieve the desired results.

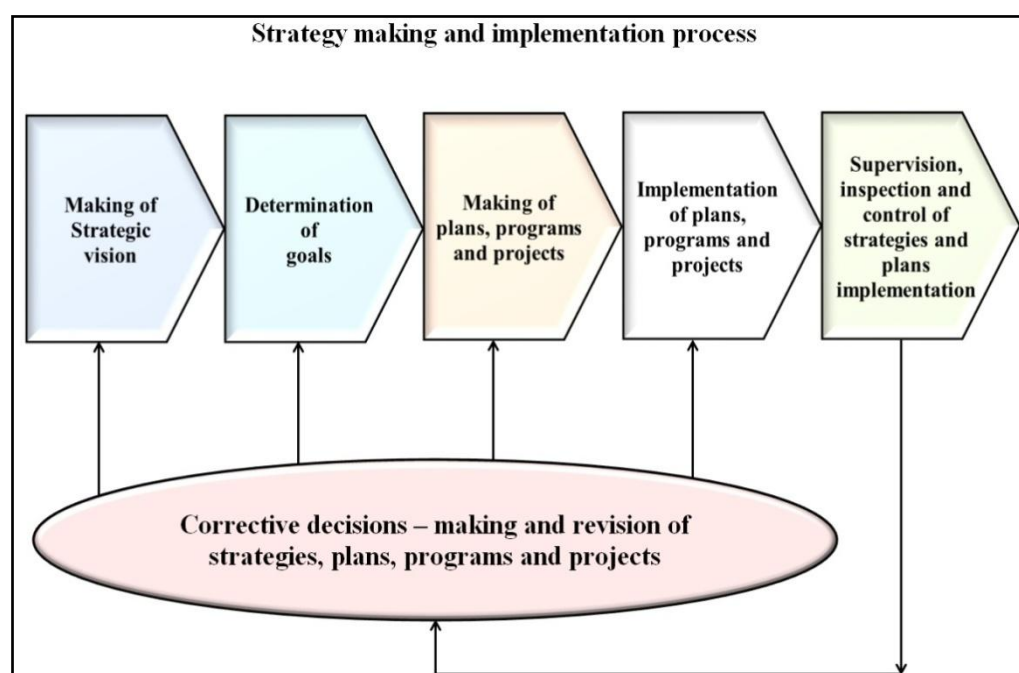

Figure 2: The process of developing and implementing strategies, plans, programs and projects

Implementation and enforcement strategy is a process with a lot of circular motion and recycling in order to harmonize and adapt the strategic visions, goals, strategies, capabilities, implementation approaches and culture, so they could match each other in the changed circumstances.⁹

Vision, goals and tasks in strategic documents are aimed at the preservation and building of operational and functional capabilities of the Armed Forces, commands and units to perform missions and tasks.

5. CONCLUSION

⁸ Ibid, pp.317-319

⁹ Ibid, p.319

The project approach involves the establishment of a comprehensive system of planning, programming, budgeting and execution. That system is an instrument of strategic management. Documents that are produced in this process usually have two parts, development and programming. The development includes: situation analysis, regarding external and internal environment, vision, mission, strategic development directions with medium-term priorities and strategic objectives, and selection of strategic options. Programming part, is implemented through a uniform system of medium-term planning and includes medium-term objectives, programs, projects and program activities, expected outcomes, performance indicators, sources of verification, as well as financial resources and sources of funding.

In order to, in provided and limited time and with provided human and financial resources, achieve the objectives that contribute to the realization of program where this project belongs, should contain information on:

- 1) Duration of the project with indicated beginning and expected end of the project
- 2) Expected results on an annual basis and upon completion of the project
- 3) Performance indicators on an annual basis and upon completion of the project
- 4) Sources of verification (who and with what dynamics follows the implementation of the project objectives)
- 5) Implementers and
- 6) Financial assets and financial resources.

The project approach in the building of operational and functional capabilities of the Serbian Armed Forces is in a function of transparency of civil-military relations and better understanding of the military profession and civilian decision-making authority in respect of budgetary spending and achievement the objectives and the required effects.

FOUR ASPECTS OF PROGRAM MANAGEMENT WITH MULTIPLE PROJECTS IN RESIDENTIAL CONSTRUCTION INDUSTRY

Ilija Nikolić¹, Zvonko Božilović²

¹Union - Nikola Tesla University, Faculty of Construction Management, Belgrade, ilija.nikolic@fgm.edu.rs

²Graditelj-Inženjering Ltd., Belgrade, office@graditelj-inzenjering.co.rs

Abstract: *This article refers to the presence of four types of problems in managing a program of multiple projects (with the usual continuous review plan period) and stresses the specificity of residential construction industry: (1) program selection from the set of potential projects, (2) planning of approved projects with available resources (scheduling projects over time), (3) supervision of projects execution and re-planning when some disturbances occur or anticipate, and (4) terminating certain projects and repeating the process with a selection of new projects if unfinished projects still exist. The result of this research involves the formation of the budget with appropriate time dynamics so that available money has a decisive effect on the program liquidity, project deadlines and program duration. Assumed is the usage of the software and the creation of an adequate information system. Presented is the program planning for the construction of four residential buildings.*

Keywords: *management, program projects, apartments, budgeting, liquidity programs.*

1. INTRODUCTION

Many authors conduct research of the simultaneous management of multiple projects that compete for the common resources (see, for example <http://www.visitask.com/managing-multiple-projects.asp>, http://technicalpathways.com / Consulting / Managing_Multiple_Projects / managing_multiple_projects.html, Drobnjaković (2001), Nikolic (2002-2003)). In recent times increasingly is emphasized the portfolio management of projects, programs or projects (see, for example, Jovanovic et al. 2007). Every project is a set of appropriate activities aimed at realizing the set of goals (see, for example Kerzner, H. 2003) and the PMBOK edition 1998-2008). Standard Software for Project management (PM) is supporting the needs of practice, supported simultaneous management of multiple projects that compete for limited resources, long time before the expression of the theoretical interest in this area. For example, software CA-2 is supported SuperProject managing multiple projects since the 1990. We also presented a proper theoretical basis (Drobnjaković et al. 1995) and interpreted the use of software (Nikolic 1998). In the following years, other authors have published papers on the management of multiple projects at our various scientific conferences.

In this paper we present four types of problems for the corresponding phase of the program management of several projects in the construction of housing complex. We emphasize the provision of the program liquidity with the present dynamics of the flow of funds to cover project costs.

2. PROGRAM OF PROJECTS MANAGEMENT PROCESS IN RESIDENTIAL DEVELOPMENT

Unlike the management of one project with approved duration when considering the appropriate planning period, managing multiple projects often is characterized by continuous planning period. Generally, projects that are executed can be completed in different time periods, thus creating conditions for the introduction of new projects. Planning and construction of more housing units are subject to the general theory of management of several projects:

- (1) The program choice from the set of potential projects;
- (2) Planning of approved projects and their distribution in time;
- (3) Control the implementation of projects and re-planning when disorders occur or anticipate, and
- (4) Completion of some projects, analysis and repeating the process with a selection of new projects.

2.1. The selection of the projects program/portfolio

Project selection from the set of potential projects is carried out in accordance with the global objectives and constraints. It is justified to consider maximizing the value of the total amount of profit with the available (or planned) budget for all projects. It is important for residential buildings to consider their locations and all characteristics that are important for potential buyers.

We have shown analysis of four locations in different parts of the inner and outer part of our capital (Nikolic and Božilović (2009), Problem 52) with elements of unequal importance for the construction (land prices, construction costs, existing infrastructure, etc.), selling possibility of apartments and related facilities (customers' demand, sales prices, etc.). Multi-attribute analysis was applied (Analytical Hierarchy Process/AHP Method, Expert Choice software), with three levels of criteria (Table 1) for each location.

Table 1: Hierarchical structure of criteria of multi-attribute selection model for housing sites

F₁ – Microlocation F ₁₁ – Street building and the adjacent streets F ₁₂ – Preschool F ₁₃ – Primary School F ₁₄ – Health Center F ₁₅ – Supermarket F ₁₆ – Theatre F ₁₇ – Parks F ₁₈ – Recreational Facilities F ₁₈₁ – Playgrounds F ₁₈₂ – Swimming Pool F ₁₈₃ – River or Lake	F₂ – Macrolocation F ₂₁ – Distance from city center F ₂₂ – Public transport F ₂₂₁ – Metro F ₂₂₂ – Tram F ₂₂₃ – Trolley F ₂₂₄ – Bus F ₂₃ – Municipal road network F ₂₄ – Main Roads F₃ – Infrastructure F ₄ – Demand for housing F ₅ – Financial Aspects F ₅₁ – Costs [m.u./m ²] F ₅₂ – Profit [m.u./m ²] F ₆ – Potential new housing sites
--	---

The introduction of appropriate weights for the significant criteria and sub-criteria (requirements for their maximization or minimization are recognizable from the very name) is determined the optimal multi-criteria ranking of the considered locations. Starting from the top of the list it is chosen only one location or locations with the sum of the costs not exceeding funds available for construction costs.

The issue of portfolio projects selection was elaborated in details Lourenco and Bana e Costa (2009). It was pointed on different approaches to this area around the world (including the application of Expert Choice) and proposed a multi-criteria decision support system called PROBE which is based on the so-called 'backpack task' and the 'benefit-to-cost ratio' model, which is essentially a binary problem with values for the variable 1 (the project is included in the portfolio) or 0 (otherwise). The significance of individual projects (ratio) is defined as the ratio of profits and costs. Generated are all possible combinations of projects and the corresponding total costs (based on a case that no project is chosen up to the selection of all projects). Selected are efficient or Pareto-optimal solutions, i.e. the portfolio with the corresponding total costs. The user can choose the best portfolio depending on the levels of costs.

2.2. Planning and scheduling of projects in time

Planning of approved projects is done in accordance to available resources for which these projects compete. In general, companies in housing construction can proceed in one of the following ways:

- Using only its own resources (machinery, labor, etc.)
- Hiring specialized contractors for each phase of work (one contractor for the certain work of an object or multiple objects), for the whole object or for more projects in their entirety;
- Combining the performance of selected works from its own resources with the allocation of some tasks to other subcontractors.

Introduction of the contractors or subcontractors poses a new problem of their selection. It is expected that they offer different work elements (duration, price, payment terms, etc.). We illustrated the selection of

contractors for the project using linear models with costs and duration criteria using the software WinQSB (Nikolic and Bozilovic (2009), Problem 39-43), which can be adapted to consider a number of projects.

Detailed projects planning determines the terms of their terminations and related costs for each project and the total costs for the whole program. It follows that the initial projects selection based on initial budget planned for all projects can be adjusted (case 1), i.e. must be corrected (case 2).

- 1) If the detailed plan results in lower total costs, it is necessary to examine whether the free financial funds can be used to choose new projects from already established rankings of potential projects. For previously selected and for new projects is necessary to repeat detailed planning process and determine whether new projects can be actually introduced and what the number of such new projects is.
- 2) If detailed planning of projects requires the greater total cost, there must be omitted earlier selected projects with lower priority so, the total cost of retained projects should not exceed the budget. The process of detailed planning of such projects is also necessary to repeat.

Project management is based on the rational use of available resources. The literature usually considers the limitations of resources, types of labor and machinery, which is supported by the standard PM software (such resource leveling is done by reducing the need within given limitations - available fund of working hours per day). However, from the standpoint of cost only, it is usually stated that it needs to be made a project plan in line with available budget. So, (Rajkov and Nikolic (1999)) proposed the extension of the standard project management methodology with consideration of cash flows (cash inflows, outflows and the cash balance). Božilović (2001) extends the consideration of financial resources to manage multiple projects and (Nikolic et al. (2002) illustrate the use of MS Project software application. Here, it follows an appropriate mathematical formulation of the problem.

Liquidity planning program for a given dynamics of forming the budget

In certain business practices of construction companies is often present the case that budget for the envisaged program of projects is not available in full at the beginning of the planning period of the program than, it is formed during its execution. It can be considered that there are three forms of budget establishing for the program:

- (1) The Company finances the program from its own funds through sales of their products from the previous programs (it is planned the expected dynamics of the financial inflows from the standpoint of terms and amounts of funds in each period).
- (2) The Company uses bank loans (contracted by the corresponding inflow dynamics of finance)
- (3) The Company combines its own funds and loans (it is derived the associated dynamics of financial inflows).

Appreciation of the budget formation dynamics influences the preparation of detailed project plans so that in the terms for payment of costs there is enough money. In other words, it is necessary to ensure the solvency of the program at any time period for the payment of costs. The problem boils down to the consideration of costs at the end of each month when is determined the scope of the work done and corresponding costs. After the payment of expenses in one month, the remaining funds in the next month and the cash balance is determined as the difference between the cumulative cash flow and cumulative outflows for expenses at the relevant time period for the payment of costs.

This problem can be described with appropriate general mathematical model. Let j denotes the ordinal number of the appropriate project and considered is the set of n projects which consists of a set of indices J , $j \in J = \{1, \dots, n\}$. Denote t , as the units of time (months), the duration of the term is T and the completion of the program is T_p , so, $t \in T = \{1, \dots, T_p\}$. Each project corresponds to the term's start and a line diagram with the necessary logical dependencies and technological activities so their positions in the time determine the term of the project. Certain dependencies may be present between some projects or parts of projects. For a considered term's variant for the beginning of projects exist corresponding overlaps in time for work on various projects. With the cost $C_j(t)$ of the j -th project in t -th month determined is the cost of the program in that month. It is further necessary to observe the period Θ_t , from the beginning of the program and concluding with t -th month, marking the individual months with τ ,

$\tau \in \Theta(t) = \{1, \dots, t\}$, $t \in T$. Based on the inputs of money $C^{inp}(\tau)$ in some months τ determined is cumulative $C_{cum}^{inp}(t) = \sum_{\tau \in \Theta(t)} C^{inp}(\tau)$ for the appropriate month $t \in T$, which is needed to compare with the cumulative costs, i.e. the output of money $C_{cum}^{out}(t) = \sum_{\tau \in \Theta(t)} C(\tau)$ in the same month. Further, it can be considered the period T of the program execution including the periods T_j for individual projects when they have endings Tp_j and performed in time units $t_j \in T_j = \{t_{j,1}, \dots, Tp_j\}$, $j \in J$. Obviously, it is true that $T = \bigcup_{j \in J} T_j$ (the duration of the program execution is the union of individual projects periods) and $Tp = \max_{j \in J} Tp_j$ (program completion is determined by the project with the latest completion). Optimization program can be defined with the following multi-criteria linear programming model:

$$\text{minimize } Tp \quad (1)$$

$$\text{minimize } Tp_j; \forall j \in J \quad (2)$$

s.t.

$$\sum_{\tau \in \Theta(t)} C^{in}(\tau) - \sum_{\tau \in \Theta(t)} C(\tau) \geq 0; \forall t \in T \quad (3)$$

where: the function criterion (1) minimizes the duration of the program, with (2) minimized is the duration of individual projects j , while conditions (3) ensure the program liquidity in each month t .

The number of criteria is equal to the number of projects increased by 1. However, it is necessary to point out the following aspects that are present in practice:

- Can be considered one-criterion problem of minimizing only the program duration (1) and respecting the conditions (3).
- Criteria (2) can be introduced for all projects or only for selected projects. Specifically, projects commonly define appropriate priorities and require the shortening of its duration. In doing so, it can be proceeded in one of the following ways:
 - the highest priority is set for the program duration (1) and lower priorities to other appropriate projects;
 - the highest priority is set for one project, the next priority for the program and a lower priorities for the remaining projects;
 - higher priorities are set for specific projects, followed by the next priority for the program and then a lower priorities for remaining projects;
 - higher priorities for projects and the lowest priority for the program.
- Model (1)-(3) must respect amounts available for other types of resources (primarily machinery and labor) when the company runs the program with its own resources. The illustrative example shows that MS Project software solves the problem defined by the implementation of an interactive designed process, 'analyst – software'.
- If a program is assigned to subcontractors, it is necessary that they accept the solution of the model (1)-(3). It means that it is necessary to harmonize the solution with subcontractors, what is possible, bearing in mind that multi-criteria model can be determined by corresponding Pareto-optimal solutions.

Two Pareto-optimal or efficient solutions x^1 and x^2 can be simply defined with characteristics that x^1 is more favorable for at least one criterion than x^2 and worse than at least one of the remaining criteria. Conversely, x^2 is more favorable than x^1 for at least one criterion and worse for at least one of remaining criteria. If x^1 is better at least in one criterion than x^2 and not worse for any other criteria, then x^1 dominates over x^2 and x^2 should be rejected as an ineffective solution which is not Pareto-optimal (see, for example, Ehrgott (2000), Nikolić and Borović (1996)). Solutions of the multi-criteria model by definition is a set of Pareto-optimal solutions among which one is chosen for implementation. It is often not possible to determine all such solutions or it is not rationally to do. Because, it should be generated a selected

subset of efficient solutions for analysis when the decision maker can choose one plan which, he believes, is the most appropriate in the given circumstances for the company business. If there are subcontractors for some work, it is needed that they accept the plan. With such plan, called 'the basic plan 1' or 'the initial base plan', can be started the execution of the program.

2.3. Control of projects execution and re-planning when disorders occurred or predicted

In this phase should be determined monthly the construction work accomplished on the projects and compared with the current basic plan what is supported by the standard PM software. If there is a correspondence between accomplished and planned elements, provided that they were not made or anticipated changes of the program plan elements, it should be continued with the program implementation at the current base level. Otherwise, it is necessary to correct the current base plan and determine the new basic plan for the continuation of the program. Based on incurred or anticipated changes, the program model is solved as the earlier base plan or a new model with required elements is used. Thereby, a new basic program plan is specified for the continuation of its implementation and controls should be conducted at the end of next month. Possible changes in the elements for the continuation of the program are:

- i) Change of available resources, manpower and machinery;
- ii) Change of the cash flow dynamics;
- iii) Change of the program and projects priorities.

2.4. Completion of some projects, analysis and repeating new projects selection process

Having drawn up a plan for an earlier program and started its implementation, the construction company can plan their business in two ways:

- a) Planning to start the next program after finishing the current program.
- b) The beginning of the next program is planned before the end of the current program. In addition:
 - Some of projects have been completed (or at least one was completed) and others have varying degrees of completion, or
 - There are no completed projects and all are partially completed (with appropriate degrees of completeness).

In both cases, it is preferable to make analyses of the program implementation success and drawing conclusions for better management of future programs. The case a) has two discontinuous planning periods and the possible time interval between the completion of the first program and start of another program. For b), there is a continuous planning period with appropriate overlapping of the first and second project execution periods. Standard PM packages support these approaches.

3. SOFTWARE SUPPORT OF PROGRAM MANAGEMENT OF SEVERAL PROJECTS

Program management of several projects which is presented is not appropriate to be carried out using manual procedures, except in very simple cases. It is necessary to use appropriate software packages. Below is shown the application of the MS Project in solving the model (1)-(3), which is extended with the limitations for two types of process machinery.

4. AN ILLUSTRATIVE EXAMPLE

Let assume that exist the program plans to build $n = 4$ identical housing facilities, which are considered as separate projects (Proj-1 to Proj-4). Each project has seven stages of works with a total of 206 activities and requires involvement of 247 types of resources: 7 types of working machines (M_1 to M_7), 26 categories of workers (W_1 to W_{26}) and 216 types of materials. All projects compete for the same resources. The analysis might be necessary to restrict the numbers for some of available machines and possibly for some workers, while the materials are available in required quantities. Program planning using MS Project software consists of the following stages.

Stage 0. Defined is the beginning of the program on 2.4.12 (the first Monday of the month of April), which determines the beginning of the Proj-1. It is believed that is appropriate for any future project to start after

having finished approximately 50% of the first phase of work (earthwork) of the previous project, so there are adopted terms of every first Monday in the following month: 7.5.12 for Proj-2, 4.6.12 for Proj-3 and 2.7.12 for Proj-4. Each project has a cost amounted to €494,822 and the total cost of €1,979,287. Without resource limitations, each project has a minimum duration of 165 days (Figure 1) and the corresponding terms of endings, according to the durations of 165 days.

Task Usage	i	Priority	Task Name	Duration	Start	Finish	Cost	Details	Gtr 3, 2012				Gtr 4, 2012			Gtr 1, 2013		
									Jun	Jul	Aug	Sep	Oct	Nov	Dec	Jan	Feb	
	0		500	Program-1	230 d?	2.4.12	15.2.13	1,979,287	Cost	487,586	505,967	423,389	216,479	13,428	10,904	5,867	3,199	378
	1		4	Proj-1	165 d?	2.4.12	16.11.12	494,822	Cost	208,042	2,236	4,827	2,601	2,742	416			
	2		3	Proj-2	165 d?	7.5.12	21.12.12	494,822	Cost	235,450	208,144	2,175	4,098	3,533	2,788	528		
	3		2	Proj-3	165 d?	4.6.12	18.1.13	494,822	Cost	44,094	229,651	208,243	1,874	4,760	3,030	2,667	491	
	4		1	Proj-4	165 d?	2.7.12	15.2.13	494,822	Cost		65,937	208,143	207,906	2,394	4,670	2,672	2,708	378

Figure 1: The initial plan and program costs (Task Usage report from MS Project) without limiting resources, the minimum durations of the projects and program were 165 and 230 days respectively

Minimization of maximum demands for selected resources with minimum program and projects durations

The analysis of the plan without resource limitations determines the daily needs for program resources and also the maximum daily requirements for machines and workers for the period of program execution. It is reasonable to determine the minimum value for the maximum amount of major machines and workers of the program (minimum possible values for the maximum daily requirements), while maintaining the minimum duration of the project. Such optimal solution should be called 'real optimal solution' for minimum program and projects durations. If it is important to consider only machines, the need is maximum up to [1, 3, 1, 5, 2 and 1] machine M_1 to M_6 per day. Introducing project priorities in the order of their names and asking for lower values of maximum daily requirement of machines, in the Resource Leveling process software defines the optimal maximum numbers of [1, 3, 1, 3, 1, 1] machine per day. Starting and completion projects dates are not changed (keeping the duration of the program), but some non-critical activities of Proj-3 and Proj-4 with lower priorities were shifted. In this way are changed expenses for corresponding months on the Proj-3 (□ 5.915€ for Jun '12, +5.871€ for Jul i +44€ for August) and Proj-4 (□ 21.674€ for Jul, □ 3.024€ for Aug and +2.699€ for Sep). This also changes the program costs from Jun to Sep: □ 5.915€, □ 15.803€, □ 2.981€ and +24.699€ By analogy, can be also made the optimization of important categories of workers but this is not presented here.

Table 1: The initial program and cost plan, illiquidity for 3 months

	Costs					Cumulat. Cost	Input of Money	Cumulat. of Input	Liquidity
	Proj-1	Proj-2	Proj-3	Proj-4	Program				
Start	2.4.12	7.5.12	4.6.12	2.7.12	2.4.12				
Finish	16.11.12	9.1.13	19.2.13	12.4.13	12.4.13				
Dur (day)	165	178	187	205	270				
Months									
Apr '12	55.017				55.017	55.017	250.000	250.000	194.983
May '12	218.927	20.381			239.308	294.325	250.000	500.000	205.675
Jun '12	208.042	59.659	20.467		288.169	582.494	250.000	750.000	167.506
Jul '12	2.236	339.285	36.060	20.636	398.217	980.711	250.000	1.000.000	19.289
Aug '12	4.827	63.781	170.110	36.097	274.815	1.255.526	250.000	1.250.000	-5.526
Sep '12	2.601	1.906	255.376	13.147	273.030	1.528.556	250.000	1.500.000	-28.556
Okt '12	2.742	4.859	2.052	329.086	338.740	1.867.296	250.000	1.750.000	-117.296
Nov '12	416	2.415	4.556	83.768	91.154	1.958.450	250.000	2.000.000	41.550
Dec '12		2.295	2.951	2.121	7.367	1.965.817		2.000.000	34.183
Jan '13		228	2.784	4.911	7.922	1.973.739		2.000.000	26.261
Feb '13			453	2.170	2.624	1.976.363		2.000.000	23.637
Mar '13				2.533	2.533	1.978.896		2.000.000	21.104
Apr '13				341	341	1.979.237		2.000.000	20.763

If you reduce the number of machines M_2 from 3 to 2 and M_4 from 3 to 2, the leveling of all types of machines determines their minimum values for the maximum daily requirements [1, 2, 1, 2, 1 and 1] of the next time periods (Table 1): 165 days for Proj-1, 178 days for Proj-2, 187 days for Proj-3, 205 days for Proj-4 and 270 days for the program. It is noticeable that the Proj-1, with the highest priority, retains the minimum duration, while other projects extend their durations (decreasing project priorities increase their durations). It can be followed how significant differences occurred in the monthly program and projects costs comparing to the previous solution.

Consideration of program liquidity

Let assume that is planned the program cash inflow of €250,000 each month in the period from Apr '12 to Nov '12 (Table 1) and it is necessary to ensure the liquidity in every month.

Stage 1. Analysis of the previous program plan (Table 1) determines the insolvency or negative cash balance in three consecutive months: – €5,526 for Aug '12, – €28,556 for May and – €117,296 for Oct.

Stage 2. Avoiding the insolvency or achieving the liquidity can be accomplished by moving the work from the month where exists illiquidity to the following months. Two following approaches can be combined:

- (1) From theoretical aspects it is necessary to find out whether non-critical activities were performed in the illiquid months and move such activities (define binding terms for their earliest beginnings), taking into account the available resources (resource leveling carried out using the software). In this way, it is tried not to prolong the projects and program durations and to achieve the lower their extensions.
- (2) In practice, can be applied a simpler procedure, suitable for analysts with less experience in using the software: testing the plan variations by moving the beginnings of projects with lower priorities and doing the resource leveling.

Using the procedure (2) and moving the beginning of the Proj-4 for one month forward to the date 6-8-12, specifies the plan which could not be predicted in advance. In fact, the program and all projects maintain earlier durations. In this way is achieved: the liquidity of €30,741 for August '12, insolvencies of – € 26,886 in Sep and –€117,068 for Oct and liquidity in other months.

Table 2: Plan for the achieving liquidity in each month

	Costs					Cumulat. Cost	Input of Money	Cumulat. of Input	Liquidity
	Proj-1	Proj-2	Proj-3	Proj-4	Program				
Start	2.4.12	7.5.12	4.6.12	3.9.12	2.4.12				
Finish	16.11.12	9.1.13	19.2.13	19.4.13	19.4.13				
Dur (day)	165	178	187	165	275				
Months									
Apr '12	55.017				55.017	55.017	250.000	250.000	194.983
May '12	218.927	20.381			239.308	294.325	250.000	500.000	205.675
Jun '12	208.042	59.659	20.467		288.168	582.493	250.000	750.000	167.507
Jul '12	2.236	339.285	36.060		377.581	960.074	250.000	1.000.000	39.926
Aug '12	4.827	63.781	170.110		238.718	1.198.792	250.000	1.250.000	51.208
Sep '12	2.601	1.906	255.376	32.264	292.147	1.490.939	250.000	1.500.000	9.061
Oct '12	2.742	4.859	2.052	241.493	251.146	1.742.085	250.000	1.750.000	7.915
Nov '12	416	2.415	4.556	208.231	215.618	1.957.703	250.000	2.000.000	42.297
Dec '12		2.295	2.951	2.079	7.325	1.965.028		2.000.000	34.972
Jan '13		228	2.784	4.647	7.659	1.972.687		2.000.000	27.313
Feb '13			453	2.859	3.312	1.975.999		2.000.000	24.001
Mar '13				2.709	2.709	1.978.708		2.000.000	21.292
Apr '13				528	528	1.979.236		2.000.000	20.764

Stage 3. By placing the beginning of the Proj-4 on 27-8-12, it is reduced the duration of Proj-1 from 205 days to its minimum duration of 165 days. Retained are the previous durations of all other projects and programs. It results in illiquidity of - €6,110 in Sep '12 and liquidity in other months.

Stage 4. The beginning of Proj-4 on 3-9-12 determines the liquidity in all months (Table 2). Retained are the durations for all projects, but the later start of Proj-4 extends the duration of the program from 270 days to 275 days. Considering that the program liquidity is achieved, this plan may be regarded as acceptable.

5. CONCLUSION

The paper stresses the specificities of managing the program with several projects in the residential construction industry comparing to the general case of the program with multiple projects: (1) selecting the program from the set of potential projects, (2) planning of the approved projects based on available resources (scheduling the projects in time), (3) supervision of projects and re-planning if disturbances occur or anticipate, and (4) terminating certain projects and repeating the process with a selection of new projects if unfinished projects exist.

Described are two different approaches for the selection of potential projects for the program with available budget (using Expert Choice software and the PROBE systems for decision making support while selecting the portfolio of projects). Research was particularly focused on the next phase: the formation of the budget with adequate time dynamics and determining the project plan which ensures the liquidity in the terms of payments of costs. A corresponding general mathematical model is defined to minimize the durations of the program and individual projects which was successfully tested using the MS Project software for planning of the construction of four residential buildings. For the given dynamic of budget formation for the program funding, it is pointed out on two approaches and their combination for the achievement of liquidity at the end of each month when determining the cost of work performed to be paid: (1) moving non-critical project activities or to achieve the lowest project extensions, and (2) moving the beginnings of the projects. The goal is not to prolong the lives of the projects (consequently, the program duration) and to achieve as small as possible extensions. Presented is another approach to the discussed limitations of the available number of working machines, which can be extended to the limitations for significant or all categories of workers.

Further research is necessary to dedicate to the possible forms of funding programs and associated cash flow dynamics, especially for the use of bank loans.

CONTRIBUTION TO CONVENTION INDUSTRY DEVELOPMENT USING A MULTIPROJECT MANAGEMENT CONCEPT

Marija Markovic¹, Marko Mihic²

¹BBN Congress Management, marija.m.markovic@gmail.com

²Faculty of Organizational Sciences, University of Belgrade, mihic.marko@fon.rs

Abstract: *The purpose of the paper is to point out positive effects of applying a multiproject management concept in an event management organization on its development and the growth of the entire convention industry. The idea is to illustrate the above-mentioned effects first by defining the basic aspects of multiproject management and event management, and then by analyzing the way in which the multiproject management concept could be implemented in event management, through both theory and case study. Methods used in the paper include induction and deduction, comparison, analysis and synthesis, and the case study analysis. Having in mind that the case study presented in the paper uses the example of an event management agency from Belgrade, Serbia, underdeveloped convention industry in Serbia and regional countries will be addressed to a lesser extent.*

Keywords: *convention industry, event management, multiproject management, selection, resource allocation*

1. INTRODUCTION

During the crisis period in ex SFRY, from 1992 to 1995, the economic capacity of the region was significantly affected and one of the results of a bad economic situation was the absence of modern management methods and techniques in doing business, including project management. Means of doing business in Serbia and the region began to prosper and develop in the mid-nineties with creation of quality higher education management programs, and even more after the revolution in October 2000, with the arrival of numerous foreign investors and various EU supporting funds that demanded the use of modern methods in managing projects in order for funds to be granted. (Cicmil, Djordjevic, & Zivanovic, 2009)

Event Management, in its current form, is a relatively young business. The need for systematic approach in organizing an event, including thorough planning and detailed financial procedures exists because any serious event demands substantial resources, managed properly and also as one of the main objectives of the business has become earning profit. Any profit-oriented business demands a formal framework and once established numerous event managing organizations were formed leading to significant reductions of time needed for organizing an event and a rapid growth of convention industry by creating many new jobs. However, nowadays, especially referring to Southeastern Europe, the outdated approach in event management is obvious and inconsistent with rapid development of the convention industry and a growing need for events. Not enough time is devoted to planning. Realistic schedule and resource allocation do not exist, nor the reliable budgets to guide the organization of event in an efficient manner. Also, as event management agencies are relatively small businesses with very limited resources often managing a great number of major or minor events during one calendar year, many activities logically overlap and require more resources than the company is able to provide, as well as advanced managerial methods. The need for improvements exists and a possible answer lies in the application of the multiproject management concept. By implementing the concept of project-oriented enterprise as a frame for management system, supported by an adequate organization, team work and project culture, it is possible to significantly improve business results, provided that modern project management tools and techniques are used. (Jovanovic, Mihic, & Petrovic, 2007)

2. MULTIPROJECT MANAGEMENT

Multiproject management concept (MMC) is increasingly used as an integral part of many organizations with tendency of being widely accepted managerial form of each business entity. Multiproject management represents coordinated management of a project portfolio in order to achieve certain set of business objectives. (Reiss, 2004) Its intention is to improve the efficiency of resource utilization in an organization, assuming resources to be limited. Multiproject management includes both analyses of existing resources within organization as their distribution among projects that the organization is managing. (Görög, 2011) By using available resources efficiently an organization creates favorable

environment for achieving its strategic goals as well as its short-term, operational ones. Projects managed may be differently dependent or totally independent.

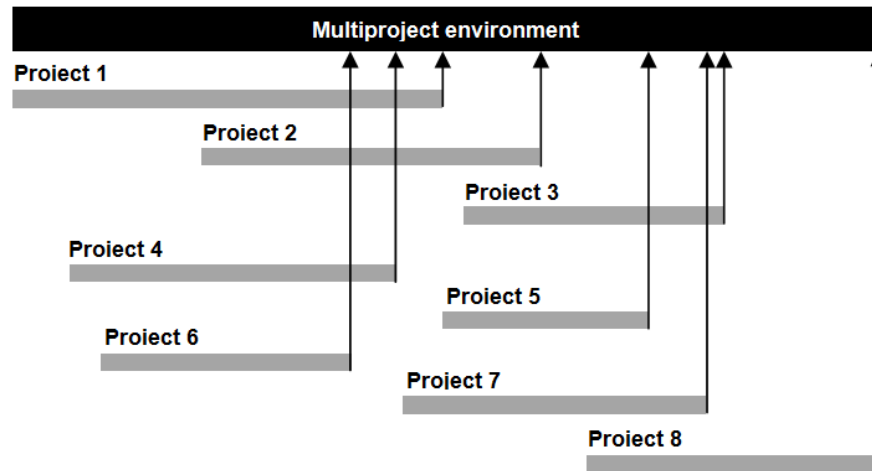

Figure 1: Graphical illustration of projects within multiproject environment

Source: Pennypacker JS, Dye LD. *Managing Multiple Projects - Planning, Scheduling, and Allocating Resources for Competitive Advantage*. Marcel Dekker Inc., USA; 2002.

The purpose of applying concepts of project or MM in an organization is to create a competitive business strategy that will position the organization on global market through more efficient manner of doing business. (Srivannaboon, 2006) Efficient multiproject management, beside good knowledge of the relative value of projects, risks associated with each of them, resources current state and statuses and the availability for new projects, involves making right and strong decisions of what projects will be managed, when and how, if they are taken into consideration, based on the understanding of each project's potential and value it can bring to the organization. Two main aspects of multiproject management are **selection and prioritization of projects** and **analysis and allocation of available resources**, aimed at creating efficient portfolio schedule, as well as reliable financial plans.

2.1. Selection and prioritization of projects

The selection process includes assessment of all possible projects and selection of most suitable, in accordance with certain critical parameters, of greatest importance to the organization. Some of the most fundamental are: (Jung & Lim, 2007)

- Compliance of projects with objectives and mission of the organization that manages the portfolio
- The obvious contribution to the strategic goals of the organization
- Project duration – the goal is to create an ideal mix of short-term and long-term projects
- Impact on organization's financial statements – financial aspects of a project
- Project impact on available resources – both quantitative and qualitative need for resources

The selection process also includes the assessment of the optimal number of projects to manage considering the available resources, as well as the creation of high-quality portfolio. When the optimal number of projects is selected, they are prioritized.

For calculating priorities it is necessary to establish adequate calculation model, dependable both on the basic characteristics of the managing company and of all projects. The general calculation model consists of four basic components: (Rod & Levin, 2006)

1. Criteria to be used – objective so that projects cannot be shifted in order to ensure favorites
2. Range of values for each criterion
3. Measure unit and a description for each value in the range
4. The importance or weight of the criterion – weight of the criterion is a measure of value of certain criterion in comparison with others, therefore it is important not only to assign the value to each project based on certain criterion but also to compare the weight of criterion with weights of others; a project given the highest value for the criterion of greatest importance is considered to be of top priority

AHP is a mathematical process designed to assist the user in defining priorities as well as in decision-making processes using both qualitative and quantitative approach. (Rod & Levin, 2006) AHP makes decision making easier by taking the prioritizing process to a comparative one-on-one system of different parameters reducing all given results into one. The reasons why AHP use is logical when managing multiple projects is because it does not force a consensus, although the same may occur, and also because all criteria is compared with one another, forcing objectivity in decision making. (Strang, 2011) Over time, as technology advanced, various software tools using AHP were created such as Expert Choice. (Rod & Levin, 2006)

2.2. Project scheduling and resource allocation

When allocating resources in multiproject environment, organizations must take into account that resources must be distributed efficiently among projects with different priorities, resource requirements and accompanying risks. The system must be dynamic enough so that there is a possibility of introducing new projects and re-allocating resources if necessary. There are five steps for creating an effective plan for portfolio management: (Pennypacker & Dye, 2002)

- Preparation of time-fixed projects schedule - due to little or no flexibility these projects require to be given priority as delays are not allowed
- Identification and distribution of necessary resources for each time-fixed project and its activities
- Determine resources left available for other projects - This can be determined by constructing a resource time availability network, showing how much free time each of the remaining resources has and the total amount of free time.
- Allocation of least available resources - to optimize allocation of resources, resources are ranged and allocated from least available to most available
- Determination of final schedule

Creation of portfolio schedule can also be considered a definition or analysis of a critical path. There are three main objectives of creating an efficient schedule all assuming that the cost of completing an activity is based on time required for execution and resources engaged. (Vanhoucke, Vereecke, & Gemmel, 2005)

1. Minimizing cost of carrying out projects with respect to given deadlines
2. Conduct activities for the shortest possible time without exceeding given budget
3. Complete all projects within portfolio as soon as possible, within a given budget, making the optimal use of available resources

3. EVENT MANAGEMENT (EM)

Possibly the most accepted definition describes event management as complex social undertake characterized by sophisticated planning, fixed implementation date and numerous stakeholders. (Van der Wagen, 2007). EM involves assessment, definition, acquisition, allocation, management, control and analysis of time, cost and resources in order to achieve certain goals using tools for planning, organizing, implementing, monitoring and evaluating event design, activities and production. (Raj & Musgrave, 2009) Simply put, event management presents planning and producing an event no matter of what type. (Allen, 2009)

Participants in EM are all those with an interest in it, not necessarily of financial nature and the main are: **organizers** (institutions creating the project and providing financial support to it, with or without sponsorship assistance), **associations** (professional formations within a particular sector providing to its members networking, communication and support) **committees** (grouped representatives from institution organizing the event and those supporting it), **suppliers and contractors** (provide services and competencies that organization managing event doesn't have because of its limited size) and the **organization managing event**. (Bowdin, Allen, O'Toole, Harris, & McDonnell, 2006)

Organizations managing event present organized groups of professionals whose expertise is to plan and implement an event for ceratain fee or income percentage, usually of small size. (Van der Wagen, 2007) PCO (Professional Congress Organizer) Agency provides complete organization service for conferences, seminars and other events, mostly of commercial nature, for its clients, event organizers. (Kongresni turizam, 2007) DMC (Destination Management Company) agency is concerned with incentives and related events. (Kongresni turizam, 2007)

4. APPLICATION OF MULTIRPROJECT MANAGEMENT CONCEPT (MMC) IN EM

Each planned event is actually a project and thus areas managed are the same - scope, content, time, human resources, cost, risk, communication and demand. (Toole & Mikolaitis, 2002) Each area is managed dependable on the nature and size of the event and whether the same was already organized or not. The paper addresses management of time and resources. EM organization can also manage one larger project or program, such as the Olympics, which, due to its large volume, can be divided into a number of almost separate projects. In both mentioned cases there's room for applying MMC.

What is specific for EM is the overlapping of project phases, which leaves agency with phases of resources being more or less occupied. Phases in which agency organizing the event occupies fewer resources are ideal for working on getting new jobs.

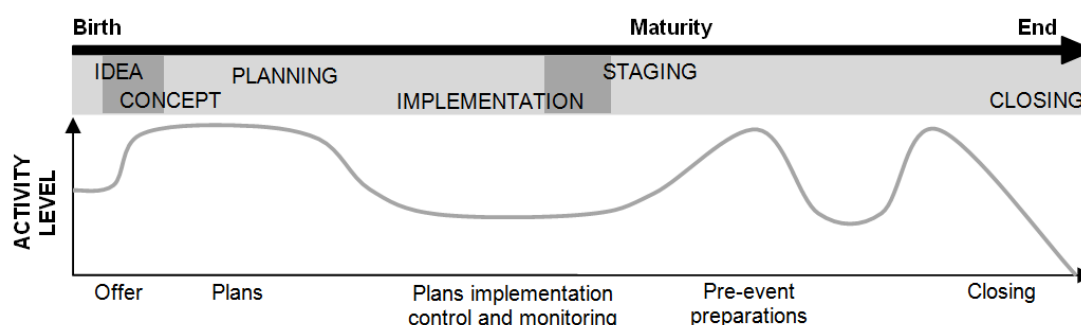

Figure 2: Event Life Cycle

Source: Toole, W. O., & Mikolaitis, P. (2002). *Corporate Event Project Management* (p. 305). John Wiley & Sons, Inc., New York, USA.

On figure 2 overlapping phases and the amount of activity at all times are shown. As planning for EM is the most important phase, activity is lowest in phases of controlling and monitoring of plans implementation. The implementation phase takes a significant amount of time though and provides an ideal opportunity for the agency to involve in getting a new job and maintain its business liquid enabling further development and growth.

The use of multiproject management methods and techniques in organizing an event will be shown through relevant theory and a case study. A case study presents activities of the agency from Belgrade, BBN Congress Management, between September 2010 and December 2011, when five events were simultaneously organized.

BBN Congress Management Ltd. founded in 1989 in Belgrade is among first private agencies registered for the professional conference organization. Currently the agency hires four permanent staff members and has many regular and reliable external associates.

BBNCM 2010/2011Portfolio: (BBN Congress Management, 2011)

- **ICED** is an international conference held biannually in Serbia for many years. Investments in the organization are great, but the importance of the conference and the long-standing tradition attracting over 800 participants and 50 exhibitors, imply a very high income, great profits and significant opportunity to gain contacts and potential clients. Even though resource requirements, costs and time needed aren't low this event for BBN is always a top priority.
- **EE&RES** Fair Study Tour - BBN as a unique partner for Serbia is contracted to organize a group from Serbia to visit the event that annually brings together over 300 exhibitors. Investments are low and considering that over 50 participants from Serbia regularly visits the fair for the fee of over 50 Euros per person revenues are quite significant, which places EE and RES among top priorities. Both time and resource requirements are extremely low.
- **RESEP** conference is a joint project of BBN Congress Management and organizers, so the company is particularly committed in managing this event. The event is financially supported by the Serbian government and government agencies, so with relatively low investments event earns high income.

- **CEM** is a small but significant annual conference that brings together approximately 100 experts from around the world. Revenues are not significant, although there is profit, but investments aren't high and the event provides important international contacts of high profile experts in the field of energy.
- **THERM** Company 10th Anniversary – BBN CM managed all pre-celebration, on-site and post-celebration activities. BBN's fee is fixed and defined, there's no income, since it is a celebration, the costs are very high and all these features place the event at the bottom of the priority list, and the last in line for allocating resources.

Modern businesses being opened, complex and changeable provoke instability and create need for organizational forms flexible enough to adapt to a multiproject environment and enough solid to unite the basic managerial processes. (Jovanovic et al., 2007) The most suitable organizational form for agencies engaged in multiproject management is a matrix structure.

For each event within BBN CM, one resource is appointed as manager while also performing regular responsibilities in its field of specialization. All other resources are also participating in the organization of the same event, in their fields of specialization. Thus, each person within agency has a dual role and is engaged in the preparation and execution of all events organized by the company.

4.1. Selection and prioritization of events

Every agency organizing events usually focuses on one particular group of events the reason being that when selecting agency takes into account its previous experiences, knowledge, contacts, available resources, regular staff and their characteristics, existing cooperation with suppliers etc. (Conway, 2009) For a success of an event it is necessary that all these components are consistent with the event type. When selecting an event not only mentioned internal factors are important but also many external ones such are: (Conway, 2009)

- The end goal of the event
- Characteristics of the organizers - organizational structure and its strategic goals, staff qualifications, available resources, business history
- The circumstances in which the event is organized
- Potential participants

BBN gives priority to corporate events, in the field of energy, international or regional and profit-oriented.

Internal factors are used for ranking selected events and developing schedule of activities. Since events typically have a specified time in which they should be held one of the criteria for setting priorities is certainly urgency. Other criteria are closely related to criteria used when selecting projects. For the event management agency it is important that the event is profitable, that the agency has necessary resources for its completion, necessary liquidity to cover the costs of implementation before income is realized, which normally begins after relatively higher percentage of costs has already occurred, and finally every event is an opportunity for the agency to get new contacts and clients. Numerous other criteria are possible. The Agency itself defines the criteria important to her and that will bring to it events for achievement of business objectives, as well as the methodology to be used.

BBN example given within paper uses the AHP implemented within Expert Choice. Top criteria BBN uses are time required for implementation, expected revenues and costs and resource requirements.

When prioritizing with Expert Choice, first given criteria is ranked, by scoring them with a value from 0 to 1, so that the sum of all assigned values is 1. Then each event is assigned certain value in relation to each criterion, following the above mention scoring system. The synthesis of all calculated results is made and events are given their priority value and thus a rank. The next step is to produce a solid schedule following given priorities.

Since BBN is a small agency with very limited resources and capacity to organize only several events in one year, revenues of the event are regarded as the most important criterion while costs are second as they determine whether profits will be possible and also if agency will be capable of bearing the weight of the event, determined by the altitude of its costs. Events with revenues expected to be high are given the highest score and those with cost expected to be high the lowest. Costs are good if low, but not at the

expense of desired quality and disrespect of client's requests. High revenues mean higher earnings for BBN as it often operates on percentage of total revenues. Resources, as agency regularly hires only four people, are third, but not the most important, as there is a possibility of hiring additional resources, dependable on revenues and other costs. Finally, time, certainly very important criterion, as it shows for how long available resources will be occupied. It is preferable that event resource requirements are lower so as the time needed for event to be realized. Lower resource requirements and reduced period of time needed reduce costs.

Figure 1: BBN Priority Criteria Ranked

In order to give value to events for all criteria used, BBNCM relies on historical data, except for THERM celebration, where all necessary data are submitted by the company. Historical data used are the number of participants in previous years, realized costs and revenues, number and profiles of people involved in the organization before. Data used for the study tour are based on pre-organized tours and by the event organizer.

Figure 2: BBNCM Portfolio 2010/2011 Events Ranked

For reasons explained before, ICED is, as expected, first at the priority list, study tour the second, RESEP and CEM almost the same and THERM occupying the last place.

4.2. Event scheduling and resource allocation

Earnings for an event are directly related to the ability of the company to manage time effectively. (Goldblatt, 2005) Events are time-limited projects. For most events, due date is predefined and cannot be changed during planning and implementation processes, so all the activities preceding the event, must be completed on time. Agencies that organize many events, with numerous overlapping phases, must manage time efficiently and distribute resources accordingly. Parkinson's rule says that a task can be completed only within time planned for its implementation. (Goldblatt, 2005) If this is not the case, chances are that they generally will not be realized at all.

In order to understand scheduling multiple events first it is necessary to understand how to schedule one. There are five steps, shown on the figure given below. (Tum, Norton, & Wright, 2006)

Figure 3: Scheduling an Event

Source: Tum, J., Norton, P., & Wright, J. N. (2006). *Management of Event Operations*. Management (p. 304). Elsevier Ltd., Oxford, UK.

ECB is similar to PBS (Product Breakdown Structure). The event is divided into units which can be managed independently, each directly related to defined event objectives. ECB guides management and also gives stakeholders some insight into the entire process. (Tum et al., 2006)

Activity Analysis - a more detailed stratification of the event, intended for assistance in defining resource requirements – type and amount of resources needed, is there a need for additional resources, needed suppliers, the role of the organizer, etc. This phase is also assisting in drafting budget.

Determining the order of activities - This step can be viewed as a critical path analysis. (Tum et al., 2006) Given the fixed date of an event, bottom-up approach is applied by examining interdependences among activities.

Time schedule and resource allocation – When all activities needed to be done for successful realization of events are defined, determined resources are allocated and based on resource availability, time for performing each activity is defined, as well as for the entire project. Given the budget and resource limitations it is important for resource utilization to be optimized and efficient.

When it comes to multiple events environment the procedure for resource allocation and scheduling is the same except that the agency must take into account the needs of other events managed simultaneously. Resources are distributed among events based on their pre-defined priorities, as with project management. The broader the portfolio of events is and more diversified those events are more complex is the need for resources. Even though, the most important resources in event management are people. Optimized use of resources when speaking of events assumes no idle time, minimum amount of time spent in meetings with clients and time spent that way used efficiently. Event management is also specific for its wide use of insufficiently experienced resources such are volunteers and temporary staff. It is necessary that less qualified resources are allocated intelligently, on less demanding jobs and under supervision.

Once the activities are entered in MS Project BBNCM calendar is defined with all vacations and extra working hours (during conferences). After defining the calendar, dependency connections are defined between activities (start-start, finish-finish, etc) and then to each activity appropriate resources are assigned. First responsibilities are assigned to employees of the Agency. Problem of preoccupied resources is sorted out with thorough examination of exact hours needed to do a certain job. Even though one day is assigned for certain task, it does not mean that the resource will be engaged for the total of 8 hours. Certain activities are spread on several days in order for few less occupying but relatively urgent jobs to be done. For several urgent jobs requiring no special skills, for example packing promotional leaflets in envelopes, part-time resources are hired in phases of great occupancy of regular resources.

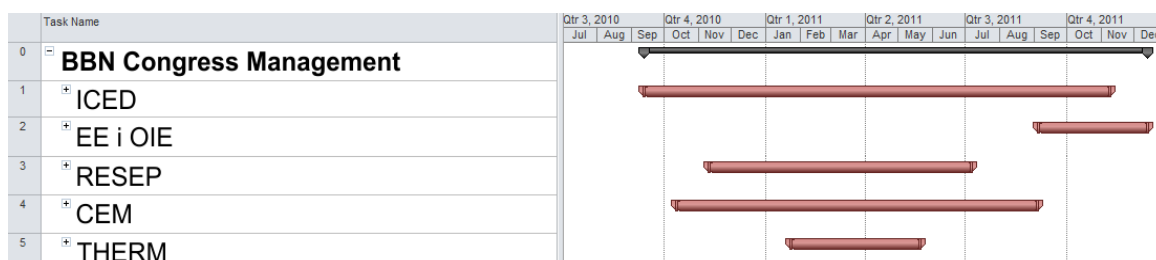

Figure 6: BBNCM 2010/2011 Portfolio Gantt chart

Positive effects of multiproject management concept application in BBNCM: The whole portfolio takes 321 days. For the organization of ICED conference 295 days are needed. Two other conferences being smaller in scope require less time, CEM 222 days and the RESEP 156. EE&RES takes only 76 days and THERM 85. Although there are only few critical activities, others are of lower flexibility given that one follows another and all together lead to realization of a conference that cannot be rescheduled. The entire portfolio would normally take around 800 days, superficially speaking, so by applying the MMC the rough estimate of the amount of time needed is reduced for around 500 days. Normally the agency would not be able to accept this amount of job, so by applying MMC, it was able to accept more events than it

would normally be possible. Simultaneous organization would be possible by hiring many additional resources, or with existing resources working extra hours, so by detailed planning the expense of both situations is avoided. As all activities were performed in due dates, with high quality service, realized profits, except in the case of THERM, expectations of all clients and participants were met, even exceeded.

4.3. Managing risk in EM

An important part of multiproject environment is to pay attention to possible risks that may create problems with defined event plans. Risks aren't 100% avoidable but by applying principles of multiproject management – predict risk, possibility of occurrence and possible answers - the possibility of occurring can be reduced at a minimum.

As it can be seen from previous paragraph, the greater the event the earlier planning processes begin. As ICED is a conference of 800 attendees, it is necessary for the venue to be extremely spacious, and as in Serbia there aren't many possibilities for events of these magnitude, it is important that an adequate venue is pre-reserved even before closing the contract with the organizer. BBN usually makes a pre-reservation of venue a year and a half before the event and couple of months before closing contract with the organizer. Also, another important aspect for every event is never being 100% certain of the number of participants that will register and sponsors that will be drawn. In order to avoid high expenses with insufficient revenues to cover them, numerous steps are taken. It is important to recognize all possible reasons for this occurrence and avoid them, and if impossible, reduce expenses where possible – cheaper attendee's bags, conference proceedings on a CD, not printed, cheaper gala dinner menu, less social activities included in registration fee, require foreign participants to apply in advance for which lectures will they attend in order to limit simultaneous interpretation costs, etc.

4.4. Implementation and reporting (event closing)

Implementation of the events referred to as event coordination represents integrated realization of various activities in order to meet all operational and logistical requirements of events based on a defined set of plans made previously. Operational requirements are those elements that must be carried out before the event and logistical requirements represent activities to be carried out on-site. After each significant event different reports are made of informational and promotional character intended for organizers, present and future participants, sponsors and others. Closing and financial reports are intended for government authorities and organizers of the conference. There are reports produced during implementation for internal use, and event organizers.

5. CONCLUSION

Convention industry is a modern life product and includes a number of different institutions joining efforts in improving event organization and making realization of event objectives possible, such are hotels, tourist organizations, venues, exhibition halls, service providers (catering, technicians, printing), etc. In the past decade the amount of business travels increased 53% compared to previous years and there's a belief that until 2020 the share of international conference tourism will rise up to 45% in total tourism income. (SEE Business Travel & Meetings, 2010)

Numerous PCO associations exist worldwide. IAPCO - The International Association of Professional Congress Organisers is the best known and of widest recognition, accepted as a leading authority and universal standard of quality. (IAPCO, 2009) The fact is that within IAPCO no members from Serbia exist, except Sava Center, while also the number of members from other countries of the region is very limited. (IAPCO, 2009) The reason is that only few agencies possess the capacity to manage organization of major international events, whose organization is one of the preconditions for joining IAPCO.

Given the good conditions of the region to become a European destination for conference tourism such as location, value for money, growing infrastructure, unexplored beauties, in addition to the large profits convention industry can make and improved international reputation, it is useful to invest in development of all aspects of this industry, including among others, event management agencies. (SEE Business Travel & Meetings, 2010)

Organizations with systematic and serious approach to event management positively affect development of the entire meetings industry, although not being the only precondition. When efficient in their operations it enables them to create room for more events, even though not yet being sufficiently developed and employing a limited number of personnel. By managing more events, the organization allows itself to grow and develop and it becomes more professional and sophisticated.

Based on data provided by ICCA (International Congress and Convention Association), in recent years, Serbia and Belgrade have made a remarkable leap in the list of countries ranked by the number of meetings organized in country by international associations and organizations reaching 43 place in 2010, among 95 countries, with 46 international events. (ICCA, 2012) From 2001-2003 Serbia hadn't even been qualified for entering the list, due to below 5 international events organized.

Abstract: *In this paper, we discuss the implementation of an organized framework for selecting projects using a web-based approach. Project portfolio selection is a crucial decision in many organizations, which must make informed decisions on investment, where appropriate distribution of investment is complex due to varying levels of risk, resource requirements, and interaction among proposed projects. A “project portfolio” is usually defined as a centralized collection of projects managed jointly to enhance advantages to the organization or to minimize risk. From a technical point of view, within Project Server 2010, a portfolio of projects should be defined as a set of projects that share the same cost or resource constraints. This paper aims to present a model for evaluating the effectiveness of the project portfolio, the processes within the project portfolio, and the Project Web Access as a tool for implementing project portfolio management using a web-based approach. Furthermore, this paper presents results obtained by experts in the field, as well as future directions for the implementation of project portfolio management using a web-based approach.*

Keywords: *Project portfolio, Project Web Access, framework, selection, web-based approach.*

1. INTRODUCTION

This paper briefly sets out the challenges and problems facing the current project management practices, using web based approach for project portfolio planning, implementation and controlling. Projects today are far more complex than ever before. They involve larger capital investments, embraces several disciplines, widely dispersed project participants, a lot of stakeholders, tighter schedules, specific quality standards, etc. These factors coupled with high-speed developments in Information and Communication Technology have influenced project management practices to take a new turn taking advantage of newly developed management tools and new technology. Project portfolio management (PPM) is a set of processes used to support a business in conducting the mix of projects, which best fit the organisation's various needs. This set of processes includes the selection of projects an organisation conducts, maintaining the selected projects in portfolios, and periodically reviewing the mix of projects, to check whether the selection still supports the main business goals. Some of the drivers that create new trends in project management are: 1. Globalisation of the marketplace; many industries are facing a lot of pressure due to this factor. Tariff barriers are virtually falling and labour has become more mobile. 2. The economical forces; this factor may significantly affect the client organisation and subsequently can impact the initial objectives of their projects. 3. Increases in project complexity; project complexity has increased due to extent of scope and fragmented parties around the world having to communicate with one another for efficient project execution. The complexity of the projects is reflected by the large number of specialists who contribute to the decision-making process. 4. The need to achieve faster results with the given resources; this factor places severe time pressures on the entire project team. 5. Rapid changes to project scope to expand benefits; some scope changes take place very rapidly before even realising the benefits of the changes 6. New procurement practices; the emergence of new procurement practices changes the way the team members are interrelated. 7. Client sophistication; this has become a major driver for productivity improvements in construction.

2. RELATED WORK

The idea of a balanced portfolio is based on modern portfolio theory by Markowitz (1952). This theory has been adapted by strategic management literature in the 1970s, where different approaches were introduced by several management consultancies. Applied to project management the desired

* The paper is a result of research within the framework of Project No.179081, named: “Researching contemporary tendencies of strategic management using specialized management disciplines in function of competitiveness of Serbian economy”, which is supported by the Ministry of Education and Science of the Republic of Serbia

combination of projects is a balanced portfolio that enables a firm to achieve its objectives without being exposed to unreasonable risk. According to project management literature, a portfolio has to be balanced along a range of dimensions to provide the best value to the organization. (Meskendahl, 2010)

Linton described how Lucent Technologies have used data envelopment analysis (DEA) to rank the relative efficiency or attractiveness of their large portfolio of R&D projects based upon a comparison of established, company-standard sets of input and output measures common to all projects. He specifies measures of: product life cycle, intellectual property lifecycle, and required investment, while the corresponding output set consists of a three-figure estimate of the potential financial returns as measured by its net present value - pessimistic, most likely, and optimistic. Linton demonstrated that by evaluating Lucent's R&D projects using DEA, it becomes a relatively straightforward task to stratify portfolios of potential projects into three fundamental groupings: superior projects that can be readily accepted for implementation; inferior projects that should be immediately rejected from further consideration; and an intermediate project grouping needing additional management oversight and assessment before any final accept/reject decision. (Linton, Morabito, & Yeomans, 2007) Cooper prepared research with 35 leading firms in various industries and found the following key problems:

- The portfolio of funded projects does not reflect the business strategy. There are disconnects between spending breakdowns on projects and the strategic priorities of the business.
- The quality of R&D portfolio is poor. The success rates of funded projects are inadequate.
- The Go=Kill decision points are weak. Funded projects tend to take on a life of their own.
- There is a lack of R&D focus. Most firms confess to having too many projects for the limited resources available.
- Some firms admitted to having too many trivial projects, i.e. modifications, updates and extensions, but too few projects to yield major breakthroughs and competitive advantage. (Chien, 2002)

Beaujon suggests a mathematical formulation of an optimization model designed to select projects for inclusion in an R&D portfolio, subject to a wide variety of constraints (e.g., capital, headcount, strategic intent, etc). The model is similar to others that have previously appeared in the literature and is in the form of a mixed integer programming problem known as the knapsack problem. Beaujon suggests that the problem might best be formulated as a non-linear programming problem, but that there is a need for further research to determine an appropriate expression for the value of a partially funded project. In light of that gap in the current body of knowledge and for practical reasons, the linear programming (LP) relaxation of this model is preferred. (Beaujon, Mari, & McDonald, 2001)

In each budget cycle, the enterprise invests a certain percentage of the total R&D budget in each stage. Within each stage, the budget may be further invested into technical area programs. Second, the enterprise invests funding in specific R&D projects. This may occur at several different times during a budget cycle. Fundamental to the project selection problem is the ability to attach value to each project. To do this, one must be able to estimate its costs, its contribution to free cash flow after deployment, and the probability of its successful completion. Traditional approaches to R&D use discounted cash flow methods to compute a net present value (NPV) for a proposed project. A positive NPV means favorable consideration for funding. (Bodner & Rouse, 2007)

3. FRAMEWORK FOR PROJECT PORTFOLIO ANALYSIS

The following listing describes the goals which an optimization approach for the project selection problem should support: 1. Consider and limit the available resources/budget per timeframe; 2. Support "must-select" restrictions; 3. Take synergy effects into account; 4. Take logical relationships into account; 5. Maximize the overall strategic alignment value; 6. Support balancing of risk, project categories and return time; 7. Maximize potential portfolio return; 8. Provide possibility to define project starting timeframes. (Kremmel, Kubalík, & Biffl, 2011) Portfolio optimization is a process in project portfolio management that creates the best mix of projects, out of all potential candidates. Selection of projects, and optimization of projects can be conducted either manually or automatically. Manual approaches to select projects are for example the Analytic Hierarchy Process (AHP), Q-Sort, scoring models, and portfolio matrices. Commonly used manual approaches are based on some sort of direct comparison and ranking of the alternatives based on project data and individual preferences. We suggest eight steps for project portfolio selection using a web-based approach for selecting projects:

1. Data collection for the portfolio and the interpretation of these data
2. Prioritization of projects and programs
3. Determination of the optimal project mix that is consistent with the goals of the organization and coordination of the portfolio of projects, such coordinate projects to mix long and short term factors, the risk versus reward, research versus development, and so on.
4. Providing information and recommendations at all levels of the organization
5. Monitoring the implementation of projects and project portfolio performance analysis
6. Comparative analysis is performed for new opportunities compared to the existing portfolio of projects
7. The inclusion of new projects in the portfolio
8. The continued increase in knowledge base and evaluation of business benefits after the implementation of projects

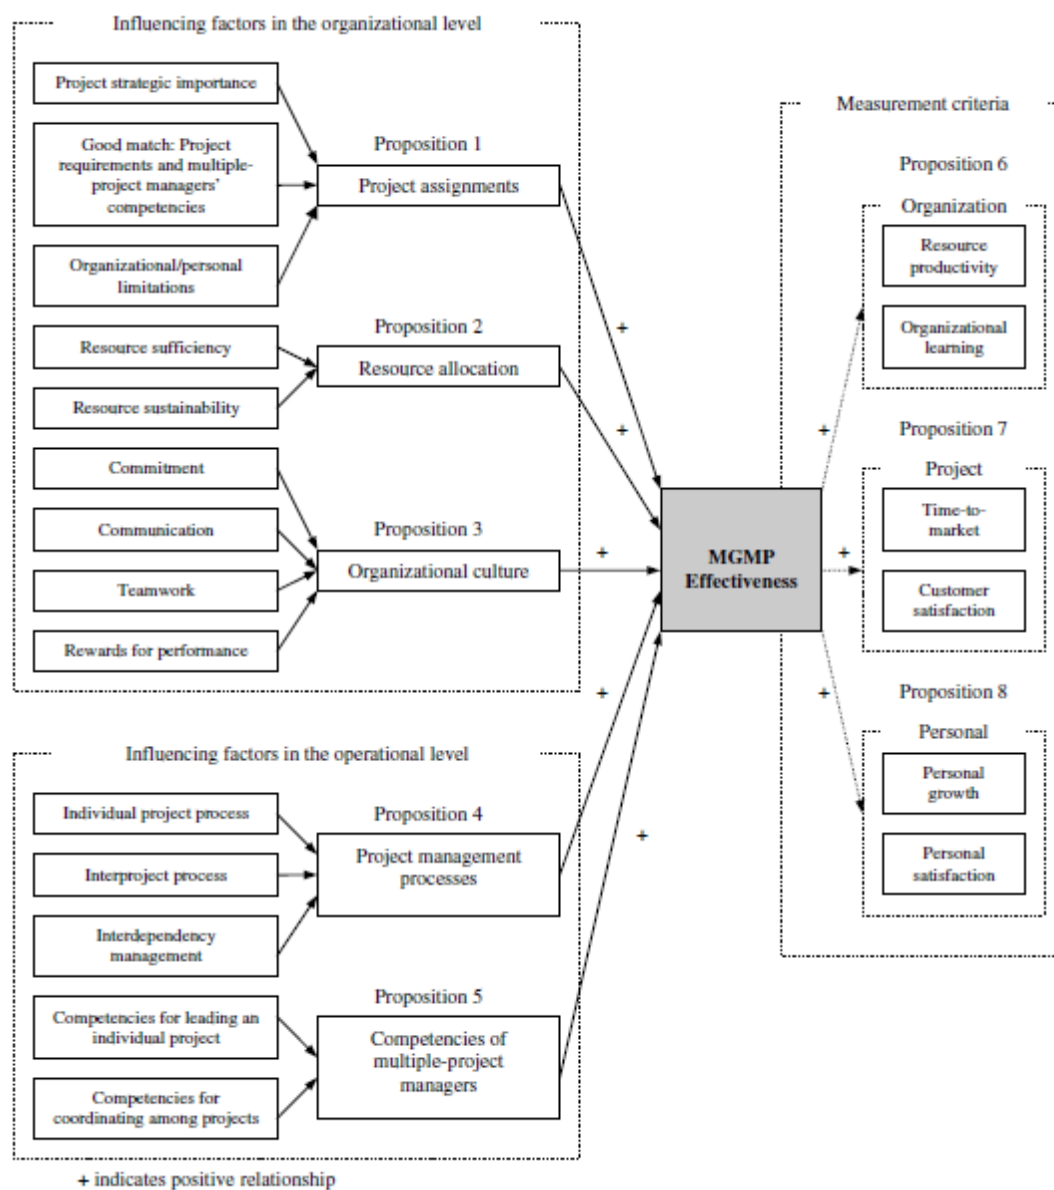

Figure 1: A framework underlying the effectiveness in the management of a group of multiple projects (Patanakul & Milosevic, 2009)

Proposition 1. The greater the consideration of project strategic importance, the good match between project requirements and competencies of multiple-project managers, and the organizational/personal limitations during project assignments, the greater the effectiveness in the management of a group of

multiple projects. Proposition 2. The greater the resource sufficiency and sustainability, the greater the effectiveness in the management of a group of multiple projects. Proposition 3. The greater the organizational culture cultivates commitment, communication, teamwork, and rewards for performance, the greater the effectiveness in the management of a group of multiple projects will be. Proposition 4. The greater the systematic management of individual project process, interproject process, and project interdependency, the greater the effectiveness in the management of a group of multiple projects. Proposition 5. The greater the multiple-project managers' ability to lead each individual project and to coordinate among projects, the greater the effectiveness in the management of a group of multiple projects. Proposition 6. The greater the effectiveness in the management of a group of multiple projects, the greater the resource productivity and organizational learning. Proposition 7. The greater the effectiveness in the management of a group of multiple projects, the greater the achievement of time-to-market and customer satisfaction. Proposition 8. The greater the effectiveness in the management of a group of multiple projects, the greater the personal growth and satisfaction. (Patanakul & Milosevic, 2009)

The success of a project portfolio management system is multidimensional consisting of the three dimensions of (1) process effectiveness, (2) portfolio success, and (3) portfolio-related corporate success, which will be affected by changes in the PPM system consecutively.

Table1: A multidimensional success framework for project portfolio management (Jonas, 2010)

Dimension
Effectiveness of the management process
Information quality
Allocation quality
Cooperation quality
Portfolio success
Average project success
Use of synergies
Strategic fit
Portfolio balance
Project portfolio-related corporate success
Business success
Preparing for the future

4. FROM IDENTIFICATION TO PROJECT SELECTION

In accordance with the product definition process, product portfolio identification involves a multistage process among customers, marketing folks, and designers. Portfolio problems often involve a set of characteristics, for example, risk and return of financial portfolios, or different kinds of benefits to be achieved by project portfolios. Portfolio problems with a set of criteria are often approached using compensatory methods. For example, additive aggregation and multiplicative aggregation of the local ratio preferences of each alternative into an overall preference are frequently used in multi-criteria decision making models. However, there are several practical situations in which non-compensatory approaches based on outranking relations seem more appropriate. This is the case if the decision maker has a preference structure which by nature is non-compensatory, or is unable or unwilling to establish trade-offs required to specify the parameters for compensatory methods. Such situations have been reported in several applications. Comparisons of the use of outranking procedure with multiattribute utility theory have been done for example in contexts such as risk analysis of natural gas pipelines and the selection of outsourcing contracts. (Vetschera & Teixeira de Almeida, 2012)

The front-end of new product development has caught the attention of researchers and companies. Some of the reasons for this interest stem from its strong impact on the success of new product development and its ineffectiveness when compared to other parts of the new product development process. Also, the front-end creates a link between business goals and the new product development process which makes it an important connection to achieve successful innovations. The activities of the front-end of new product development precede product design, determining product opportunities in terms of strategic goals, market needs and technological solutions. These, in turn, lead to product concepts and to projects to deliver these concepts. (Oliveira & Henrique, 2010)

Modern portfolio theory is a theory of finance which attempts to maximize portfolio expected return for a given amount of portfolio risk, or equivalently minimize risk for a given level of expected return. Return is measured by the expected value or mean of the probability distribution of payoffs for the stock or asset being considered. Risk is measured by the variance or standard deviation associated with that payoff distribution. The very reasonable assumption that investors and decision makers prefer less risk to more risk, all other things held constant. Unlike the decision maker who may characterize risk as that portion of the uncertainty that has “downside”, the standard deviation measure does not differentiate between “downside” and “upside” uncertainty. In this context, portfolio analysis based on standard deviation (as described by Markowitz) considers extremely high and low returns equally undesirable. As a further benefit, integrating portfolio management and the preference analysis approach enables the firm to incorporate their financial risk tolerance into the portfolio analysis and portfolio selection process. This step is generally intuitive to the decision maker who has an abundance of knowledge about the individual characteristics of the assets in the portfolio—and what financial risks he faces. (Walls, 2004)

Because of various uncertain aspects and circumstances involved in resources, technology, environment and competition, the decision of selecting new product development project can be regarded as a fuzzy multi-criteria group decision problem. By using the fuzzy method, the management would be able to make adequate decision based on incomplete and imprecise information under various kinds of pressure. Traditional quantitative methods such as mathematical programming and economic models require information of the target market, financial prediction, resources availability and decision timing, which are all unreliable and imprecise; consequently, the decision made would be in great suspicion. The classical logic focuses on duality of yes or no, and most discrete events are solved using traditional means. Therefore, the value of outcome can only be classified as zero and one (binary programming). Obviously, when an event is with value of outcome between zero and one, the duality cannot be applied. Event of this kind is called continuous event and can be solved by fuzzy theory, which measures the relationship between element and set using membership function, and the result is the degree of membership. (Wei & Chang, 2011)

5. PROJECT WEB ACCESS AND PORTFOLIO SELECTION

Portfolio Analysis within Project Server is treated as a separate technical module, with its own data tables within the Project Server databases. Project Web Access is the interface (web page) to the user, providing information about projects and portfolios. Each analysis is created as a separate data entity within the Project Server database. There are a very large set of possible constraints, which can be invoked through constraint equations. A guarantee that each project, if selected, will not start twice during the planning horizon:

- Maximum expenditures will not exceed specified amounts in each of a set of time periods,
- Other resource demands, such as personnel or facility requirements, must not exceed the amount available in each time period,
- All of the projects selected must be completed within the planning horizon,
- Precursor projects must be completed before successor projects start,
- Certain projects are mandatory and must be scheduled,
- Only one of several mutually exclusive projects can be chosen. (Ghasemzadeh & Archer, 2000)

The same project may exist in multiple portfolio analyses simultaneously. This is important when reviewing some of the user questions that have already appeared in the newsgroups on the topic. For instance, one of the frequent questions observed has been “How do I report on the priority of each project within the analysis?” The priority will not appear in any of the project tables. Instead, the priority is flagged to each project on a scenario by scenario basis, and is stored in the analysis tables. One project may have multiple priorities, each one in a separate analysis. In Project Server 2010, the first step in preparing to analyze projects within the Portfolio Analysis module is to define and rank the specific business drivers that will be used to assess the strategic value of the Project and programs. Second step is to perform pairwise analysis on the driver set to identify relative priorities. In pairwise analysis, the drivers are not assigned objective values, but are instead compared with other drivers to develop a relative ranking. Thus, the drivers must be compared to each other to develop a prioritization matrix. Typically, an organization would implement a driver prioritization for each portfolio of projects defined.

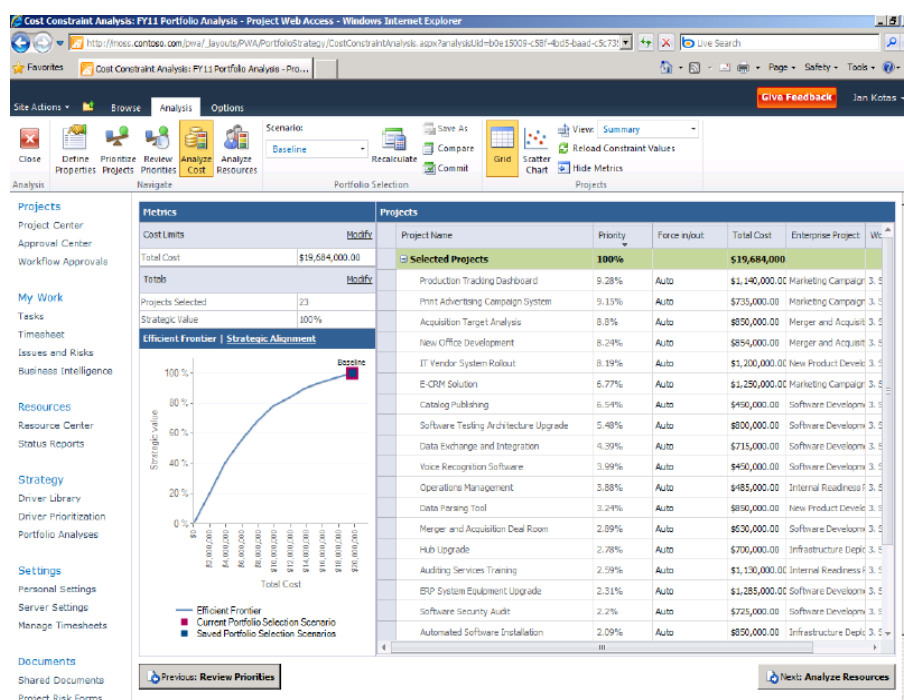

Figure 2: Project Web Access – Cost Constraint Analysis view (Enterprise Project Management Solution Guide, 2009)

6. IMPLICATIONS ON DECISION MAKING

The objective of this paper is to have a better understanding of the elements that contribute to the impact of a Project Web Access and project performances. The study results are discussed in terms of direct and indirect effects on PMIS project success. To ease the discussion, the elements are grouped in three dimensions: technical (PMIS quality and quality of information), managerial (PMIS use and impact on project manager), and organizational (PMIS impact on project success. First, it is worth noting that a reverse or “feedback” relationship is possible between individual impacts of a PMIS and its use. As project managers perceive the PMIS to be beneficial to them, it is likely that they will increase their use of the system. Second, other dimensions of project management, related to the organizational environment, evidently play a role in explaining project performance; thus the managers’ authority on project activities, their involvement in project design, and their accountability in meeting project objectives are potential success factors other than the PMIS. Third, another interesting aspect to consider is the possible reluctance of project managers to report “bad news” on a project, and the subsequent effect it could have on the accuracy of project reports and on the assessment of project success. Future studies of PMIS success could evaluate project success or performance from the client’s perspective, that is, evaluate if the impacts of the PMIS on project outcomes provide an adequate solution to the client’s problem, bring true advantages to the organization in terms of quality of product/services offered, greater output volume, quicker delivery, and better strategic positioning, and provide tangible benefits such as increased sales and revenues. (Raymond & Bergeron, 2008)

A summary of changes in the IT project context that change the demands made upon project managers, and a more extended description of changes in project management and the mindset they exemplify. The first change is the increased strategic and operational importance of IT projects. They are no longer confined to the back-office. Their success has a direct connection to the success of the business. Consequently, projects are more exposed to changes in the competitive environment. This contextual change implies that during a project’s life more change is likely to occur and will therefore require adaptation to the project plan. Second, speed of change arising from intensified competition requires businesses to respond faster. Time becomes more critical for projects that affect business outcomes, for example through expediting or delaying product launches. This implies compressed project schedules and more agile methods because of the demand for shorter lead times to delivery. Third, clients increasingly see IT as an investment from which they seek a return comparable to that for other investments. In seeking value for money, clients press project managers to achieve better ROI. These pressures

encourage a greater focus on value and a willingness to innovate in order to meet otherwise unachievable demands. Fourth, clients are seen to have matured in their understanding of IT projects. This maturity reveals itself in a greater understanding of the complex issues that confront IT projects and, therefore, a deep skepticism about the ability of IT departments and suppliers alone to deliver value. (Sauer & Horner Reich, 2009)

There is also growing acknowledgement of the critical role of the project manager and a willingness to treat the project manager as a key player. This is particularly apparent among IT services companies but is also apparent in organizations that retain in-house project management. (Sauer & Horner Reich, 2009) This encourages project managers to invest in their own future and that of their organization by experimenting with new project management practices and focusing on personal development. In short, expectations of projects are more ambitious, the job has got tougher, and the requirement for delivery is tighter in terms of business value as well as cost and schedule. Together these drivers require project managers to explore new ways of thinking. We refer to the combination of these principles and qualities as the new mindset:

- Focus on ultimate value.
- Deep personal identification with project goals.
- Investment in trust.
- Devolved, collective responsibility.
- Willingness to continually adapt.
- People development.
- Learning orientation.
- Creativity and innovation.
- Proactive view.

Our research model links PMIS information quality to decision making quality. Project and information overload are considered to influence PMIS information quality, while satisfaction with and use of PMIS, together with PMIS information quality, influence the quality of decision making. PMIS have become “comprehensive systems that support the entire life-cycle of projects, project programs, and project portfolios”. They can support project managers in their planning, organizing, control, reporting and decision making tasks, while evaluating and reporting at the same time. Studies have shown that there are several important factors that encourage project managers to use PMIS. First, whether or not project managers will use PMIS strongly depends on the quality of the information generated by the PMIS. Second, project managers are more eager to use an information system if it provides them with the appropriate level of detail in relation to their needs. Third, it is important that the information generated is free of complexity, easy to understand and easy for project managers to share with the project team's members. Fourth, PMIS facilitates continuous monitoring of progress. We point out some important features.

- Information overload has a negative impact on the PMIS information quality in a multi project environment.
- Greater PMIS information quality is associated with more adequate decision making in a multi project environment.
- Greater PMIS information quality is associated with greater satisfaction of the project manager with PMIS in a multi project environment.
- Greater satisfaction of the project manager with PMIS is associated with intensified use of PMIS information in a multi project environment.
- Intensified use of PMIS information has a positive impact on the quality of decision making in a multi project environment. (Caniëls & Bakens, 2012)

7. CONCLUSION

The selection of projects in which an organization invests its resources is an important strategic function. Inevitably, it involves the tradeoff of many competing constraints: basic research, customer driven research, budgetary considerations, workforce skills, etc. First of all, the details that differ between organizations include some common goals: the harmonization project mix between basic and applied research, encouraging creativity while trying to achieve the objectives, linking research and development with internal and end-users, measure out research and development in terms of importance the organization itself. Challenges in an attempt to achieve these objectives include: conducting research and

a long period of development functions, and specialized research and development skills that limit the transferability from one project to another. The proposed framework guides the construction of measuring scales of the various portfolio attributes and facilitates possibly required tradeoffs among the portfolio attributes. The contribution of this framework resides in creating the taxonomy that describes the different functional relationships between the portfolio attributes and the contributing project attributes. Nevertheless, the development of appropriate methodologies for constructing measuring scales of the various portfolio attributes, to certain extent, is problem-specific and indeed another research topic. It is useful to derive results from the implementation in more specific situations that should lead to the identification of the limitations of this framework and the circumstances in which this framework can be applied. Further research is also needed to develop various instruments to assess the required inputs for evaluating alternative portfolios. The instruments should be improved so as to maximize the reliability and validity. Dealing explicitly with the project interrelation will encourage communication and interaction of different project teams. A generic taxonomy of interrelationships is needed to deal with different types of project interrelations in portfolios. In addition, to fill the gap between theoretical development and empirical applications, portfolio selection approaches for selecting projects should also be able to serve a mechanism for asking questions, collecting information, sharing opinions, and facilitating interdepartmental communication. That is, an effective R&D management system to assist the decision makers in prioritizing projects and managing an optimal portfolio of R&D projects is needed. Until the proposed framework is tested for the practical utility, this research offers merely novel ways of thinking about R&D portfolio selection issues.

Abstract: *Project success has been widely discussed in the project management literature. Great number of research papers deal with dimensions of project success, measuring matrix and factors that influence project success. Traditionally, project success criteria are defined as time, cost and quality. It is difficult for various authors to reach a consensus about project success criteria, but many studies have expanded project success criteria into other aspects, including stakeholders satisfaction, organizational objectives, future potential to organization, etc. This paper offers a presentation of three different perspectives (mostly accepted in literature and applied in project practice) for measuring project success. The first of them is based on stakeholder analysis, concerning different perceptions of different interested parties of project success. The second one looks into project life-cycle phases and the “owners” of these phases in order to define key performance indicators and assess project results. The third one is a value-centred proposal for assessing project success with defined two key concepts: the net project execution cost (NPEC) and the net product operation value (NPOV), as well as a developed scheme for measuring project success based on them. The paper also provides a summarising review of main characteristics of those three concepts, with their advantages and disadvantages. Different perspectives of project success indicated that as there are different needs and different goals of any given project, success measurement should also be tailored for each project.*

Keywords: *project, project success, stakeholders, project life-cycle, value-centred approach.*

1. INTRODUCTION

Project success/failure is multifaceted and hard to measure. It is usually measured according to the previously set objectives and indicators or comparing the situation before the implementation of a project to the situation after the project. (Olsson et al., 2010). Assessment of the success and efficiency of the completed project is very important, particularly to develop “lessons learned” that can help in management of future projects. The focus of most studies of project success is on dimensions of project success and factors influencing project success.

A useful starting point for considering the project success and the importance of its measuring is making the distinction between project performance and project performance management. Performance represents project’s results, while project performance management represents a usage of performance measurement results to:

- achieve positive change in organizational climate and business processes,
- level resources,
- inform top management about the need for a change of strategic objectives and
- achieve effects of the systematically stored experience of the project (lessons learned) that is transmitted through the organization, creating new knowledge as a basis for continuous improvement.

Prior to the 1980s it was common to focus exclusively on project performance, which was defined narrowly as meeting cost and time and quality objectives. Researches during 1990s aimed at investigate project success dimensions has led to common agreement that project success is multidimensional and that different people measure project success in different ways at different times. (Bryde, 2003) Developments in the project management discipline suggest that new models of project performance need to reflect the “multi-dimensional/multiple-stakeholder/quality of process as well as product for defining success. (Bryde, 2005)

* The paper is a result of research within the framework of Project No.179081, named: “Researching contemporary tendencies of strategic management using specialized management disciplines in function of competitiveness of Serbian economy”, which is supported by the Ministry of Education and Science of the Republic of Serbia

Cookie-Davies (2002) pointed out a difference between project success and project management success. Project is successful if overall objectives are achieved, yet project management success is measured against the widespread and traditional measures of performance - cost, time, and quality. A project can be viewed as "successful" despite poor project management and vice versa. For example, a project might be delivered late and over budget, yet it might lead to an increase in the capability of the organization to better manage future projects. Project management cannot succeed unless the project manager is willing to employ the system approach to project management by analyzing those variables to success or failure. (Kerzner H, 2003)

Cookie-Davies (2002) also highlights the difference between the success criteria and success factors. Success factors contribute to achieving success on a project, identifying what is necessary to meet desired deliverables. On the other hand, success criteria are the measures by which the success or failure of a project will be judged. Factors constituting the success criteria, presenting internal measures or metrics that can be reviewed on a periodic basis throughout the life cycle of the project (Kerzner, 2003) are known as key performance indicators or KPIs. Key performance indicators are the compilations of data measures (either by quantitative or qualitative data) used to assess the performance of the project. (Toor & Ogunlana, 2010)

2. STAKEHOLDER'S INFLUENCE ON PROJECT SUCCESS

During the last two decades of previous century, researches have been pointed out that success criteria of project evolve new dimensions. Traditional view of project success was meeting time (schedule), cost (budget) and specification (quality), but the „iron triangle“ was criticized in by many for many reasons (Shenhar et al. 2001) (Gardiner & Stewart, 2000) Evaluation of project success, by the dissimilar interested parties (stakeholders), in different times, can be done in diverse ways. According to PMBOK project success criteria shall include the golden triangle and satisfaction of key project stakeholders. Many researchers came to the conclusion that project is considered successful only if it meets their quality criteria.

Although project stakeholders have been defined in numerous ways, the most common definitions view project stakeholders broadly as any group or individual who can affect or is affected by the project. In PMBOK, stakeholders are defined as individuals and organizations that are actively involved in the project or whose interest may be affected as a result of project execution or project completion. (PMI, 2004) It is widely agreed that a project has many stakeholders, whose interest may be related or in conflict. Considering increasing influence of stakeholders, a new focus in the project management literature is on the development of models that apply the theory of the interested parties, their classification and their inclusion to the project environment. (Qureshi et al., 2009) Stakeholder theory provides a solid standing point for identifying, classifying and categorizing stakeholders and understanding their behavior in order to better manage them, and to define key performance indicators as measures that are used to assess the project performance.

Crucial stakeholders are internal stakeholders - members of the project team, other employees in the organization, top management in the organization (who usually support the project). It is very important for internal stakeholder to be aware of how project success is defined, and what are key performance indicators. This highlights the importance of communication quality between team members and other employees in the organization, the method of knowledge transfer, and delegation of responsibilities. Anbari et al. (2008) pointed that organization structure reflects the type of organizational culture that holds away and also tackling information flow, knowledge transfer and overall organizational culture. Choice of a project organization structure should consider the above balance between all stakeholders. (Figure 1).

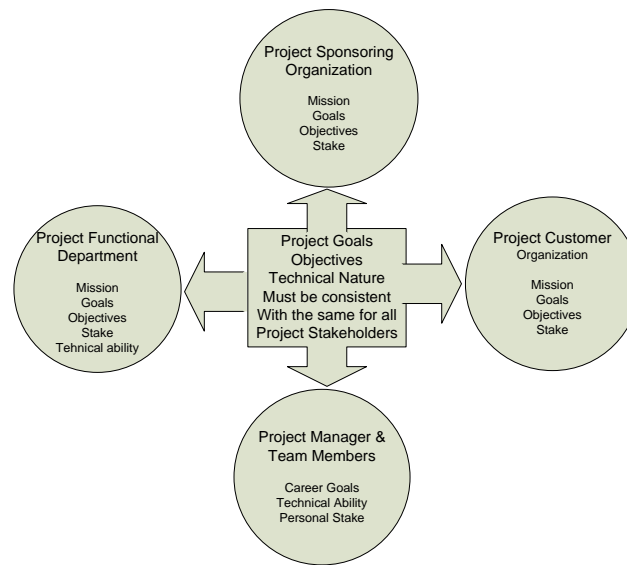

Figure 1. Projects and stakeholders interests (Anbari et al., 2008)

3. PROJECT SUCCESS PERCEPTION TROUGH PROJECT LIFE-CYCLE PHASES

When considering project success criteria, it is essential to be clear of how we defined project. Do we use a product oriented definition, according to wich “*a project is a temporary endeavor undertaken to create a unique product or service*” (PMI, 2004 p. 5); or objective oriented definition in wich project is conducted to deliver beneficial objectives of change? Depending of definition key performance indicator can be differently defined.

Beside that, Yu et al. (2005) looking at the key performance indicators in relation to the phases of the project life cycle. Every project has certain phases of development known as life-cycle phases. A clear understanding of these phases permits managers to better control resources to achieve project sucess. The teoretical definitions of the life-cycle phases of a system can be applied to a project. These phases include: conceptual, planning, testing, implementation, closure. (Kerzner, 2003)

Some organizations have established policies that standardize all projects with a single life-cycle, while others allow the project management team to chose the most appropriate life cycle for the project.

Project life cycle can be very general or very detailed (Figure 2). One of the common characteristics for most project life cycle is that cost and staffing levels are low at the start, peak during the intermediate phases, and drop rapidly as the project draws to a conclusion. (PMI, 2004)

Figure 2. Project life-cycle (PMI, 2004)

When people work in an project-oriented organization or in environment where program and portfolio management practices are used, they need to understand how project success is defined and how it is measured, particularly in terms of the project and product life cycles, because project success is aggregated in program or portfolio success. Looking at the basic life cycle stages, we can see the difference in what the "owner" stage (shown in Table 1).

Table 1. Project/Product lifecycle stages and milestones (Yu et al., 2005)

	Project lifecycle	Product lifecycle	Owner/Actions
Stage 1	Project conception	Product feasibility	The client organisation, assisted by specialists
Milestone 1	Project commitment	High level product requirement produced	The client commits to the project and appoints a project team
Stage 2	Project execution	Design, development or acquisition	The project team (the prime contractor assisted by subcontractors)
Milestone 2	Project closure	Product created	The project team delivers the created product to the client
Stage 3	N/A	Product operation	The client organisation, possibly transferred to a customer/user

In relation to the "owners" key performance indicators can be defined. This approach is using product-oriented definition. As shown in Table 1, the project team might be considered to own Stage 2 (stage 2 has been referred to as the project in the "micro" sense). On the other hand, client owns Stages 1 and 3 directly.

The ownership changes are associated with project milestones. Each milestone is marked by actions performed by the owner of the previous stage. At Milestone 1 after Stage 1, the client commits to the project and appoints a project team. The ownership for the Stage 2 is passed on to the project team. At Milestone 2 after project execution (Stage 2), the project team delivers the created product to the client. The project is completed but the product lifecycle usually continues. The client has the ownership to operate or dispose (for example sell).

4. VALUE-CENTRED PROPOSAL FOR ASSESSING PROJECT SUCCESS

A typical project can be viewed as an investment. As such, the project consumes resources during execution phase. All benefits from the project are materialized in stage of product operation. It is very useful to separate project cost and product value to reflect the project/product life cycle reality. Value-centred proposal for assessing project success is defining two key concepts: the net project execution cost (NPEC) and the net product operation value (NPOV), and presenting scheme for measuring project success based on them. Net project execution cost - NPEC is defined as difference between the cost that has client minus benefits accrued to the client during project execution. If C_{project} means all project costs and B_{project} means all benefits realized in the project execution, we have

$$NPEC = C_{\text{project}} - B_{\text{project}} \quad (1)$$

Net product operation value NPOV captures all the benefits a client derives from the created product during product operation ($B_{\text{operation}}$) minus any associated operational cost ($C_{\text{operation}}$):

$$NPOV = B_{\text{operation}} - C_{\text{operation}} \quad (2)$$

NPOV may include less tangible benefits (strategic benefits, competitive advantages, etc.) and less tangible costs (e.g. negative externalities), and it is limited to product operation only. The separation of project execution and product operation is important in providing a meaningful measurement of the project in the “micro” sense. (Yu et al., 2005)

If C_o is the estimated value of NPEC, and V_o is the estimated value NPOV, the project will be acceptable for the client if $C_o < V_o$, and vice versa.

5. CONCLUSION

Traditional approach shows that a general framework can be used as a guide to measure the success of a project at macro and micro levels. Iron triangle (on time, under budget, according to specifications) has been widely accepted criteria during last couple of decades, but it was also criticized. As we can see from previous sections of this paper, different perspectives of project success indicated that as there are different needs and different goals of any given project, success measurement should also be tailored for each project.

As Table 2 shows each of those perspective has some advantages, that make them suitable for some type of projects, yet they have some disadvantages.

Value-centered approach does not consider different perspective of different stakeholder, but this approach gives a matrix to measure project success, which is the main distinction comparing to other approaches presented here. Stakeholder analysis takes into account different interests of different parties involved in a project and their perceptions of project success, but it is not giving an answer on how to measure project performance and how to assess project results. Using project life-cycle concept to evaluate project success is something between those two. In some way it considers stakeholders, not all of them, but the most important one (client and project team including contractor assisted by subcontractors) looking at main phases of project life-cycle and its „owners“.

Those perspectives can be seen as complementing rather than as mutually exclusive. Project success perception through life-cycle phases can be extended including other stakeholder analysis. In addition to the client and project team other interested parties (stakeholders) should be considered when defining key performance indicators. Looking at the value-centred approach, if there are many interested parties (stakeholders) to enjoy the effects of the project, it should not be a problem as long as the effects are uniformly distributed; otherwise their interest must be considered. Many projects create a series of external effects (positive or negative) that affect third parties who are not directly involved in the project. That initiated the need for calculation of all cost and benefit from their point of view and consideration of their interest for making realistic assessment of project success.

Table 2. Main characteristics of different perspectives of project success

	Stakeholder's analysis	Project life-cycle	Value centred approach
Link with project definition		✓	
Developed the scheme for measuring project success			✓
Considering organizational structure and organizational culture,	✓		
Adopting the single cost-value dimension for assessing project success			✓
Defining project stages and its owners to		✓	

examine project success criteria			
Considering information flow and knowledge creation	✓		
Considering different perceptions of project success of different interested parties	✓	✓ / -	

Assessment of project success should be a vital part of project management, as it presents a significant contribution to project management improvement, and a great source of knowledge for future projects.

MANAGING GLOBALLY DISTRIBUTED INNOVATION PROJECTS: CULTURAL DIFFERENCES AND CONFLICT RESOLUTION (REFLECTION ON PROJECTS EXPERIENCE)

Stevo Pavićević

MSc in Global Innovation Management, Department for Design, Manufacture and Engineering Management, University of Strathclyde, Glasgow, United Kingdom, stevo.pavicevic@strath.ac.uk

Abstract: *This paper identifies the impact that cultural differences have on conflict resolution in globally distributed innovation projects. The aim of the research is to discover potential relationships between different conflict management strategies and diverse cultures. The main hypothesis is that cultural differences are being expressed in project teams during conflict situations. The paper consists of two main parts. After the literature review, the results of Thomas-Killman test for all project team members (including eight countries: Australia, China, Malta, Philippines, Mexico, Columbia, India, Indonesia) are presented and then compared with the results from previous researches in this area. As a conclusion, a reflection is offered on how cultural differences affected the conflict resolution in IKEA UK and WAUDBY's design projects.*

Keywords: *innovation projects, global design, cultural differences, conflict resolution strategies*

1. INTRODUCTION

Rapid changes that have happened during the last twenty years, mainly as a part of the globalisation process, lead to the increased cultural diversity in companies. Besides, the development of information and communication technologies created a platform for working virtually in distributed project teams which members can be spread all over the world. There is more and more global projects launched every day and there are many factors that influence the complexity of these projects. One of the key issues is cultural diversity.

Different cultures have different systems of valuing what is acceptable and what is unacceptable behavior. This means that nations have diverse standards which can cause significant gaps between project team members. The fact that differences among multicultural project team members are more emphasized makes more space for conflict situations. Even though there is a lot of well known conflict resolution strategies, application of any of them should be considered with taking into account cultural differences that may exist among team members. Cultural differences may, and probably will affect the conflict overcoming process.

The purpose of this research is to examine how cultural differences affect conflict resolving processes, how different national cultures approach conflicts and which resolution strategies are the most widespread. The flow of the paper is as follows. Firstly, a short literature review of culture, conflict management and conflict resolution strategies is presented. This is followed by presenting the Thomas-Killman test-based research methodology used for discovering conflict resolution strategies among team members of two global innovation projects. In total, ten members from eight different countries were examined. The results are then compared with some of the previous researches in this area in order to check how individual profiles of team members fit into their national culture's profiles. Finally, the reflection of the results on project teams' performance is presented.

First project conducted in IKEA's UK branch was aimed at the design and development of a new, innovative package for a specific product line of wine glasses and was performed by University of Strathclyde from United Kingdom in cooperation with Tongji University from China and Swinburne University from Australia. The aim of the second project was design of an innovative faucet. This global design project was executed by University of Strathclyde in cooperation with University of Malta.

One of the limitations of the study is that it included only one or two national representatives which may not have typical profiles as the majority of the population in a country. Personality can have a strong influence to conflict management which is why it can be very hard to make a strict distinction between cultural and personal aspect of conflict resolution approach. Furthermore, the validation of the results from previous research that are used for comparative analysis has not been done. Besides, in order to have more reliable results more people should have been tested. However, the opinion of an author is that, for

the purpose of this paper in which the reflection of the experience obtained from the two above-mentioned projects should be shown, the conducted survey is completely appropriate.

2. CULTURE

The etymology of the word *culture* can be found in Latin word *colere* which can be described as *to cultivate*. Over the time, many definitions of culture emerged. One of the most well-known definitions, given by the most important author in this field, states that culture is *the collective programming (thinking, feeling and acting) of the mind which distinguishes the members of one group or category of people from another* (Hofstede, 2001). In addition, Hofstede also defined three levels of culture: individual, collective and universal. Taking into account the fact that almost all the aspects of his work were cited many times and the purpose of this research, no deep analysis of his work will be presented. Beside Hofstede, many authors contributed to this field of study. Trompenaars was, for example, examining different dimensions of culture including: universalism vs. particularism, individualism vs. communitarianism, specificity vs. diffusion, affective vs. neutral, achieved status vs. ascribed status, internal vs. external control and sequential time vs. synchronous time (Trompenaars, Hampden-Turner, 1997). On the other hand, Hall (1996) was trying to analyze culture through three different variables: time, context and space. In his work, he was mainly focused on discovering the differences between monochronic and polychronic cultures.

No matter whose work or which research one takes as a base, one thing should be always kept on mind: different cultures should be respected, but in the same time, it should not be allowed that they become a barrier for any kind of communication or cooperation. According to (Lather et al. 2010) all the people on the planet are fundamentally the same, but it is the culture that makes the differences among them. By forming their own culture in order to meet different needs, wishes and objectives, people are actually distinguishing themselves from other groups of people. Those cultural differences are especially emphasized in the multi-cultural environment. Working in an international project team for example, brings many challenges and overcoming the cultural differences is one of the key issues. This does not mean that one should give up his cultural background, but that cultural differences should not be the obstacle for team performance and goals fulfillment.

Being aware of cultural characteristics of numerous countries allows us to better comprehend the way that people from different parts of the world think, behave, feel and what their expectations are. This is specifically important for effective cooperation in multinational project teams. Different studies trying to point out main influences that culture has on project teams' performance were conducted. Samarah et al. (2002) pointed out main links between culture, conflict resolution and project team performance. Similar research about culture and conflict management styles of project managers was presented in (Mohammed, White, 2008). Research about main differences between individualism and collectivism and the impact they have on team cohesion can be found in (Freeman, Bordia, 2001). Furthermore, there are lot of studies investigating the relations between particular countries and different aspects of project management performance. For example, (Fletcher, Olekalns, 2005) pointed out key differences among Asia-Pacific region, while Mohammed and White (2008) were focused on India. Ulu and Lalonde (2007) conducted a research in order to find out differences between Turkey and Canada. Another important research that examined more than six thousand people from around twenty countries is presented in (Herk, et al. 2011).

Culture influences the majority of mental models of individuals (Hofstede, 2001 cited in Samarah et al. 2002). These models can be attitudes, personality, perceptions, beliefs etc. and they all affect the way we behave. Thus, the group efforts, interaction of members among teams and the level of success of a project team are partially determined by the behavior of the team members. If there is a divergence in behavior caused by different mental models, conflicts may occur. At this level, culture affects the way team members will perceive the conflict situation (Chan, 2010) but at the same time it will affect the way individuals would like to handle with the existing situation. There are many different approaches to conflicts and all at once various strategies which can be used for their resolution. The successful resolution lies in proper direction by project managers or team leaders. This is the point when conflict management starts playing the most important role. Therefore, the next few paragraphs will discuss more deeply key issues in conflict management as well as some of the key strategies for conflict resolution.

3. CULTURAL DIFFERENCES AND CONFLICT MANAGEMENT

There is a wide range of factors that affect the performance of the distributed project teams. The performance of a global team can be contingent upon time differences, collaborative technology used, project schedule, expected deliverables, but at the same time the homogeneity (heterogeneity) of the team in terms of the culture can significantly affect teamwork success. Moreover, cultural diversity can be the source of conflict situations. The explanation for this phenomenon was given by many authors from different disciplines. For instance, a group of psychologists including Watson et al. (1994) observed that culture exhibit various patterns of group interactions. This is why a culture can be considered as an obvious source of differences in the way humans behave. And conflicts are nothing but another trigger of a particular behavior.

Ting-Toomey (1985) defined conflicts as a *form of intense interpersonal and/or intrapersonal dissonance between two or more interdependent parties based on incompatible goals, needs, desires, values, beliefs, and/or attitudes*. It is interesting that, some other authors like Rahim and Magner (1995) used the same word – dissonance (within or between social entities), to describe the essence of conflicts. Generally speaking, any kind of clash between two or more persons or groups can be considered as a conflict. Transferred to the project management terminology, any kind of a disagreement between project team members which cannot be quickly overcome without interrupting the flow of the project should be considered as a conflict.

Conflicts have become inseparable part and parcels of our lives (Brahnam, 2005) and we are able to experience conflicts on a daily basis. The same author pointed out that conflicts are inevitable component of the human activity. According to Brett (2000) conflicts are unavoidable in all cultures, but over the time, every culture developed a different way of managing them. At the same time, the globalization process increased the number of interactions between people (Kaushal, Kwantes, 2006), which is why there is more space for conflicts to occur. Therefore, it is very important to understand the cultural differences in conflict management (Watson et al. 1994; Brett, 2000; Montoya-Weiss et al. 2001; Samarah et al. 2002; Brahnam et al. 2005; Mohamed et al. 2008; Thomas, Killman, 2010).

Different researches on the way cultural variations affect the conflict resolution strategies, of which some have already been referred to in this paper, have been conducted and the common conclusion is that there are significant differences in the use of strategies for conflict resolving. The question that naturally arises is, which conflict resolution approaches actually exist? Again, different authors have presented these approaches in several ways, but all of these can be summarized in five main conflict resolution approaches presented in (Thomas, Kilmann, 2007). These include avoidance, accommodation, competition, collaboration and compromise. Wood and Bell (2008) presented these approaches in a following graph.

Figure 1. Conflict Management Approaches (Thomas, Kilmann, 2007; Wood, Bell, 2008)

Avoidance is the approach that does not include actual dealing with the conflict. Instead of facing the conflict situation, there is the intentional avoidance of other members in the group while the project goes on as nothing is interrupting its flow. On the other hand, *accommodation* means higher concerns about the others' needs than the own needs of an individual. Completely opposite approach is *competition*, during which no concerns for the other team members is expressed. More interactive approach is *collaboration*, which means integration of needs and interests of all parties that are involved in the conflict situation. Often recommended as the best approach (but not for all situations) is *compromise* which occurs when the solution which addresses the interests of all members is found. For each of these approaches, Tsai and Chi (2009) have defined appropriate conflict resolution strategies which are, together with the main concerns, presented in the table below.

Table 1. Five Conflict Handling Strategies (Adapted from Tsai, Chi, 2009)

Behavioral Approaches	Strategic Attitudes	Concerns	
		Personal Goals	Disputant Relationships
Avoidance	Withdrawal	Low	Low
Accommodation	Soothing	Low	High
Competition	Forcing	High	Low
Collaboration	Problem solving	High	High
Compromise	Sharing	Moderate	Moderate

The selection of an appropriate conflict resolution strategy that matches the existing conflict situation is recognized as one of the key factors for determining the quality of the outcome resolving the conflict (Lawrence & Lorsch, 1969; Ramirez, 2010). The fact that cultural differences have to be taken into account makes the problem even more complex.

4. RESEARCH METHODOLOGY

As already mentioned in the introduction, the aim of this research is to examine if the cultural differences among Swinburne-Tongji and Malta project team members had an impact to conflict resolution strategies during the global design projects. The aim of the first project was development of an innovative cardboard package for the IKEA Hederling wine glass. For that purpose, a distributed project team made of students from three universities namely Strathclyde University from Glasgow, Swinburne University from Australia and Tongji University from China, was formed. Eight project team members were from six different countries: Australia, China, Mexico, Philippines, Indonesia and Serbia. The second project which aim was the design of an innovative faucet was performed in cooperation with University of Malta, and among five team members, four different nationalities including Malta, India, Columbia and Serbia were present.

In order to analyze cultural diversity in project teams and the impact it has on conflict resolution, a survey was performed on all team members from the two projects (excluding the author of the paper). This means that, in total, eight countries were covered with the research. The survey was based on the Thomas-Kilmann Conflict Mode Instrument (Thomas, Kilmann, 2010) which is a test-based tool for assessing individual behavior in conflict situations. According to answers obtained from the questionnaire, the Thomas-Kilmann score was calculated for each team member. This score allowed relating the test results with the most common conflict resolution strategies used by a particular team member. Furthermore, each team member was considered as a representative of its national culture. After this phase, a deep research about the similar previous studies was conducted in order to identify which conflict resolution strategies are the most common in the countries from which the team members came from. Finally, the national average figures from previous studies were compared with the scores of every team member in order to identify how much each of the team members' profiles fits into its national profile in terms of conflict management.

4.1. Thomas-Kilmann Conflict Mode Instrument

Thomas-Kilmann Conflict Mode Instrument (TKI) is a questionnaire-based tool that consists of thirty matched statements designed to identify conflict management behavior of an individual. The statements in the questionnaire are based on five different conflict approaches, already presented in Figure 1. The x-

axis presents cooperativeness, which is the extent to which the individual attempts to satisfy other's concerns (Thomas, Kilmann, 2010). On the other hand, y-axis presents assertiveness, which is the extent to which the individual attempts to satisfy his/her own concerns (Thomas, Kilmann, 2010). These two axes allow definition of the five specific approaches of dealing with conflicts. The pattern for calculating individual TKI scores allows us to identify which conflict resolution strategies are dominating in once behavior. In the final stage, the TKI scores are transferred into percentages which represent the distribution between the five basic conflict resolution approaches.

4.2. Comparative analysis

After calculating individual TKI scores, these were compared with the results found in few similar researches that were conducted during the last decade. All of these studies were performed on the samples of various sizes and contain average data for different countries. India's team member TKI score was compared with figures found in (Mohammed et al. 2008). For the analysis about Australia and China, relevant data from (Fletcher, Olekalns, 2005) were taken. In addition, the same research was used for data comparison about Philippines, but due to the fact that no detailed data for that country were available, Pacific region was taken as a referent. Figures from (Herk et al. 2011) were used for analysis about Mexico and Indonesia profiles, and the figures for France were compared with Malta team members because no particular data for Malta exist. Finally, no available data for Columbia was found, which is why the country is exempted from the comparative analysis.

In the end, a brief discussion about the influence that cultural differences had on conflict resolution in teams during the global design projects is presented.

5. RESULTS

First of all, the graphs showing the distribution of conflict resolution approaches between the five existing, for each of the team members from eight nationalities examined in the research, are shown.

Thomas Killman Score - China

Thomas Killman Score - Malta

Thomas Killman Score - Columbia

Thomas Killman Score - Philippines

Thomas Killman Score - India

Thomas Killman Score - Indonesia

Figure 2. Individual TKI profiles of team members

If referring to the Figure 3 below which compares individual TKI profiles of team members it can be concluded that the overall trend shows prominent usage of the compromising approach among almost all of the team members. The highest score for this approach is achieved by Maltese team members, who use this conflict resolution strategy in more than one third of all conflict situations. The second mostly used approach is soothing, especially emphasized in the case of Indonesian team member. Collaborating as a conflict management approach is to similar extent used by all countries and the score varies between 10% and 20%. Together with accommodating this is the most common approach among Australian team members. The highest score for avoiding approach (30%) was achieved by Indonesian and Indian team members. Furthermore, it is interesting to notice that Columbian team member uses competing as a conflict resolution approach significantly more often than the other team members. Moreover, in case of that team member, it is the dominant conflict management approach.

Graph summarizing the gathered data from all team members is presented below.

Figure 3. Comparative analysis of TKI profiles of team members

It is quite obvious that there are big differences between conflict resolution approaches within the team members. However, this analysis still does not give us much clue about whether cultural differences have impact on choosing a particular conflict management strategy, because certain behavior can also be caused by personal and social factors. In order to deeply analyze potential influence of cultural diversity on conflict management, the results obtained from team members are compared with the results from previous studies (which used much bigger sample). This will help us to identify how much each of the team members' profiles fits into its national profile in terms of conflict management.

Table 2 showed below allows comparison between data obtained from team members with the appropriate national averages from few previous studies about the most common conflict resolution strategies used by different countries.

Table 2. Comparative analysis

Country	Source of data	Sample	Competing (forcing)	Collaborating (problem solving)	Compromising (sharing)	Avoiding (withdrawal)	Accommodating (soothing)
AUSTRALIA	Swinburne University	2	10.0%	26.6%	16.6%	16.6%	30.0%
	Fletcher, Olekalns (2005)	378 undergraduate 2-year students	5.6%	15.8%	22.2%	19.3%	37.1%
CHINA	Tongji University	2	10.0%	10.0%	26.6%	23.3%	30.0%
	Fletcher, Olekalns (2005)	378 undergraduate 2-year students	9.2%	11.7%	34.2%	20.1%	24.8%
MALTA	University of Malta	2	0.0%	16.7%	33.3%	23.3%	26.7%
	Herk et al. (2011) (Data for France)	6000 people from different countries	3.3%	34.2%	16.6%	22.7%	23.2%
COLUMBIA	Strathclyde University	1	30.0%	20.0%	26.6%	10.0%	13.4%
	No relevant studies for comparison	/	/	/	/	/	/
PHILIPPINES	Strathclyde University	1	10.0%	16.7%	30.0%	20.0%	23.3%
	Fletcher, Olekalns (2005) (Pacific region)	378 undergraduate 2-year students	5.6%	15.8%	22.2%	19.3%	37.1%
INDIA	Strathclyde University	1	3.4%	23.3%	20.0%	30.0%	23.3%
	Mohammed et al. (2008)	150 Project Managers from multinational telecom organizations	7.14%	17.86%	19.64%	32.68%	22.68%
INDONESIA	Strathclyde University	1	6.7%	13.3%	16.7%	30.0%	33.3%
	Herk et al. (2011)	6000 people from different countries	15.1%	4.5%	29.6%	11.4%	39.4%
MEXICO	Strathclyde University	1	10.0%	23.3%	26.7%	13.3%	26.7%
	Herk et al. (2011)	6000 people from different countries	11.0%	24.0%	15.0%	7.9%	42.1%

In case of Australian team members, only slight differences between individual and national profile can be found. Accommodating is the most common used conflict resolution approached with around one third of all conflict situations. The bigger gap is only recognized in the case of collaborating approach. According to two Australian team members it is used in around 27% of conflict situation, while the national average is a bit lower (15.8 %). Similarly as with Australian, Chinese team members fit into its national profile, with

variations that are not exceeding more than 5%. However, accommodation as a conflict resolution approach is slightly more often used by the two team members than the national average is. At the same time, compromising is somewhat less used – 27%, compared to a national average of 34%. Maltese team members showed results that significantly differ from their national average. According to the Herk et al. (2011) the most frequently used conflict resolution strategy in Malta is collaborating with 34.2%, while in the case of two Maltese students mostly used is accommodation with 26.7%, followed by the avoiding that is used in 23.3% of all conflict situations. Maltese team members never use competing as a conflict resolution strategy and the average figures for the country are also very low – around 3%.

Some gaps between Philippine team members and their national averages are also noticeable. The mostly used conflict resolution strategy in Philippines according to Fletcher and Olekalns (2005) is accommodating, while the team member's profile shows the domination of compromising. There are almost no differences in figures for the other three approaches. The distribution of usage frequency of conflict resolution strategies by the India team member almost perfectly fits into the national TKI profile. Minor differences can only be recognizes in case of collaborating, which is in the case of India team member for around 5% lower than the national average. The biggest differences are found in case of Indonesia, as the team member profile is completely different from the national. Individual results show that the most frequently used conflict resolution approaches are accommodating (33.3%) and avoiding (30%). On the other hand the national average for avoiding is around 11%. Differences in percentages can be found in other approaches too. Similarly, disproportion in results regarding the Mexico is also significant. Research results that can be found in (Herk et al. 2011) say that the most commonly used strategy is accommodating with 42.1%, while the individual score of a Mexican team member shows almost equal usage of three conflict resolution approaches: compromising and accommodating (26.7%) and collaborating (23.3%). Comparison for Columbia cannot be done due to the fact that no figures about national averages are available.

6. DISCUSSION AND REFLECTION ON PRACTICAL PROJECT EXPERIENCE

Even though not many conflict situations during the global design projects occurred, there were few circumstances which confirmed the conflict resolution profiles from the team members.

For example, during the material selection phase of the asynchronous Swinburne-Tongji project, there was a significant problem between Australian and Chinese students. Team members could not agree about the type of cardboard that should be used for the final package development, and during the two days they completely interrupted the flow of the project. Both sides had complaints about the others, but no dialog, in order to overcome different opinions, could be established. Finally, after realizing that the conflict can cause the failure of the project two sides decided to start collaborating. Due to the impact of the third part – University of Strathlyde, Australians and Chinese students started paying much more attention on others' proposals. During the next few days they were open for discussion and finally the cardboard type was chosen. This was an obvious example of the collaborating conflict resolution strategy, because both teams started working on a problem solution while taking into account what the other side thought. At the same time, Australians used the accommodation strategy too, because they became more concerned about the others' needs than the own needs of an individual. Taking into account the previous scenario, we can say that this conflict situation confirmed research results because accommodating in case of Australian, and compromising in case of China, are in the two mostly used conflict management approaches.

During the synchronous global design project, another conflict situation happened. It occurred during the idea selection phase when the consensus about the design proposal that is going to be chosen, could not be reached. However, after reviewing the proposals and changing some details in the design, compromise was found. Due to the fact that all team members recognized that the goal of the project is more important than individual opinions of team members, it can be concluded that this was a typical example of compromising approach. Moreover, compromise is with 33% the most commonly used conflict resolution strategy for Maltese students.

Both of these examples have once again confirmed that diversity and conflicts are very complex topics that include many dimensions, which is why they have to be analyzed from different aspects. Further, this is also the reason why the conclusion from this research cannot be generalized for other contexts. There is a lot of factors such as tradition, core cultural values, religion, the level of education, personality, age

differences, sex differences etc. that affect the conflict resolution process. However, the conclusions are very useful for better understanding of different cultures. Besides, other benefits that I found are the knowledge about the necessity of using different conflict resolution approaches in different situation, with different people and in different project environments.

7. CONCLUSION

Globalization has changed the business environment which is why is in the best interest of all stakeholders to take into account the cultural diversity in the workplace. At the same time, the internal management of conflict situations, especially in global distributed project teams, is vital for the project success. Researchers have also recognized the importance of the topic, which is why many studies about the influence that cultural diversity has on conflict management exist. The research presented in this paper provides insights into conflict-handling style of different nationalities that were present in the two global design projects. Even though, the research reflects on the experience from only two projects, findings can be useful for better understanding of the topic. The main conclusion that should be pointed out in the end of this paper is that cultural diversity always has to be considered as an important factor that will certainly impact the conflict resolution process. Further research in this area should examine the impact that culture has on a communication among the project team members, as well as the impact that personality, age, sex and religious differences have on conflict management.

MANAGEMENT OF UNEXPECTED EVENTS IN CONSTRUCTION PROJECTS

Ana Rakita

Faculty of Organizational Sciences, ana_rakita@yahoo.com

Abstract: *Unexpected events are events that have not been planned to emerge during the project, and they are usually caused by external factors. The aim of this paper is to understand these events in construction projects and to point how project managers deal with the unexpected. The research methodology selected comprised a comprehensive literature review and a questionnaire to civil engineering experts. Fourteen experts were involved in research and they explain unexpected events from their experience. Results point to four fields of managing unexpected events: Characteristics of organisations that successfully manage unexpected events, Methods for reducing uncertainty, Practice of adapting the project plan and Strategies to deal with unexpected events. These four fields show which characteristics of organisation are important for providing successful response to an unexpected event, how to reduce a possibility of the unexpected, how to adapt the project plan if such an event has occurred and which strategies have been proved successful.*

Keywords: *unexpected events, project management, construction projects*

1. INTRODUCTION

As projects are inherently uncertain, appearance of unexpected events is inevitable. Geraldi, Kutsch & Lee-Kelley point out that these are events that may have been predicted (or not), but are not expected to happen. They compare unexpected events with the sinking of the Titanic, because hitting the iceberg could have been predicted, but nobody expected that it could sink the boat. Unexpected events are uncommon situation that have a strong impact on the project. If this event happen, it is necessary to act quickly. Therefore it makes the time pressure on managers. It is concluded that there are three key steps to successfully manage unexpected events: responsive and functioning structure at the organizational level, good interpersonal relationships at the team level and competent employees at the individual level (Geraldi, Kutsch & Lee-Kelley, 2010).

Understanding these events is important from the point of managing uncertainty in whole project. Uncertainty depends on project characteristics. Researches show that it is higher in multi-national projects, and in projects that are more complex and lasts longer (Aaltonen, Murtonen & Tukiainen, 2009).

The risk management procedures are in place to mitigate consequences of external factors that may have a negative impact on the project. It is known that environmental relations need management attention but as the relation become more complex it is also becoming less possible to foresee and less possible to plan. The possibility of unexpected events is higher on projects that depending on several partners. The partners usually have different objectives which could cause conflict among them (Söderholm, 2008).

Although the classical treatment of projects suggests that they can be well-planned, there is plenty of room for unanticipated events to interfere with plans. Projects are frequently bid on a fixed-time, fixed-cost basis.

Thus, unanticipated events may quickly rise to the level of crises if they happen to lie on the critical path that determines the time for completion (Hällgren & Wilson, 2008).

There is an increasing awareness that unexpected events will happen. Many authors pointed that it is not a question of „if“ but „when“ unexpected events will emerge (Hällgren & Wilson, 2008; Söderholm, 2008; Sun & Meng, 2008).

2. PROJECT ENVIRONMENT AND STAKEHOLDERS - IMPACT ON CHANGING PROJECT

As it is done in a dynamic environment, the project has to be more or less dynamic category. In the project management context dynamics is taken to be a dimension of a project that represents the extent to which a project is influenced by changes in the environment in which it is conducted. Rapid changes in the environment, including tools, methods and tendency for innovation, increase the uncertainty of the project (Collyer & Warren, 2009).

Stakeholders of the project are defined in the literature in different ways. Most common is the general point from which they represent any group or individual, or affect the project or project affects them (Aaltonen & Sivonen, 2008).

The project involves different stakeholders, whose interests and demands have to be taken into consideration in order to ensure success of the project. So, one of the key parts of project management is managing stakeholders (Olander & Landin, 2005).

Although the risk associated with stakeholders is often ignored in risk analysis, it is important to identify all stakeholders and if it is possible to make a stakeholders map. Their expectations and interests need to be explored and understood. Each project has several stakeholders, so it is required to manage their relationships. The stakeholders' conflict can have a negative effect on the project itself. It is a frequent cause of unexpected events and brings significant financial losses. It is therefore important to do the stakeholder analysis, to reduce the uncertainty. The complexity of the network of stakeholders is directly related to the probability of appearance of unexpected events. The more complexed the network is the greater is the likelihood of the unexpected. Position and influence of different stakeholders is changing during the project lifetime. Therefore, monitoring stakeholders must be continuous, during the implementation of the project. These changes of stakeholders influence can significantly change the course of the projects progress (Aaltonen, Murtonen & Tukiainen, 2009).

As the stakeholders have high impact on project, managers engaged in these projects have to develop different strategic responses as a result of the stakeholders pressures. Those strategic responses are: adaptation strategy, compromising strategy, avoidance strategy, dismissal strategy and influence strategy. In a situation where stakeholders require changes, responses could be redefined (Aaltonen & Sivonen, 2008).

A negative attitude to a construction project by stakeholders can severely obstruct its implementation. Such obstruction will cause cost overruns and exceeded time schedules due to conflicts and controversies concerning project design and implementation. A method of stakeholder mapping and the power/interest matrix are some techniques that could be used to identify stakeholders and their influence on the project (Olander & Landin, 2005).

3. CATEGORIZATION OF UNEXPECTED EVENTS BY CAUSAL FACTORS AND RESEARCH RESULTS

The following division of unexpected events is based on external factors that cause those events. Division is based on the division of the key risks in construction projects (Zou, Zhang & Wang, 2007), and is adjusted to unexpected events literature and results of the research. Approximate frequency of the unexpected events is shown after the event category. Data are based on experts' answers, given in questionnaire. Unexpected events generally influence project objectives in terms of time, quality and cost. This influence is listed below.

Unexpected events related to investor. He is one of the most important stakeholders in the construction project, and the one that provides funding. Two events related to investor will be explained below.

- Unexpected project funding problems (50%). In this case, project team tries to find a way to continue the implementation of the project (deferred payment to suppliers, companies using the contingency fund or by borrowing from financial institutions) and only in extreme cases stops project, until funding is provided.
- Investor entries unexpected variations in project changing projects original plan (60%). This could happen if he changes his mind, or if there were misunderstandings during the project contracting. This event has impact on time, quality and project cost.

The most of unexpected events are related to contractor.

- Unexpected problems because of inadequate soil test (25%). According to experts' answers, this could influence on object design (for example, type of foundation) which have to be adapted to unexpected terms. Event has impact on cost and quality.
- Getting lawsuit (not frequent). Reasons for lawsuit could be different (for example workers are not insured, serious air, water or noise pollution, disregard of rules, ect.). This event has indirect impact on projects' objectives.
- The unexpected cancellation of the contract - the contractor is unable to complete the project (20%). This event is not common, but it directly impacts project completion time.

Suppliers usually affect the project time, because the delay in delivery causes delay of whole project.

- Supplier is unable to deliver materials on time (30%).

The government is an external stakeholder that influences the occurrence of unexpected events.

- Unexpected problems with government regulative. Examples of such event are disabling transfer of machines from one country to another because of government regulative, then stopping the project by inspection because government regulation did not define building megaboards (it is only defined for public surface).

Other external factors that could cause unexpectedness:

- Extremely bad weather conditions. It influence on postponing building.
- Unexpected changing material price. It influence on overcoming planed project budget.

Chart 1 shows research results for most frequent events. On the abscissa are offered answers, and on ordinate are answers in percentage.

Chart 1: Frequency of the unexpected events

4. FOUR FIELDS OF MANAGING UNEXPECTED EVENTS

Managing unexpected could be divided in four fields. Knowing those fields could help managers to reduce uncertainty, or to answer on unexpected events successfully. These four fields shows which characteristics of organisation are important for giving successful response to unexpected event, how to reduce possibility of unexpected, how to adapt the project plan if event appeared and which strategies of response are proved to be successful.

4.1. Characteristics of organization that successfully manages unexpected events

Success, upon emerging of unexpected event, greatly depends on the characteristics of the organization, team and individuals working on the objective of the given project. That is why characteristics that increase the likelihood of success, on organizational, group and individual level, stand out while managing unexpected events (Geraldi, Kutsch & Lee-Kelley, 2010).

1. Organizational level-flexible and functional organizational structure.

Fast decision making and their implementation. Top management is involved in the process and it ensures political support and fast reactions. Responsive structure implies correctly timed appropriate answers to changes. Responsibility and authorization should be awarded with key people in each specific situation. Project manager requires great freedom of choice to produce successful answers, if not, a lot of time gets wasted on getting approvals and filing reports. As something unexpected is surely going to happen, time buffers should be left while planning, which will help the team to make a successful response.

2. Group level – good interpersonal relationship.

Relations with stakeholders are essential for two reasons: firstly, their full support is needed while solving these situations, secondly, negotiating with all of them is required (clients, suppliers, members of the team). Good flow of information is also required.

3. Individual level – competent individuals

Leader and the team have to know what to do, have available sources and adequate skill sets, function with the group. The leader has to be able to manage team members' behavior in stressful situations.

According to experts answers the most important factor for solving unexpected problem is competent project manager. Research results are shown in chart 2. They mark importance of each factor on a scale of 1 to 5.

Chart 2: Importance of factor for successful response to unexpected events

4.2. Methods for reducing uncertainty

Uncertainty can be defined as a gap between information that are needed and the ones that are available while project is in motion. Investigating construction projects, author defines three ways to overcome this gap (Leijten, 2009).

1. First is increasing the expertise of the client (project proprietor). Both case studies show that the client is incapable overseeing and judging efficiency of certain project phases.
2. Second way is engaging another company to do part of the job (outsourcing). It is positive to include a private company in the project so that company itself would accept responsibility and it would have its own interest in project completion.
3. Third way is adjusting to circumstances and it implies minimizing the gap in a way that the need for information would be reduced, if its flow could not be increased by one of the before mentioned ways. In practice, it means adjusting (probably lowering) ambitions, in a sense of prolonging the dead line or decreasing functionality.

Meaningful step in reducing uncertainty and avoiding the unexpected is following work signals. Management by early warnings ensures extra quantity of information which closes the gap of uncertainty. The most useful fact is that this concept provides information for the event that is yet to happen, which increases chances of successful overcoming of possible problems (Nikander & Eloranta, 2001).

4.3. Practice of adapting the project plan

As a result of the influence of the parties involved, managers react in one of the following ways, adapting the project plan: re-opening, revision and daily fine tuning of project (Söderholm, 2008).

1. Re-openings mean that restrictions, in terms of deadlines, tasks and expenses, are re-defined. They are caused by changing stakeholders' requests and they are very frequent on project depending on several stakeholders. It is also possible that some stakeholders quit and others enter into project, which cause changing requests.
2. Revisions and adaptation of the initial plan are often, as long as the plan is made for longer time period and as long as the project depends on other projects and companies. Revisions and changes of initial plans are however very common and most managers would argue that they are inevitable for any project that is extended over some time.

Daily fine tuning is third way of adapting project plan. It implies constant flow of information with environment and adaptation to variable terms. It will always be channels for exchange of experiences and knowledge not only within a project but also among projects or from project to surrounding organization. Consequently there is a daily fine tuning of project work and outside commitments.

4.4. Strategies to deal with unexpected events

Four common strategies are set up through research to deal with unexpected events (Söderholm, 2008). Team leader and whole project team has a vital role for success of each strategy.

1. Innovative actions. They represent creative ways of managing unexpected changes, unusual actions that stand out of set boundaries.
2. Curriculum with frequent meetings and short-termed coordination. It is essential to observantly follow the situation and consequences of unexpected event, but also to ensure constant flow of information between members of the project team. Extensive meetings include frequent decisions on resources or assignments among team members.
3. Strategy of separation. Isolating revision consequences, to lessen the impact on other parts of the project, or creating another sub-project which will manage the revision.
4. Negotiating skills and preservation of project. To change some of the limiting factors and ensure essential terms for successful project completion, through negotiations with executive board and other stakeholders.

5. LIABILITY FOR UNEXPECTED EVENTS IN CONSTRUCTION PROJECTS

Occurrence of unexpected events often causes great unplanned expenses. For that reason, unless liability is defined by contract, it is open to a lawsuit for any resulting damages or a court order to perform (as in a breach of contract or violation of statute). If it comes to that, court must define who has liability for failing to complete on time. Following is taken into consideration are: if the contractor is liable for the delay, if the machinery is properly maintained, if there were any other parallel delays which affected the project failure, etc. If it is found that neither side is liable, expenses are covered by project owners, investors. All relationships are defined by contracts based on some internationally accepted models of contracts, for example FIDIC (Baker, Mellors, Chalmers, & Lavers, 2009).

One of the most distinctive features of professional building practice in recent years has been the overlapping of performance of tasks by people with difference types and standards of training. The courts have now becoming less reluctant to differentiate skills simply on the basis of labels attached to the party performing them, especially of the expanding functions undertaken by the person trained as an engineer. This is not to say, however, that the courts are anywhere near saying that all who offer advice on the design, construction or performance of a building are to be deemed to have the same skills and competence. At a practical level, the way to avoid future problems (of perhaps being attributes with skills that individuals may not actually possess) is to work towards greater co-ordination of educational and vocational training. The differences between the undergraduate work of a trainee architect, surveyor and engineer are considerable, yet there is considerable overlap of responsibility in the end when out in the field (Chai, 2005).

6. CONCLUSION

Although we plan and try to take all possible risks into consideration, something unexpected can always happen on a project. Those are usually events that drastically change the realisation of the project and that is why they require special attention. Given that they are caused by environmental factors, most often stakeholders, special attention have to be given to those stakeholders and their relationships. Early warnings must be noticed and uncertainty gap must be decreased. Organization has to be equipped to deal with these types of situations, because even with aforementioned precautions unexpected can arise. Flexible planning, higher authorizations of project manager, good team and qualified individuals, would increase responsiveness and decrease reaction time. Such organization, by use of tactics as innovative actions, curriculum with frequent meetings, strategy of separation and negotiating skills has great chances to successfully realize the project, despite unexpected events. Although we are unable to completely foresee the future, by applying these solutions to manage the unexpected the managers are more able to make their own luck.

PROCESS OF MOVING FROM WATERFALL TO AGILE PROJECT MANAGEMENT MODEL

Sanja Vukićević¹, Dražen Drašković²

¹Faculty of Organizational Sciences, University of Belgrade, vukicevicsanja@yahoo.com

²Faculty of Electrical Engineering, University of Belgrade, drazen.draskovic@etf.bg.ac.rs

Abstract: *This paper focuses on the process of migrating from the Waterfall Project Management Model to the Agile Project Management Model. The main idea is to present the Waterfall and Agile Models, their advantages and disadvantages, as well as the procedure which should be followed in order to move from the Waterfall Model into the Agile Model. Expected risks of the process, which may jeopardize the project, have also been defined, and the means for their mitigation and elimination are put forward. The study has emerged as a result of insight into the project leaders and project consultants' reports. This paper will help project managers as well as developers to understand and be aware of all risks and benefits that may come up while adopting the Agile Project Management.*

Keywords: *Waterfall Model, Agile Project Management, extreme programming, risk management*

1. INTRODUCTION

In addition to the right choice of technology, in software development it is extremely important to decide on the correct model of project management. In search for the pattern that would lead to the guaranteed success and safe project finalization, the first model appeared as the appropriate one – the Waterfall Model (Winston, 1970). Then, the other models kept appearing, such as: Prototyping Model, Incremental Model, Spiral Model, Rapid Application Development Model, Engineering Driven Model and finally in 2001 the Agile Software Development was created. The reason for such great number of models lies in the percentage of failure to manage projects which is still very high, but in the mean time, project management has also displayed certain betterment.

Table 1 shows the general percentage of project success, regardless of the project management model in the period from 1994 till 2009. In 1994 the Standish Group published the CHAOS Report asserting that 31% of projects were cancelled before they ever had got completed. Then, 53% of projects were cost and time overrun and only 16% of projects were completed on-time and on-budget. According to the Standish Group CHAOS Report in 2000, 23% of projects were cancelled, cost/time overrun had gone down to 49% and there were 28% of projects completing required features and functions on time. The last report, published in 2009, has shown that percentage of success has not that much progressed considering the time period. Namely, 32% of projects was completed successfully, 44% with delay and 24% were cancelled.

Table 1: Software Project Success Through Years According To Standish Group Chaos Reports

Year	Successful (%)	Challenged (%)	Failed (%)
1994	16	53	31
1996	27	33	40
1998	26	46	28
2000	28	49	23
2004	29	53	18
2006	35	46	19
2009	32	44	24

Project leaders use the Waterfall Model quite often. The majority of project leaders do not want to jeopardize the project by converting the management to agile methods. Nevertheless, the analyses have shown that the project success of the project managed by agile methods is almost guaranteed. According to the CHAOS Manifesto of Standish Group, published in 2011, as illustrated in Figure 1, the probability of project failure is even three times greater if the Waterfall Model was used, and not the Agile Model.

Figure 1: Differences Between Waterfall And Agile Model In Project Success

The basic problems which are encountered during software development are: failing to meet the deadlines, abandoning the projects mostly after failing to meet the deadlines, the piled up architecture, lots of bugs in code (therefore, the program is useless), project participants replacement. However, using agile methods in project management contributes to diminishing the number of the above stated problems, and the way this is achieved will be explained in the remainder of this paper.

Section 2 describes the Waterfall Model principles, while in section 3 Agile Model principles are described. The way how the Waterfall Model-led project may be transferred into the Agile Model-led project is described in Section 4. Section 5 describes specific problems arising in the course of transition to agile methods. The final section summarizes our research and provides the conclusion.

2. WATERFALL MODEL

This model is called in such a way because the model develops systematically from one phase to the other in a downward fashion, like a waterfall. The phases are: defining requirements, designing system an software, implementation and unit testing, integration and system testing and operation and maintenance (Sommerville, 2011). The linearity of this method indicates that each phase may be assigned to the separate team, and only after one phase is completed, another one would begin.

Advantages of this model lie in the fact that a lot of emphasis is dedicated to paperwork in this method when compared to the newer methods. When new workers enter the project, it is easier for them to carry on the work from where it has been left. The newer methods don't document every step in their developmental process which makes it difficult for a recently new member of the team to understand which step is going to follow. The second advantage is that Waterfall Model is well known amongst the software developers, and therefore it is easy to be employed.

There are many disadvantages of this model. Many software projects are dependent upon external factors, amongst which the product purchasers is the biggest factor. It could happen that the product purchaser changes the project requirements thereby influencing an alteration in the normal construction plan, and hence the functionality as well. In such a situation, team must return to the first phase and go through all phases again. The second negative aspect of this model is that a huge amount of time is wasted while running project. If designers are still designing software, time of developers is completely wasted. Also, because the outcome is expected at the end of the phase, usually workers are not so hardworking at the beginning of the phase, and then as the deadline is closer, they overwork in order to finish in time. The phase deadline is often missed. Another disadvantage of this method is that the testing period comes quite late in the developmental process and for that reason the design flaws are found late and all phases have to be repeated. Elaborate documentation during the Waterfall method has its advantages, but it is not without the disadvantages as well. It takes a lot of effort and time to maintain valid versions of documents.

Due to the various disadvantages there are couples of modified versions of this model. For example Sashimi Model overlaps the phases so the developers start to work on implementing design while

designers are creating documents for the rest of the requirements. Since they overlap, one can return to the previous step if desired.

3. AGILE METHODS

Agile methods care for different values in relation to Waterfall Model. Individuals and interactions are more important than processes and tools. Working software is more important than comprehensive documentation. Customer collaboration is more important than contract negotiation and quick responding to change is more important than following a plan (Cohn, 2006). It may be freely said that solutions created by agile methods evolve during the development.

According to Agile Alliance there are twelve principles showing what 'agile' really means. Principles are given in Table 2 below.

Table 2: Twelve Principles Of Agile Model

No.	Agile principles
1.	The most important is to satisfy the customer through early and continuous delivery of valuable software. Hence, the satisfied customer is priority.
2.	Change request is allowed even late in development. This can be used as advantage over the competitors.
3.	Functional software is delivered often, from a couple of weeks to a couple of months. Shorter period is preferred.
4.	Business people and developers must work together daily throughout the project.
5.	Projects are built around motivated individuals. Principle is to give them the environment and support they need, and trust them to get the job done.
6.	Face-to-face conversation is the most efficient and effective method of conveying information to and within a development team.
7.	Primary measure of progress is working software.
8.	Agile processes promote sustainable development.
9.	Continuous attention to technical excellence and good design enhances agility.
10.	Keeping simplicity is essential.
11.	The best architectures, requirements, and designs emerge from self-organizing teams.
12.	The team inspects periodically good and bad procedures and accordingly tunes and adjusts its behavior in order to become more effective.

The overall product development is divided into small iterations which require minimum planning time. Iteration is the short time interval – time box (which mostly lasts one to four weeks). In every iteration a team will go through all the phases of software development (planning, analysis, coding and testing). The iteration result is product release which is functional and which may be presented to the clients. The finalized iteration implies the set of features, and each feature is precisely specified with regard to its function and is tested in details. There is no iteration duration prolongation, and no new requests addition in the course of iteration. If it is observed that the team cannot fulfill all planned requirements, the request of lower significance is tasked and they are switched off the release iteration.

Agile methods should be implemented in high dynamics environment conditions. If there is no dynamic environment, agile methods should not be applied. It could easily happen that there is lack of documentation, because the design is sometimes discussed at meetings and then no person writes it down. Also, the risk is if the customer representative is not clear about the final outcome they want. Then the project can easily get taken off track.

4. PROCESS OF MIGRATING WATERFALL TO AGILE

Agile methodology migration is viewed as a type of experiment by managers. With the beginning of the migration process from waterfall to agile project managers display fear of failure. This is the reason why this process develops gradually and there are many transitional phases. We may say that Waterfall Model mutates into Agile Model at speed which depends on project participating team capabilities.

If there is no one in team who is experienced in agile methods, than it is advised that the consultant should be employed thus monitoring the project flow and helping the team to grasp the agile project management by learning from their own mistakes. So, it is very difficult to implement all agile methods from the beginning, and that is why they are being acquired gradually during each iteration (Sureshchandra & Shrinivasavadhani, 2008). The team usually learns in the more difficult manner by deciding not to accept a method which seems complex to them and which they evaluate as being time consuming. It is only when failure occurs, the team realizes that it happened due to lack of that method usage. Thus, this is usually the most common way of adopting agile methods.

The process begins by agreeing on the way of meeting management. Agile methods favor stand-up meetings. On the first meeting, the team should make a plan defining a number of iterations to be done and which functionalities are being planned for each of them. This plan should not be elaborate, but rather an outline according to which the things would function and which would be updated after each iteration.

Iteration is composed of the following steps:

- Iteration duration time is specified and functional specification requirements for that iteration are written down. The meetings should include also the product purchasers in order to define functionalities correctly thus avoiding the huge number of change requests.
- The team is having daily meetings while there is a meeting with a product purchaser once a week.
- Coding standards should be defined before the beginning of the coding. In this way, developer hesitation and confusion is being prevented from occurring, uniformity code is achieved, code quality is enhanced and the code review and refactoring time are being reduced.
- Automatic tests are composed and used during the code development.
- Daily builds should be made during the development phase.
- Iteration result is the product version and the implemented functionalities list. The product is submitted to the team which tests the product like a user. If the bugs are detected, they are submitted to the team and the team should decide whether they would be corrected in the next iteration or be left for some later iteration.

Iterations are executed one after the other. But one iteration finalization should not be waited for in order to begin with the other, but rather, iterations should overlap (Ming et al., 2004). Figure 2 displays iterations overlapping. The team members may be divided into three groups: those composing functionalities specifications, those coding and testing and those verifying the product. Therefore, one iteration may be displayed through three phases: functional specifications writing (FS), coding with testing (C+T) and verification (V). In the first iteration, when developers work on coding phase, a product architect in collaboration with the product purchaser prepares functional specifications for the other iteration. Thus the developers after finalization of coding phase deliver a release to the verifiers and immediately initiate coding phase of the second iteration. After the verification finalization the verifiers obtain the new product release and this lasts up until the final release has been obtained.

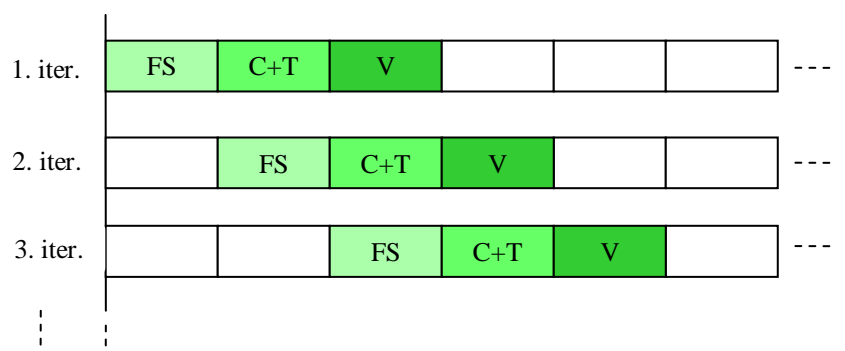

Figure 2: Overlapping Of Agile Iterations

The above mentioned agile methodologies are described in detail in the part which follows: Stand-up meetings, Burn-Down charts, Coding standards, Test Driven Development, Behavior Driven Development and Daily builds.

Stand-up meetings and Burn-Down Charts

The simplest agile methodology easily accepted by team members is in the form of stand-up meetings. A stand-up meeting is a daily team meeting held to provide a status update to the team members. During these meetings each member is asked three questions: 1. What did s/he do yesterday?, 2. What does s/he plan to do today?, 3. Are there any problems? This lasts 15 to 20 minutes at maximum and gives rhythm to iteration.

Another agile method shows how project develops by means of the Burn-Down chart. A Burn-Down chart is a graphical representation of work left to do, versus time. The outstanding work (or backlog) is often on the vertical axis, with time along the horizontal.

Coding standards

Individual style is great when you're working alone. In team software development, however, the goal is to create a collective work that is greater than any individual could create on his/her own. Because requirements are changing very often and code is amended or fixed in iterations, it is needed to have clear code. That's where coding standards are welcome. Code standards are guidelines on which all the developers agree to adhere while programming. However, when you are putting together your coding standards, don't fall into the trap of arguing about formatting. There are more important issues.

Test Driven Development or Behavior Driven Development

One of the differences between agile and traditional testing methods, such as the Waterfall Model of software design, is that testing of the software is conducted at different points during the software development lifecycle. Waterfall Model applies testing after complete system development. Agile Model applies techniques such as Test Driven Development where the tests are written before the code. Since the result of entire iteration is one final product version which implements certain functionalities in order to be sure that these functionalities function correctly and that their introduction has not jeopardize product remaining part, the products must be frequently tested during the iteration. The common practice is that each developer before code committing, starts up all the tests or at least those which s/he regards that cover changes. Before release announcement all the tests should be implemented successfully.

In agile approach, the other testing way is also frequent, and it takes into account sense. This one is called Behavior Driven Development where the scenarios are written before the code, after which automated suite of tests are written. Scenario represents a natural sequence of actions which are possible within the product verifying whether the code meets the required functionality and/or quality standards.

Daily builds

Frequent releases provide product purchasers with current product functionalities, so that they may check out the earlier phase functionality accuracy. Product purchasers may also give their own comments and requests which are used for next versions planning. Both daily builds and automated testing ensure that the code base is not broken after code has been checked in.

5. POTENTIAL PROBLEMS AND HOW TO HANDLE THEM

The risks accompanying stand-up meetings refer to the instances when meetings are prolonged due to problems which are elaborated by a team member and the others willing to help by providing advice. This problem is easy to solve by discussion interruption and if further solving is required additional meeting should be scheduled (Hines et al., 2009).

Many project teams insist on trying to define all of the requirements in advance. This is not just dangerous, but is actually waste of time, since you can almost be assured that a certain percentage of those requirements will be invalidated and the time spent for analyzing them will be for naught (Churchville, 2006). An agile approach to requirements definition is to defer detailed analysis as late as possible, which is typically just before the work is about to begin. Until then, you capture requirements in the form of "user stories", which are brief descriptions of customer relevant functionality.

It is really important to change project manager role from controlling the team to removing roadblocks which impend to the team's progress. Team has to suggest the action and project manager has to approve or disapprove it. Also, the estimation of remaining effort has to be left to the team. The estimation would be more realistic if it comes from the team and there would be more ownership and enthusiasm to complete the iteration in time. Also, decision making is faster. It is better to make a decision quickly even if being a bad one and thus achieve continuity, than wait for weeks on decision which may again be bad and require changes.

It is very hard to make daily builds of a product, especially in the early stage of adopting agile methods. Usually, weekly builds are done and it is satisfying modification of agile methodology as well as there is a build at the end of the week. Something is better than nothing. If project leader notice that none of the developers had checked in their code for the weekly build because they were not sure if the code was working, there is a time to include Test Driven Development. It will ensure that developed code actually meets the requirements.

6. CONCLUSION

This research is base on published reports of team members, project leaders and project consultants, all of whom migrated from Waterfall to Agile Project Management Model. The authors themselves participated in one such project.

On previous projects, we were involved in projects that were Waterfall Model-led. Frequent problems were: the team overworks during 4 to 5 weeks preceding the release, many times the release date has had to be postponed due to delay in development and testing, too many defects have been raised by the customer during acceptance testing, etc. After this, first project was carried out successful by combining agile methods - Extreme Programming (XP) and Scrum. The results were: high productivity of team members, production of high quality code, product purchasers were satisfied because they were involved in project from start to finish.

Process described in this paper is useful for the teams migrating from Waterfall Model to Agile Model. However, knowing this process could be useful for the teams willing to migrate from any other project management model to Agile.

Abstract: *In Serbia, the crisis has caused unimaginable devastation and its economic and financial consequences will be felt for a long time. General economic instability, constant political turmoil and financial hardships are hindering the process of European Union accession. The fact is that Serbia and its neighbouring countries have very favourable predispositions to become a developed and attractive location, interesting to many EU investors. One of the primary aims of our country is to end the economy transformation and to enhance national competitiveness in order to move closer to the EU membership. The main aim of this paper is to emphasize one of the possible measures in the process of solving the economic and financial problems in Serbia and to accelerate the EU accession in the light of enhancing its competitiveness. As the main source of data, we have used the Global Competitiveness Report as a basis in our research on actual and previous values of the global index and sub-indexes of competitiveness in Serbia. By detailed analysis of twelve key pillars of competitiveness we will define the actual competitive position of Serbia and note its change compared to the previous years. The purpose of our work is to point to the main factors that distort competitiveness of our country and propose measures which will reduce or even eliminate effects of the mentioned factors in order to improve the competitive position of Serbia which tends to advance towards the EU membership.*

Key words: *European Union, Membership, Crisis, Competitiveness, Index, Sub-indexes, Pillars of Competitiveness*

1. INTRODUCTION

Taking into consideration that improvement of competitiveness of Serbia is the primary driver of its economic recovery and future economic prosperity, we all note that during the period of overcoming the consequences of crisis and accelerating process of EU access, it is highly desirable to analyze its competitive position. In recent years, global economic crisis has been an area of interest and actions of economic policy makers, professional organizations and institutions, researchers and scientists, and it has certainly been a hot topic in various media, so that it indirectly affects the population as well. Precisely at a time when developing countries have made some progress in the way of their own transformation and started hoping for a better future, they came across a huge disappointment and became quite discouraged in the struggle to improve their economies. Serbia is also among the mentioned countries, which is economically and financially very weak and it has huge difficulties to overcome one of the largest global recessions and become EU member. Huge contractions in consumer demand, sharp rise of unemployment, reduction of foreign investments, and decline in demand for export products are just some of very serious problems that our country had to face. The influence of global economic crisis on Serbia is manifested primarily in two ways: in terms of money getting more expensive and the difficulties in export. More expensive money leads to increases in prices of servicing existing debts and new loans, while the difficulties in export are a result of falls of economic activities and lower demand for Serbian economy on main export markets (Knjiga preporuka Nacionalnog Konventa o EU u Srbiji, 2009). In a difficult global economic environment, it is very important for Serbia to realistically examine its own economic situation and realize its competitive position, so that it could be able to act towards its improvement on time. The overwhelming consequence of globalization is such that competition is no longer observed only within national borders (Jenkins et al., 1999). If it uses and analyzes the reports of the World Economic Forum, it will become able to perceive competitive strengths and weaknesses, improve its competitive position, create better conditions for the promotion of its own economic growth and development, and thus leave the whirlwind of the global crisis and accelerate its EU access as soon as possible. In addition to explaining the research methodology applied by the Forum, and processing all the elements that constitute a complex competitiveness concept, in this work we will put special emphasis on the analysis and possible measures to improve the competitive position of Serbia. Using gradual deduction of the

Global Competitiveness Index, into individual sub-indexes and pillars of competitiveness as their parts, we will create a realistic picture of Serbian economy and catch sight of its current competitive advantages and disadvantages.

2. THE WORLD ECONOMIC FORUM AND IMPROVEMENT OF THE GLOBAL COMPETITIVENESS

For nearly forty years, the World Economic Forum has been monitoring and analyzing the indicators of development of national economies, finding answers to numerous economic issues and suggesting solutions to current global problems. It is an independent, international organization established as a Swiss non-profit foundation with the purpose of providing detailed estimates regarding the productivity of global economy and national economies. The motto of this organization tells us quite a lot about its aspirations and goals: “entrepreneurship in the global public interest” (A Partner in Shaping History – the first 40 years, 2009). One of the goals towards which this organization gravitates is encouraging the development of all countries by providing an adequate basis in the form of useful and current data, information and calculations of economic character. One can often read a statement in many Forum reports which says that economic progress without social development is not sustainable, and that social development without economic progress is not feasible. The importance of corporate governance and fostering social and ethical values in the process of development of both individual businesses and entire national economies is also constantly being emphasized.

The World Economic Forum was originally conceived as a partnership of world leaders who contribute to improving global economy and engage in the creation of global and regional plans. Gathered in order to achieve common goals and led by common interests, the leaders say that the role of the Forum is triple:

1. The most prominent organization that establishes and promotes the development of leading global communities.
2. Creative force that shapes global, regional and industrial strategies.
3. The catalyst of choice for its communities when undertaking global initiatives to improve the current situation in the world.

The Forum has successfully achieved set objectives thanks to a wide network of over a hundred partners throughout the world that are doing research on public opinion within national frameworks. These are usually reputable, professional institutions dealing with the aforementioned issues and they periodically send to the Forum high quality and useful information obtained as a product of various research undertakings. Within our regional area, the World Economic Forum cooperates with the Center for Advanced Economic Studies – CEVES in Serbia, National Entrepreneurship and Competitiveness Council in Macedonia, National competitiveness Council in Croatia and School of Economics and Business in Sarajevo in Bosnia and Herzegovina. The Forum publishes summarized results of conveyed researches, classified by areas, in its numerous publications, including the Global Competitiveness Report. It provides multiple useful data on competitive positions of most world countries, as well as their current competitive advantages and disadvantages.

3. RESEARCH METHODOLOGY IN THE GLOBAL COMPETITIVENESS REPORT

Certainly, one of the most significant research publications of the Forum is the Global Competitiveness Report which presents the calculated values of global competitiveness index and individual sub-indexes, in addition to many useful data on achieved levels of economic development of most world countries. Each analyzed national economy is first ranked according to the achieved result of global index, and then according to results of all three sub-indexes and twelve pillars of competitiveness. The end of the report provides a detailed overview of the constituent elements of competitiveness pillars, and results and positions achieved according to all of the analyzed criteria, making a total of over a hundred researched variables that are eventually manifested in the form of competitive advantages or weaknesses of a certain country.

The value of the index provides a better understanding of key factors that determine economic growth of each country, and it also provides the answer to one of the fundamental economic questions: Why are some economies more successful than the others in implementing the process of raising the population's standard of living? The Global Competitive Index records microeconomic and macroeconomic foundations of national competitiveness (The Global Competitiveness Report, 2009). In the current period of overcoming the consequences of economic and financial crisis, a very important role of this index in

measuring the impact of global recession to sustaining long-term competitive advantage of a certain country is strongly emphasized. We can extract three sub-indexes of competitiveness from the abovementioned index.

Figure 1. Sub-indexes of competitiveness

Source: Extrapolation of data from "The Global Competitiveness Report 2008-2009"

Presented sub-indexes consist of twelve pillars of competitiveness that are not independent but mutually connected, with the tendency of impact of one pillar on strengthening another and vice versa. Individually speaking, each pillar has different importance and unequal level of impact in the process of forming competitiveness of an individual country, primarily because of obvious differences in the level of development of countries.

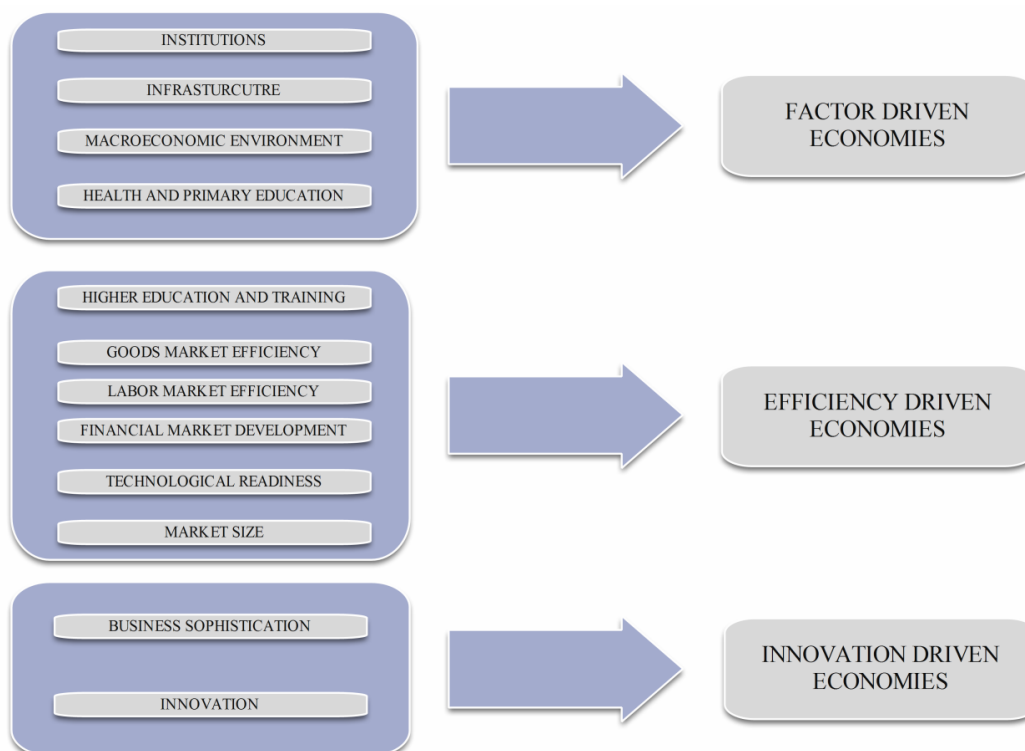

Figure 2. Pillars of competitiveness in various phases of development of national economy

Source: "The Global Competitiveness Report 2009-2010"

During the calculation of Global Competitiveness Index, the infallible and certainly the key fact is the level of development of national economy. In the initial stage of economic development, a certain country predominantly owns basic resources so it enters the competitive battle with the support of production factors, qualified labour force and natural resources in its possession. Further improvement of development is conditioned by growth of real wages and creation of conditions in order to enter the next phase where the emphasis is placed on encouraging efficiency. The country becomes competitive if it implements more productive manufacturing processes and improves the quality of its key products. In the mentioned phase it is essential to invest in the education of human resources, adopt new production technologies, improve manufacturing processes, create high quality products, create such an economic environment that is suitable for attracting foreign investors (reduction of customs tariffs, decrease of taxes, administrative procedures etc.), as well as to establish stability in the financial market. The last phase of development suggests that a certain country is able to keep wages at a significantly higher level and to provide an increase in living standards only if its companies are competitive in producing new and unique products. Developed countries, whose economies are precisely in this last phase, dedicate a great amount of attention to improving corporate culture, introducing innovations, protecting intellectual property and investing in research and development projects. The belonging of a certain country to any of these developmental phases also indicates the size of the Index, sub-indexes as well as its overall competitive position. In accordance with the previously described process of development and pillars of competitiveness that accompany each of the mentioned phases, we can derive three sub-indexes from the Global Competitiveness Index: Basic Requirements, Efficiency Enhancers and Innovations and Sophistications Factors. While calculating the Index, it is very important to adjust individual measurements to the degree of development of a specific country, and to take into account the contribution of each pillar of competitiveness to the final result. The methodology based on data from The Global Competitiveness Report 2010-2011 is as follows:

$$GCI_{ij} = W_{j1}Basic_i + W_{j2}Efficiency_i + (1 - W_{j1} - W_{j2})Innovation \quad (1)$$

$k = 1, 2, 3$

i – Index of a country

j – Stage of country development

W – Ponder

We note that the final result actually represents a weighted average of several different components, each of which represents only one part of the complex concept of competitiveness. All three sub-indexes of competitiveness are directly involved in the calculating of the global index, and therefore also basic pillars as their constituent elements that mutually influence each other in order to create a better final result. The determination of weights depends precisely on the participation of each sub-index in the mentioned developmental phases.

If we want to calculate the value of the Global Competitiveness Index of a country that is in the second phase of development, whose economy is driven by efficiency enhancers such as highly educated labour force, technological equipment, sufficient size and efficiency of the market, then the values of the weights are as follows: $W_{21} = 0.4$ / $W_{22} = 0.5$ / $W_{23} = 0.1$ and they determine the final result. The calculated value of the Index varies between 1 and 7 measure units, and it is value that affects the achieved position of a national economy on the list of global competitiveness, that according to the report from 2011 contains 142 countries.

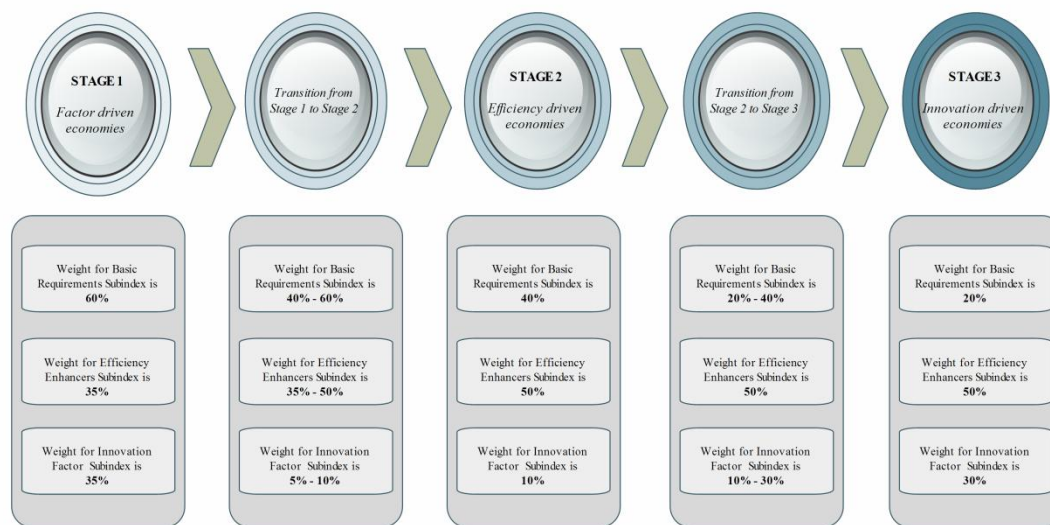

Figure 3. The participation of competitiveness sub-indexes in certain developmental phases of national economy

Source: Extrapolation of data from "The Global Competitiveness Report 2011-2012"

4. SERBIA – EFFICIENCY DRIVEN ECONOMY

In order to define the belonging of a national economy to a certain phase of development, it is necessary to take into account the realized value of GDP per capita, which represents a widely applied and readily available measure of national welfare. It is used instead of the amount of wages in a certain country, since this information is not internationally comparable nor it could be obtained easily. The Forum has set the following reference values of GDP per capita that determine the belonging of a certain country to a specific phase of development:

Figure 4. Value of GDP per capita in certain developmental phases of national economy

Source: Extrapolation of data from "The Global Competitiveness Report 2011-2012"

According to the results of a research conveyed by the World Economic Forum, Serbia is in the second phase of economic development – efficiency driven phase (Konkurentnost Srbije i Vojvodine, 2009). Apart from Serbia, our neighbours are also in this phase: Macedonia, Bosnia and Herzegovina, Albania, Macedonia and Romania, while Croatia and Hungary have a real chance to move into the third phase of development.

Figure 5. Value of GDP per capita in Serbia in the period between 2007 and 2010

Source: Extrapolation of data from "The Global Competitiveness Report 2011-2012", "The Global Competitiveness Report 2010-2011", "The Global Competitiveness Report 2009-2010" and "The Global Competitiveness Report 2008-2009"

We note that the value of GDP per capita from 2008 was reduced by as much as 1.500 US\$ in 2010, the year that can also be identified by the initial wave of economic and financial crisis. One of the key goals of further development of Serbia is precisely the increase in value of this indicator, i.e. the provision of greater social welfare. To reach this goal, Serbia must focus its strategy of economic development primarily on achieving dynamic economic growth as the basic material prerequisite for quicker increase in standard of living, and reducing unemployment and poverty (Bajec & Jakopin, 2006).

5. ANALYSIS OF COMPETITIVE POSITION OF SERBIA

Global Competitiveness Index of Serbia

In order to further deepen the analysis itself and to gain better insight into the movements of the Index, apart from Serbia, we showed the achieved results and positions of five strongest and weakest economies, especially for proper and objective consideration of the competitive position of our country. According to the last year Report, the research included 139 countries, whereas the current report includes 142 countries. The table below shows current results of the Global Competitiveness Index and, based on this, the positions of certain countries, with reference to the data from the previous year in order to detect changes.

Table 1. Values of the Global Competitiveness Index (GCI) in 2010 and 2011

Country	GCI 2011		GCI 2010
	Position	Result	Position
Switzerland	1	5,74	1
Singapore	2	5,63	3
Sweden	3	5,61	2
Finland	4	5,47	7
USA	5	5,43	4
Serbia	95	3,88	96
Yemen	138	3,06	<i>not measured</i>
Angola	139	2,96	137
Burundi	140	2,95	138
Haiti	141	2,90	<i>not measured</i>
Chad	142	2,87	139

Source: The Global Competitiveness Report 2011-2012

It is interesting to note that the top of the global competitiveness list no longer belongs to the USA, which used to be a common occurrence. Due to its fall from 4th to 5th position, in front of it now are Switzerland, Singapore, Sweden and Finland which, compared to the previous year, made a giant step forward, from 7th to 4th place. The last five countries, whose economies are in an early developmental phase, constantly occupy the bottom of this list it's just their order that changes from year to year. Serbia has also changed its competitive position, so from its best place, 85th in 2008 and the achieved result of 3.9, it dropped all the way to 96th place in 2010. It is interesting that the same global index value of 3.9 in 2011 provided Serbia with 95th place that year, since the list of competitors was expanded by adding new countries.

Figure 6. Changes in competitive position of Serbia in the period between 2007 and 2011

Source: Extrapolation of data from "The Global Competitiveness Report 2011-2012", "The Global Competitiveness Report 2010-2011", "The Global Competitiveness Report 2009-2010" and "The Global Competitiveness Report 2008-2009"

The apparent drop in the positioning of Serbia in this case refers to overall competitiveness, which in turn does not necessarily mean an identical fall within individual fields as well. However, it is still, compared to many countries of the world, at a low level of general economic development, whereas hindered conditions of functioning of Serbian economy in the period of crisis have certainly boosted the adverse results.

Sub-indexes of competitiveness of Serbia (*Basic – Efficiency – Innovation*)

We have previously stated and explained in detail that the Global Competitiveness Index contains three sub-indexes that indicate the achieved positioning of a country depending on the developmental phase to which it currently belongs. It is obvious that the sub-indexes are mutually conditioned and that only a highly competitive economy achieves good results in all three fields. The basic resources that a country possesses are its key source of competitiveness and the base for further development and conquering higher competitive positions. Improving efficiency and market expansion, high quality education and adoption of new technologies are characteristic for countries in development such as Serbia. Serbia will remain in this phase for a long time since it is still very far from the possibility of building high quality, sophisticated business systems and undertaking innovative business ventures as contemporary sources of competitive power.

Figure 7. Changes in competitive position of Serbia from the aspect of competitiveness sub-indexes in the period between 2008 and 2011

Source: Extrapolation of data from "The Global Competitiveness Report 2011-2012", "The Global Competitiveness Report 2010-2011", "The Global Competitiveness Report 2009-2010" and "The Global Competitiveness Report 2008-2009"

We note that Serbia is very poorly positioned in the field of achieved innovativeness and business culture, and that there is evident deterioration from one year to another (91→94→107→118). We can freely conclude that the lack of financial resources is a crucial factor in neglecting this area; that will undoubtedly lead to low rankings of Serbia even in comparison to some transition countries and put it at the bottom of the competitiveness list. It takes many years to reach a satisfactory level of economic development, provide financial resources and especially to change the consciousness of Serbian citizens about the importance of researches, patenting and scientific achievements.

If we take a look at the second sub-index, we will note that Serbia achieved slightly better results compared to the previous, but yet again there is deterioration in position in the observed years. Satisfactory health care, especially in the field of prevention of infectious diseases and the obtained level of primary education of the population had the largest effect on the better result of the second sub-index. It is also important to point out that investors interested in Serbia come across flexible wages, suitable employment policy and low cost of layoffs, which represents a significant competitive advantage. However, these privileges for the investors sometimes can be extremely disastrous for the country that is invested in, i.e. the host country. The dismissal of workers by foreign investors stipulates that unemployment may be a huge social cost which is manifested in its worst forms – urban violence, rising crime and social and political unrests. But even if there are no such problems, there are high costs of unemployment (Stiglitz, 2002).

The work of public institutions and infrastructure development in Serbia represent very problematic areas, which is confirmed by its poor positioning in the case of first sub-index of competitiveness. The abovementioned was also contributed to by uncontrolled spending of funds from state budget, citizens' discontent with the government, the rigidity of state measures and lack of judicial independence and efficiency.

Pillars of competitiveness of Serbia

We strongly support the above mentioned facts by breaking down and analyzing each sub-index in detail, citing the results and achieved positions in the field of individual pillars of competitiveness in the period between 2008 and 2011.

Table 2. Pillars of competitiveness of Serbia in the period between 2008 and 2011

Pillars of Competitiveness	Achieved position			
	2008	2009	2010	2011
Institutions	108	110	120	121
Infrastructure	102	107	93	84
Macroeconomic environment	86	111	109	91
Health and primary education	46	46	50	52
Higher education and training	70	76	74	81
Goods market efficiency	115	112	125	132
Labor market efficiency	66	85	102	112
Financial market development	89	92	94	96
Technological readiness	61	78	80	71
Market size	65	67	72	70
Business sophistication	100	102	125	130
Innovation	70	80	88	97

Source: Extrapolation of data from "The Global Competitiveness Report 2011-2012", "The Global Competitiveness Report 2010-2011", "The Global Competitiveness Report 2009-2010" and "The Global Competitiveness Report 2008-2009"

We are aware of the fact that Serbia has a very poor infrastructure network, and we are also witnesses that, in this sector, the process of liberalization has not yet started, and that the reforms are being carried out very slowly. Transition in the sector of economic infrastructure of Serbia demands progress in key areas such as tariff reforms, commercialization, competitiveness, privatization and legal institutional development (Bajec & Jakopin, 2006). Serbia constantly achieves its best position in the field of health care and elementary education. It gains its competitiveness through adequate ways and means of prevention of infectious diseases, extending the life expectancy of its residents and establishing a cost-effective and yet high quality system of elementary education. The institutional sector of Serbia and especially the government that takes care of macroeconomic stability deserves most severe criticism since it constantly lowers Serbia to the bottom of the competitiveness list. Governments often spend too much energy doing things they should not do. It distracts them from what they should really be concerned about. The problem is not only in the enormous size of the government, but also in not doing the right thing (Stiglitz, 2002). Lack of effectiveness of the goods market and extremely low level of business culture are particularly critical areas that we can clearly see in the analysis of the current position of Serbia from the aspect of individual pillars of competitiveness.

Figure 8. Competitive position of Serbia in 2011 from the aspect of pillars of competitiveness

Source: Extrapolation of data from "The Global Competitiveness Report 2011-2012"

It might seem impossible, but according to the current data on the goods market efficiency, our country is ranked similarly to undeveloped African countries. Such placement is primarily caused by inefficient anti-monopoly policy, high degree of market control and constant interference with its free functioning. Competition in the national market is at an unenviable level, whereas the entry of new, foreign competitors is rather difficult due to very unfavourable and inflexible conditions offered to foreign investors. Consumers in Serbia are not sufficiently informed about all aspects of purchasing, are unprotected from possible risks that arise from the act of purchasing and subsequent usage of the product, and they certainly lack the manners of modern consumers. The 130th place rank in the area of business sophistication seems very daunting, especially to foreign investors wishing to invest their capital in Serbian companies. It is very difficult to change previous habits and established, rigid norms of behaviour of workers and employers in the Serbian market. They are primarily not interest enough for developing a positive business culture as well as to creating a pleasant working environment. Employers often consider investments in education and training of their employees as irrecoverable costs and unnecessary waste of capital.

Actual competitive advantages and disadvantages of Serbia

In order to determine leading factors that impede the normal functioning of the economy and prevent smooth conduct of business activities in Serbia, the World Economic Forum and the Serbian Centre for Advanced Economic Studies – CEVES have conducted a survey among entrepreneurs and managers regarding the mentioned issues and singled out the most critical areas.

Figure 9. The most problematic factors for doing business in Serbia in 2011

Source: Extrapolation of data from "The Global Competitiveness Report 2011-2012"

Current business instabilities are generated exactly by those factors that influenced low values of global index and sub-indexes of competitiveness and caused Serbia to gain extremely poor position in the competitiveness list. Inefficient government, high levels of corruption, lack of funds and poor credit conditions, as well as high inflation rates generate almost half of the problems in the business activities of Serbian entrepreneurs. The aforementioned and other presented factors strongly reject foreign investors from the idea of starting a business on the Serbian market. They are particularly concerned about

constant political instability, very expressive corruption, rigid foreign exchange regulations and poor work ethic. Long lasting procedures for obtaining building and other permits, insufficiently precise legislation governing many business areas and unfavourable tax treatment of business entities are additional elements that make Serbia a very unattractive investment destination. In 2006, the Serbian Government adopted the "Strategy of encouraging and developing foreign investments" that defined the activities aimed at improving the business environment, providing support and incentives in order to attract foreign investments and boosting export. The action plan for removing administrative barriers for foreign investments includes measures and activities in the following areas: establishment of companies with foreign capital, infrastructure development, functioning of companies, reforms of public administration, judicial reforms and other system measures (Bajec & Jakopin, 2006).

By breaking down the presented pillars of competitiveness into constituent elements, we can obtain data on over a hundred variables that are manifested in the form of competitive advantages or disadvantages of Serbia. The implementation of this process is not performed according to the same methodology for all countries, but depends on the ranking of a certain country on the overall list and the realized value of the Global Competitiveness Index. Advantages and disadvantages of the countries that occupy the top 10 places on the abovementioned list are also differently determined compared to those in places from 11th to 50th, as well as countries that are ranked in the second half of the list, i.e. below the 50th place. We have concluded that in 2011 Serbia takes 95th place; the value of its Competitiveness Index is 3.9, in which case we apply the following rule:

1. If a certain variable enables ranking of Serbia onto any place above the 50th, it represents a competitive advantage.
2. If a certain variable enables ranking of Serbia onto any place below the 50th, it represents a competitive disadvantage.

Taking into account the abovementioned rule, we come to a very discouraging conclusion. According to current measurements of the World Economic Forum, Serbia has only 14 competitive advantages, while nearly a hundred remaining variables represent competitive weaknesses. The advantages themselves are quite modest, since they are manifested in the form of widespread telephone and Internet networks, mass usage of mobile phones, low costs of workers' severance pay and established legal regulation of the financial market. Serbia also has advantages in the field of successful prevention of infectious diseases such as tuberculosis, malaria and AIDS, whereas a satisfactory level of elementary, secondary and higher education of citizens and high quality math and science education could become potential competitive advantages.

6. CONCLUSION

In the period of overcoming the consequences of the crisis, continuing economic transition and accelerating process of EU membership, Serbia has to pay more attention to improving its own competitive position in order to create real opportunities for attracting foreign investors and to start economic growth. This goal is very ambitious and requires a lot of time, resources and sacrifices in order to begin its implementation. One of the obstacles is the institutional sector of Serbia that is at a very low level of development, especially due to inadequate functioning of the government, presence of organized crime, anti-competitive behaviour of companies and lack of interest in providing more convenient conditions to foreign investors. Dilapidated and unmaintained roads and railways hinder both usual and business movement of people, and slow down and often prevent normal functioning of trade flows. The most important problems in the energy sector are insufficient capacities for generating electricity and the dependence of the country on energy imports. A critical issue every winter is the insufficient capacity for storing natural gas used by households and industry for heating (Bela knjiga, 2009). The constant threats of inflation, unfavourable interest rates and government budget deficit are constant problems whose solution is very uncertain at the moment. Serbia can be praised for the rapid development of telephone and internet network that in the future may become its significant competitive advantage. In recent years, there has been significant progress in the prevention of infectious and other diseases, protection of human health and prolongation of its life expectancy. If we add to the aforementioned the improvement of elementary, secondary and higher education system by introducing more modern principles of operating,

we can note that the competitive potential of Serbia definitely lies in capable, professional and qualified labour force. However, young professionals are rarely provided with adequate treatment after completing their education, which contributes to further continuation of the phenomenon of “brain drain” from Serbia in the future. The dominance of individual over global goals, as well as the aspiration of the governing coalition to meet their own interests has led to rapid impoverishment of Serbian population. One of the key competitive weaknesses that make Serbia a very unattractive for foreign investors is underdeveloped business culture, lack of work professionalism and disrespect of ethical values.

PUBLIC SECTOR MANAGEMENT IN CRISIS: DISORIENTATION CASE OF SLOVENIA

Lea Prijon¹, Uroš Pinterič²

Abstract: *Since 2007, when the economic crisis in the world started, we have been facing various attempts to improve economic stability and re-introduce growth in individual economies around the world. However, despite some indications that after 2010 economy slowly started to recover, today it is more or less obvious that it was just a false hope before a further step downwards. In this general trend, Slovenia has not been an exception. However, what makes the case of Slovenia different is its transitional struggle with economic principles, especially in the light of its lack of political maturity. The article itself is mainly focused on different measures that have (not) been taken in order to improve economic recovery in Slovenia.*

Key words: *economic crisis, public sector, Slovenia, reforms, politics, transition*

1. INTRODUCTION

Severe economic situation in the world since 2007 opens several serious questions. However, governments as well as economy in individual states as well as globally, are mainly addressing only those which are considered as mainstream supportive. Such behaviour can be understood contra-productive and not solving the economy. However, situation itself directly influences not only private sector but public sector as well. Despite the article shall discuss influence of recovery measures on the public administration or better on public sector in Slovenia, it is necessary to set certain point of perspective which can help us to understand mismanagement of public sector in the time of crisis. Thesis that we will try to support in this paper is that economic crisis in certain state can be generated by state or recovered with help of state but it remains economic crisis and not state crisis. European Union (in some cases for sure absolutely justified, but not in general) was searching for the opportunities to create next cycle of economic growth in systematic cutbacks of public expenditures of highly indebted states. However, little incentives were offered for economic recovery. Greek case was used as potential scenario for each state that did not take all the necessary steps to reduce the size of public sector to almost minimal level. In 4th year of economic stagnation or recession Brussels realized that reducing public expenditure is not working and in mid-April first information on starting economic incentives was released. Initial information is that there will be 200 billion Euro investment plan in order to start new economic cycle based on investments into infrastructure, green energy and hi-tech development. By changing the direction of recovery plan, European Union indirectly admitted that public sector cannot be responsible for economic crisis in a sense of being shock absorber for what went wrong in private sector. However, states can be held responsible for bad management of public finances during the years of economic growth which helped to low possibilities for state intervention in economy during the recession.

2. HISTORICAL BURDEN OF SLOVENIAN PUBLIC SECTOR

After change of political and economic system Slovenia should start transition in what is market economy and democracy. However, it seems that political transition (in the sense of establishing transparent and relatively free, plural electoral system) was much more effective than economic one. Main problem that was never completely resolved was privatisation. Slovenian government tried to keep main state companies under control as long as possible and it was trying to support them in order to reduce the chances for bankruptcy. By doing so Slovenia managed to reduce the risk of social instability due to increased number of unemployed, but on the other hand, state was systematically spending enormous budgetary funds, not only on social security but also on preserving status quo in the semi-private sector. By doing so, Slovenia developed system of semi-state owned or state controlled (via ownership shares) companies which existence was secured by the state budget (state in fact guaranteed for their loans). Same goes for the biggest bank system in Slovenia (NLB d.d.) which is state owned and considered of strategic importance which opts-out possibility for foreign investment. In recent years, state invested hundreds of millions of Euros in order to keep NLB d.d.

2 Uroš Pinterič, PhD. is senior researcher at Faculty of Social Sciences, University of St. Cyril and Methodius in Trnava, Slovakia, uros.pinteric@gmail.com

working. By doing so, state was clearly indicating mainly one thing. It will not let allow classical capitalist logic take over the private sector. In this perspective state was trying to introduce different measures also after 2008, not only to keep jobs but also to keep bad companies alive.

3. MAIN ISSUES OF SLOVENIAN ECONOMY

Slovenian economy was due to the historic development of market economy relatively closed to foreign investments and at the same time domestic companies were due to the administrative and taxation burden eager to move abroad. Despite Slovenian workforce is rather expensive, the main problem is lack of innovation and lack of its flexibility on the individual level (people prefer state support than searching for working opportunities). Despite state sees this mainly as the problem of structural nature at labour market, it is more likely to be problem of classical socialist assumption that state should take absolute care of unemployed person. Despite some measures were taken (need to take job opportunity given by unemployment agency in order to keep unemployment subsidy, need to take offered job for education level lower for two levels after certain period of unemployment, etc.) people were mainly misusing these opportunities. People were attending job interviews and openly saying that they are not interested to work, getting employed and sabotaged the work in order to get fired and receiving unemployment subsidy again.

In order to introduce better opportunities for self-employment state was issuing grants in the approximate size of 4500 Eur from European Social and Structural funds under condition that company of self-employed person will work for at least two years. This was misinterpreted by state as providing starting opportunity and by grant receivers as free money. Because when self-employed person started the business quickly realized that grant will cover barely social security fees while burden of accounting, other taxes and salary is absolutely on the worker, who started business usually with 4500 Eur of free money in the mind and without serious strategic plan, how to run business and also without proper knowledge of the economy. In this sense waste majority of such enterprises was closed down after initial two-year period.

On the other hand, established companies have interesting approach of seeing state role in the economy. They are systematically demanding reduction of state burden for private sector in three different ways. First is lower taxation burden on the profit. Main reason shall be increased share of profit for reinvestment into business, but there is significant doubt that companies would sign the agreement which would oblige them to do so. On the other hand, avoiding taxation, companies are trying to run around zero profit level. Second, companies demand lower burden of work force price. Each worker cost company about 30-40% more than just net salary due to prepayment of personal income tax (25%, social and healthcare benefits and pension fund). We need to add also travel cost reimbursement and lunch payment or provision which are rights that belong to workers. Third demand from private sector is need for labour market liberalisation, which would enable companies to hire and especially fire people much faster and with less negative effects for the company.

From this perspective private sector is on one hand avoiding taxation and on the other hand it demands less security of jobs. They are not interested in level of life standard and quality. Answer who should protect individuals remains unanswered. From this perspective slavery should be ideal economic regime from private sector perspective.

However, it is interesting that private sector in general sees state responsible for keeping them solvent. This goes especially for state controlled companies. In this sense we observe situation when owner shall take care of the resources which should enrich shares for it. State owned company should try to realize as much as profit on market in order to support state budget and not ask for financial support from the owner. And owner (state) should sell or let go bankrupt company that is not doing so. From this perspective we can call such pattern of economy still transitional at its best or we can critically refer to it as reversed communism of private sector, where private sector demands from the state planned economic policy enabling private sector to develop environment of state secured zero profit level with benefits.

In this situation state follows political logic of keeping the power as long as possible between active economic elite and passive public/work-force. In this situation state is much more willing to create economic and labour policy according to the demands of the private sector. Because they always count on the fact that people will slowly get used to any negative change which will not take effect immediately before the election. Second problem with the state in the case of Slovenia is that, state is still one of the greatest domestic consumers, especially for certain types of the products, such as construction. At the same time economic crisis revealed also that state is one of worst payers. In the case of construction industry, economic crisis revealed that companies were not paying workers social, healthcare and pension fees, as well as not sub-contractors for months and that on the other hand state was not paying for projects in timely manner. Consequently all mayor construction companies were destroyed (SCT, Vegrad, GP Grosuplje, Primorje), few thousands of workers become jobless and sub-contractors are mainly not paid off because banks have

priority in the process of paying off the debt of certain company. At the same time construction companies were creating their own companies in order to spread revenues and for keeping low profit.

In this sense state is more than obviously protecting capital prior to labour because it is allowing the system where debt to the banks shall be served in the process of bankruptcy prior to other debts, which usually causes that there is little or no lefts to pay off sub-contractors and workers. By doing so state actively support lowering the standard and life quality as capital oriented economic policy. By doing so, state creates extra budgetary costs due to higher requests for social security by workers/citizens. Under described situation there is no possibility for budgetary balance and even less for sustainability without serious reforms of whole economy.

4. PUBLIC SECTOR IN THE CRISIS

Description of the general situation in previous part leads to the increasing pressure to change work of the state or public sector. In order to understand the situation better, we are presenting few data on Slovenian budgetary, and public sector situation. According to the Slovenian Statistical office debt of the state was growing form 18,6% GDP in 1995 to 47,6% in 2011.

Table 1: Government gross debt as % of GDP

year	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011

Source :Internet 1 (3.5.2012)

However, all the threats with Greek scenario and similar cases can be considered as general overreaction and media supported intimidation. Main goal of such activities is aforementioned need to cut public expenditure and reduce social security. Eurostat data on the Government gross debt as % of GDP. (Table 2) shows that Slovenia has only about 60% of EU member states debt average in 2011.

Table 2: Comparative government gross debt as % of GDP for 2011

Source: Internet 2 (3.5.2012)

Table 2 shows that Slovenia is 12th least indebted country within the EU. In order to get to the point of Greece technically, Slovenia would need to in-debt itself for another 4 times. And if we compare Government debt in Germany one can see that it is almost twice as high as in Slovenia in 2011. From this perspective it seems that public spending, despite it is far from sustainable is not main problem of economic recovery in Slovenia

Table 3: GDP growth rate (in %) compared to the previous year, sorted descending on basis of 2011

Source: Internet 3(3.5.2012)

From table 3, one can see that Slovenian GDP growth drop in 2009 was fifth most serious after Estonia, Latvia, Lithuania and Finland. Only difference is that in 2011 aforementioned countries are realizing among highest levels of GDP growth while Slovenia, keeps bottom with Japan, Portugal and Greece.

However we can nicely see from the unemployment table that Slovenia in the time of crisis did not take appropriate measure to act against unemployment problem. This shows inability of state and economy to cope with increasing number of jobless workforce. Despite general unemployment in Slovenia compared to other states or different averages is still relatively low Slovenian unemployment rate almost doubled from 2008 to 2011 while in some other states such as Czech Republic, Belgium, Sweden, Finland as well as in the Euro zone and EU27 unemployment rate was stabilized in 2010. In concrete numbers this means that since 2008, Slovenian unemployment rate rose from approximately 65.000 to approximately 115.000 unemployed people available for work. According to statistical data from Slovenian Statistical office highest unemployment rate was in 1993 with 9,1% (Internet 5), which indicates that current economic situation has as devastating impact on labour market as change of political and economic system had it 20 years ago.

Under these circumstances, Slovenian public sector needs to take measures in order to save economic situation according to the government plan. Slovenian labour market consists from approximately 1 million workers out of which 8,2% are currently unemployed and around 930.000 are working. According to the report of Agency of the Republic of Slovenia for Public Legal Records and Related Services at the end of 2007, Slovenian public sector had 154.500 employees and by the end of 2011 number raised up to 160.900 public sector employees³. Total number of those that were directly paid from the budget dropped from approximately 42.800 to 42.600 employees (Internet 6) The difference of 111.000 to 120.000 employees is composed from employees in public services such as pre-school education, all three levels of public education (primary, secondary and higher education), public research institutions, healthcare and social security system. According to the same data set there is approximately 3.750 employees in public sector on individual contract (usually directors of public sector institutions) with the average gross salary of 3.557 Eur, while rest of 157.000 employees, working on the basis of the collective contract receive average gross salary of 1.785 Eur. At the same time, general (of both, private and public sector) average gross salary was, according to the data of Slovenian statistical office, 1.546 Eur.

Possible solutions are going in two different ways. One is reducing the size of public sector as such, despite its size is relatively close to the size of public sector in any other EU member state (in relative terms). Any significant cut in public sector size would increase the number of patients per doctor, and students (pupils)

3 Number is estimated on the sum of working hours.

per teacher. It is known that Slovenia has already huge problem to provide adequate number of doctors of different profiles to serve the needs for healthcare. Privatization of the healthcare and education could partly solve the problem, but there is significant doubt that private pricing would mean also private quality. This is questionable especially in higher education where Slovenia is facing serious problems by lack of control over quality of knowledge as well as over the quality of performance. Problem is connected to the general idea that state should take care of all the risks while profit will be collected by private institutions. In general Slovenian public sector represents approximately 18% of all working force and in such situation government sees main solution to the economic crisis in reduction of size of public sector.

Second suggested option is reduction of public sector expenditures. Current government is proposing 800 million Euro savings project which reduce salaries in public sector for more than 10%, shorten 100% covered maternity leave from 1 year to 3 months and in the last quarter to approximately 70-80% of full subsidy. Different other benefits or incentives could be limited as well. However, at the same time, government is not really pressing on state owned companies to act more responsibly and it is thinking about new additional financial investments in order to save them from bankruptcy.

Additional level of cynicism is shown by some high civil servants who are calling public sector for more responsible behaviour in a private sector terms. Especially in the field of research and development there are demands for more market oriented or applicative research that will produce some added value for economy. Such approach might be seen as good thinking but the problem is that economy – especially Slovenian one is mainly relying on state support than on innovation and application of theoretical findings in the practice. Hereby, civil servants usually forget that higher education has double role (one is basic research in any given field and second is transition of the knowledge on the young generation). Role of the new graduates and economy is to find the way how to apply knowledge into innovative products. Demanding otherwise is like expecting doctor to do the diet on patients' behalf.

6. CONCLUSION

From the general development of current economic situation in the world and aforementioned changes in EU policy, where member states realized that cutting the expenses was not very effective solution. At the same time, general statistical data (at least those which are usually presented as indicators of the problem in Slovenian case) show relatively low level of relevance on the solution side of thinking. Slovenian Public sector was not growing exponentially and 160.000 employees mainly include those people who are providing services of higher life quality (education, social and healthcare security, cultural development, etc.). Reducing the size or costs of these services can have significant influence on the long term potential for the development of the state. Despite there are possibilities to rationalize and reorganize public sector, there is for sure no reserve to save almost one billion Euros without serious danger to general quality of life.

In this sense Slovenian government shall concentrate on recovery of economy by investment in perspective products and services (even if this means some additional increase of the debt in first phase) and only in the phase of recovery state should start to think about savings.

Last point which should be stressed again is that Slovenian government should provide higher level of transparency of use of public finances, should do more in the field of separation of political and economic elite and in final stage should decide to provide serious transition in economic sphere where state will be on the side of protecting the quality of life for general population (providing public goods and services) and where private sector will have nothing more but fair chance to compete for those projects which would be outsourced by the state. In order to achieve this, state shall start to demand from state owned enterprises to produce profits (in the cases where public goods are not in question) and on the other hand state should not interfere into economy by saving enterprises but by providing stimulative competitive environment on one hand and protecting level of life quality on the other hand. Surviving on the market shall be issue of owners and managers of the companies.

THE SELECTION OF SOFTWARE FOR THE INFORMATION SYSTEM IN UTILITY SERVICE DEPARTMENT „VODOVOD IN VALJEVO“

Dejan Stajčić¹

¹ Utility service department „Vodovod in Valjevo“, stajcic@verat.net

Abstract: *This document shows the research carried out on the selection of software for the Information System in Utility Service Department Vodovod in Valjevo. It also clarifies the basic alternatives and criteria which were taken into serious consideration while making the best choice of software for the Information System in Utility Service Department Vodovod in Valjevo. The most important reason for introducing a new software for the Information System is the inadequacy of the current one as well as the growing necessity of introducing a software which will integrate all organizational units into Utility Service Department Vodovod in Valjevo. The aim of this research is to analyze all relevant solutions and to select a solution which is compatible with the needs of the organization. The research has been carried out in three different phases. We developed and used "Additional questionnaire" in the first phase of the research, Delphi method was used in the second stage of the research whereas AHP method together with application software was used in the third stage of the research. After a detailed study, we concluded that the most acceptable and adequate alternative for the implementation of the system is Digit alternative. Utility Service Department Vodovod in Valjevo has all rights to change the given parameters. This model of making the best selection, which includes three phases (together with the developed 'Additional questionnaire') as well as the combination of decision-making methods with the use of the software, can also be used as a model of decision-making when other organizations have to choose the best software for their Information Systems.*

Keywords: *Information, System, Integrated, Software, Solution, Choice, Decision, Analytic, Hierarchy, Process,*

1. INTRODUCTION

All organizations that want to develop their businesses successfully and to retain their dominant positions in the market economy environments have to value information properly and manage with it adequately. The developed information system makes it possible to achieve.

„An information system can be defined as a set of interrelated components that collect, manipulate, store and disseminate data and information and provide a feedback mechanism to meet an objective“ (Vavpotič., 2012). Therefore, each organization should dedicate itself fully to the selection of adequate software for its information system. That particular software should suit the needs and specific conditions of a particular organization. This means that all relevant decision-making criteria as well as alternatives, which are suitable for the implementation of a concrete system, need to be defined when choosing the best software for the information system. The selection of software for the information system must be adequate because the successful development of all organizations depends exactly on this selection.

2. THE REASONS FOR DECIDING ON THE SELECTION OF THE SOFTWARE FOR THE INFORMATION SYSTEM

Utility Service Department Vodovod in Valjevo is an organization with proactive plans for the future which keeps pace with the latest market innovations. The Management Sector of the company in association with Development Service has defined the goal of the company which is based on the need of introducing new software in the information system, so that the goals set could be efficiently achieved in the future. New information system should be integrated into all business functions inside an organization i.e. it should be involved completely in its business activities. Two basic sectors which would be fully integrated by introducing new information system are presented in the organizational scheme. These two sectors are: 1. Economic Legal and General Operations Sector, 2. Technical Production Sector.

New integrated software should consolidate these two sectors. Also, it should enable its users to exchange information in an effective and efficient way. With the help of such an exchange of information the management of the company will be able to handle with difficulties and to make proper decisions in time.

The introduction of new integrated software would enable the introduction of a higher management level, the development and application of new business strategies, lower business expenses, and the increase in

productivity. Also, it would allow the increase in flexibility, standardization, in the quality of information, integration of business activities, and reengineering. Furthermore, new integrated software would allow the enhancement of business processes, higher level of their efficiency, fast data entry and the implementation of professionals' methodical and rich experience accompanied by the professional training.

Considering the fact that keeping pace with the latest innovations in Information Technologies is indispensable part of any business activity, the Management of Utility Service Department *Vodovod* in Valjevo has decided that the top priority of the company is to introduce new software for its information system.

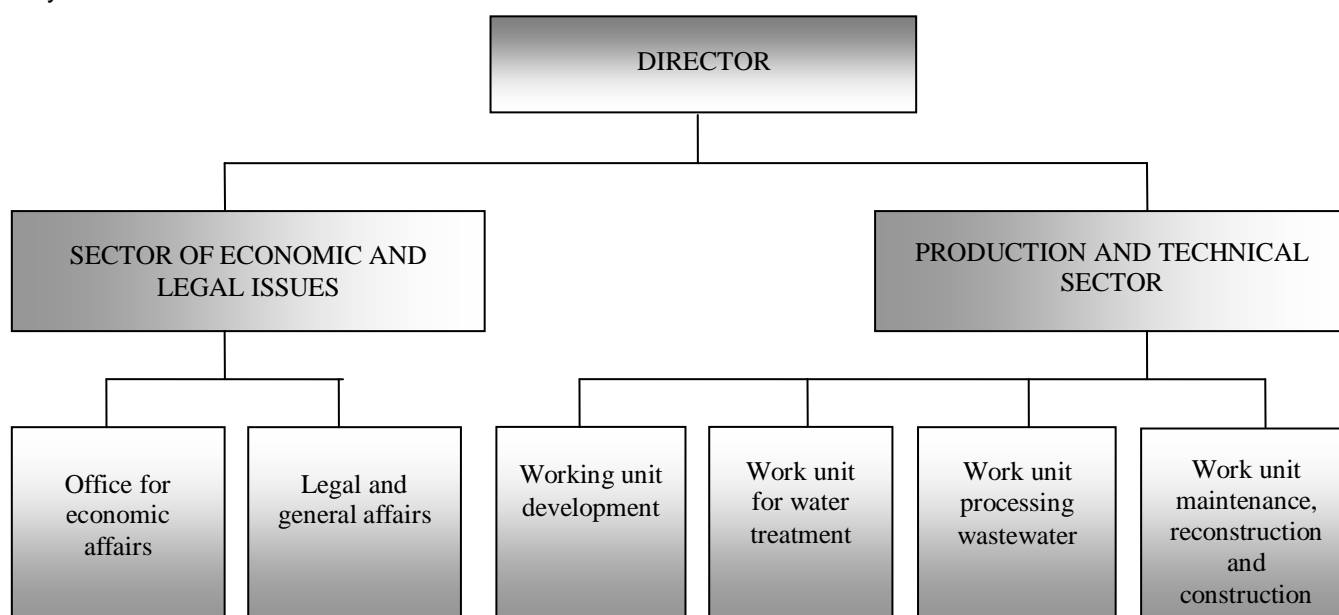

Figure 1: Organization chart in “Vodovod – Valjevo”

3. DECISION ALTERNATIVES

The Department of Development has defined five decision alternatives. These alternatives are the most available and current possibilities for the introduction of the integrated software on our market. All five alternatives have been listed in the first decision-making.

- Mycrossoft Dynamics,
- AB soft,
- Digit,
- SAP and
- The company's own alternative.

Microsoft Dynamics NAV 6.0

The main *Microsoft Dynamics NAV 6.0 platform* features and benefits are: it has more than 46,000 users, more than 2,000 partners with licences, more than 41 localized versions of a product which was sold in more than 130 countries. The offer of the project for the implementation of *Microsoft Dynamics NAV 6.0 CS* includes the information system's concept design, a questionnaire, an interactive meeting, presentations and an opportunity to share the experience gained on a similar project for the implementation of the information system in Utility Service Department *Naissus* in Niš. The offer is based on:

1. the usage of 12 (twelve + 1) licences for simultaneous users (BSC Software., 2012),
2. the operating modules which are the part of a standard licence range: Financial accounting, the basic assets and a low inventory, planning and budgeting, supplies and obligations, storage and storehouse operations, sales, marketing and receivables, Personnel records and business analytics;
3. additional modules for *financial reports* such as: input calculation, VAT (value-added tax) records, cards GK, a client supplier, articles and fixed assets. The *specific modules designed for Utility Service Department activities*: the system of customers' personal information, the system of personal property water measurements information, tellers' operations (unlimited number of counters, mobile counters). The *specific modules designed for the water-supply activities*: the control of the maintenance of water meter, the control of the maintenance of the network and storehouse, the

- register and calculation of water consumption, complaints, collection letters as well as preparation for the integration into Web application that allows water meter reading entry,
4. the formulation of the project plan and documents,
5. the implementation and
6. providing training and support for customers.

AB soft

AB soft business software is designed for only one legal person and for only a specific number of users set by the company business who can install and work on this software. *AB soft* includes: „financial management service (financial service accounting, financial executive, the Treasury), the management of material resources (material accounting and fixed assets), the staff management (staff records and earnings accounts), the information system management (it implies the formation of users who have certain legal rights to access different parts of the information system)“ (Ab., 2012). There are several levels of customers' rights which could be adapted to suit the needs of each customer individually. Customers' performance data (data entry, data change, data deletion...) is recorded in data base.

Primary maintenance of *AB soft* business software includes 12 months, starting from the day when a customer signs the contract to legally use *AB soft* business software. Primary maintenance includes: the usage of the adaptation of the original *AB soft* business software, which is produced when the need for it arises, in order to adjust changes of regulations in database processing and to eliminate possible latent failures of the business software. After the expiry of these 12 months starting from the day when a customer signs the contract, *AB soft* will continue the standard maintenance of the contracted *AB soft* business software provided that a customer decides to sign the contract with *AB soft* which implies extension of the standard maintenance of contracted *AB soft* business software. Annual *AB soft* business software usage fee is 20 % of the royalty fee when using the contracted *AB soft* business software, starting from the day when a customer decides to sign the contract with *AB soft*, which implies extension of the standard maintenance.

Digit

Software package *Digit* from Belgrade is a product which consolidates modular and parameterized functional units which are implemented in more than 20 related businesses. Software package *Digit* from Belgrade suits the needs of all customers. „It is based on the experiences and real needs of numerous users“ (Digit., 2012). It can be automatically filtered and it enables users to search and select different information by various attributes. It is vital that all future users are well-prepared to deal with this software. It includes: the registration of the connection requests, the analysis of the connection requests, an issue of incorporation, the registration of customers, the registration of product consumption, settlement of accounts, accounting for manufacturing businesses, collecting customers' charges, customers' exclusion from the system, the system of products classification, the description of the integral elements in complex products as well as planning when providing supplies. It also includes: the classification of products, storehouse activities when providing supplies, the registration of the fixed assets as well as of the equipment and set of tools, the maintenance of the fixed assets, equipment and tools, financial accounting (general register), customers, suppliers, the treasury, material accounting, project accounting, budget planning, monitoring of budget realization, the definition of parameters for income account, the registration of performance data and income account, the definition of the organizational structure, the organization of workplaces, the registration of employees' personal information, the registration of employment changes, employment record book, the registration of documents (registry) and the electronic archive system.

The development of company's own alternative is seen as a decision-making alternative. The development of company's own alternative would create the alternative which suits the needs and requirements of the Utility Service Department *Vodovod* in Valjevo. However, the implementation of such an alternative wasn't achieved because the company lacks proper technical and time potentials. The investment in new equipment and the employment of skilled and highly experienced professionals in this field of work would bring about considerable expenses.

Also, this alternative would require a considerable amount of time to create, develop and test its new possible solution. Because of these limiting factors this alternative was rejected after the first stage of decision-making (*Delphi method*)

SAP ERP software is designed to suit the needs and requirements of large and middle-sized companies covering all industrial organizations and sectors:

- SAP ERP Human Capital Management – transforms the role and the value of human resources.

- SAP ERP Financials – transforms financial management into a strategic business partner.
- SAP ERP Operations – bring about efficiency and rapidity in company's operations.
- SAP ERP Corporate Services – modernize business processes and the analysis of expenses.

SAP ERP Financial system includes „planning and realization of budget, general register, finance, supplies, fixed assets, management accounting, material accounting, and full maintenance of technical systems and all staff activities as well as sales i.e. invoicing“. (Sap., 2012). The price of SAP system is approximately 400,000 Euros. Its high price was the dominant factor which categorized SAP system as unacceptable in the first stage of decision-making (Delphi method).

4. DECISION - MAKING CRITERIA

The next important task when selecting the best software for the information system is to define and value decision-making criteria. The Development Working Group has defined the following eight decision-making criteria:

- the price criterion,
- functionality,
- stability,
- the number of users,
- reference list (the implementation in Utility Service Departments in Serbia),
- compatibility with the knowledge and skills of the employees,
- compatibility with the hardware technical system and
- advisors' assessment.

The price criterion is the first decision-making criterion we agreed on. Taking the company's limited assets into account, we had to recognize the great importance of this criterion. When we first considered defined alternatives, the alternative number 4 SAP and the alternative number 5 exceeded the company's budget. Therefore, these two alternatives didn't reach the second stage of the decision-making analysis and weren't accepted as possible solutions. Functionality is the criterion which takes the functionality of the suggested alternative into serious consideration i.e. it examines how well the given alternative performs business activities and carries out functions set by a particular company. The stability of the selected solution is the criterion which determines the level of system reliability and safety. The alternatives which showed higher level of reliability and safety will be given a higher mark.

Another important decision-making criterion is the number of users. Each suggested alternative depends on a specific number of users. The suggested alternatives will get a specific number of points depending on the number of their users. The alternative with the largest number of users will get the most points and will be placed first according to this decision-making criterion. The reference list criterion is one of the already defined decision-making criteria. It ranges the given alternatives according to their number of implemented solutions in the systems of the same or similar business activities inside the country. In this way, we put a greater value to those alternatives with larger number of implemented solutions inside the systems of the same activities (Utility Service Department –Vodovod and sewage-in the country). The introduction of new information system faces strong opposition from the employees in every organization as they are used to the old system of working. In order to bridge the gap between the old and the new system, new information system has to be compatible with the knowledge and skills of the most employees. Therefore, the alternative which is the most compatible with the knowledge and skills of the employees will be placed first according to this decision-making criterion.

Hardware can be a limiting factor if the software solution is too demanding. Utility Service Department began the phase of introducing new computer network which is designed to fully suit the needs of the information system. Considering this criterion, the limiting factors are computers. All computers in Utility Service Department in Valjevo belong to the old generation of computers. This means that additional assets are needed in order to raise the technological level of computers. The software solution that requires lower expenses will be given a higher mark. Utility Service Department Vodovod in Valjevo is a system which has always cooperated with the most eminent science institutions in the field of Information Technology and Management. For these reasons, outside advisors took part in the decision-making process on the new software alternative and they assessed the given alternatives. The alternative with the highest mark will get the most points according to this decision-making criterion.

5. THE PRESENTATION OF A DECISION - MAKING MODEL

The decision-making model developed and implemented by Utility Service Department *Vodovod* in Valjevo consists of three phases. In the first stage, the employee, who is responsible for the Information System, decided upon the alternatives which will be the case of the further analysis and decision-making process based on the „Additional questionnaire“ (which is defined as a model for other organizations).

„*Additional questionnaire*“ enables quantitative assessment of the alternatives. 'Additional questionnaire' includes the following six questions:

- 1) The lowest market price,
- 2) The highest market price,
- 3) The optimum price,
- 4) The alternative with the largest number of functionally modular characteristics,
- 5) The alternative which is time-saving and
- 6) The alternative which requires optimum time for the implementation

An alternative has to meet the requirements for at least one of the presented questions if it is to be on the list of desirable alternatives. By comparing the possible alternatives with the list of these questions, an IT expert has formed the list of desirable alternatives which deserve attention due to their quantitative characteristics. After answering to these questions, an IT expert has formed the group of desirable alternatives. These are: *Ab soft*, *MS Dynamics*, *Digit*, *Sap* as well as *the development of company's own alternative*.

Delphi method was used in the second stage of decision-making process.

This method 'is carried out in several steps (circles) which lead to the prediction acceptable to all experts' (Matić, 2008). Delphi method determined the final list of the alternatives which will be taken into consideration during the third stage of the decision-making process. In the first stage of Delphi method decision-making, the team of experts were asked which information system is the most relevant system to be implemented in Utility Service Department *Vodovod* considering five offered alternatives: Microsoft Dynamics, AB soft, Digit, SAP and the development of company's own alternative. After we acquired results in the first stage, we moved to the second stage of decision-making. Professionals were assessing the given alternatives of all experts. While defining their claims, experts presented their marks and commented on each alternative one by one. As the final result of Delphi method decision-making process, it has been concluded that SAP and the development of company's own alternative received the lowest rating. As such, these alternatives are unacceptable for the further analysis and decision-making. Most experts' opinion is that these two alternatives are too expensive. The development of company's own alternative is not only too expensive but it is also time-consuming. Therefore, both alternatives were marked as unacceptable and they didn't enter the third stage of decision-making.

The third decision-making stage uses *AHP method* (Analytic Hierarchy Process method), together with the software for the method implementation. One of the best decision-making softwares is Expert Choice and it can be used in this decision-making process. AHP method implies analytic hierarchy process method. This method enables the person who makes a decision to include his/her personal point of view, personal experience, knowledge and his/her intuition in the decision-making process. AHP method presents complex problems as a model of hierarchy. This kind of model requires four phases: "problem structuring, data collection, the assessment of relative complexities and problem-solving decision" (Suknovic., 2010).

The price criterion

9 8 7 6 5 4 3 2 | 2 3 4 5 6 7 8 9

</

Figure 2: Comparison criteria

AHP decision-making result is shown in picture 3, Line number 1 shows Digit alternative, Line number 2 shows Microsoft Dynamics alternative, and Line number 3 shows AB Soft solution.

Figure 3: Comparison of alternatives

Table 1: Value criteria and alternatives

Num.	Criteria	Value criteria	Ateranativa rank in relation to criteria	
1.	Functionality	0,332	Digit	0,584
			Micro.Dyn.	0,281
			AB Soft	0,135
2.	Reference list	0,226	Micro.Dyn.	0,517
			Digit	0,359
			AB Soft	0,124
3.	Stability	0,158	Micro.Dyn.	0,517
			Digit	0,359
			AB Soft	0,124
4.	The price criterion	0,107	AB Soft	0,717
			Digit	0,195
			Micro.Dyn.	0,088
5.	The number of users	0,072	Micro.Dyn.	0,517
			Digit	0,359
			AB Soft	0,124
6.	Compatibility with the knowledge and skills of the employees	0,045	Micro.Dyn.	0,474
			Digit	0,376
			AB Soft	0,149

7.	Advisors' assessment	0,033	Digit	0,717
			Micro.Dyn.	0,195
			AB Soft	0,088
8.	Compatibility with the hardware technical system	0,026	Digit	0,443
			Micro.Dyn.	0,387
			AB Soft	0,169

The criteria are presented in order of their importance. According to the first criterion, the top alternative is Digit because it includes the largest number of functionally modular characteristics. According to the second criterion, the top alternative is Micro.Dyn because it includes the greatest number of relevant users. According to the third criterion, the top alternative is Micro.Dynas as it is highly reputable and reliable alternative. According to the fourth criterion, the top alternative is AB Soft as it includes the free accession of the software. A large number of users possess Micro.Dynas so it was the top alternative according to the fifth criterion. Furthermore, Micro.Dynas alternative is the most compatible with the knowledge and skills of the employees (Microsoft Office, Microsoft Windows XP...).

According to the seventh criterion the top alternative is Digit because advisors assessed it with the highest mark (Dorius d.o.o. Belgrade and an assistant at Business Administration School in Valjevo).

According to the eighth criterion the top alternative is Digit because it doesn't require special hardware characteristics.

6. MAKING DECISION

The decision on the selection of software for the information system is the result of the current condition analysis and the growing need for the new information system.

AB soft system was placed last on the list. It was assessed with 0,179 points. The next on the list is Microsoft Dynamics alternative with 0,392 points. The first on the list as the best alternative is Digit solution. It was assessed with 0,429 points. Therefore, the Digit alternative is the most suitable alternative for the implementation.

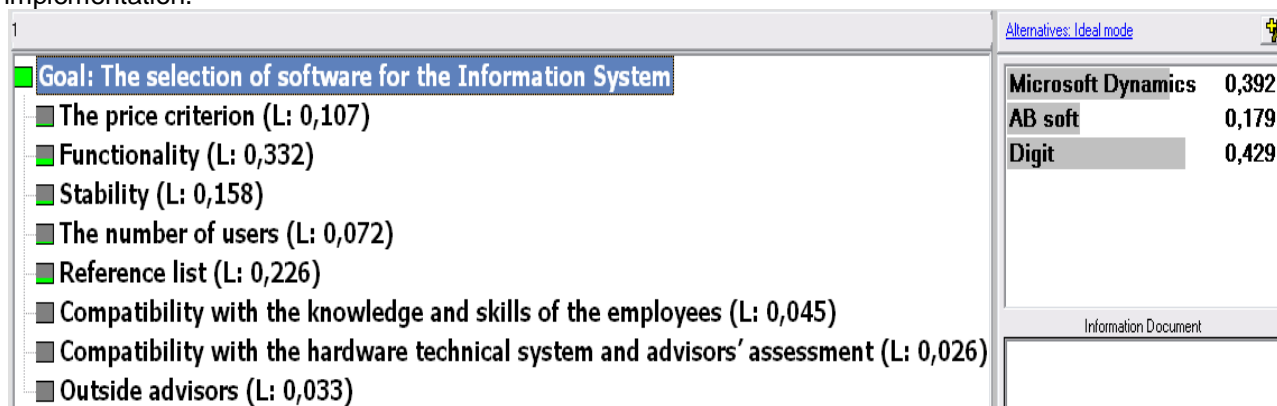

Figure 4: The result of making

7. CONCLUSION

The implementation of this decision-making model will bring lasting benefit. The advantages of this model are:

- Utilization of objective quantitative indicators,
- Inclusion of the employees (future users) into the decision-making process,
- Inclusion of experts' knowledge into the decision-making process,
- High precision and reliability and
- The selection of the most compatible alternative

The decision-making model will be used by Utility Service Department „Vodovod in Valjevo“ but it can also be very useful for other organizations if they opt to introduce new software for the information system. The implementation of the suggested software alternative in Utility Service Department „Vodovod in Valjevo“ would enable the fulfilment of a higher level of management, the development and application of the new

business strategies, lower business expenses, increased productivity, greater flexibility, standardization, higher information quality, integrated business processes, reengineering, the enhancement of business processes and their higher efficiency. Furthermore, it would enable fast data entry, and the implementation of professionals' methodical and rich experience accompanied by the professional training.

In this way, other organizations are given opportunity to have a decision-making model on the selection of software for the information system. The result of the decision-making process on the selection of integrated software is: the software which is the most compatible with the current needs and capabilities of not only Utility Service Department „Vodovod in Valjevo“ but of many other organizations.

MEASUREMENT OF INFLUENCE OF QUALITY MANAGEMENT ON COMPETITIVENESS REGARDING REPUBLIC OF SERBIA AND ISO 9000 STANDARD SERIES

Ivan Pribićević

Zavod za udžbenike, ivan.pribicevic@zavod.co.rs

Abstract: *World Economic Forum measures competitiveness of nations in its Global Competitiveness Report every year. This paper is about the influence of quality management on final ranking of nations in GCR. Measurement is conducted by comparing indicators with ISO 9001 request for organizations. The rank of Serbia in highlighted indicators is also compared with Western Balkans, EU, Japan and USA to show its weaknesses and what is needed to be done for Serbia to get better ranking in future.*

Key words: *competitiveness, quality management, Global Competitiveness Report*

1. INTRODUCTION

“Competitiveness of nations is not created by its natural wealth, work force, interest rates or national currency value. Competitiveness of a nation depends on the capability of its economy to innovate and to move forward. The more the basis of competition moved towards production and assimilation of knowledge, the stronger the role of the country became. Competitive success is contributed by differences in national values, culture, economy structures and institutions. Each country has a different competition structure and its competition sector. The suitable role of the country is to be the catalyst and stimulant; it should encourage companies to be more ambitious and to achieve even higher levels of competitive advantage. Country policies are successful once they create an environment in which companies can achieve competitive advantage, i.e. they fail when they implicate the country directly into the process, except in those countries that are in the initial stage of development. Country regulations can stimulate competitive advantage by stimulating and strengthening local demand. Strict standards related to characteristics and safety of products, as well as to the impact on the environment, make pressure on companies to ensure quality, perfect technology and ensure those characteristics that correspond with the demands of consumers and the society.” (Michael E. Porter, 1998). Main hypothesis of this paper is: Quality management influence for more than ¼ on final rank on competitiveness of country in GCR measured by World Economic Forum.

2. COMPETITIVENESS OF THE REPUBLIC OF SERBIA

The World Economic Forum is, along with the World Bank, the largest, most quoted and therefore the most significant institution dealing with analysis and competitiveness measuring today. For more than three decades, the World Economic Forum's annual *Global Competitiveness Reports* have studied and benchmarked many factors underpinning national competitiveness. From the onset, the goal has been to provide insight and stimulate discussion among all stakeholders on the best strategies and policies to overcome the obstacles to improved competitiveness. Since 2005, the World Economic Forum has based its competitiveness analysis on the Global Competitiveness Index (GCI), a comprehensive tool that measures the microeconomic and macroeconomic foundations of national competitiveness. World Economic Forum defines *competitiveness as the set of institutions, policies, and factors that determine the level of productivity of a country* (Klaus Shwab (Editor), 2011). The concept of competitiveness involves static and dynamic components, although the productivity of a country determines its ability to sustain a high level of income, it is also one of the central determinants of its returns to investment, which is one of the key factors in explaining an economy's *growth potential*.

According to the Global Competitiveness Index of the World Economic Forum for the 2011-2012, the Republic of Serbia is in the 95th rank out of 142 countries. This result is a deterioration compared to the 2009 list, when it was the 93rd out of 133 countries. Serbia's index value is 3, 9 out of possible 7. That represents a melioration compared to 2009, but only by 0, 1, considering the fact that last years' index value was 3, 8. Three years ago, Serbia was rated 3, 86, and took the 85th place. One can clearly see the impact of the world economy crisis to the fall of competitiveness of Serbian economy and its mild recuperation in 2010.

The marks are very close, however, the necessary reforms were not made and it is obvious that Serbia fell behind other countries. The index value for 2007 was 3, 78, and Serbia was at the 91st place. The competitiveness of Serbian economy was measured by this report for the first time in 2003, as the part of the State Union of Serbia and Montenegro, taking the 77th rank. The Republic of Serbia holds one rank higher place, than Montenegro, but still is in very bad position comparing to its needs for investments and developing of economy.

3. INDICATORS INFLUENCED BY QUALITY MANAGEMENT

World Economic Forum measures competitiveness of nations in 12 pillars of competitiveness using 110 indicators. Quality management doesn't influence every indicator. To measure influence of QMS on GCI, every indicator is tested with ISO 9001 requests and few of them are shown in this work. In this work is shown how implementation of QMS in organizations can influence rankings in indicators. In order to gain better ranking Serbia must enhance all indicators, but using QMS will improve indicators that are linked to QMS and Serbia will have better rank.

a. Extent of staff training

„6.2.2 Competence, training and awareness - The organization shall:

- a) determine the necessary competence for personnel performing work affecting conformity to product requirements,
- b) where applicable, provide training or take other actions to achieve the necessary competence,
- c) evaluate the effectiveness of the actions taken,
- d) ensure that its personnel are aware of the relevance and importance of their activities and how they contribute to the achievement of the quality objectives, and
- e) maintain appropriate records of education, training, skills and experience (see 4.2.4). ¹(ISO 9001:2008, 2008)

Organizations that are certificated based on ISO 9001 shall fulfil these requirements. They shall provide training or take other actions to achieve the necessary competence. Usually organizations have a procedure that defines ways to fulfil this requirement. Organizations invest a lot of money for staff training and awareness, especially for new employees. Employers invest money in order to gain economically feasible new employee who has to be productive. Trainings can be organized in house or in organization specialized for employee training. Maintaining appropriate records is necessary as method to show how competitive, trained and aware employees are. In this indicator Serbia holds 132nd rank, with score 2.9, which is well by two positions comparing to 2010-2011 Report.

b. Degree of customer orientation

One of eight principle of quality management defined in ISO 9000:2005 is Customer focus: "Organizations depend on their customers and therefore should understand current and future customer needs, should meet customer requirements and strive to exceed customer expectations." ISO 9001 requires in 7.2. "That every organization shall have processes that are focused on customers". Customer requirements shall be well understood, defined and measured. Organizations shall have resources and technologies required to fulfil customer's needs. Organizations shall be oriented on customers in order to be certificated in standard 9001. Serbia holds very bad 131 rank in GCI in this indicator, same as Bolivia and Suriname. Again in this indicator the result is worse than in 2010-2011 Report for 12 positions.

c. Buyer satisfaction

¹ ISO 9001:2008, *Quality management system – requirements*, ISO /TC 176 Committee,

ISO 9001 is based on customer (buyer) satisfaction. Model of QMS begins and ends with customer satisfaction. Customers input requirements in organization; organizations measure how customers are satisfied with their output when process is finished. It is necessary to measure customer satisfaction, because most organizations are managed based on it. ISO 9001:2008 requires in **"8.2.1 Customer satisfaction"** - *As one of the measurements of the performance of the quality management system, the organization shall monitor information relating to customer perception as to whether the organization has met customer requirements. The methods for obtaining and using this information shall be determined. NOTE Monitoring customer perception can include obtaining input from sources such as customer satisfaction surveys, customer data on delivered product quality, user opinion surveys, lost business analysis, compliments, warranty claims, dealer reports.*"; also in **"5.2 Customer focus"** - *Top management shall ensure that customer requirements are determined and are met with the aim of enhancing customer satisfaction (see 7.2.1 and 8.2.1).*" 5.2 is connected with other indicator in GCI - Buyer sophistication. Organizations that meet requirements of ISO 9001 continuously measures customer satisfaction and has obligation to enhance it. Organizations must have methods and tools to measure satisfaction and manage information's in order to enhance customer satisfaction. Serbia holds 136 rank on this indicator. Serbia has similar rank as Mauritania, Chad, Senegal and Haiti. Last year Serbia had 129 rank, so buyer satisfaction in Serbia is getting worse. Compare with 2010 rank Serbia fall for 21 places and that is a very bad sign. Every organization that has implemented ISO 9001 must improve its buyer satisfaction continuously. Interest of every organization is to have satisfied buyers. Organizations in Serbia must work on this indicator in order to gain better ranking next year.

d. Quality of management schools

The number of management schools in Serbia is getting higher, due to the foundation of private Universities and schools. Faculty of organizational science, founded in 1967, is the first faculty where management was studied. First QMS programs were studied in 1996 at the FON faculty. Education in this area surely gives better chances of using QMS in future. But now Serbia with 114th rank, and score of 3.5 holds bad position, similar to Cambodia and Honduras. Last year Serbia was 111th, and in 2009-2010 Report Serbia was 90th. This rank shows that quality of education in management schools is very bad and it is getting worse. The reason might be the multiplication of private schools, however the rank is awkward if you take in consideration the awards that students of FON won in international competitions. Furthermore comparing Serbia to Montenegro which is ranked 45th, the doubt about this rank is even bigger. It is of great importance that QMS is learned in our Universities for the sake of future rank of Serbia in GCR.

e. Local supplier quality

As number of multinational corporations in Serbia rises, raises also the importance of this indicator. Local suppliers can improve quality using ISO 9001 and gain confidence that their process and business practice has high quality. In various numbers of cases this standard is obligated in contracts, as are also ISO 14001 and OHSAS 18001. In this indicator Serbia is ranked as 94th, same as Cameroon, Ecuador, Burkina Faso, Macedonia, Vietnam and others with score 4.1. Last year Serbia scored 3, 92 and held 107th rank, so in this indicator Serbia is having better results.

It is interesting to compare rankings of USA and Japan based on these indicators, because in those countries quality management concept was founded. Japan hold first ranking on indicators that are directly linked on implementation of ISO 9001 standard, degree of costumer orientation, buyer sophistication, and product process sophistication. USA has lower ranking and holds 15 positions in average. In selected indicators average ranking for Japan is 15, and for USA is 19. Problematic is that both USA and Japan hold not so good rankings (57, 12) for quality of management schools. This is especially the case for USA because most famous and best-ranked Universities for management are in USA according to Economist magazine. Japan is 6-th for Extent of staff training and that is maybe the way to overcome bad rank for quality of management schools. Average best ranked country on these indicators is Sweden that has high third place, while second is Finland. In EU worst position holds Bulgaria, while in Western Balkans Bosnia and Herzegovina and Serbia.

Also it is very interesting to compare competitiveness of Serbia and Montenegro, because these two states were members of a joint State Union six years ago. Former Serbia and Montenegro held better rankings based on Global Competitiveness Report. Quality of management schools is better ranked in Montenegro comparing to Serbia. That is very strange considering results and ranking of Universities in both countries. Also most of the students from Montenegro that want to study management enrol to the University of Belgrade. Comparing to that fact, Serbian students don't study at Universities in Montenegro. This indicator

is measured by survey that is conducted are companies in each country and it measures level of knowledge that students obtain when they finish studies. The best ranked country for this indicator is Belgium. Montenegro holds very interesting ranking in GCI, and has better rankings than Western Balkans (103), SEE (83), and it is very close to EU average (35). First job for Serbia is to close the gap to Western Balkans average ranking.

Table 1: Rankings of Serbia comparing to Montenegro, Western Balkans, EU, Japan, USA and Sweden.

Indicator	Serbia	Montenegro	Western Balkans ²	EU	Japan	USA	Sweden
<i>Intellectual property protection</i>	107	57	89	37	22	28	4
<i>Ethical behaviour of firms</i>	130	47	90	48	18	30	3
<i>Efficacy of corporate boards</i>	136	82	94	62	24	26	1
<i>Quality of management schools</i>	114	45	80	46	57	12	9
<i>Extent of staff training</i>	132	66	103	50	6	12	2
<i>Degree of costumer orientation</i>	131	78	81	47	1	24	2
<i>Buyer sophistication</i>	136	52	99	49	1	12	4
<i>Product process sophistication</i>	129	82	94	35	1	15	4
<i>Reliance on professional management</i>	133	82	105	48	15	17	6
<i>Local supplier quality</i>	94	81	94	35	3	13	5
<i>Average</i>	124	67	93	46	15	19	4

Beside indicators described in this work, quality concept influences all indicators that are marked in table 3. In table 2 it is shown how the influence of quality management concept on competitiveness is measured.

²Avreage rank for Western Balkans: Serbia, Montenegro, Bosnia and Hercegovina, Albania, Croatia, Macedonia

Table 2: Measure of quality influence on indicators in GCI

	Pillar	Quality influence	Value	%	Sum	Sub index weights for stages of development (%)		
						I	II	III
Basic requirements	I	$((1/5 \cdot 3/4) \cdot (1/2 \cdot 1/4 + 2/4 \cdot 1/4)) \cdot 1/4$	0.1093	10.93	10.93	60	40	20
	II	0	0	0				
	III	0	0	0				
	IV	0	0	0				
Efficiency enhancers	V	$(\frac{1}{2} \cdot \frac{1}{3} + \frac{3}{4} \cdot \frac{1}{3} + \frac{1}{3}) \cdot \frac{1}{6}$	0.12493	12.49	32,3	35	50	50
	VI	$(4/14 \cdot 2/3 + 1/3) \cdot \frac{1}{6}$	0.0871	8.71				
	VII	$(2/6 \cdot 1/2 + 2/4 \cdot 1/2) \cdot \frac{1}{6}$	0.0694	6.94				
	VIII	0	0	0				
	IX	0	0	0				
	X	$\frac{1}{4} \cdot \frac{1}{6}$	0.0416	4.16				
Innovation and sophistication factors	XI	$\frac{1}{2}$	0.5	50	68.75	5	10	30
	XII	$3/8 \cdot 1/2$	0.1875	18.75				
Quality management influence for each stage of development						21,30	27,39	38,96

Measurement is conducted by defining which indicator is influenced by quality management concept in each pillar. Each indicator is differently pondered. Result of such methodology is pondered influence of quality management for each pillar. Pillars are divided in three parts that have different impact on final rank. Each development stage has its own ponder and measurements are allocated to this ponder. Influence of quality management is different depending on stages of development. The more the country is developed, the higher is the influence. In first stage of development influence of measurement amounts 21, 3 %, this is almost $\frac{1}{4}$ of all indicators. If the State uses quality management it can get better rank for $\frac{1}{4}$ in the first stage of development. Serbia is in second stage of development. Measurements show that quality management for Serbia can change its rank by more than $\frac{1}{4}$. In third stage of development influence is higher and it is almost 40%. This calculation shows big impact of quality management on competitiveness of countries. By implementing QMS standards a country can increase its competitiveness and because competitiveness of a nation depends on the capability of its economy to innovate and to move forward this is the best way to do it. In order to get certification by QMS standards organization in the country must innovate and move forward.

Table 3: Indicator influenced by quality management

Serbia

The Global Competitiveness Index in detail

INDICATOR	VALUE	RANK/142
1st pillar: Institutions		
1.01 Property rights.....	3.1	126
1.02 Intellectual property protection.....	2.7	107
1.03 Diversion of public funds.....	2.7	100
1.04 Public trust of politicians.....	2.0	106
1.05 Irregular payments and bribes.....	3.6	90
1.06 Judicial independence.....	2.4	128
1.07 Favoritism in decisions of government officials.....	2.3	124
1.08 Wastefulness of government spending.....	2.2	130
1.09 Burden of government regulation.....	2.3	134
1.10 Efficiency of legal framework in settling disputes.....	2.5	137
1.11 Efficiency of legal framework in challenging regs.....	2.6	127
1.12 Transparency of government policymaking.....	3.9	102
1.13 Business costs of terrorism.....	5.5	74
1.14 Business costs of crime and violence.....	4.5	84
1.15 Organized crime.....	4.3	107
1.16 Reliability of police services.....	3.9	84
1.17 Ethical behavior of firms.....	3.0	130
1.18 Strength of auditing and reporting standards.....	4.0	114
1.19 Efficacy of corporate boards.....	3.7	136
1.20 Protection of minority shareholders' interests.....	2.8	140
1.21 Strength of investor protection, 0–10 (best)*.....	5.3	60
2nd pillar: Infrastructure		
2.01 Quality of overall infrastructure.....	3.1	120
2.02 Quality of roads.....	2.4	131
2.03 Quality of railroad infrastructure.....	1.6	102
2.04 Quality of port infrastructure.....	2.7	133
2.05 Quality of air transport infrastructure.....	3.1	132
2.06 Available airline seat kms/week, millions*.....	53.7	96
2.07 Quality of electricity supply.....	4.5	76
2.08 Fixed telephone lines/100 pop.*.....	40.5	26
2.09 Mobile telephone subscriptions/100 pop.*.....	129.2	28
3rd pillar: Macroeconomic environment		
3.01 Government budget balance, % GDP*.....	3.5	86
3.02 Gross national savings, % GDP*.....	14.8	103
3.03 Inflation, annual % change*.....	6.2	106
3.04 Interest rate spread, %*.....	6.9	91
3.05 General government debt, % GDP*.....	44.0	85
3.06 Country credit rating, 0–100 (best)*.....	39.8	81
4th pillar: Health and primary education		
4.01 Business impact of malaria.....	N/Appl.	1
4.02 Malaria cases/100,000 pop.*.....	(NE)	1
4.03 Business impact of tuberculosis.....	6.1	34
4.04 Tuberculosis incidence/100,000 pop.*.....	21.0	43
4.05 Business impact of HIV/AIDS.....	6.3	17
4.06 HIV prevalence, % adult pop.*.....	0.1	21
4.07 Infant mortality, deaths/1,000 live births*.....	6.2	40
4.08 Life expectancy, years*.....	73.7	65
4.09 Quality of primary education.....	3.7	74
4.10 Primary education enrollment, net %*.....	94.2	58
5th pillar: Higher education and training		
5.01 Secondary education enrollment, gross %*.....	91.5	57
5.02 Tertiary education enrollment, gross %*.....	49.8	50
5.03 Quality of the educational system.....	3.1	111
5.04 Quality of math and science education.....	4.2	58
5.05 Quality of management schools.....	3.5	114
5.06 Internet access in schools.....	3.8	83
5.07 Availability of research and training services.....	3.2	113
5.08 Extent of staff training.....	2.9	132

INDICATOR	VALUE	RANK/142
6th pillar: Goods market efficiency		
6.01 Intensity of local competition.....	3.6	136
6.02 Extent of market dominance.....	2.5	139
6.03 Effectiveness of anti-monopoly policy.....	2.8	137
6.04 Extent and effect of taxation.....	2.9	118
6.05 Total tax rate, % profits*.....	34.0	50
6.06 No. procedures to start a business*.....	7	65
6.07 No. days to start a business*.....	13	51
6.08 Agricultural policy costs.....	3.4	112
6.09 Prevalence of trade barriers.....	4.2	90
6.10 Trade tariffs, % duty*.....	5.5	68
6.11 Prevalence of foreign ownership.....	3.9	116
6.12 Business impact of rules on FDI.....	3.5	125
6.13 Burden of customs procedures.....	3.7	93
6.14 Imports as a percentage of GDP*.....	43.6	69
6.15 Degree of customer orientation.....	3.6	131
6.16 Buyer sophistication.....	2.2	136
7th pillar: Labor market efficiency		
7.01 Cooperation in labor-employer relations.....	3.3	136
7.02 Flexibility of wage determination.....	5.2	64
7.03 Rigidity of employment index, 0–100 (worst)*.....	35.0	90
7.04 Hiring and firing practices.....	3.6	89
7.05 Redundancy costs, weeks of salary*.....	25	50
7.06 Pay and productivity.....	3.4	103
7.07 Reliance on professional management.....	3.3	133
7.08 Brain drain.....	1.8	139
7.09 Women in labor force, ratio to men*.....	0.78	69
8th pillar: Financial market development		
8.01 Availability of financial services.....	4.0	103
8.02 Affordability of financial services.....	3.8	93
8.03 Financing through local equity market.....	2.7	112
8.04 Ease of access to loans.....	2.4	97
8.05 Venture capital availability.....	2.0	121
8.06 Soundness of banks.....	4.4	116
8.07 Regulation of securities exchanges.....	3.3	121
8.08 Legal rights index, 0–10 (best)*.....	8.0	20
9th pillar: Technological readiness		
9.01 Availability of latest technologies.....	4.0	123
9.02 Firm-level technology absorption.....	3.7	136
9.03 FDI and technology transfer.....	4.0	110
9.04 Internet users/100 pop.*.....	40.9	60
9.05 Broadband Internet subscriptions/100 pop.*.....	8.5	57
9.06 Internet bandwidth, kb/s/capita*.....	19.2	34
10th pillar: Market size		
10.01 Domestic market size index, 1–7 (best)*.....	3.5	70
10.02 Foreign market size index, 1–7 (best)*.....	3.9	77
11th pillar: Business sophistication		
11.01 Local supplier quantity.....	4.5	84
11.02 Local supplier quality.....	4.1	94
11.03 State of cluster development.....	2.5	128
11.04 Nature of competitive advantage.....	2.4	136
11.05 Value chain breadth.....	3.0	113
11.06 Control of international distribution.....	3.3	126
11.07 Production process sophistication.....	2.6	129
11.08 Extent of marketing.....	2.8	128
11.09 Willingness to delegate authority.....	2.6	136
12th pillar: Innovation		
12.01 Capacity for innovation.....	2.5	110
12.02 Quality of scientific research institutions.....	3.8	61
12.03 Company spending on R&D.....	2.4	130
12.04 University-industry collaboration in R&D.....	3.4	81
12.05 Gov't procurement of advanced tech products.....	3.4	92
12.06 Availability of scientists and engineers.....	3.9	83
12.07 Utility patents granted/million pop.*.....	0.4	67

4. CONCLUSION

Quality management systems began to actualize in Serbia in the 90-ies, with one ambitious project of certification of the Government of the Republic of Serbia in 1992. Main goal was to make clear how much the state is committed to this concept, but like most good projects, this one has not been completed either. Application of ISO 9001 is the most applied in Serbia, as well as in the rest of the world. The state has given impetus to its implementation by insisting that the participation in public procurement requires certification by the requirements of this standard. The Serbian Agency for Foreign Investment and Export Promotion (SIEPA) provides grants to assist organizations to implement this standard, but also helps the application of other standards that may increase the competitiveness of Serbian economy. According to the latest data,

there are over one million certificates for the implementation of the requirements of ISO 9001 in the world. (ISO Survey, 2009) So far there are no precise data of the number of certificates in Serbia, but it is estimated that there are over 3000 certificates existing. Certification by these models shows continuous growth, however, there is a problem of not implementing the essence requested by the standards and also there is a need to obtain certificate so it could be used as an advantage on tenders. It is important to apply the essential requirements in order to maximize the company's ability to operate better in the future. Good example for this is Italy, which is second placed by the number of certificates while the state of its economy as well as the position occupied according to the GCR is far from that second place on the list. It is therefore necessary for organizations to operate in accordance with essential requirements that have long been superseded in modern business and represent only the base for upgrade.

The competitiveness of Serbian economy is poorly rated if the most relevant research carried out by the World Economic Forum is observed. Serbia is located in the second stage of development, precisely in the efficiency-driven economy according to this methodology. For the more mature stage of development the most important role play factors critical to the efficiency, higher education and training, good market efficiency, labor market efficiency, sophistication of financial market, knowledge and use of technology and market size. In other words, after reaching the basic factors of competitiveness, for further progress the development of above mentioned factors is important. Serbia's problem is that it is not sufficiently developed in accordance to ponder set for this stage of development.

This model of evaluation is being criticized, but it is the best there is. Compared to countries in the region to whom Serbia wants to become a leader, Serbia is located at the penultimate position, only ahead of Bosnia and Herzegovina. Countries of European Union are in average sixty positions better placed than Serbia, which means that we must skip in so many places to be in the society to which we strive. Also, comparing to the countries that have become full members of European Union, Serbia lags in average of eighty positions. Of the twelve pillars of competitiveness, Serbia achieved its best result in the field of health and primary education, while the worst position is shared by sophistication of business processes and efficiency of goods market. The analysis found that quality management has direct impact on thirty one indicators. Measurement has shown that depending on stage of development, quality management concept influences from 21, 3% to almost 40% of indicators which are important for the measurement of competitiveness by GCR. Of course, the mathematical measurements conducted in this paper do not fit the actual situation because the successful implementation of quality management triggers reforms in many segments of society so that the impact on competitiveness is indirectly expanding. The widespread diffusion of quality management techniques will make an organization, an economic sector and eventually a country more competitive. (Hassel Schuurman, 1997)

Measurement has shown that main hypothesis is true for country's that are in second and third stages of development, but for the country's in first stage of development hypothesis is not true, because influence is less than 25%. As Serbia becomes more developed, it will have to develop its innovative capacity in order to maintain competitiveness that it should gain. This year, Serbia will reduce its foreign trade deficit. However, turning the economy into an export-oriented and creating a surplus in foreign trade exchange is a process that takes a long to do. It is necessary to restructure the economy and direct it towards the export. Raising the level of competitiveness will significantly contribute to this. A quality management system standard is the ticket for foreign market and it is implied that export-oriented organizations operate according to internationally recognized standards. Apart from increasing the capacity of domestic economy for doing business in foreign markets, by increasing the level of competitiveness, Serbia will at once become more attractive for foreign direct investments. The implementation and continuous improvement of these processes should increase the quality of life for citizens of Serbia.

SME MANAGEMENT QUALITY DEVELOPMENT BY IMPROVEMENT OF PERFORMANCES “PLANS CONTENT” AND “CONNECTION OF PLANS”

Jasmina Omerbegović-Bijelović¹, Zoran Rakićević², Milica Vučković³

¹University of Belgrade, Faculty of Organizational Sciences, omeja@fon.rs

²University of Belgrade, Faculty of Organizational Sciences, zrakicevic@fon.rs

³University of Belgrade, Faculty of Organizational Sciences, milica@fon.rs

Abstract: *In this paper we indicated the possibility of increasing the “strength” (and contributing to the social and economic life) of small and medium-sized enterprises (SME), by the **innovation** of “Development of management quality”. Management itself is a complex system, so the **hypothesis** (H0) is that the enhancement in the development of management (system) quality (MQ) is obtained by improving any of the performances of this system (or their combinations). H0 is checked for only one subset/group of elements of the management system of SME-plans (as „intern management tool“, i.e. as an output of the management subsystem „Planning“) and, more specifically, for (only) two **performances of plans**: „Plans Content“ and „Connection of Plans“. **The goal** of the research is to show performances of plans as important elements of the methodology of management quality development (given here SMEs), on the example of the improvement of the two mentioned performances. We check if it is possible (separate hypothesis H1) and if it is justified (separate hypothesis H2) improvement of the plans performances - in order to increase the management quality of SME, and therefore in order to increase business success of SME. Hypothesis H1 is proven by generating a „package of ideas“ for innovation and enhancement of the given performances, and H2 – (is proven by) taking into consideration practical implications of the change (in the example of SMEs in Serbia).*

*With reliance on the previous research (personal and other), the newest data has been processed (about 27 SME in Serbia). Doing survey, interviews (of entrepreneurs, owners or/and managers of the SME) and doing analysis of the content of records about inconsistency of SME management quality (data about too large deviation from the desired quality), **the problem** of inadequate quality of plans is also been considered (so is the planning and whole managerial process), and by using the methods (of replicating) the best practise (benchmarking), brainstorming, and trial-and-error, the „package of ideas“ has been generated for (H1) improvement of the given performances; also we did analysis of reports of the cases of management quality improvement – to support our conclusion about the justification (H2) of the plan performances enhancement (so as performances of planning and whole management). With the given research we confirmed hypotheses H1 and H2, i.e. it is determined that is possible and justified improvement of performances of plans and, similarly, (improvement of) performances of other subsets/groups of elements of management (SME and other companies) in order to develop quality of management.*

*By generating the „package of ideas“, we defined a tool for **improvement of the given performances** of the plans (and planning and management), by which we also created a basis of methodology for the further development of the management quality and business of SME, with – potentially – broader and more far-reaching consequences for the society; also we created entrepreneur's inspiration for original, **practical and applicable tool for using managerial reserves** (i.e. potential for management quality improvement). In practise, these findings should use to stakeholders of SME to be able to look, in a more clear way, the needs and ways to help SME in the **development of the management quality** (and therefore in their business, and survival). The findings which we here presented may help to all organisational systems (not only to enterprises, and especially not only to SME in Serbia) – because the quality of the management directly determines the success of the work of organisational systems; unused managerial potentials are, by the rule, present everywhere and should be treated as unwanted reserve, i.e. they should be used for the benefit of the stakeholders.*

Key words: Management quality development; Planning/Management; SME; Improvement of plan performances; Plan content; Connection of plans; Managerial reserves, Management quality improvement tool.

1. INTRODUCTION

Small and middle-sized enterprises (SME) are important generator of working positions, values, goods and services, profit, general-domestic product (GDP), ideas applications (innovations), competition, business opportunities recognition, resources integration and contribution to social-economical life; therefore, from the middle of XX century, bigger attention and support has been given to them. In that spirit, Science also gives contributions – in detecting, formalizing, studying and problem solving in the sector of SME.

It has been determined, for example, that the success of the SME depends on the quality of the management of the SME (see: Omerbegović-Bijelović, J. 1995b), and that is especially on the competence of SME owners to define and delegate goals (see: Ljamić-Ivanović, B. 2008), and also depends on consistency of the support of the surroundings with the real needs of SME (or, at least, those needs which are recognized by the owners/managers of SME (see: Rakićević, Z. 2012). Management quality (MQ) can be defined as an indicator of the goals fulfilment, which are created for the management by stakeholders (SHs), so it is in the SHs interest that the MQ is as high as possible. (As MQ is a multidimensional vector and as their dimensions are measured by different units, it is better to say “as developed as possible”, as opposed to “as high as possible”). There are couple of different methodologies that can be used for the development of MQ (see: Omerbegović-Bijelović, J. 1998), for science still attractive, topics – which are related to: inputs, outputs, processes, resources (where tools are also included), structure of the management system.

In management of SME (and for MQ) very special role have entrepreneurs, owners and managers of SME, as well as tools they are using in management. Among managerial tools, the most important are plans – taking into a consideration that they are connecting and directing all managerial activities. Plans and planning are important everywhere in the world, and especially in “the countries in a transition” (especially those which are created from SFRJ – where in the 80s, in XX century, planning stopped to be mandatory enterprise activity and where it was almost forgotten how important and how to do planning.) Not even rare textbooks, nor limited competency of the employees (not only in SME) ensure the required quality of plans and planning (as well as managing itself) – in order to achieve competitiveness – required for survival.

Therefore, it is necessary to introduce the problems of planning and plans (their quality, i.e. their performances), and how that is connected to MQ.

2. THE QUALITY OF SME MANAGEMENT AND PROBLEMS OF PLANNING

As the management of any organisational system is its translation (i.e. translation of their characteristics/performances) “from the given to desired (or its close) state” (Omerbegović-Bijelović, J. 2010. p. 140), the same can be said for SME management. Specificity of SME management is connected to specificity of SME as a category of an enterprise. Among SME specifics there are (see: Regionalni centar... 2012): modest capacities of the SME resources, incapability to use business opportunities of a bigger volume, entrepreneurs/owners is rare and professionally competent (managerial) governance of SME, successful management of SME requires “renaissance type” of employees (i.e. their competance for different jobs and in different business functions), in most cases short term management, minimal knowledge of plans and planning, reactive or proactive behavior (and very, very rarely – leader), being focused on market niches, not enough skills (in resources assignment, optimizing of the business, application ICT, software-support in management etc). Taking into consideration these characteristics of SME, it is not surprising to see unsatisfying quality in practise of SME management, and therefore also poor business success of SME (and their big „mortality“).

That is the reason we are searching for way to improve/develop MQ and, in that way, to increase competitiveness and probability of SME survival. As the survival of companies (and of SME as well) depends on the development of management quality (of SME), and development – from the growth of potential/capacity to invest in the development (like in: Omerbegović-Bijelović, J. 1998), we can conclude that it is necessary to obtain means for investment in the development. Here we make an indication to a possibility to generate means for development (Fig. 1) by using better/more complete exploitation of the „managerial reserves“ (i.e. by more complete usage of potential of performances of management quality); that is possible to accomplish by improving performances of the complete management or, more realistic, by improving the chosen performances of the chosen elements of management (e.g. performances of plans).

Figure 1: Schematic representation of the chain of conditions for provide SME survival

It is expected that the improved performances of the plans will make that the managerial cycles are better driven, i.e. to be more effective and efficient, and therefore the business of SME more successful and survival more probable.

2.1. Management quality and Planning quality

Management is seen as a system – due to its complex nature, and its two most important, mutually conditioned (see: Adizes, I. 1994b), attributes are processes and structure. The goodness of the management is manifested as the “quality of management/management quality” (MQ); it is determined by the “goal fulfilment (by the quantity of the goal value and by the moment of desired value fulfilment) and by the trajectory (activity employing resources) which are used for the system to be lead to the goal; those basic characteristics - goal and trajectory – are more precisely defined in the first phase of management - in the phase of planning” (from: Omerbegović-Bijelović, J. 2010. p. 140). (Mentioned basic characteristics are more commonly known as effectiveness (in goal accomplishment) and efficiency (rationally-acceptable relationship of the value of effect/goal and value of investment so that goal is accomplished).) That's where the idea comes from, to consider possibilities and justification of improvement of performances of SME plans, in the goal of increasing the value, i.e. the development of MQ.

The process of management (managerial cycle) is done via sub-processes:

1. Planning of goals and ways (activities and resources) for their accomplishment;
2. Organizing – as goal delegating (to groups and individuals) and assigning authority for: a) necessary resources availability and b) activity initiation (for the goals accomplishment);
3. Realisation of goals – via resources preparation (till the supply/“closure” of workplaces) and transformation of work objects;
4. The control of accomplished goals (with recording: deviations, reasons for deviation, operational-applied measures for breaking deviations, ideas for further improvement).

Each of the given managerial sub-processes is working in the corresponding sub-system, and has its own inputs and outputs, resources, activities... Their elements have their own performances, and these are measured by its own „packages“ of indicators.

Then MQ is the synthetic/collective indicator of the intensity (by the nature of the performance and intention) of the chosen indicators of the quality of the elements of the managerial system and their coefficient of importance. Therefore improvement any of the performances any of the elements of the managerial system lead to increment in the value of MQ (see: Omerbegović-Bijelović, J. 1998. pp. 70-93). (That – measuring of MQ improvement/increasing – is not a subject of the given research.)

Planning is first, and directing phase of management; it is used (from: Omerbegović-Bijelović, J. 2010. p. 141) to:

- Define and decompose goals (by time horizons, by objects of management and planning and by other criteria of classification);
- Define trajectory/strategy/roads/ways for goal accomplishment (i.e. defining activity and resources – by category, quantity, suppliers, dynamics etc.).

Planning runs in non-material flow – having on mind the fact that the inputs and outputs of the planning sub-system (in which the process of planning runs) are of non-material nature (data, information, knowledge). The output – plan (more exact: package of plans) – as a set of managerial decisions (grouped in a logically based cells) is also of non-material, informational nature. Planning scholars argue (Brinckmann, J., Grichnik, D. & Kapsa, D. 2010, p. 27) “that the benefits of business planning increase especially in dynamic and unstable external environments as business planning reduces uncertainty, facilitates faster decision-making, introduces controls for personal bias or subjectivity, and develops new forms of actuation”. From the plan content (structure and intensity of activity which, by plan, should be done) depends how the given organisational system (here: SME) will be managed. Plan is, therefore, at the same time and output from the

managerial sub-process/phase “Planning”, and input into the next managerial phases. So the quality of the plan is determined by the quality of planning and it self determines the quality of the next managerial phases, and the complete MQ itself.

Plan performances defined originally Fayol (from: Rajkov, M. 1980) – looking for a plan to be: unique, continuous, flexible and precise. For Rajkov (1980; p. 180), the characteristics of a good plan of actions are, in short: reality (to know what can be done, from desired), being integrated (integrated individual plans), inter-related (changes of one plan also involve changes in the rest), continuity (checking and correction of plan assumptions), efficiency. To the package of the characteristics/performances of the plan, we can also add (Omerbegović-Bijelović, J. 1998; pp. 34-37): clarity, relevant, interactivity, attractiveness, suitable, promptness, reliability, or, in short (ibid.), efficiency and effectiveness. As a component of MQ, planning quality (PQ) is also determined in a similar way.

2.2. Problems of planning and quality of plans in SME

In attempting to at least sustain competitiveness and business success, SME (as the other economic and non-economic organisational systems) are faced with different problems. All those problems – against which SME (and other enterprises) can take action (to a greater or lesser extent) – belong in the category of managerial problems. Here we consider problems (discovered in widening of the research - described in Regionalni centar... 2012) which are caused by non-adequate processes of planning – „producing“ plans which (chosen - nonadequate) groups of characteristics are:

1. Insufficiently expressed: completeness, clarity, relevance, plans usability;
2. Insufficiently manifested: connectedness, consistency, timeliness, continuity, coordination of plans etc.

Since the mentioned characteristics which we indicated are related to plans performances (and to “quality of plans”), and taking in to a consideration that the plans are result (product) of planning, the problem located in the area of “quality of planning” (and even broader, in the area of “management quality”). So, if we improve the quality of planning, the quality of plans are also gone be improved; if the exact chosen characteristics will be improved, it depends on which area of planning is improved.

First group of inappropriate characteristics of plans indicated to non-adequate “Content of plans” (PC) – as a plans performance, and the other (group) to non-satisfying “Connection of plans” (CP) – as a plans performance, also. It is verified if the improvement of PC and CP will lead to the improvement of the mentioned characteristics of plans (and to the MQ development).

2.3. Development of the management quality by solving problems of planning in SME

Solving problem-appearance of inappropriate, i.e. not sufficiently expressed (and desirable) performances of plans can be done in one of the three ways:

- a) Complete elimination of the problem, i.e. bringing expression of desirable performance of the plan to the desirable level, with eliminating possibility for the same problem to appear again;
- b) Problem attenuation, i.e. increasing expression of the desirable performances of the plan, but not till the desirable level, with a possibility that the same or similar problem appears again;
- c) Protection of the negative consequences of the problem or/and avoiding the problem, i.e. generating measures/means or adequate mechanisms which the system (SME) is protected from the appearance or from the consequences of the problem.

The process of recognizing the causes and generating solution is going on in the following order: first we try to eliminate the problem; if there's no success in that, we look for solution which will at least make it smaller, and if that's not possible, we create a solution which gives a protection from negative consequences of the problem. The biggest effect is accomplished by elimination and the least with protection from negative consequences of the problem.

In every case (a, b or c) improvement in the plan (and planning) performances will result (in the following cycles), and hence in the management quality also (of an SME or any other organisational system). Such, improved, management increases competativeness and the survival possibility (of SME etc.)

There are two questions: 1) Is it possible to improve plan performances? and 2) Is it justified? If both the answers are „YES“, then the solution is in eliminating the problem connected with plan quality and, partially, with planning too; the other, desired improvements follow as a consequence.

3. IMPROVEMENT OF SME PLANS PERFORMANCES AND MANAGEMENT QUALITY

Solving problems which interfere with planning in SME (and make their quality smaller), contributes to the development of quality of plans, and to the quality of future cycles of planning and complete management. Taking into consideration the importance of the quality of a plan (therefore and validity of their performances), we should check if it is possible and justified to find a way to improve (here, as an example only two chosen) performances of plans. If it is shown that is possible and justified, we can give recommendation for „Methodology of development of management (system) quality by improving performances of its elements“.

3.1. Methodology for testing of hypothesis about plan performances innovation

As it is mentioned in this research paper, we look at the problem of non-adequate quality of plans (and planning and complete management) – on the example of SME. (As stimulus, we used: Perry (2001), who found that non failed firms did more planning than failed firms (p. 202).) We start from an hypothesis (H0) that the contribution to the development of management quality (MQ) is accomplished by improving any of the performances of the management system (or their combination). Bearing in mind the number of elements of the planning subsystem and multiplied number of their performances – for illustration (and testing) of the innovaton idea, here, we use performances of one element of the subsystem – package of plans. (We are talking about more complementary plans which create „package of plans“.)

As plans are an output from the subsystem „Planning“ and „internal managerial tool“ and as they are characterized by large number of performances, here we made a choice of only two (performances of plans): „Plan Content“ (PC) and „Connection of Plans“ (CP). All performances of management, and performances of planning, influence the management quality (of SME e.g.) and their business success, competitiveness and survival. If we prove that the improvement of these two performances can contribute to the development of management quality, by analogy we can conclude that the „shift“ can be done by improving any of the performances (or group of performances) of any element (or a group of elements) of the SME management system (or any other organisational system).

From the general hypothesis H(0), by deconstructing, we get two intermediate hypotheses:

H1: It is possible (by generating the corresponding innovations) to improve the performances of plans;

H2: It is justified (there is sense to it – as it aids MQ development) to improve the performances of plans.

Hypothesis H1 is proved by generating an „idea packet“ for innovating/improving of the viewed performances, and H2 is proved by considering the contribution the two innovated/improved performances make to improvement/development of SME management quality, i.e. by detecting, useful for actual practise (business success of SME), implications of improving the performances (in the example of SME in Serbia, together with reference to the earlier research (both own and that of others) and to the newest data about 27 SMEs of Serbia).

Bearing in mind that the cheking of general hypothesis H0 (more accurately, H1 and H2) is being conducted for performances „Plan Content“ (PC) and „Connection of Plans“ (CP), it is necessary to further deconstruct intermediate hypotheses into particular ones:

H1;1: It is possible to improve the performance „Plan Content“ (PC);

H1;2: It is possible to improve the performance „Connection of Plans“ (CP);

H2;1: It is justified to improve the performance „Plan Content“ (PC);

H2;2: It is justified to improve the performance „Connection of Plans“ (CP).

Methodology of checking the truth (defined in this paper) of the general hypothesis H0 is, therefore, represented in the following steps:

1. Deconstructing the general hypothesis (H0) into intermediate ones: H1 and H2;
2. Deconstructing the intermediate hypotheses into particular ones: (H1,1; H1,2) i (H2,1;H2,2);
3. Regrouping the particular hypotheses according to the chosen performances: „PC“ and „CP“;
4. Proving of the particular hypotheses – grouped according to performances (where, for each particular hypothesis, at least one (measurable) indicator will be defined, which will aid in concluding – proving the truth of that particular hypotheses):
 - a) It is possible and justified (H1,1; H2,1) to improve performance „PC“;
 - b) It is possible and justified (H1,2; H2,2) to improve performance „CP“;
5. Concluding about more complex hypotheses (up to the level of general hypothesis H0) on the basis of proving simpler (mainly particular) hypothesis.

Naturally, the number of intermediate and particular hypotheses, as well as the number of indicators on the basis of values which the truth of the particular hypotheses is being tested can also be modified (in relation to the observed element of the managerial system, observed performances, adequacy of indicators, scientific strictness etc.). However, if – already in this example – it is proven possible and justified – by improving particular performances (of any) element of the managerial system – to add to the development of management quality that said system, then what is left is to apply the proven conclusion in SME practise and that of other organisational systems, i.e. to improve the management performances, to achieve better business results and, it is expected, to improve the overall quality of life.

3.2. Improving the chosen performances of plans

In this, 4th step of the Methodology for checking the truth (here defined) of the general hypothesis H0, it is necessary to check the particular hypotheses – grouped according to the observed performances. For every one of the performances the truth of relevant particular hypotheses must be checked, hence it is necessary (for each observed performance) to undertake the following activities:

A1: Generate innovative solutions (innovation suggestions);

A2: Proving the justification of the performance improvement (MQ development contribution).

At the same time the performance indicators will be observed, respectively (I1 – for A1; I2 – for A2):

I1: The number of generated suggestions for innovation/improvement of the observed performance, in [innovation suggestion], to prove that the performance improvement is possible;

I2: The number of cases in practise when the improvement of a certain plan performance has contributed to MQ development, in [case], to prove that the performance improvement is justified.

In research which is shown here, bearing in mind the nature of the problem and the logically unassailable truth of the general hypothesis (H0), minimal values of the observed indicators (for accepting individual hypothesis) are: I1min = 1 [innovation suggestions] and I2min = 1 [case]. The value of indicator I1 larger than 1 will indicate that the potential (managerial reserve) is greater to improve the observed performance, and by the same token for MQ development. Value I2 larger than 1 will show that at least several SMEs (and/or other organisational systems) are aware of the justification for improving the observed performance, as well as of the fact that its potential aids MQ development.

Scientifically speaking, it would be correct to describe also the sample on which the hypotheses are being tested. Old (own and others') and new (in 27 SMEs) research has already been mentioned so, for every individual hypothesis, the researched sample will be pointed out.

3.2.1. Improving performance „SME Plans Content” (PC)

By actual improvement of the performance „Content of plans” (PC), i.e. by presenting at least one idea for PC innovation, it will be proven that (a) particular hypothesis H1,1 – that it is possible to improve PC performance, and (b) by showing (at least one) example from practise of improving PC the particular hypothesis H2,1 will also be accepted – that it is justified (that there is a point) to improve PC performance. (First of all, we need to clarify that the plans we are talking about here relate to the regular business making in an SME, and not to radical business changes – the justification of which is tested by a business plan.)

The plans of „regular business” are made regularly, with a regulated frequency – according to the time horizon which relates to: long term plans – 3-5-or more years, medium term plans – 6-12-18 months and short term plans – 7-10-30 days. By Yusuf, A. & Saffu, K. (2005, p. 482): “In the case of small firms ... planning frequently results as a response to particular occurrences in the firms' operating environment. Planning in small firms, therefore, is mostly adaptive in nature, short-term oriented, and concerned with the manipulation of scarce and limited resources... Planning in small firms is generally typified by intense personalization. It is highly influenced by the preferences, experiences, attitudes, prejudices, and general personality sets of the entrepreneur or whoever as control of the firm.”

If in the given SME there are any written down (not only „stored” in the head of the entrepreneur/owner) plans, they tend to be notes or A4 sheets of paper with meagerly structured (and sometimes sparse filled out) tables – hardly ever in Excel, with acronyms in titles of lines and columns, frequently without units of measurement or with acronyms clear only to those who wrote them. Since they are made by „planners” – entrepreneurs/owners – for their (personal) needs in driving the business, the content of such plans is, as a rule, a mixed bag – i.e. it contains everything – for the author/“planner” – relevant categories of the plan – both the sale related ones, as well as the production/transformational and supply ones, and quite frequently also notes about stock and distributors (or even debts) and bigger buyers (and claims); naturally, given the (driven and restless) nature of the entrepreneur, there are also notes and drawings to be found – ideas for

innovation of the existing or for creating a new job. That is by no means the end of the „informedness“ of entrepreneurial/owners „planning“ improvisations: free calculations, logical and calculus errors, illegible data, lost sheets of paper (as the „plan“ is, at best, a few sheets of paper placed in a folder) and – placed in some drawer somewhere. (Or perhaps on a shelf? Or in a cupboard – at home, or on notes to be found in pockets). Assuredly, the use of such „plans“ is „artistic freedom“: they are filled out *ad hoc* – according to need and inspiration, as well as occasion (start of new year/season, bringing out a new product or going into a new market) and their role is finished the moment they are „put to paper“ (or, if they are again found, the next time something is being „planned“).

(a) In checking H1,1 data obtained by the research „Innovative SME management in Serbia“ is used (conducted in April 2012 in 27 SMEs in Belgrade and surrounding areas). In that research, the 11. Question of the questionnaire related to the entrepreneur's/owner's or (in only 3 cases) manager's mark of planning within their SME. The question, some answers and their marks are given in Table 1.

Table 1: Table for marking the planning in SME in Serbia (2012)

N ^o	Description of planning in your SME	Marks (visible to researchers)
1	2	3
1	We do strategic planning for 5 or more years ahead	3 (acc. to Likert: 5)
2	In doing our yearly plan we look 2-3 years ahead	2 (acc. to Likert: 11/3=3+2/3)
3	Every 12 months we make a plan for the coming year	1 (acc. to Likert: 7/3 = 2+1/3)
4	We have a great deal of work and have no time to plan ahead	0 (acc. to Likert: 1)

Collated answers/marks (collected through the above mentioned research) give the results – planning situation in SME in Serbia (Table 2).

Table 2: Distribution of marks for planning in SMEs in Serbia (2012)

11. Question: Planning in SMEs in Serbia		
1	2	3
Mark	Number of times it appears in sample group (27)	Value
3	4	12
2	2	4
1	19	19
0	2	0
$\Sigma = 27$		35/27=1.30

The average mark for planning in SMEs in Serbia (at the beginning of 2012) is 1.30. According to Table 1, that means that in SMEs in Serbia make yearly plans.

By further research (interviews), it was established that the only things definitely planned for a year ahead are the obligations to the government (according to the achieved yearly income) and consequently the creation/presentation of the required documentation.

In proving H1,1, and considering the state of planning (and plans) in SMEs in Serbia, the following planning (and plan) innovations are suggested:

- Bringing in „plan packets“ – for every SME, according to which the plans would be created according to the time horizons (3 types of plans – for: long, medium and short term time frames) and according to the phrases of the business cycle (5 types of plan – for: paying suppliers, procurement, production, sales, payment); that „packet“ would have 15 plans (at least);
- All SME plans should be in Excel format – as single pages of the same document (the plan package of the SME in question);
- Every plan should have a full, precise and exact name (including organisational unit which is referred to as well as the period to which it relates);
- Data in the plan must be accompanied by clear units of measurement;
- Plans must be legible (as, in Excel, the spaces or cells into which data is entered can be customised);
- Contents of the long term SME plans would refer to the program of products and/or service offerings, to more important, bigger buyers and suppliers, to already contracted business-technical cooperation (with an estimate of the value of future business dealings), to planned development of new products/services, markets, capacity, location et sim. and planned investments; their role would be to establish regular business communication with the biggest partners (and for as great a volume of exchange as possible) etc.;

- The contents of the medium term/yearly/main SME plans are related to sales, production and budgeting, procurement and stores, employing and firing, hiring subcontractors, profit etc.;
- The contents of short term SME plans would be: operative tasks, job assignation according to workplace, orders planning, job-shop plans, launching plans, operative organisation plans (overtime, worker replacement for people on sick leave, supplying/"closing" workplaces etc.), maintaining contact with operative preparation of resources and with those employed in the control segment etc.;
- Plans need to have instructions both for their creation and for their use;
- Bringing in aggregate plans (for periods from 6-18 months) – for choice of operational strategy, i.e. „response to forecasted demand“ (combination of production, stores, employment/firing, hiring subcontractors etc.);
- Bringing in a mechanism for improving all types of plans – by analyzing how well the plans were achieved in previous periods and learning from mistakes (own and others').

The number of here suggested (more or less original) ideas for innovation (and/or generating) of SME plans is $I1(PC) = 11$ [innovation suggestions], and the defined limit for accepting the individual hypothesis is $I1min = 1$ [innovation suggestions]. Therefore, it is considered that the particular hypothesis H1,1 – that it is possible to improve the PC performances – has been proven! (Also that there are huge „managerial reserves“ to be found in the managerial subsystem that is Planning.)

(b) In testing H2,1 – that it is justified (that it makes sense) to improve PC performance, Research „Current State, needs and problems of entrepreneurs in Serbia“, which was conducted – at the behest of NARR – by Statistical Institute of Serbia (march-april 2011) in 3096 SME in Serbia, amongst other things, shows (Table 3) how the „ways and means“ for business improvement are seen by those SMEs who took part. The penultimate place was taken by „Better management“ and for that same item, as the best way to improve SME business, 6.7 [%] of the participants (i.e. 207 SMEs!) voted. Therefore, at least that handful of SMEs understands (and presumably have experience of the fact) that better management is the „key“ to business improvement. As managing can not exist without planning, the same conclusion goes both for planning and plans; authors of this paper have the experience – collected over many years – in improving performances of plans and planning (as well as management systems and business results). By this ($I2(PC)=207^+$), the particular hypothesis H2,1 – that it is certainly justified to improve the PC performance – is considered proved.

Table 3: How to improve business (Source: Republička agencija za razvoj MSPP, 2009, p. 23)

N ^o	Ways of improving business	Part
1	2	3
1	More state support	29.5 [%]
...
6	Better management	6.7 [%]
7	Other	2.1 [%]

(More about particular cases of improving planning performances, and as a consequence improving business results can be found in Omerbegović-Bijelović J. (1995a).)

3.2.2. Improving the performance of SME „Connection of Plans“ (CP)

By actual improvement of performance CP, i.e. by presenting at least one idea to innovate CP, it will be proven that (a) particular hypothesis H1,2 holds true – that it is possible to improve the CP performance, and by showing (at least one) example from practise of improving CP the particular hypothesis H2,2 will also have to be accepted – that it is justified (that it makes sense) to improve CP performance.

(a) In checking H1,2 the need for plans to be connected according to time horizons is shown – connected into „concentric loops“ (as in Omerbegović-Bijelović J., Osnove Operacionog menadžementa, Sl. 4, p. 140), as the short term plan is applied according the corresponding number of times in the space of a medium term plan, and correspondingly, a medium term plan is created (and applied) a corresponding number of times within the framework of a long term plan.

In addition to pointing out the time aspects of plans, one has to bear in mind the „movement of data“ along in the process of planning: data from the long term plan – about potential markets of selling and procuring are used to create contracts within medium term sale and procurement; and so the data about, e.g. planned production are used as orientation for keeping available capacity required according to the short term plan. Hence the processes of creating particular types of planes are shown also as algorithms (with input and output data packets and their transformations within the activities of the planning process).

The idea by which H1,2 is proven (the possibility to improve connections between plans) is shown in Fig. 2. It consists of simultaneous (matrix like) connection of plans both according to time horizons and type of plan (objects), which increases the availability of data and consequently the quality of the plans. Another innovation would be „creative use“ of the colours of documents. Hence: $I1(CP)=2$ and H1,2 is considered proven.

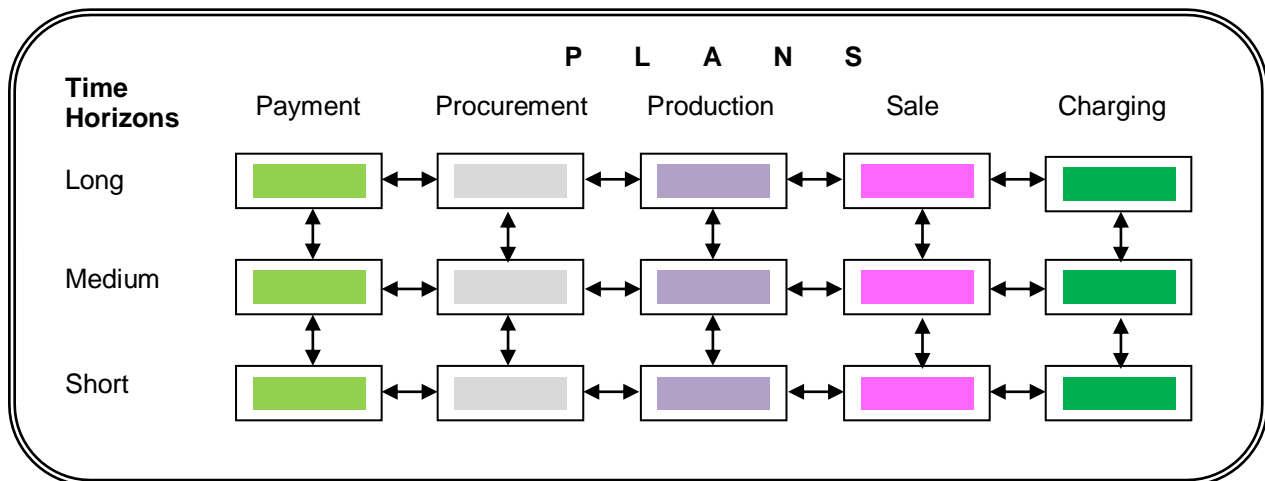

Figure 2: Matrix like connection of plans, using colours as symbols

(b) In checking H2,2 – justification of connecting plans, the necessity for just such a connection is pointed out: if the connections were not there, the plans would lose their sense (as plans of shorter time frame are used to plan achieving goals which are defined by plans of longer time frame). Namely, plans are the „carriers“ of the goals, and for them it holds true that operational goals are ways of achieving medium and long term goals; and reverse, long term goals are the purpose, the reason and the justification for the existence of medium and short term goals.

On the other hand, except for aims, plans also share data relating to the current states, norms, flow (of capacity) etc. – everything which is necessary for plan generation. In addition, the many years of experience the authors have in planning and improving connections between plans (in theory as well as practise) confirm that the value of $I2(CP) \gg 1$; hence H2,2 can be considered true.

* * *

When the particular hypotheses H1,1 and H1,2 are proven, it can be concluded that the intermediate hypothesis H1 is also proven – that it is in fact possible to improve „plans content“ (PC) as performance of plans. Proving particular hypotheses H2,1 and H2,2 therefore proves intermediate hypothesis H2 – that it is in fact possible to improve „connection of plans“ (CP) as performance of plans.

Since intermediate hypotheses H1 and H2 are proven, it can be concluded that the general hypothesis H0 is also proven – that improving (at least one of) performances of plan (or any other element of the managerial system) contributes to management quality (MQ) development and, consequently, to increasing SME „strength“ and its contribution to the social-economical life.

4. CONCLUSION

This paper set out to show that it is important to develop management quality and that every improvement of managerial system element performance contributes to it. It has been shown, on an example of two performances of a plan (as an element of a managerial system), what the methodology for checking the truth (defined here) of general hypothesis H0 could look like and it was concluded that, indeed, every improvement of performances brings with it a development of SME (as well as other organisational systems) management quality (MQ) – which is a contribution to the definition of „Methodology of development of management (system) quality by improving performances of its elements“.

For further research there are a great many questions. We would like to ask some of them here: the order of performances improvement, intensity of change/improving performances and intensity of the consequences (MQ development and improving business results), as well as questions of practical implication: connecting phases in the SME life cycle and improving performances, training for improving performances, practical

tools for improving performances (as well as for designing, implementing and maintaining suggested innovations of plans and planning) etc.

Science has no end, but even so – this paper was certainly limited in many respects. There is always the hope that it may perhaps inspire our younger colleagues – to partake of this interesting and useful research, as well as to be, when it comes to methodology, more demanding and consistent (than, on this occasion, the authors of this paper managed to be).
