The present story goes within a circular cycle that roughly has the following flow: you have to be accredited –you accredit for what you want – for that you must meet certain standards – for the standards you need personnel, equipment and space – you must have financial means – funding is provided through good enrolment – it requires attractive study programmes. Additionally, the enrolment number of students from the accreditation is usually much larger than the number of budget students receiving funding from the state, which is insufficient for the simplest reproduction. Now it is possible to see the reason why the government gave up the appointment of directors - it actually expects from the management team to take care of the school and independently provide funds for quality work and development. However, it remains the founder and owner of the school and completely controls the entire operation. Thus, a normal, even good life is ensured by good management that should fulfill the primary task: enroll the number of students anticipated in the accreditation since it is the only way to enter the magical circular cycle, remain in it and function. If there is a university in your vicinity with similar academic study programmes, but with a large number of budget places, as well as private colleges where perhaps exams are more easily passed, then all this is not easy.

As mentioned, this paper refers to the higher education schools of professional studies where the system of management including its role and importance is completely different than in university colleges (the current situation at a higher level, more budget students, the existence of funded research projects, etc.). In private colleges the situation is again quite different in relation to all the state educational institutions.

The accreditation of study programmes is the most critical moment in the course of decision making of the executives. They must select the number and type of study programmes that will ensure good enrollment fulfilling at the same time all requirements regarding standards set by the National Council. Particularly unfavorable is the validity of the acquired accreditation limited to just five years, which means a constant and exclusively successful management. The second cycle of accreditation of higher education schools of professional studies has just been completed in Serbia. Valuable experiences have been gained and the differences concerning the two schools, of today and yesterday, are obvious and clearly indicate the need for a successful management today (Ružić Dimitrijević & Nikolić, 2010). In that process, a competent school should be built, which means a school without boundaries, with enlarged environment and cooperation with the outside world. And these are exactly the responsibilities of management executives that must create the idea and realize it till the end to the implementation. This is normal because only the management with new challenges ahead is the real one.

4. BASIC MANAGEMENT REQUIREMENTS IN HIGHER EDUCATION

What is expected from the managerial structure is to set objectives at the beginning of each year, so that it becomes the guiding idea in its behavior during the year and through the realization of all tasks. The development of management from the hated former 'slave-driver' to the modern co-operative management has resulted in changing its functions or tasks. Essentially, the development rout goes from an emphasis on the function of ordering to the emphasis on the function of motivation. It is logical that the functions and objectives of management have changed over time (Đorđević, 2006). Some of the objectives specific to management in recent times are the following:

- **Total revenue increasing**, but the increase cannot be realized by raising the cost of some services including tuition fees. The quality of higher education funding is provided by the quality of financing sources, financial planning and transparency in the use of financial resources, which leads to financial stability in the long run. The management must have long provided funds necessary for the implementation of the educational and scientific process, scientific research, artistic and professional activities. The long-term financial stability is ensured through continuous successful operation and existence, accreditation of a large number of attractive study programmes, and profitable and substantial cooperation with industry (Nikolić, 2007). These schools receive funding for their activities from the following sources:

1. Funds provided by the founder;
 2. Tuition fees from the self-financed students are the largest part of the revenue;
 3. Funding of scientific research and professional work that is scarce;
 4. Projects and contracts related to the realization of teaching, research and consultancy services;
 5. Charges for commercial and other services.
- **Development and introduction of the quality system** in all areas (Kamberović, 1998) to facilitate the managerial and organizational work of the executive team. The quality of the management in the higher education institution and the quality of non-teaching support are provided by establishing authorities and responsibilities of executive bodies and non-teaching support units, and by permanent monitoring and verification of their course of work and, naturally, by the assessment of performance concerning the management structure.
 - **Definition of new programmes, new ways of teaching, etc.** aiming to develop all elements of the system. This can include the introduction of a distance learning system, specialist studies, master studies, studies outside the headquarters of the institution, etc.
 - **Intensive and continuous work to improve student enrolment** in all study programmes through various promotional methods.
 - **Promotion of lab work**, making the school labs available to the surrounding community and economic systems and development of new laboratories.
 - **Continuous evaluation and improvement of the quality of teaching** in order to increase enrollment, particularly of high-quality students. The quality of the teaching process is provided through interactive teaching, including examples in teaching, professional work of teachers and staff, making curricula for all courses and their implementation, as well as through monitoring the quality of teaching and taking necessary measures in cases where it is found that the quality of teaching is inadequate. The teaching process is significantly improved compared to the previous period, in terms of teachers' engagement and understanding of new directions. Employing a large number of young associates, allowing work in small student groups, is only one possible solution. The quality of the study programme is provided through monitoring and verification of its objectives, structure, student workload, and by constantly updating the content and collecting information about the quality of programmes from relevant organizations in the region. Objectives and outcomes of study programmes are constantly analyzed and their compliance is monitored. Corrections and updates of the content in accordance with new developments and technologies are continuous (Nacionalni savet za visoko obrazovanje, 2006).
 - **Continuous improvement of working conditions** of teachers and students through the modernization of equipment and space.
 - **Participation in public tenders** for projects in order to provide additional funding and development of scientific, professional and research activities.
 - **Special attention is to be paid to the improvement and development of teaching and non-teaching staff** through cooperation with foreign countries, industry, participation in scientific conferences, specialization and training, as well as through organizing seminars and issuing own publications. A higher education institution must work on encouraging, providing conditions, monitoring and checking the results of scientific research, artistic and professional work and their involvement in the educational process, and, by establishing their unity, coordinate them with the strategic goals of the institution and national and European goals and standards of higher education. The obtained knowledge is then included in the existing teaching process, and the institution publishes results of its work.

The above requirements are just a few of those that are set as objectives in the new system of management and executive activities. Obviously, these requirements could have been set earlier, but definitely it was not the case. All of the requirements aim to increase employees' standards, the quality of services in education, and to improve the business itself.

5. STANDARDS ISO 9001 AND TQM AS MODELS OF THE SYSTEM OF QUALITY MANAGEMENT

As mentioned earlier, one of the goals typical of management is the development and introduction of management systems in all fields, including education, in order to facilitate the steering and organizational work of managers.

The quality of management of a higher education institution is covered by many standards. One of the fundamental principles underpinning the policy of quality of higher education schools is the worldwide standard ISO 9001, which is a revised series of standards ISO 9000 from 1987. The implementation of ISO 9000 series of standards is the first and most important step toward the process of continual quality improvement in education and acquisition of confidence in the market (Gemović, 2006).

The main intention of implementing ISO 9000 series of standards is to achieve the best financial results and competitive performance in the market. These standards do not prescribe how every single institution or school should work, but defines the underlying principles and provides a basis for the improvement of quality. There are several elements that are an integral part of all standards, which most users do not use in full: improvement of management, change of management style at all levels, process improvement, establishing a connection between direct management and improvement activities, equipment maintenance, continuous professional development of personnel, and reducing the size of documentation (Gemović, 2006). The Standing orders on integrated management system (Poslovnik integrisanog sistema menadžmenta) in higher education schools is the basic document of the quality management system

Beside the introduction of the five-year accreditation cycle, the reform of higher education has introduced the obligation of external quality control for higher education institutions, which, among other things, includes self-evaluation and quality assessment of study programmes, teaching process and working conditions. Process of self-evaluation of teaching quality must be continuous and needs to include perpetual improvements of the quality management system, as shown in Figure 1. Schools that have implemented a quality management system perform the self-evaluation much easier. The main goal is to identify omissions, discrepancies, weaknesses and potential errors in the system or results. Systematic approach to the self-evaluation ensures adequate planning of the process improvement.

The highest executive body in the higher education school is responsible for quality management. Quality management is that aspect of the overall management function that establishes and implements the quality policy. Quality policy defines the objectives related to key elements of quality, such as convenience for usage, performance, safety and reliability. The quality system consists of an organizational structure, responsibilities, procedures, processes and resources for implementing quality management. The main purpose of this system should be directed to the prevention of deviations between the planned and the realized, rather than detecting them after creation. The management of the higher education school is particularly responsible for the introduction, development, implementation and maintenance of the quality system in the institution.

Management is increasingly pointing to the fact that the quality should be the outcome of the management process. Applying the principles of quality management in all aspects of the business will result in the emergence of the concept of Total Quality Management (TQM) whose main goal is based on a continuous improvement. Such an approach is necessary to achieve a competitive advantage in modern environment. These results can clearly be measured through economic and financial indicators. Through the ISO 9001 standard, which more strictly prescribes requirements that any organization, including schools, must satisfy, the principles of TQM leave much more freedom here, but they set much broader requirements to users. It can be said that the standard ISO 9001 is a set of requirements that schools must meet to be somewhat closer to the concept of TQM. The concept of TQM is, in principle, based on the use of human resources and management skills to achieve the desired goal. This is why in the process of improving, the quality and the capacity of the management are essential (Gemović, 2006).

Top executives should lead, encourage and promote activities related to the quality management. This implies that quality is not something special, something that can be extracted, but it must be included in all business activities. For the continuous quality improvement, there are a variety of techniques. The role of the top management of the school, the involvement of all employees and long-term efforts to educate employees are irreplaceable in this process.

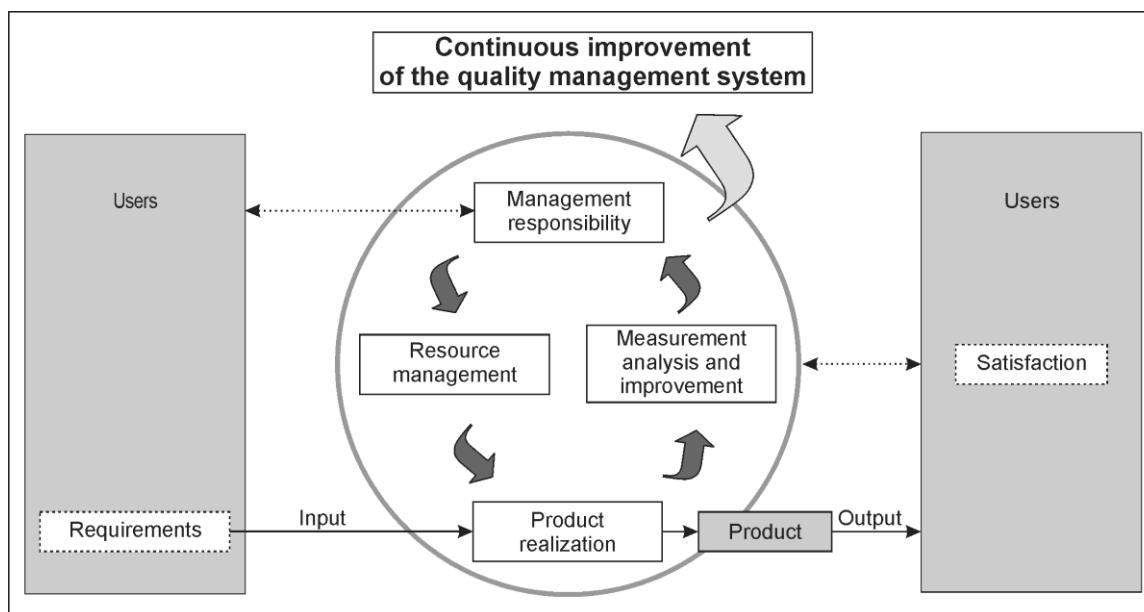

Figure 1: Model of Quality Management System according to ISO 9001

6. CURRENT STATE ANALYSIS

The entire change of policy and environment in Serbia has introduced significant changes in the role and work of management, whereas in higher education the changing of the law in accordance with the Bologna declaration has led to even greater changes and introduced completely new categories of management and leadership in education (Nikolić, 2007).

The difference between private and public institutions of higher education should be pointed out, since there are examples of the private institutions in Serbia that are top business at the moment, very profitable, as opposed to the state-owned ones that carry the prefix of unprofitability. These two types of educational institutions have two totally different management systems.

Also, there are differences between faculties (colleges) and higher education schools. The former exist in the law as legal entities outside the university, but in Serbia the state ones are still part of the university, existing as legal entities although by the law that right applies only to their university. At the same time, the state higher education schools are now only schools of professional studies and exist independently as legal entities. The system of management in all the above subjects differs a lot.

Leadership is undoubtedly one of the basic principles of TQM, quality management and management in general. Only organization led by trained leaders with a special sense of leadership and dealing with people can be successful in today's market. This is the first and fundamental prerequisite for the efficient functioning of an integrated management system. Through the requirements of all international standards that define specific segments of the integrated management system this prerequisite is clearly defined. The support of top management and not only support but also an active leadership are the basic and necessary condition of functioning of the management of any kind (Gemović, 2006).

Higher education school management in today's open world market conditions requires highly educated executives, i.e. managers. This education includes knowledge of economic principles in the business world, effective use of the latest information technology, foreign languages, a highly developed culture of communication, negotiation skills and acquired and innate qualities of leaders (Pokrajac & Tomić, 2011).

The management of higher education institutions is assigned to evaluate the performance of faculty, including their own, based on the assessment of students, and teaching and non-teaching staff, which is a novelty that is difficult to accept, but it is clear this is the only way to achieve true quality in their work. Thus, each institution of higher education is required to conduct self-evaluation in the five year period between the two accreditations (Nacionalni savet za visoko obrazovanje, 2006). That process evaluates study programmes, teaching performance and working conditions by using defined procedures of the quality management system.

On the bases of the policy and development objectives, as well as the needs and requirements of society and the recommendations and work policy of the ministry, the management directs the work of teachers and establishes the level of results to be obtained.

Although it may seem strange it is not true that the power of the management in an authoritarian system was higher than today. Today's system gives the management a great influence on the educational system through the above mentioned tools, such as the influence of students, non-teaching staff and teachers.

The latest development strategy of education, which is currently in public discussion, contains a number of novelties that put new challenges in front of the school management (Ministarstvo prosvete i nauke, 2012). Let us mention just two of them.

The first is that schools can decide independently on their income. At first glance it looks very tempting. However, what is to be expected behind this is a more liberal attitude from the state and less concern about schools in financial terms. So, schools will even more rely on their own work and be particularly dependent on the success of the management.

Another innovation is the possibility of vocational higher education schools to introduce master studies. This would surely increase their competitiveness in the market but it would require considerable engagement, starting with good ideas to the fulfillment of the requirements for their implementation. Among the requirements the major ones are those dealing with the teaching staff, its quality, equipment and space.

If we perform a SWOT analysis (Pokrajac & Tomić, 2011) of the altered role of management in higher education, the findings based on the previous discussion show the following:

- Strengths and advantages (**S** – *Strengths*) that the management in higher education got through the higher education reforms are in its greater independence of decision making in achieving business goals.
- Weaknesses (**W** – *Weaknesses*) may occur due to poor communication among employees. A substantial number of employees in higher education have difficulties to accept the new system of work, which requires greater involvement of teachers throughout the year and a new relationship in which the student becomes a client. Consequently, many teachers just formally work after the Bologna system, and in fact stick to the old system that favours campaign studying and allows professors to occasionally "visit" the school only at teaching times.
- Options and Opportunities (**O** – *Opportunities*) are in improving the business by monitoring interests of prospective students, by starting attractive study programmes and introducing new methods of learning. In order to achieve this, it is necessary to invest in staff training and modern equipment, as well as in the cooperation with similar institutions at home and abroad. Many programmes of cooperation supported by the state provide participation in joint projects and exchanges of students and professors.
- Threats (**T** – *Threats*) may occur due to poor economic conditions in society that does not give opportunities to achieve the desired results, and the state intervention/assistance are missing, or even worse, the government, collecting political points, intervenes in favour of unwarranted student demands at the expense of higher education institutions.

7. CONCLUSION

In the former advanced school there was a state of lethargy, because the system was fully covered by the care of the ministry. The price of that sluggishness was a relatively low salary. No management (good or bad) could not substantially improve nor ruin those relationships. There was no sign modern management, because the directors were essentially government officials merely carrying out its decisions and instructions.

New higher education schools are much more independent and the greater role of management is now crucial to running of the school. Some of the basic elements of that independence in existence, work and decision making are the following:

- reduced state funding and the opportunity to generate significant own income;
- the process of forming new study programmes through accreditation;

- short, five-year validity duration of accreditation;
- introduction of the quality system and continuous monitoring, assessment and control of processes;
- development of the staff and programmes;
- a new process of studying – Bologna process;
- new dimensions in the proposal of the education strategy until 2020; and
- other issues emphasized in the goals.

The above mentioned activities require a lot of work, good work organization, team involvement, substantial resources and highly qualified and professional managers and experts.

Abstract: *This paper applies a theory of leadership and management to improve educational and scientific activities of the Department of Tactics of the Military Academy. The Department of Tactics is structurally organized into two sections: the Section of the Army and the Section of Air Force and Air Defense. The department is functionally organized according to the level of education. Levels of education on which the Department of Tactics implements educational and scientific activities are: Graduate Studies (Bachelor), Basic Command and Staff Course, Command and Staff Course and Reserve Officers School. At certain periods during the school year, it is necessary to effectuate a greater number of classes and a number of additional obligations, which leads to increased stress and fatigue in the teachers. Therefore, it is necessary to apply some techniques and procedures from the theory of leadership and management. The theory of leadership and management helps department members to effectively and efficiently cope with themselves, people, resources, activities and information. This is the most important reason for writing this paper. The main objectives of the study are the application of the theory of leadership and management, and finding specific solutions for improving educational and scientific activities of the Department of Tactics. The basic methods used in this study were content analysis, inductive-deductive method, statistical method, analysis and synthesis and testing techniques. The research findings are related to the increased strain on teachers on one hand, and on the other hand, to the methods and techniques of leadership and management for overcoming this problem and improving educational and scientific activities of the Department of Tactics. By studying the theory of leadership and management and analyzing educational and scientific activities of the Department of Tactics, we have had new findings that point to the possibility of the leadership and management theory application in accordance with the methodology of the Institute of Leadership and Management (Institute of Leadership & Management) Meritum International. The article could be of use to departments and other institutions dealing with educational and scientific research activities.*

Keywords: *Department of Tactics, leadership, management, enhancement, theory.*

1. INTRODUCTION

Educational and scientific activity at the Department of Tactics involves the participation of the Department members in planning, organizing and implementing teaching in the field of tactics, participation in certain projects and specific scientific-expert conferences of national and international importance. Members of the department are engaged in the realization of certain exercises and other activities. Also, due to organizational changes and the retirement of certain members of the department, there is a fluctuation of personnel in the departments. To a certain degree, these specifics have affected the work of the Department of Tactics. Educational and scientific activity of the Department of Tactics can be improved by using the theory of leadership and management. This study uses the theory of leadership and management by methodology of the Institute of Leadership & Management Meritum International. Also, the role of organization and the manager, the subject of improving the situation in the Department of Tactics by means of SWOT analysis, and suggestions for improving educational and scientific activities of the Department of Tactics by The TOWS MATRIXS analysis were analyzed.

2. ORGANIZATION AND MANAGER ROLE

Each member of the Department needs to know the organizational structure of their organization and the connection between their internal organization with the main organization. In this particular case, the Military Academy is organizationally connected with the Ministry of Defense, and is functionally connected with the University of Defense. The Military Academy is structurally organized in the Secretariat, Dean's Office and National Defense School. Military Academy may be organized functionally: by level of education – Graduate Studies, Basic Command and Staff Course, Command and Staff Course, Reserve Officers School, and in accordance with received tasks (e.g. implementation of joint exercises). The organizational structure of the Military Academy is shown in Figure 1

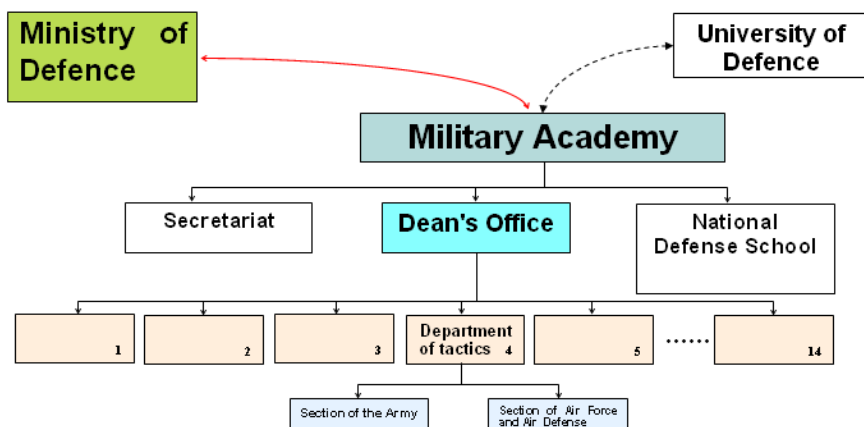

Figure 1: Organizational structure of the Military Academy

2.1. The purpose of the organization

The Department of Tactics, in accordance with the mission of the Military Academy, is principally engaged in performing tasks in the field of educational and scientific research.

The major tasks of the Department of Tactics are:

- planning, organizing and conducting teaching, exercises and special forms of teaching from the master object,
- control and monitoring of teaching, examinations and other tasks,
- planning, organizing and implementing professional military training for members of the Department,
- planning and implementation of scientific research projects in the stem area of interest to the Serbian Army,
- maintaining and improving the material base,
- conducting the prescribed teaching documents.

In addition, the Department is the carrier of the planning, organization and implementation of joint (complex) exercises, and participant in certain meetings of national and international importance.

In accordance with the organization's purpose of each department member (from Head of Department to teachers) need to analyze own continuous professional development until the arrival of the department, and to make continuous professional development plan for the next period. Continuous professional development plan may include a period of one academic year to many years.

2.2. The organizational structure of the Department of tactics

Head of Department commands and manages the Department of Tactics. It is an officer of the rank of Colonel with a PhD or completed General Staff School. The current Department organization predicts the existence of two Sections. Each of the Sections is the responsibility of an officer of the rank of Colonel with completed General Staff School or a PhD. Scheme of organization of the Department is shown in Figure 2.

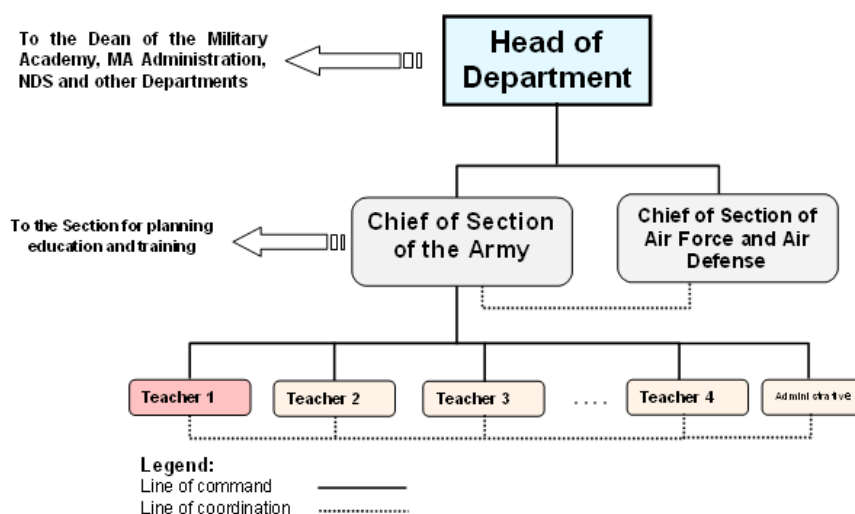

Figure 2: Scheme of organization of the Department of tactics

Head of Department receives orders from the Vice Dean of the Military Academy, gets assignments and to whom he is responsible for the Department. He cooperates with other departments, National Defense School and the Secretariat of the Military Academy, all in order to successfully complete common tasks. Chiefs of Sections are subordinated to Head of Department, and they are responsible for planning, organizing and conducting teaching in their sections.

2.3. Analysis of manager role and functions

Teachers, Heads of Sections and Head of Department of Tactics should analyze their own manager roles and functions. The analysis should include:

- responsibility for the implementation of the teaching process in its field,
- cooperation with certain officers for the planning and organization of teaching,
- studying of literature for the realization of objects in the field,
- participation in certain scientific and professional conferences of national and international importance,
- current way of organizing life and work at the Department.

2.4. The Management and Leadership styles

Continuity of command within the Department of Tactics involves delegating responsibility. Head of Department may delegate a part of the responsibility to Chiefs of Sections and to teachers. Therefore, all members of the Department are in the position to use different leadership and management styles. The most commonly used is a combined leadership style based on a democratic-style amended by authoritarian style. The authoritarian style of leadership is applied exclusively when required by the system of command and military subordination, and there is enough time for making a decision. They should strive to create an atmosphere of fair interpersonal relationships, mutual respect and professional attitude towards work. They should give a personal example in work to associates, to exercise good communication, develop initiative and creativity, a remarks amount fair with a proper respecting of associates personality. This style of leadership has proven quite effective in work so far¹.

3. SUBJECT OF IMPROVEMENT

The subject of improvement relates to the situation and why it must be improved. It should show the effects of the current situation on other organizational units of the Military Academy (interested parties - stakeholders) and details of current goals or target groups and the monitoring and control procedures that are currently used.

¹ Above conclusion is reached on base of work results and on base of interviews with Heads of Sections and teachers in the Department at morning reporting during the period from 01.09. to 30.12.2012.

3.1. The situation which is improving

Educational and scientific activity in the Department of Tactics is implemented with increased efforts and without major problems. Teaching is carried out at four different levels of schooling: Graduate Studies, Basic Command and Staff Course, Command and Staff Course, Reserve Officers School. In addition to class lectures, teachers from the Department of tactics are involved in the development of primary literature and the specific scientific and professional conferences of national and international importance. During the implementation of educational and scientific activities the following problems occur:

- inability of full teaching realization,
- recruitment of teachers outside the teaching process,
- lack of communication between members of Department and the Generas Councils,
- great strain of teachers.

The situation in the Department of tactics was analyzed using SWOT method and is shown in Figure 3.

Strength (S): <ul style="list-style-type: none"> - education (1 PhD, 2 General Staff School, 3 MSc, 4 Command and Staff Course, 1 spec); - experience in the implementation of the teaching process (great, teachers implement lessons from 3 to 15 years); - experience in military service (great, four teachers with more than 15 years of experience in the troops, two teachers have less than 10 years of service in the troops); - participation in conferences of national and international importance (5 teachers from the Department actively participates in conferences); and - family status (all members of the department, except one, are married and have children) 	Opportunities (O): <ul style="list-style-type: none"> - possibilities of improvement in scientific and professional view (education in the country and abroad); - possibility of promotion to a higher rank (3 places are the rank of colonel and 9 places are the rank of lieutenant-colonel); - opportunity to participate in scientific and professional conferences and certain scientific discussions; - possibility of writing professional literature (each member of the Department is involved in the production of certain textbooks and military lexicon).
Weaknesses (W): <ul style="list-style-type: none"> - lack of technical equipment (it is necessary to provide the necessary number of computers and equipment); - inability to increase the number of places in the department (a new organization, can not be changed in the near future); - Separation of insufficient financial resources for the development of literature - (in the year of 2011 granted funds for textbooks only); - insufficient sharing of experiences with the commanders and command in the Serbian Army; - a certain number of members of the department should be retired in the near future; - incapacity to implement all planned courses in given time. 	Threats (T): <ul style="list-style-type: none"> - great burden and fatigue of teachers; - reduce of quality of the implementation of the teaching process (not enough time to monitor trends in armed conflict); - disapproval of the required amount of money to create professional literature and obtaining of the necessary resources; - lack of communication between Department and units; - inability to change organizational structure and to expand Department of tactics; - obsolescence of certain technical literature; - routine implementation of the educational process and transition to monotony;

Figure 3: SWOT analysis of the Department of tactics

3.2. Effects on stakeholders

The effects of the interested parties can be seen through stakeholder analysis of the Department of Tactics. Stakeholder analysis should include: identification and classification of stakeholders, identification of stakeholders' interests, determining the possible stakeholders' impact, definition of key stakeholders and ways of gaining support of key stakeholders.

Identification and classification of stakeholders include: primary stakeholders, secondary stakeholders, key, internal and external stakeholders.

The primary stakeholders include: Training and doctrine department, Military Academy Secretariat, Dean's Office, Military Academy Logistics, cadets and officers.

Secondary stakeholders are: Training Command, Army Command, Air force and Defense Command, Faculties of the University of Belgrade (BU Faculties).

Key stakeholders are: Department of Organization, Dean's Office, Department of Tactics, teachers, cadets and officers attending higher levels of education.

Internal stakeholders are: Military Academy Secretariat, Military Academy Logistics, cadets, teachers and non-teaching staff engaged in the learning process.

External stakeholders are: Training and Doctrine Department, Strategic Planning Department, Commands, BU Faculties.

3.3. Current targets

Head of the Department of Tactics, Chiefs of Sections and all teachers need to recognize the goals that will influence the improvement of educational and scientific work in the department for a certain period of time. The goals should be operational through tasks, implementing the terms of execution. Objectives may include: forming a team to create the organizational structure of the Department of Tactics, legally regulate engagement of external associates in the Department of Tactics, legally regulating the hiring of teachers from the Department of Tactics to realize the joint exercises, participation of the Department of Tactics in the development of curricula at all levels of education, preparation of documents for the implementation of curricula, preparation of teaching material basis, participation of Department members for the development of teaching literature and at conferences of national and international level, an analysis of the teaching contents and additional forms of teaching in the school year.

3.4. The existing procedures for monitoring and control

Basic procedure for monitoring and control to achieve the objectives are:

- personal participation of Chiefs of Sections in teams for creating the organizational structure of the Department of tactics
- development of organizational structure in accordance with legal provisions taking into account the overall workload of teachers,
- submission of daily reports to Head of Department on teaching and extracurricular activities,
- control of compliance of the Department's organization suggestion in accordance with the Statute, the Law on Education and Labor Law,
- support and control of the development of teaching realization plan for the next school year,
- control of development and submission of material providing,
- control of development and submission of proposals for the participation of the Department members on scientific and professional conferences,

CONTROL OF THE DEVELOPMENT OF THE ANALYSIS OF TEACHING.4. SUGGESTIONS FOR IMPROVEMENT

Based on the opinions of teachers from the Department of Tactics² and the analysis of teachers' stress we come to the conclusion that teachers are overworked. Accordingly, it is necessary to change the organizational structure of the Department and shift from classical organizational structure to project oriented organization. In addition, it is necessary to test Department members to determine the role of teamwork³, create opportunities for personal improvement of Department members and for numerous participations in conferences, trade shows, receptions. It is also necessary to motivate the Department members on the basis of the following needs: to succeed, to have power, to self-actualize, to succeed and to belong.

Improving the situation described above through the Tows Matrixs of Department of tactics is shown in Figure 4.

² On the morning reports every teacher displays thinking about realization of educational and scientific process, with suggestions for improvement.

³ One possible test is the test for determining teamwork by Dr Meredith Belbin. Based on this test, it is possible to determine which members have the greatest propensity as: implementer, coordinator, modeler, the originator, the examiner resources, the supervisor-evaluator, team worker, complete refiner or specialist.

	Strength (S): <ul style="list-style-type: none"> education; experience in the implementation of the teaching process; experience in military service; participation in conferences of national and international importance and family status. 	Weaknesses (W): <ul style="list-style-type: none"> lack of technical equipment for the Department members; inability to increase the number of seats in the department; Separation of insufficient financial resources for the development of literature; insufficient sharing of experiences with the commanders and command in the Serbian Army; a certain number of members of the department should be retired in the near future and inability to implement all planned courses in given time.
Opportunities (O): <ul style="list-style-type: none"> possibilities of improvement in scientific and professional view; possibility of promotion to a higher rank; opportunity to participate in scientific and professional conferences and certain scientific discussions. possibility of writing technical literature. 	SO strategies: <ol style="list-style-type: none"> 1. Improvement of the educational process through personal development of department members; 2. Improving the educational process by exchanging educational experiences; 3. Improving the quality of the Department members by participating in the meetings; 4. Motivation of Department members by promotions to higher ranks; 5. Increasing the efficiency and effectiveness of the Department with good organization and preparation of technical literature. 	WO strategies: <ol style="list-style-type: none"> 1. Improving the quality of teaching using modern technical means; 2. Improving the quality of the educational process at a time when it is not possible to increase the formation; 3. Focus on creating the most important literature in terms of limited budget; 4. Through the implementation of joint exercises improve communication with units. 	WT strategies: <ol style="list-style-type: none"> 1. If you do not have modern equipment use the existing and rely on the library of Military Academy; 2. Separate planning from execution; 3. Shape the work of the department and give more time to rest when the intensity of classes and extracurricular activities are lower; 4. Associate with members who are soon to retire to gain extra motivation for the most effective implementation of teaching.

Figure 4: The TOWS MATRIXS of Department of tactics

5. CONCLUSION

The Department of Tactics as an organizational unit of the Dean's Office realizes teaching at four different levels of schooling. In addition, members of the Department participate in scientific research and implementation of other activities. The situation in the Department is analyzed daily, monthly and annually. Every day is realized a morning refer with the Head of Department, monthly and annually prepare an analysis of teaching and extracurricular activities. An analysis of the situation in the Department concluded that in certain periods of time the workload of teachers is increased, which affects the implementation of scientific and educational activities in the department. This problem can be accessed in terms of leadership and management. Using theory of leadership and management by methodology of the Institute of Leadership & Management Meritum International, we analyzed the situation in the Department of Tactics, using the SWOT analysis and gave some suggestions for the improvement of educational and scientific activities through the Tows Matrixs analysis.

Further work on this issue is necessary in order to prevent the fluctuation of Department members, changes in organizational structure of the Department, education and training, design work, and motivation of the members of the Department.

Abstract: *Visiting spas for the reasons of both physical and mental health concern and treatment of various diseases has existed ever since the prehistoric times. Spas have been growing into cultivated oases of greenery and tranquility. Their natural landscapes are supported by cherished environment, parks and promenades. Recreational and touristic content of spas most often comprises modern accommodation facilities, playgrounds, parks and swimming pools. Besides recreation, the reason for visiting spas can be learning about culture and cultural and historical heritage of the place where the spa is situated, enjoying the glory of nature, visiting various events organized in spas and their surroundings. Spas are also places for organizing various conventions, seminars and other large-scale gatherings. They are also beneficial for sport team preparation. The present study analyzes the aspect of positive 'exploitation' of a spa's opportunities from the educational point of view. The analysis of the gained findings shows a beneficial effect of spa environment on young people and emphasises opportunities for their successful education in this specific surroundings. The valid results are obtained by means of surveys and comparative analysis.*

Keywords: *spa environment, tourism, education, communication, organization*

1. INTRODUCTION

Starting from the strategic advantage of the Republic of Serbia, ground and surface waters, wealth of thermal springs and traditional spas, established by the Tourism Development Strategy of the Republic of Serbia ("Official Gazette of RS", No. 91/06), have been marked as great and unused potential.

Exactly the lack of sufficiently qualified hotel and tourist managers and staff in new tourism occupations has been given as the main deficiency in the development of tourism by the same Strategy.

WTTC(World Travel and Tourism Council) predicts that by 2015 the number of employees in tourism will be 269.5 million people (compared to 221.5 million in 2005) making it 8.9% of total world employment or 1 out of 11 possible jobs.

The Republic of Serbia has chosen to build its competitiveness in tourism upon human and natural potentials, in long term, especially regarding ground and surface waters, rich archaeological and architectural heritage, with emphasis on the monasteries, historical sites, spiritual creativity, as well as festivals and other occasions and events, which can provide Serbia the opportunity to present its own lifestyle.

Investments in the tourism sector of the Republic of Serbia, in the period up to 2015, based on detailed projection of the growth of accommodation capacities, according to the clusters established by the strategy: Vojvodina, Belgrade region, West Serbia and East Serbia have been estimated at around four billion euros, most of which have been intended for the development of West Serbia, in the amount of 1,567.8 million euros or 38.8% of total investments in tourism of the Republic of Serbia.

2. VRNJCI SPA AS A TOURIST CENTER "FACE AND REVERSE"

The attractiveness of tourist destinations can be defined as a set of elements such as geographical location, climatic conditions, natural environment, infrastructure, accommodation facilities, entertainment content and the like. Physically intangible things characterized as a tourist destination and other services is a set of feelings, beliefs, images and opinions that the individual has the ability to provide appropriate

destination satisfaction. Based on these factors we analyzed Vrnjci Spa as a new university center from the perspective of the before mentioned fundamental basic elements.

With a long tradition of tourist, health and cultural center, Vrnjci Spa has seven springs of natural, healing, hot and cold mineral water, where the center for treatment and rehabilitation - AQVAE ORCINAE was built back in the Roman Empire.

Archaeological sites, such as: pool and Roman spring of mineral water- FONS ROMANUS, also originate from this period. Uniqueness of Vrnjci Spa lies in the fact that there are numerous springs of mineral waters of different composition, temperature, radioactivity and healing properties in a relatively small area, as well as in the fact that these waters meet high scientific standards and are effective in treating many diseases.

There are also the medieval monuments in the vicinity of Vrnjci Spa, which are considered to be a real cultural treasure, and the most valuable of these, such as: Studenica, Zica, Djurdjevi Stupovi, Gradac, Sopocani and the first Serbian Archbishopric, represent the greatest heritage of Serbian spirituality and culture. In its immediate vicinity, there are also the most important winter sports centers: Kopaonik and Goc.

For these reasons, Vrnjci Spa and its surroundings are one of the most interesting tourist areas of Serbia, with extensive accompanying events, such as events in the field of fine arts, graphical art, sculptural art, film and musical art, literature and ongoing archaeological and historical settings.

On the other hand, looking at the population according to age groups, we can conclude that the normally low share of young population is still decreasing. Accordingly, it can be said that there are 115 inhabitants older than 65 years for 100 inhabitants aged up to 15. The dominant number of inhabitants falls into the category of the working age population, which can be considered as a significant development potential. In the educational structure of the population aged 15 years and over, in the area of Vrnjci Spa, completed high school is the most common form of education for both sexes (43% of inhabitants), primary education is in the second place (23%, mostly the older part of the population), while 10% (2.326) of the population of the municipality have university and higher degree. It is important to mention that almost 50% of the population of the municipality have primary and lower education, which undoubtedly requires greater engagement in education of the population, through additional training, retraining and continuing education programs. Having in mind that intensive education reform in this field is carried out in Europe, in order to raise the overall level of service quality and offers of tourist centers, it is logical to improve the system of staff education in the field of hospitality and tourism in the educational system of Serbia.

3. EDUCATION IN SPA ENVIRONMENT

Starting from the above facts and the development directions established by the law and strategic development documents, the University of Kragujevac and the holders of executive and legislative authority of local government of Vrnjci Spa have jointly assessed that there is a need to establish a higher education institution that will educate staff in the field of hospitality and tourism. In March 2010, the Council of the University of Kragujevac has passed the Decision on Accepting the Initiative and Signing the Protocol on Joint Activities on Establishment of the Faculty of Hotel Management and Tourism. With this document, the Municipality of Vrnjci Spa and the University of Kragujevac have agreed that the mutual goal of the Municipality of Vrnjci Spa, as a tourist center of Serbia, and the University of Kragujevac, as a provider of higher education, scientific and spiritual development of macro-region of Sumadija and West Serbia, is to achieve plans of their own strategic development, by education of lacking highly qualified staff of educational profiles that are necessary for the development of tourism, not only in Vrnjci Spa, but on the whole territory of the Republic of Serbia, by establishing the Faculty of Hotel Management and Tourism, based in Vrnjci Spa, and which will be part of the University of Kragujevac.

The Faculty of Hotel Management and Tourism was opened in 2011 and it filled the planned capacity in the first year of its existence, by enrolling 100 students in the first year of studies. The interest in this, although a new and novel faculty, was great. For the meantime when the Faculty is largely planning the 2012/13 school year, with interest steadily deepens, and the administration of the Faculty staff is trying to solve the upcoming "positive" problems brought a new entry in the summer 2012th. Knowing the approximate structure of the first generation students of the Faculty of Hotel Management and Tourism in Vrnjci Spa, we started the analysis taking into consideration the reasons of enrollment to the study at the Faculty, as well as the impact of environment on the choice of spa tourism and hospitality studies.

4. CHOICE OF FACULTY AND SPA ENVIRONMENT – ANALYSIS OF RESULTS

The aim of our research was to analyze the reasons for enrollment as well the influence of spa environment on the study choice within the Faculty of Hotel Management and Tourism in Vrnjci Spa..

The research started from the assumption that the spa environment had a positive influence on the study choice of our respondents. Using a specially formulated questionnaire, we polled 65 students (around 70%) of the Faculty of Hotel Management and Tourism in Vrnjci Spa about their reasons for enrolling in these studies and came to interesting findings which we shall present in this paper.

Students of the first year at the Faculty of Hotel Management and Tourism in Vrnjci Spa are young people of an average age of 20. Females accounted for 67% of the surveyed students and 33% were male. Among them, the majority were those financially dependent on parents – 87%, while only a small number of them work and thus financially support themselves during the studies. This data does not differ greatly by comparison with the analysis of other faculties in other areas since higher education in our country is formulated in a manner that the students are practically completely disabled to work and study regularly. Observing this data and having knowledge of possibilities that the spa environment provides to the students who are studying to work in tourism, we believe that the future organization of studies should enable all interested students to work in the field of their education. Thus, the students would also gain practical knowledge beside the improvement of their financial status. Nowadays, however, they are enabled to work only during lecture breaks in the summer when Vrnjci Spa has the most tourists.

Chart 1. Distribution of respondents according to whether they are residents of Vrnjacka Banja

It is interesting that a large number of students, as many as 79% of them, have come to Vrnjci Spa in order to enroll in this Faculty, and only 21% are locals (**Chart 1**). This is the manner in which the number of young people is increased throughout the year, and especially from October to June when normally fewer tourists visit Vrnjci Spa. Also, the total number of young people living in Vrnjci Spa is increasing, which all implies the increased number of cultural events for young people (parties, concerts, cinema screenings) that otherwise do not occur in Vrnjci Spa in the mentioned time of year. Residents who rent apartments fill accommodations with the students of the Faculty of Hotel Management and Tourism even during the months when it was not the case in previous years, which improved the financial status and standard of the locals throughout the weaker tourist months.

Chart 2. Distribution of respondents according to previously completed high school

Among the students of the Faculty of Hotel Management and Tourism, the highest number comprises those with a degree from the Hospitality and Tourism School, which is also an expected finding since this Faculty is a logical continuation of such secondary education. Detailed distribution of respondents per completed school is provided in the chart (**Chart 2**).

Students who believe their secondary education had influence on the faculty choice make 40% and 21% would not enroll in this Faculty if it were in some other area. This data indicates the fact that the spa environment received a very positive evaluation from higher education beneficiaries.

Regarding the contents of sports activities, the respondents deem that they were not important for them when choosing the studies and neither were the cultural events. They assess the entertainment events, however, as important and this finding is quite expected considering the fact that young people are in question. It is interesting that they assess the peacefulness of Vrnjci Spa as an important part of the environment for studying (**Chart 3**).

Chart 3. Distribution of respondents according to how they evaluate the peacefulness of Vrnjacka Banja as an advantage of study environment

Also, the role of parks and gardens in Vrnjci Spa has a high percentage of positive influence on their student life. Since this spa is widely known exactly for these characteristics, they were also recognized as important by the higher education beneficiaries, which is an extremely important finding. Natural resources could certainly be exploited better and we assume that they are a factor toward the development of a better study environment in the spas of Serbia.

Chart 4. Distribution of respondents according to the importance of low off-study costs as a factor for choosing the study environment

Considering the generally poor financial situation, we assumed that the lower cost of rental apartments and cheaper living conditions would have a positive influence on the choice of study place. However, the respondents do not find this factor particularly important (**Chart 4**). Certainly those respondents who financially support themselves assess this segment as somewhat more important than those respondents who are financially dependent on parents during their studies, as expected.

5. CONCLUSION

Based on the analysis and results of the research, we may conclude that the spa environment is favorable for studying, especially if observed from the perspective of hotel management and tourism studies. Only a portion of data is provided in this paper which discusses the environment, and certainly some other time there shall be more on the spa environment from the perspective of conducting practice and satisfaction of students with such a specific, and for our standards, new study environment.

Plans to open a faculty of medicine and some other departments of University of Kragujevac faculties in Vrnjci Spa could favorably influence the development of that municipality, rejuvenation of population and reduced departure of young people to other places and cities in the region. We think there are environments that are not necessarily urban, i.e. city, which could become bases for certain faculties depending on the nature of higher education institutions.

Possibilities provided for studying by such an environment may be a significant potential, naturally without diminishing the significance and importance of university centers existing in our tradition.

ATTITUDES AND EXPECTATIONS OF THE UNEMPLOYED IN TRANSITION CIRCUMSTANCES IN SERBIA

Gordana Milosavljević¹, Zorica Tanasković²

¹Faculty of Organizational Sciences, Belgrade, gordana@fon.rs

²High business-technical school, Uzice, zorica.tanaskovic@vpts.edu.rs

Abstract: *Social disturbances are always an associated notion of transitory changes. What is a decisive factor for this process to move towards the right path? On the one hand, leading role is played by development policy and economic strategy, but on the other hand, each individual must be engaged in finding opportunities and personal improvement in order to find his own place in the business world. The changes and job opportunities are most easily adopted by highly educated youth. Finding a job in the new circumstances is a big issue for both the middle aged and less qualified employees.*

Keywords: *transition, human resources, organization, commercial development, economic development, employment, stress*

1. INTRODUCTION

The beginning of this century is featured by a more intense globalization process and completion of transition process, but also by a world economical crisis that shook the entire economic order, introducing new economic leaders (China, India, Brasil...)

The basic assumption of the complete social-economic transition is the privatisation process aimed to create economic conditions for free enterprising activities of individuals.

Actual economic movements in transition period have an immediate effect on the conditions and movements in all spheres of life. For the last 15 years, commercial conditions have been featured by: large downfall of industrial production, reduction of foreign exchange, lack of significant investment activities, general insolvency of commerce. These adverse movements have brought the changes in the field of employment and employment rate: reduction of recorded employment, accelerated growth of open unemployment, high skill-wise and qualification-wise structure of the unemployed with a tendency of growth above average in the total unemployment, high „hidden“ unemployment, high underground employment and a large number of the employed in insolvent companies. The problem is a huge time discrepancy between the following two activities: redundancy activities in the companies and creating condition for re-employment at other or similar job positions.

2. PARTICULARITIES OF TRANSITION CHANGES IN SERBIA

One of the toughest issues escalating in transition process is unemployment. It is known that Serbia inherited abt 30% over-employment from the previous (socialist) society. This problem escalated in the privatisation process. Reformers assured that this problem would be present for only a few years, that it would be eased by social programmes, that it would finally be eliminated once new small and medium enterprises are founded and that Serbia would be then faced with the lack of manpower.

Transition and employment potentials – typical attitudes of the unemployed

It is a fact that those looking for a job must change their habits. On the other hand, state and institutional authorities must create a strategy to resolve the employment issue in the new circumstances.

Who is affected in transition period?

Most of the Serbian citizen will remember the transition as a period when a job was either easy to loose or hard to get. Those citizen are certainly the immediate victims of transition processes and they experience the most drastic consequences.

In reality, everyone is affected in transition process. In fact, this is the period when the fact that no one is secure in terms of reliable and full time employment must be accepted. Self-governing system, which had

been dominant in our society both formally for a long time and even longer through acquired habits, guaranteed relatively quick and secure employment. It also guaranteed a privileged role of the employees in occupational disputes. Unfortunately, it was frequently economically unjustified. It is a fact that these commitments made us enter the transition processes with redundancies in most of our enterprises. Having changed to market method of doing business, the circumstances have been fully changed. New employers stick mainly to economic rather than social motives.

Noone has got a job secured. Employment growingly depends and will depend on the employers' needs and interests. One should not forget that these needs and interests are subject to frequent and often radical changes.

What should be done when there is no secure job?

There is no recipe to help anyone find a job easily and reliably – it is just a delusion.

One should not wait but look for a job. Although a state of full employment is an ideal for each society and government, although there are specialized departments acting as employment mediators (first of all, Employment Service), a success in looking for a job mostly depends on the person searching for it. Different State authorities assign certain assets in order to incite employment. However, the problem of unemployment is hereby solved only on a general rather than individual level. Furthermore, when the number of job positions available is small and the number of the people competing for the job is large, an individual can only rely on the services rendered by Employment Service.

Job search is an active rather than a passive process. It was duly noticed in the Employment Service – now they organize trainings for an active job search. Such opportunity should be utilized as this kind of training is rendered free of charge.

I am only interested in a full time job. The delusion of being employed at a single company „until retirement“ is still present with a big number of our citizen. The sooner it is realized that each job position is a „temporary“ one, the sooner the unemployment issue will be resolved.

For example, during the year 2006, out of the total number of the employed 68,4% is employed part time while 31,6% is full time employed. That is, employers mostly decide to apply this kind of employment. If an individual decides to work part time, he must take into account that the quality of his work is the factor determining whether the employer will offer him a job again. The employers' logic is primarily based on interest which is possible to be accomplished only with the help of good employees.

I am only interested in the public job. Despite delays in meeting the given deadlines, privatisation process has moved far forward and is close to the end. Anyway, many people consider public jobs more attractive. How many state owned companies are there? The answer is – less and less each day.

In spite of the fact that privatisation is one of the topics being discussed most, there is still a lot of citizen taking previously socially owned companies as public ones, although these were acquired by private individuals quite some time ago. It particularly applies to successful companies, i.e. those which are attractive for employment.

Simply, it is much more likely to get a job at a private company than at the state owned one, regardless of what it involves. „State owned“ is in majority, at least it will be reduced to public sector. Those looking for a job must know that it is burdened with redundancies. It is a matter of days when a necessary cut will be made here.

I have got my diploma. Majority of investors, especially those coming from abroad, organize their own training courses for the recruits. Many of them are not interested in what will be presented to them as formal education. They are only interested in actual skills, i.e. what and how much an individual is capable of doing. If one wants either to get a job or to keep it, one must be ready to permanently improve own skills. If an individual has proven own skills and knowledge at the previous job position with similar tasks, it is still not a crucial recommendation. Foreign investors, in particular, introduce a different organization, comprehension of working habits and alike. They know well that our country has deteriorated in terms of technology over the last decades; thus the individual skills achieved with such technology will not be very helpful.

There are no vast differences even with those looking for a job for the first time. A diploma acquired at school will not consequently bring a job opportunity; it primarily implies a capability that the knowledge acquired will be applied to a concrete job position. There is a delusion of foreign investors insisting on young manpower and they are almost exclusive in such opinion. The reason of this way of thinking is their attitude towards the socialist working habits of the elder, i.e. of those having been working in socialism. At the same time, the fact that Yugoslav commerce was functioning on different principles than those from real-socialism countries is often neglected.

This is the issue that must be dealt with by both the State authorities and all those involved in solving the problem of employment, since the most affected age group of the unemployed is the one starting from 45 years of age and more. Such delusion should be eliminated, i.e. it is necessary to assure the foreigners that the connection between youth and experience is the best in our circumstances. All this must be further followed by incentives for employment of this population.

Employment Service renders help in this domain by organizing various kinds of trainings and re-trainings. Apart from this one, there are other services involved in this job.

I can only accept a job in my town. Apart from professional, new circumstances involve other kinds of adjustments. In order to make a detailed analysis, it turned out that there is a number of job positions available for the skill profiles included in the unemployment record.

The problem is that the free job positions are out of our town. We have to change our habits in this sense as well, as we have to be much more ready to, for example, change the residence if the job position assigned is really necessary and if our existence depends on it. It is a common notion in a major part of the world. People travel to get a better job for hundreds and thousand of miles. Of course, this may involve certain either emotional or cultural disturbances. One should always consider what implies harder consequences – above mentioned or the life without a job and means for existence.

I am not capable of having my own business. The solution to the unemployment problem does not mean that everyone should run own business. The true is that not everyone was born as a businessman. It is an option that should be seriously considered in case someone has lost a job. It is experienced that the majority of those that had obtained severances spent their money on either a real estate or consumables purchases. The function of severance pays is completely different - they were paid out in order for someone to permanently support own existence rather than temporary increase the standard. It can be said that the severances were low in some companies and thereby insufficient to be taken into account for running a business on one's own. Anyway, they enabled joint ventures with those found in the same position. Further, beside a large number of unfavourable loans, there are some loans that are really incentive and beneficial for those starting to run own business. These are mainly the loans approved by republic, regional or municipal authorities. Apart from granting these favourable loans, these authorities are liable to form departments rendering counselling service to the runners of the own business, especially to those from the Employment Service record.

I am loyal to my company. Corporate loyalty is certainly a praise-worth feature of an employee. But, what happens when a company is not „loyal” to you? A whole army of people in this country was and is still working for low, irregular or literally no wages. To stay at such job position is maybe a good decision, especially if it is taken into account that it is hard to get a job these days. But, it is a bad decision for sure if there is another more favourable possibility, particularly if the loyalty motives are the non-economic ones. Very often, loyalty is based on the motives referring to friendship at work, habits or justifications such as „I know everything here” „I have spent the entire career here”. Job is a matter of economy rather than emotions or anything similar. That is, if a company is in a bad position, it is not a sin to look for another job. It does not necessarily mean one have to quit immediately. We still think that an advantage during employment is given to the unemployed. It is wrong.

Employment Service have changed their working method so that they have recorded a significant number of those, already employed, looking for a job. All people searching for a job are equal regardless of their current status.

If i pull some strings, i will get a job. This used to be the shortest way to get a job but it is not the case today. The reason for that is the change of circumstances referring to the change of ownership structure.

Employer invested his capital in the business and he has the full right to judge who is going to work for him. In private companies, the best „strings“ are skills and abilities. In public sector, there are redundancies so that „pulling strings“ is just a waste of time.

The delusion like: „I am not going to work for a stranger“ or „ Private owners exploit workers“.... are still present. Some of these delusions have some ground in reality but it is a delusion to make the rule out of individual cases.

Getting a job primarily depends on the person searching for a job. But, it does not mean that others are relieved from solving this problem. On the contrary, it is a serious issue of both the government and local authorities. The problem may be solved only by a series of measures leading to concrete results – new job positions. Further, trade unions must play a more active role in this process, particularly as far as the people with interrupted careers are concerned. Such role must be rather creative than just critical. On this job, a high level of partnership is required. Although the latest indicators hint positive tendencies in the employment sector, it should be taken into account that each figure and statistical data represent concrete human beings with a large problem to support their own existence. Therefore, nobody is allowed to be slow in this process; therefore, we all need to be partners in this.

3. CONCLUSION

One should not wait but look for a job. Although full employment is an ideal for both the society and the State, although there are specialized mediate services for employment, the success in finding a job mostly depends on the one searching for it. A job search is an active process.

Delusions on being employed at a single company „until retirement“ is still present with a large number of the employed in Serbia. The sooner it is realized that each job is a temporary one, the sooner the unemployment problem will be solved.

Although privatisation process has moved far forward and is close to its end, public jobs are still considered the most attractive.

It is not enough just to have a diploma. Majority of investors, those coming from abroad in particular, organize their own training courses for the recruits. They are only interested in actual skills, i.e. what and how much an individual is really capable of doing. If one wants either to get a job or to keep it, one must be ready to permanently improve own skills.

New circumstances typical for transition involve other kinds of adjustments, apart from professional. Habbits must be changed, i.e. one must be flexible to, for example, change the residence in order to find an adequate job influencing the existence of an individual and his family. Remaining loyal to a company in spite of low and irregular wages is justified only if it is borne in mind that it is hard to get a job nowadays. Getting a job by „pulling some strings“ used to be the fastest shortcut once upon a time, but it is less and less present today.

MANAGER TRAINING WITH THE PURPOSE OF INCREASING THE EFFICIENCY OF ROAD TRANSPORT COMPANIES

Predrag Ralević¹, Sanja Ilić²

^{1,2}Rico Training Centre, Accredited Training Institute IRU Academy

Abstract: A constant demand for increased efficiency forces road transport companies to promptly find new technical and technological solutions that will make transport organizations more efficient. Modern technology in road transport, or, in other words, new technical and technological solutions have to follow highly professional and permanent education, aligned with standards and regulations on the global level. The paper deals with the problems and difficulties that arise in organizations due to lack of training of the managers who are responsible for efficient transport, organization and control of vehicles and drivers. The idea of the authors is to point out a need for training of managers, who have the key role in the effective realization of transport services, and providing education to staff, which is an investment and not a cost for transportation companies. Professional training programs for the employed in road transport, which the IRU Academy in Geneva conducted through its Accredited Training Institutes, provide educational opportunity for all participants in the transport process. Continuous training enables human resources function to have highly professional managers who are able to meet all the requirements dictated by modern transport.

Keywords: manager training, road transport companies, professional competence, CPC

1. INTRODUCTION

All scholars are agreed on that human being is the most important factor for scientific, technological and social progress, and that staff are a key resource of the organization. Human resources are the main wealth and potential, not just for one organization, but also for the entire state (Hewlett, 2002). Human resources are more important than natural resources (Richardson & Thompson, 1999). Even countries that do not have natural resources, can achieve a high level of economic development, if they have the appropriate human resources. Bearing in mind that in contemporary theory, the term staff means trained, educated and trained professional staff, organized in order to meet the personal and socio-economic interests and needs, and not just the highly educated professionals and managerial staff of companies (Merriam, 2001). Analogous to the strong influence of the degree of social development, human resources is a fundamental prerequisite for successful development of the individual organization (Mihajlović & Ristić, 2011). Therefore, the growth and development of enterprises depends of the formation of adequate staffing levels and its efficient use. Due to such a great importance of human factors in the company, investments in staff is far more attractive compared to the investment in physical capital (Nerdrum & Erikson, 2001).

Modern business of transport company requires alignment of the management to organizational resources with a variety of changes in the current environment, both nationally and internationally. New technology in traffic requires new knowledge and high level of expertise and specialization of personnel in that area. According to the estimates made by the European Union, more staff will be working in transport, but there will be a need for capable personnel to solve the problems at all levels: researchers, planners, designers, constructors, in the logistic chain conveyors, traffic experts in the cities, and particularly successful managers. Assumption is that in the future development of traffic the most critical component will be the staff, because in the most countries, the traffic is studied sporadically at the universities. Only recently has been increased the number of courses in the field of transport. It is also estimated that an advantage in the development will have those areas that have developed infrastructure and the ability to train staff. In that sense, the training of highly educated transport personnel involves multidisciplinary profession.

The staff must have knowledge in management, logistics, haulage forwarding, road safety, traffic engineering, marketing, ecology, computer science and language courses. The quality of personnel can be provided only by planned improvement of current and new staff with adequate education, that is, the proper management of human resources. The way we manage the stuff highly depends the business

efficiency of transport company and its future development. Personnel policy defines, among other things, the profile of staff necessary for the transport organization, the way they are recruited the way we are motivate and stimulate them and especially education because of the permanent changes that occurs and in the terms of technology and regulatory aspects. Modern business practices, and anticipating trends, indicate that the success and survival in the market will achieve only organizations that are constantly improve and adapt to the environment (Pfeffer & Sutton, 1999). The dynamic development of science and technology requires the development of a dynamic organization and all its components. Transport companies that accept such a business philosophy must adequately provide the training and changes in their own staffing structure. In other words, they must have a modern approach to planning and development of staff, that is reflected in the permanent education and training of new and current employees.

2. TRAINING OF MANAGER TO IMPROVE PROFESSIONAL COMPETENCE IN THE ROAD TRANSPORT COMPANY

The general trend in Europe is moving towards a knowledge society that is acquired and maintained through continuing education and training. Certainly, training is essential because it allows employees to adapt to new technological and legal solutions. It should include all employees to increase their contribution to the realization organization goals. Training is a complex task that refers specifically to an organization where to be found that knowledge and to what extent they will be presented to users. Good practice is achieved if the train managers who can effectively communicate their knowledge and skills to other employees through continuous learning process. This is especially important for organizations conducting business in an international environment where there are constant technological and organizational changes. For the adoption and implementation of international standards that regulate the organization's business managers need to have diverse and multidisciplinary knowledge necessary to effectively operate at the international level. In order for organizations to be successful in this business is a new approach to training employees, which means that training is the task and obligation that is being undertaken and whose implementation control (Perović, 2007). Past practice shows that the trained individual in non-trained environment does not produce the expected results and that training will never be at a higher level of training that employees need to exercise it. This fact implies the need for training should be organized for groups, where on joint discussions by all participants familiarize themselves with newspapers, methods and procedures.

Road transport of passengers and cargo is by nature a transnational area, and most segments of the transportation is defined at the international level with conventions, agreements, directives and regulations with the goal of efficient and safe transport organization. Regulation allows to road transport companies an efficient and safe transportation from one side, but on the other requires constant adaptation to new technological and legal solutions. Constant changes that occur at the international level will result in the necessary knowledge and skills they need to have before all others, managers of transportation and all other participants in the implementation of transport. Successful organization of transport is only possible through improving the quality of work through continuous investment in education and training in order to introduce and implement legislation and the latest technological solutions in road transport.

Such an approach allows:

- Implementation of international standards
- Engaging in international flaws
- Competition in the market
- Greater productivity
- Monitoring the ecological requirements of the modern world
- Improving image of profession.

Training as a mechanism of positive adjustment of road transport companies to all the changes that occur in the environment on one side is necessary because there are constant changes dictated by international regulations, while on the other side, it is a real need because it allows for the efficient operations of the company in the transport market that is growing and develops. Because the overwhelming influence of human factors on the safety of road users, these training have been increasingly imposed as a necessity regardless of the law. Therefore it is necessary to constantly professional development of all road users in order to raise the level of traffic safety, increase the competitiveness and raising productivity of companies in road transport.

The data shows that professional driver is the most professions today. The needs for professional drivers in the market of the European Union are 100000 professional drivers per year. Approximately 9 million people work in European transport sector. In road transport works more than 50% of all employees in transport sector and road transport achieved 20% of the European Union's GDP.

An important element of European regulations which relates to the road transport company is Directive 1071/2009/EC. This Directive acknowledges interest of road passenger and cargo carriers, mutual recognition of diplomas and evidence of formal qualifications. The Certificate of Professional Competence (CPC) in international and national transport for road haulage provides right to freedom of transport activity. Directive 1071/2009/EC has a significant impact on road transport of passengers and cargo. This Directive defines basic concepts, conditions relating to the requirement of professional competence, conditions necessary for perform activity in road transport and conditions necessary about financial position of transport company. It means the efficient and stable control system in the transport company, the good reputation, the financial capability and the necessary competence. The necessary competence can be achieved by the Certificate of Professional Competence in international and national transport for road haulage.

Need for education transport managers derived from the volume of work they perform:

- To monitor various activities inside the department as well as the safe transportation of products and services from the company to the scheduled delivery location (to control complete transportation operations of the company)
- Resolve issues surrounding product delays, customer and shipper complaints, and employee misconduct
- Cooperation with government agencies to look into accidents involving the company's transportation vehicles
- Supervises all transportation personnel and their daily operations - this include hiring and training qualified staff, setting policies and safety procedures for workers to maintain while working, conducting training sessions and mandatory meetings, and assisting with scheduling and payroll activities
- Conducts routine maintenance checks on all vehicles and equipment
- Analyze and develop plans to improve the transportation department's budget to purchase new vehicles and equipment, as well as discuss and consent to contracts with various suppliers

3. CPC MANAGER PROGRAMME

Professional competence today is a prerequisite for ensuring a competitive advantage to companies active on local and international markets. Establishing and managing a successful road transport company is becoming increasingly difficult in light of the multitude of complex International and National goods and passenger transport legislation currently in place. With today's increasing awareness of security and environmental challenges, road transport professionals must comply with existing and anticipated regulations, and be familiar with the latest technologies that address these key issues. In the face of these challenges, the road transport training industry needs an exemplary framework for capacity-building to enhance its professionalism, efficiency, effectiveness and accountability. The CPC Manager programme has been developed with a strong focus on these priorities. Going beyond compliance with the sole criteria of compliancy, it aims at providing professionals with the knowledge and skills to perform in an environment in constant evolvement.

The IRU Academy has established training standards for the Certificate of Professional Competence in international and national transport for road haulage on the basis of EU Regulation EC/2009/1071, international legal instruments and best practices. The IRU Academy CPC standards are completely compatible with EU legislation and add value by providing comprehensive standards and information, ensuring that training institutes, accredited as corresponding to these standards, maintain the highest quality of training and, through an international network of training institutes, best training practices.

The IRU Academy standards have been organized so as to offer maximum flexibility. Training institutes can devise a single training programme to cover all the requirements for both road haulage and road passenger transport operations, for national and international traffic. This course is geared towards transport operators and other employees in order to comply with "access to the profession" requirements. The programme also suits the needs of managers and other staff who would like to improve their career prospects and develop their management skills and transport knowledge as well as to entrepreneurs and operators who would like to start their own transport enterprise. The IRU Academy course standards have

been developed to allow maximum flexibility to the Accredited Training Institutes (ATI) to adapt their training programmes to meet national needs, regulations and specific features.

Rico Training Centre is Accredited Training Centre of IRU Academy from Geneva for professional training of employees in road traffic through the following training programs:

- CPC manager programme
- CPC professional driver programme
- ADR programme (for drivers and manipulators)
- Digital tahcograph programme
- Safe Loading and Cargo Securing

However, all Accredited Training Institute CPC programmes must cover the following subjects:

- International standards, Conventions and national regulations in the field of passenger and haulage transport
- Road safety and technical standards
- Economic and financial subjects
- Legal issues concerning employment and commercial law
- Health

It is left to individual training institutes to deliver the programme and modify its sequence according to local needs, methodologies and pedagogical approaches. Additionally, where and when applicable, relevant national legal provisions have to be included in the programme.

Rico Training Centre has adapted its lesson plan to the current national legislation and put into plan all relevant national legal acts in the field of CPC programme for professional education personnel in road transport.

4. CONCLUSION

Implementation of new technical solutions in road transport is only possible through the permanent education of employees in this area, based on European experiences. Professional development and preparation of employees is necessary, because of all the adjustments and changes dictated by the requirements of current and dynamic regulation in road transport. This paper has presented the integration of European solutions of organization of international and national transport. The paper is particularly based on the CPC program managers that educate managers for the successful organization of haulage and passenger transportation. The program allows the manager to enforce all safety procedures and rules and all applicable standards and regulations. Because the prevailing influence of human factors on the safety of road users, the training are necessary regardless of the Law. Therefore, it is necessary permanent professional development of all road users in order to raise the level of traffic safety, increase the competitiveness and raising the productivity of businesses in the road transport.

TRAINING AND ENABLING THE POPULATION FOR PERSONAL AND MUTUAL PROTECTION

Branko Babić¹, Dragan Babić²

¹ Higher Technical School of Professional Studies in Novi Sad, babic_sombor@yahoo.com

² MA student at the Faculty of Philosophy in Novi Sad, draganb.com@gmail.com

Abstract: *The paper elaborates on the problem of population education for personal and mutual protection as an elementary requirement for reducing the consequences of weather disasters and other accidents. In accordance with a legislation category, every citizen (especially the youth in elementary and secondary education) should be educated in order to obtain knowledge on dangers from accidents and the ways of protection from them. The aim of the paper is to point out the importance of education of the whole population as a preventive measure for lowering risks in extraordinary situations. The paper uses the methods defined in law and bylaw acts for the analysis of the documents. The obtained results of the research are devastating, since they indicate that the regulations of the Emergency Management Law have not been carried out even three years after their enactment and that training has not been effected, which directly increases risks in case of extraordinary situations. The paper should encourage the subjects of the civil defense who are responsible for this area to prescribe a curriculum for training the population and start educating them. The paper can serve as a starting point for planning and organizing education and preparation of the population for acting in extraordinary situations and is directed towards the Ministry of Education and Science, the Ministry of Interior, the Ministry of Human and Minority Rights, Public Administration and Local Self-Government*

Key words: *education, emergency management, curriculum*

1. INTRODUCTION

The Emergency Management Law (hereinafter: Law) [1] presents a starting document for planning and organizing the education of the population. The Act 119 of the Law defines that “in order to gain necessary knowledge of personal and mutual protection, the citizens are trained and enabled for preventive protection and rescue. The training is done during the elementary and secondary education in order to gain knowledge of dangers from natural and other accidents and protect from them, in accordance with the special law and appropriate programme.” The smaller part of the population, as well as the members of the headquarters and units of the civil protection, is trained for executing the tasks of the civil protection by the Ministry of Interior, through the courses, seminars, trainings, exercises and mock mobilizations.

The Act 15 of the Law gives the jurisdiction the units of local self-government to organize, develop and lead the personal and collective protection, train and enable the commissioner, the deputy commissioner and the units of general purpose and to form, organize and supply the units of general civil protection. In addition to that, the local self-government is, under the Local Self-Government Law [2], obliged to organize protection from weather disasters, other major disasters and fire, and create the conditions for reducing and removing their consequences.

The Acts 16 and 17 of the Law oblige the companies and other legal entities to plan and provide the means for organizing, supplying, enabling and training the units of civil protection they form, to organize and prepare personal, mutual and collective protection, and to conduct the means and tasks of civil protection of their employees, material and other goods.

Personal, mutual and collective protection is defined by the Acts 8 and 52 of the Law. **Personal, mutual and collective protection** is the most wholesale form of preparing and organized participation of the population in protection and rescue that includes the means and actions of their immediate protection and rescue in business and living buildings, other objects and places where they live and work.

In order to accomplish personal, mutual and collective protection, the state bodies, the apparatus of autonomous province and the units of local self-government, the companies and other legal entities

provide and maintain the necessary means and equipment for personal, mutual and collective protection and train their employees in civil protection. The citizens and owners of buildings provide and maintain the necessary means and equipment for personal, mutual and collective protection. Further regulations concerning obligatory and equipment for personal, mutual and collective protection were brought by the Government.

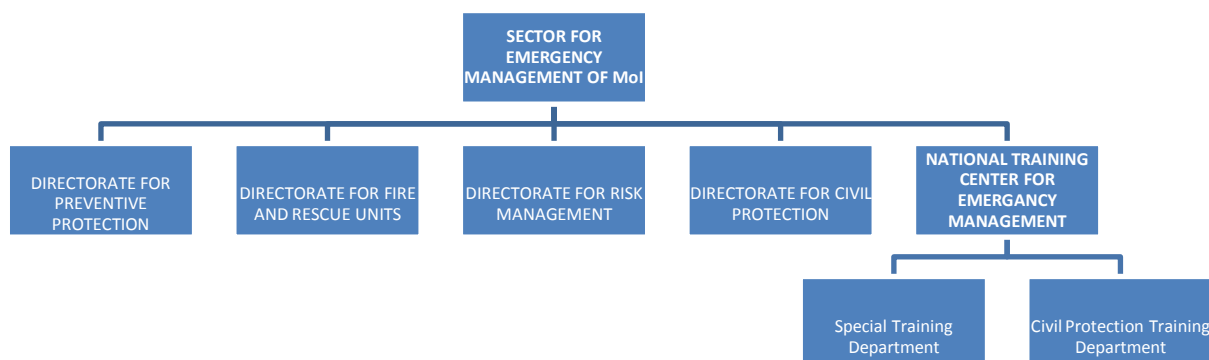

2. THE LEVELS OF TRAINING

Considering the training and enabling the citizens – on all levels of organizing and preparing the population for civil defence – for the needs of active involvement in the Protection and Rescue System of the Republic of Serbia, one can conditionally talk of several levels of training and commitment of the civil subjects on that plan (scheme 2).

The highest level of training is organized and conducted by the **Ministry of Interior** (hereinafter: Ministry) via its Sector for Emergency Management and National Training Center for Emergency Management (scheme 1) which includes the Specialist Training Department and the Civil Protection Training Department.

The aim of the National Training Center for Emergency Management is the standardization and enhancement of the protection and rescue training, in accordance with the Law and the European standards.

Scheme 1: The position of the National Training Center in the Sector for Emergency Management

Source: author

The task of the National Training Center for Emergency Management is the basic training and enabling all the members of the protection and rescue system:

1. employees of the Sector for Emergency Management,
2. headquarters for emergency management (state, province, district, town and municipality headquarter for emergency management),
3. specialized units of civil protection,
4. apparatus of the companies,
5. other legal entities important for protection and rescue,
6. **citizens**, in order to gain necessary knowledge of personal and collective protection, and
7. foreign citizens who can be trained in accordance with the regulations and bilateral and multilateral contracts.

The higher levels of training for protection and rescue are conducted, as entrusted tasks, in *the humanitarian centre*, a legal entity founded in accordance with the agreement between the Governments of the Republic of Serbia and the Government of the Russian Federation concerning the cooperation in the area of humanitarian reaction in extraordinary situations and emergency management, prevention of weather disasters and technogenic accidents and removal of their consequences ("Official Gazette of Republic of Serbia", no. 10/10 – International Contracts) [5]. Only foreign citizens can be trained in the humanitarian center.

The law prescribes the Minister of Interior passes the further regulations concerning the methods of education, curriculum and standards for teaching devices and equipment for training the members of the civil protection. However, after two and a half years since passing of the Law, the curriculum has not yet been established, the training of the population has not started, the units of the civil protection are still not formed, which decelerates the training and enabling process of all the subjects of the defence and their implementation in the system of defence.

The next level of training is performed on the level of **units of local self-government** (municipality and town). Local self-governments organize and conduct training and enabling of the commissioner, the deputy commissioner of the civil protection and the units of general purpose that are formed, organized and supplied for their territory. They also develop, lead and train the organizations and citizens in the personal and collective protection. So far, no measures have been initiated to start training the citizens according to the place of their life and work.

In addition to that, the units of local self-governments have, based on the Local Self-Government Law and Act 15 of the Law, passed the resolution on organizing and functioning of civil protection on the territory of a municipality or a town. It defines:

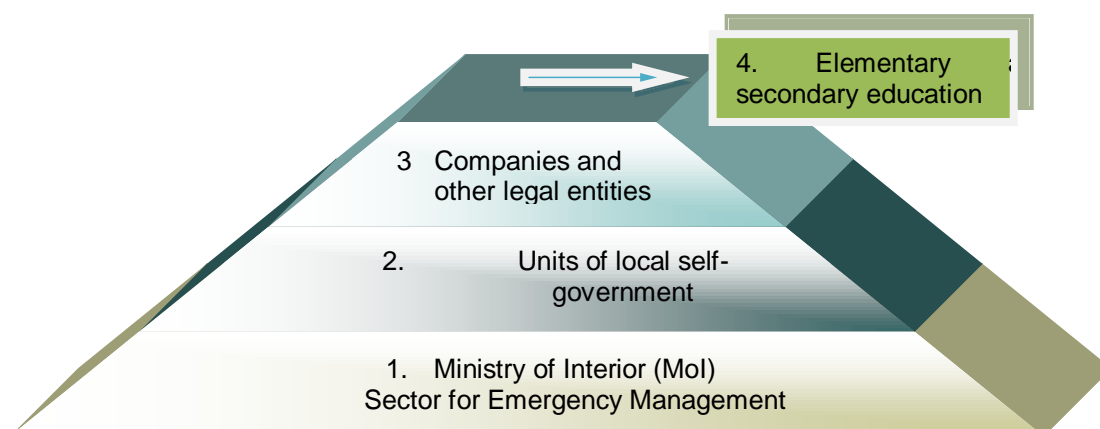

- organization and functioning of civil protection on the territory of a municipality or a town,
- duties of town organs in protection and rescue and in producing an evaluation of endangerment and plan of protection and rescue in extraordinary situations,
- constitution of Emergency Management Headquarters,
- appointment of the commissioner and the deputy commissioner of the civil protection in populated areas,
- formation of civil protection units for general purposes,
- determining enabled legal entities for protection and rescue, and
- financing and other issues concerning civil protection.

Different services execute professional, planned and organized tasks of protection and rescue: in Sombor, it is the Agricultural Department; in Vranje, it is appointed body of the City Administration; for the Nova Crnja municipality and the city of Zrenjanin, it is the especially formed Municipal Service for Protection and Rescue, etc. Every unit of local self-government also defined *the personal and collective protection training*, according to the place of life and work. Those who own buildings and houses are obliged to, for the purposes of personal protection and rescue and for the protection and rescue of the members of their household, provide and possess in working condition the means and equipment, as required by the regulation of obligatory means and equipment for personal and collective protection against weather disasters and other accidents [3].

In cooperation with the Emergency Management Department and the Commissioner for Civil Protection, they are also obliged to prepare the regulations and other publications that are to conduct the education of the population concerning the procedures in possible or occurring situation, in particular the education of the population on the reactions in earthquakes, floods and fire.

A special position in the level of local self-government is held by the commissioners and deputy commissioners in the areas where they initiate special measures in order to include the citizens in conducting the means and tasks of the civil protection and personal and collective protection, and manages the civil protection units of general purpose. They also provide special instructions to the citizens who live in the endangered areas and conduct all operative means for rescuing the endangered citizens.

Scheme 2: The levels of the personal and collective protection training

Source: author

The third level of training is conducted with **the companies and other legal entities** [1, 4] that plan and provide the means for organizing, supplying, enabling and training of the units of civil protection (that they form); they *organize and prepare personal, mutual and collective protection*; they conduct the means and tasks of civil protection of their employees and the material and other goods.

In addition to that, all companies that include protection of more people are obliged to plan, organize and conduct the measures and tasks of the civil protection of their employees and the material and other goods.

Humanitarian organizations and associations participate in the preparing and conducting the tasks concerning the protection and rescue connected to their normal activity. The Red Cross of Serbia performs the training of the citizens and the units of civil protection in giving first aid, in accordance with the public authorization and by established curriculum and criteria.

The fourth level of training is conducted in **the elementary and secondary schools**. Its purpose is gaining knowledge of the dangers from natural and other disasters and how to protect from them, in accordance with a special law and appropriate curriculum. On the basis of the Law, the Minister of Education and Science was obliged to prescribe a way of training in the elementary and secondary education, which has not been done yet.

3. ANALYSIS OF THE CONDITION OF PERSONAL AND MUTUAL PROTECTION

Reaching the level of organization and preparedness with the population for personal and mutual protection completely depends not only on the reached level of the civil protection's development, but on the general and special conditions in certain areas where people live and work (general condition of live and work, endangerment from accidents caused by the weather and other elements, material, cadre and other possibilities, etc.). Personal and mutual protection cannot be more or less successfully developed if not connected to the other elements of the civil protection and the existing general and special conditions in certain areas.

Personal and mutual protection is the most widespread element of the civil protection which includes all capable citizens (the element of widespread), regardless of gender and age. The effects of the severe economic crisis are seriously reflecting on the general state and mood of the whole population, and on the development of personal and mutual protection as well.

It is not enough to merely reach the level of this element's development. The state in most areas is concerning, yet there is no suitable and comprehensive response by the citizens – except in individual cases – when it is necessary. After the more severe weather disasters and other accidents, it would be desirable to review, analyze and determine the behavior of the citizens in case where the mutual help and protection was, at some point, the only possibility to help the individuals in danger (catastrophic earthquakes and floods, fires on wider areas, severe precipitation, low temperature, etc.). It is certainly

necessary to determine the responsibility, if present, of the carrier of the population's preparations for personal and mutual protection.

Personal and mutual protection (training and enabling the citizens, organizing a network of commissioners of civil protection and units for general purposes, etc.) does not receive the necessary attention, so the level of preparedness of this element of civil protection is the lowest when compared to the other elements of civil protection. It must not be forgotten that organizing and preparing personal and mutual protection is the hardest task and what seems to be important to many carriers of the preparations is that the results cannot be shown as they are not visible.

The current condition and the reached level of preparedness of the personal and mutual protection indicate that the moment has finally come to, first, realize the importance and the role of personal and mutual protection in population's surviving in case of weather disasters and other major accidents, including wars, and then to take actions to overcome all past attempts that brought us to this absurd state where personal and mutual protection is, according to preparedness in the most cases, the least important element of the civil protection.

When one considers the fact that a very small fraction of the population was supplied with protective masks in the 1990s (their expiration date has passed as well), that the number of build shelters is below the minimum and that those present are in a very bad condition, that a network of commissioners of civil protection has not yet been established in all areas (not to mention their preparedness), that the units of specialized and general purposes are in the forming phase (their forming is expected to be completed by the end of 2012), that the most citizens are not trained and enabled for the tasks of protection and rescue – it is easy to established the state and reached level of development of personal and mutual protection. In other words, the participation in the tasks of protection and rescue is left to the citizens and is most commonly without the consequences for those responsible for conducting the necessary preparation of the population.

Conducting **the solidarity actions** should be added to the all mentioned difficulties and weaknesses in organizing, preparing and fulfilling personal and mutual protection. There are no general criteria which should, in more difficult cases, automatically act in order to provide additional means for first aid to the endangered and for healing the emerged consequences. The current condition of the fund for this sort of help is obviously not sufficient to cover all the needs in difficult situations. Due to that, solidarity with the endangered still usually depends on those individuals, bodies, organizations and communities that can, with no hidden agenda, sympathize and help those in trouble.

This state of personal and mutual protection should certainly concern, first of all, the carriers of the population's preparations, but also the organs in charge from the municipalities and town's and their executive bodies which are the most responsible for solving the problems of development of the certain areas in accordance with the Law and passed Acts. The development of personal and mutual protection is regarded only when an accident occurs. In those situations, material and financial resources are sufficient.

A question must be raised: **Where are we** in the area of personal and mutual protection? Unfortunately, it can be said that we are still „at the beginning“ and that we have not yet begun applying the Acts of the Law. Some of the problems include:

- the most important issue during the preparations must be enabling for personal and mutual protection,
- for conducting the training, it is necessary to provide professional lecturers and teaching material and aids, as well as the systematic monitoring and popularization of the population's preparation for protection via the means of public informing,
- the population *must* be provided with the most necessary means of protection,
- measures should be initiated to supply the people with the means for personal protection, and all the other subjects with the means for mutual protection,
- provide the most necessary means for extinguishing initial fire in buildings, etc.

The issue of responsibility for those who do not comply with the Law has not been designated yet, so what is accomplished in preparing the population for personal and mutual protection is basically nothing, since the reached level and results of development of personal and mutual protection do not satisfy, and the state of preparedness of this element of civil protection is worrying in most areas.

Another question that is raised is: **How to continue?** In searching for the answer, one must start with the fact that the training in personal and mutual protection has not started yet; with the noticed objective problems in the society and subjective weaknesses; with the fact that the future organizing and preparing of personal and mutual protection must be based on a realistically set goals and planning and higher responsibility of all carriers of the protection tasks.

Personal and mutual protection can seem spontaneous, uncontrolled and disorganized. The actions of personal and mutual protection should be organized in cases of severe destructions with consequences on a broad area and when endangerment of high number of people appears simultaneously. Due to that, in all areas where people work and live it is necessary to appoint an appropriate number of commissioners of civil protection and their deputies who must be enabled to organize and direct personal and mutual protection and rescuing of working individuals. The basic precondition for successful performance of this function is complete knowledge of this element of the civil protection – training.

During the further development of personal and mutual protection, the carriers of preparations, in addition to enabling the citizens, have to advocate and provide organization of complete network of commissioners of civil protection and forming the unit for general purposes in all areas where it has not yet been done. That would enable simultaneous and more successful conducting the actions of personal and mutual protection and rescuing the citizens on all endangered areas at the same time.

It is necessary to precisely determine the rights and jurisdiction of the commissioners of civil protection and their deputies regarding management, directing and acting in the area of personal and mutual protection of the population.

4. CONCLUSION

No appropriate solutions for enabling the population has been suggested yet, as it includes two very important aspects – training and supplying, which, besides good organization, requires considerable material and financial means. The need has to be defined, and the priorities determined. In accordance with the possibilities, the financial means for realization of the training should be planned. Another major issues has not been solved – how can unemployed citizens, pensioners and parents of underage children acquire the means for personal and collective protection that are defined by the Government? One of the possible solutions is funding from the mutual funds that are issued for the needs of the defence system by the Emergency Management Fund [6].

Equally important problem is how to regulate, organize and conduct the training of the population, from the issue of who needs to attend to the continual attendance, not to mention all the other difficulties that arise in the process of conducting training: securing appropriate cadre, needed teaching aids and manuals, premises and heating, schedule, costs of transportation of the citizens and possible feeding, evidence and monitoring the training, etc.

The issue of training is too serious to be neglected, but, the way it is handled now is not satisfying. The conditions must be provided in order to scientifically research the problem, seek the solution and the answers for its resolving.

For starters, one should foresee informing and providing necessary instructions to the population via radio and television, daily and other newspapers, stating short and clear notices, handing out short printed reminders and manuals, etc. That would significantly affect preparation of the population for personal and mutual protection. It is clear that the Higher Technical School of Professional Studies in Novi Sad holds its place in that organization.

It has to be noted that the planned tasks can be executed only by engaging professional, capable, certainly younger and ambitious cadre. Unfortunately, in many areas, these tasks are done by people who lack appropriate qualifications or are semiskilled, yet they do their jobs for a long period of time and do it as a routine with no innovation. Again, Higher Technical School of Professional Studies in Novi Sad seeks its role with its study programme: Civil protection and rescue in extraordinary situations.

Of course, all suggestions are critically evaluated and verified, but the fact is that this is the last moment to take radical measures in this area if we wish well to the citizens of the Republic of Serbia.

Abstract: *The evaluation of school effectiveness has long been an elaborated issue over the past few decades. Throughout the educational process, three breaking points occur: the first - finishing elementary school, the second – finishing high school, and the third – graduating from college/university. Elementary school is compulsory for all children in most countries throughout the world. In accordance with this, the first breaking point is the most important one to evaluate. The rank of effectiveness of elementary schools can be compared by using the average grades received in the last three years of elementary school and final high school enrolment tests (the sublimation of knowledge from elementary school in mathematics and the student's respective native languages). In this paper, the statistical I-distance method is thoroughly explained and has been applied to 100 elementary schools in Belgrade in order to rank them by effectiveness.*

Keywords: *elementary school education, elementary school effectiveness, I-distance, ranking, statistical methods.*

1. INTRODUCTION

Since elementary schools are very often cited as being the most crucial component of education (Bekleyen, 2010), it is of great concern whether elementary schools are effective (Petty & Green, 2007). In contemporary literature, there have been several attempts to evaluate school effectiveness (Kyriakides & Tsangaridou, 2008; Kyriakides & Creemers, 2008a; Kyriakides & Creemers, 2008b; D'Haenens, Van Damme & Onghenab, 2010; Botha 2010). The degree of knowledge adopted during students' eight-year long elementary education and the level of knowledge represented on entrance examinations can be used to rank elementary schools, based on the results of their students.

While educators often identify socioeconomic status (SES) as a significant factor in predicting academic achievement or other measures of student performance, researchers are examining whether the diversity of a school or lack thereof may also play a role (Clayton, 2011). Thereafter, a quantitative assessment of how much one school is better or worse than another can be made. Schools which are able to identify their weaknesses and take actions to improve their policy on aspects associated with teaching and their school learning environment (SLE) are able to improve their effectiveness status (Creemers & Kyriakides, 2010).

In this research paper, I-distance will be thoroughly explained and applied in order to rank Belgrade elementary schools by their effectiveness. After elaborating Ivanovic distance in section 2, section 3 shall present and discuss the results of this research project and, finally, section 4 shall summarize the key contributions and the idea for following researches.

2. THE I-DISTANCE METHODOLOGY

In order to create a synthesized indicator of elementary school effectiveness, selected variables are incorporated into the analysis through use of the statistical I-distance method; one which has been utilized by Ivanovic (1977). Various authors used this method of ranking in numerous publications (Dobrota, Jeremic & Markovic, 2012; Jeremic, Bulajic, Martic & Radojicic, 2011a; Jeremic, Vukmirovic, Radojicic & Djokovic A, 2011b; Milenkovic N, Jeremic V, Djokovic A. & Dobrota M, 2011; Radojicic, Isljamovic, Petrovic & Jeremic, 2012).

I-distance is a metric distance in an n -dimensional space. Ivanovic had originally devised this method to rank countries according to their level of socio-economic development based on several indicators (Ivanovic 1973a, Ivanovic & Fanchette 1973b). In this research paper, five indicators were considered and the problem was how to use them in order to calculate a single synthetic indicator, which would thereafter represent the rank.

For a selected set of variables $X^T = X_1, X_2, \dots, X_k$ chosen to characterize the entities, the I-distance between the two entities $e_r = (x_{1r}, x_{2r}, \dots, x_{kr})$ and $e_s = (x_{1s}, x_{2s}, \dots, x_{ks})$ is defined as

$$D(r, s) = \sum_{i=1}^k \frac{|d_i(r, s)|}{\sigma_i} \prod_{j=1}^{i-1} (1 - r_{ji.12\dots j-1}^2)$$

where $d_i(r, s)$ is the distance between the values of variable X_i for e_r and e_s e.g. the discriminate effect

$$d_i(r, s) = x_{ir} - x_{is}, \quad i \in 1, \dots, k$$

σ_i the standard deviation of X_i and $r_{ji.12\dots j-1}$ is the partial coefficient of the correlation between X_i and X_j , ($j < i$).

The construction of the I-distance is iterative; it is calculated through the following steps:

- Calculate the value of the discriminate effect of the variable X_1 (the most significant variable, that provides the largest amount of information on the ranked phenomena)
- Add the value of the discriminate effect of X_2 which is not covered by X_1
- Add the value of the discriminate effect of X_3 which is not covered by X_1 and X_2
- Repeat the procedure for all variables. (Mihailovic et al. 2009).

Sometimes, it is not possible to achieve the same sign mark for all variables in all sets, and, as a result, a negative correlation coefficient and a negative coefficient of partial correlation may occur. (This makes the use of the square I-distance even more desirable (Al-Lagilli, Jeremic V, Seke, Jeremic D & Radojicic, 2011). The square I-distance is given as:

$$D^2(r, s) = \sum_{i=1}^k \frac{d_i^2(r, s)}{\sigma_i^2} \prod_{j=1}^{i-1} (1 - r_{ji.12\dots j-1}^2)$$

The entity with the minimal value for each indicator or a fictive maximal or average values entity can be set up as the referent entity. The ranking of entities in the set is based on the calculated distance from the referent entity.

3. RESULTS AND ANALYSIS

Overall, 12,137 students from 100 elementary schools in Belgrade were analysed in this study. The data examined refers to the end of the 2010-2011 school year. For each student, the following information was gathered: the grade point averages (minimum 1, maximum 5) of the school's students in the sixth, seventh and eighth grades and their scores on their math and Serbian (i.e. native) language tests (minimum 0, maximum 20 – for both tests). In accordance with this grading system, only a total maximum of 60 points is achievable in one's elementary school marks (the sum of GPAs for the 6th, 7th, 8th grades, multiplied by 4). However a maximum of 40 points can be obtained from tests (20 points multiplied by two (math and

Serbian language test)). This data was used to calculate I^2 -distance for each school. To achieve this aim, a special SPSS plug-in was developed and implemented into SPSS 20 software. The results achieved by the I^2 -distance ranking method for evaluating efficiency of elementary school are presented in Table 1.

Table 1. The Results of the I^2 -distance Method, I^2 -distance Value, and difference between ranks

School name	Test points	Total points	I^2 distance	I^2 rang	Total points rank	Difference I^2 -distance rank versus total points rank
Drinka Pavlovic	32.819	87.7846	96.84	1	1	0
Kralj Petar I	31.93	86.7768	95.42	2	2	0
Kralj Aleksandar I Karadjordjevic	33.593	86.7642	87.81	3	3	0
Janko Veselinovic	32.535	86.0038	84.44	4	5	1

Jelena Cetkovic	32.03	83.58	69.13	11	12	1
Svetozar Markovic	32.428	84.2332	68.27	12	10	-2
Jovan Miodragovic	33.53	84.4244	67.79	13	9	-4
Jovan Sterija Popovic	31.327	82.9382	67.23	14	18	4
Ljuba Nenadovic	29.701	81.787	67.07	15	30	15
Cirilo i Metodije	31.834	83.2512	66.62	16	15	-1
Nadezda Petrovic	30.348	82.1664	66.37	17	27	10
Milos Crnjanski	31.389	83.2918	66.27	19	14	-5
Mihailo Petrovic Alas	31.88	83.1308	66.27	18	16	-2
Majka Jugovica	32.019	83.1286	64.78	20	17	-3
Ujedinjene nacije	31.174	82.304	64.01	21	25	4
Svetozar Miletic	30.4	82.0216	63.02	22	28	6
Josif Pancic	31.713	82.841	62.7	23	19	-4
Gornja Varos	30.142	81.6732	62.4	24	33	9
Stefan Nemanja	29.46	81.1392	61.9	25	35	10
Ivan Gundulic	31.666	82.3684	61.51	26	24	-2
Banovic Strahinja	31.112	82.5396	61.37	27	21	-6
Veselin Maslesa	30.956	81.9636	60.77	28	29	1
Braca Baruh	29.958	81.0896	60.32	29	36	7
Rade Koncar	32.248	82.398	59.92	30	23	-7

The results are not surprising considering the fact that ranks of top three schools remained unchanged and that in most cases there is not a major difference between I^2 -distance rank and total points rank. Drinka Pavlovic and Kralj Petar I tops the list and we may say that these schools provide high level of education. Students from these two schools have excellent average marks in last three years of schooling. Entrance tests results from math and native language of these students are extremely high. This data set was further examined and a correlation coefficient of each indicator with the I^2 -distance value was determined. The results are presented in Table 2 (using the Pearson correlation test).

Table 2. The Correlation between I^2 -distance and Input Indicators

<i>Indicator</i>	<i>r</i>
1. Average marks in the 7 th grade	0.902**
2. Average marks in the 6 th grade	0.846**
3. Average marks in the 8 th grade	0.772**
4. Scored points on math test	0.706**
5. Scored points on Serbian (native) language test	0.684**

** $p < 0.01$

The three most important indicators are the grade point averages of the school's students in the sixth, seventh and eighth grade. As can be seen, the most significant variable is average mark in the 7th grade, $r=0.902$, $p<0.01$. As expected, average mark in the 8th grade is the least significant indicator of first three, since the eighth grade teachers usually have lower evaluation criteria. Scores on math and Serbian language tests are on 4th and 5th place, which means that these two indicators provide lower information about elementary school effectiveness. That is not surprising, regarding the fact that first three variables are presenting the result of three-years-long work, while test results do not necessarily need to represent the right level of knowledge of elementary students. The fear of making mistakes may cause the lack of concentration in that moment, which can result lower scores on math and Serbian language tests.

Furthermore, research results show that students achieved better performance on Serbian language test (15,207) then on mathematics test (14,334). One reason for a smaller gap in math performance is due to the rigidity of mathematics instruction (Ferguson, 2003). Teacher expectations for students were less of a factor because of the more prescribed way in which math is taught when compared to Serbian language. Elementary school teachers are a vital tool for this human development, because of the considerable amount of interaction and discussion between children that they involve (Cave 2011).

Various significance of indicators caused changes in ranking between I^2 -distance rank and total points rank. Ljuba Nenadovic, Nadezda Petrovic and Stefan Nemanja are schools that moved towards in list because elementary students in these schools have better grades in last three years of schooling. They are above schools whose students have better results on scores on math and Serbian language tests because of explained and elaborated level of importance of these five indicators.

4. CONCLUSION

Establishing a successful scholastic system is of great importance for any country, considering the fact that knowledge is essential for humankind. The aim of this paper was to rank elementary schools in Belgrade by their effectiveness. The analysis presented here may be able to provide a proper framework for the evaluation of elementary school education. One possibility would be a national program for the continual evaluation of schools. This program could be easily applied and implemented throughout the entire country and re-evaluated each year in order to determine whether Serbian elementary school education is on the right track.

Yet another point of view to efficiency of elementary schools is to determine the interrelationships between elementary school education and secondary school entrance exams. Due to different teachers' demanding standards, we would have to define some kind of measure of correlation between students' average marks in elementary school and the points they scored on their secondary school entrance test. That measure would be able demonstrate schools that suffer from irreconcilable inconsistencies. These are schools where students have excellent average marks but perform poorly on entrance tests (lower standards in grading students), as well as schools where students have lower marks but perform excellently on entrance tests (higher standards in grading students). In a line with this, it is necessary to implement some kind of input-output analyse in order to determine the relationship between average marks and entrance exams, but that will be explained and elaborated in following researches.

Abstract: *Our paper aims to present new ideas in evaluating Shanghai University's Academic Ranking of World Universities (ARWU). An issue frequently put forth in various publications is that the Shanghai rankings are sensitive to the relative weight they attribute to each variable. As a possible remedy for this issue, the statistical I-distance method is proposed to be used. Based on a sample containing 94 higher education institutions which are placed on the ARWU Top 100 during 2007-2010, the statistical I-distance method was performed. We present the obtained results and propose a modification of relative weight attributed to each variable.*

Keywords: *ranking of universities, the I-distance method, ARWU, statistical methods, ranking criteria*

1. INTRODUCTION

The issue of ranking higher education institutions (HEI) has drawn much attention as of late. Many different stakeholders, especially students, use rankings as an indicator of a university's reputation and performance (Agasisti & Perez-Esparrells, 2010; Bowman & Bastedo, 2011; Hien, 2010; Stolz, et al., 2010; Dehon, et al., 2010; Jeremic, et al., 2011a; Torres-Salinas, et al., 2011). Almost certainly, the most cited ranking list is the Academic Ranking of World Universities (ARWU) which has been the focus of researchers since its first creation in 2003 (Aguillo, et al., 2010). The Shanghai (ARWU, 2010) ranking is based on six different criteria and aims to measure academic performance. Within each category, the best performing university is given a score of 100 and becomes the benchmark against which the scores of all other universities are to be measured. Universities are then ranked according to the overall score they obtain, which is simply a weighted average of their individual category scores (Dehon, et al., 2010). The variables "Alumni" and "Award" measure the number of Nobel prizes and Field medals won by a university's alumni ("Alumni") or faculty members who worked at an institution at the time of winning the prizes ("Award"). The next three variables, "HiCi", "N&S" and "PUB" reflect their researchers output. "HiCi" is the number of highly cited researchers of the institution, "N&S" is the number of articles published in "Nature" and "Science" journals, and "PUB" is the number of articles indexed in the Science Citation Index Expanded and the Social Science Citation Index. The sixth and final variable, "PCP", is a weighted average of all the scores obtained from the previous five categories, divided by the number of current full-time equivalent academic staff members. The variables "Award", "HiCi", "N&S" and "PUB" each make up 20% of the final score, while "Alumni" and "PCP" are each given a slightly lower weight of 10% (Dehon, et al., 2010; Jeremic, et al., 2011a; Docampo, 2008; Docampo, 2011; Docampo, 2012).

Yet, almost immediately after the release of its first ranking, the ARWU attracted a great deal of criticism (van Raan, 2005a,b; Liu & Cheng, 2005; Liu, et al., 2005; Billaut, et al., 2010). In this paper, an attempt shall be made to investigate how relative weight of variables influences the University ranks. This potential weakness in ranking shall be examined by applying the statistical I-distance method to data provided by the ARWU's rankings for the 94 HEI which are placed in Top 100 for each of the years (2007-2010).

2. I-DISTANCE METHOD

Quite frequently, the ranking of specific marks is done in such a way that it can seriously affect the process of taking exams, entering competitions, UN participation, medicine selection and many other areas (Ivanovic, 1973; Ivanovic & Fanchette, 1973; Jeremic & Radojicic, 2010; Al-Lagilli, et al., 2011). I-distance is a metric distance in an n-dimensional space. It was originally proposed and defined by B. Ivanovic, and has appeared in various publications since 1963 (Ivanovic, 1977). Ivanovic devised this method to rank countries according to their level of development on the basis of several indicators; many socio-economic development indicators had been considered and the problem was how to use all of them in order to calculate a single synthetic indicator which would thereafter represent the rank.

For a selected set of variables $X^T = (X_1, X_2, \dots, X_k)$ chosen to characterize the entities, the I-distance between the two entities $e_r = (x_{1r}, x_{2r}, \dots, x_{kr})$ and $e_s = (x_{1s}, x_{2s}, \dots, x_{ks})$ is defined as

$$D(r, s) = \sum_{i=1}^k \frac{|d_i(r, s)|}{\sigma_i} \prod_{j=1}^{i-1} (1 - r_{ji.12\dots j-1}) \quad (1)$$

where $d_i(r, s)$ is the distance between the values of variable X_i for e_r and e_s , e.g. the discriminate effect,

$$d_i(r, s) = x_{ir} - x_{is}, i \in \{1, \dots, k\} \quad (2)$$

σ_i the standard deviation of X_i , and $r_{ji.12\dots j-1}$ is a partial coefficient of the correlation between X_i and X_j , ($j < i$), (Ivanovic, 1973; Jeremic, et al., 2011b).

The construction of the I-distance is iterative; it is calculated through the following steps:

- Calculate the value of the discriminate effect of the variable X_1 (the most significant variable, that which provides the largest amount of information on the phenomena that are to be ranked)
- Add the value of the discriminate effect of X_2 which is not covered by X_1
- Add the value of the discriminate effect of X_3 which is not covered by X_1 and X_2
- Repeat the procedure for all variables (Mihailovic, et al., 2009; Jeremic, et al., 2011c).

In order to rank the entities (in this case, Universities), it is necessary to have one entity fixed as a referent in the observing set using the I-distance methodology (Radojicic, et al., 2012; Knezevic, et al., 2012). The entity with the minimal value for each indicator or a fictive minimal, maximal or average value entity all may be utilized as the referent entity, as the ranking of the entities in the set is based on the calculated distance from the referent entity (Jeremic, et al., 2011d).

3. RESULTS OF THE I-DISTANCE METHOD

The results achieved by means of the I-distance method are shown in Table 1.

Table 1: Results of the I-distance method, the I-distance value and rank for the period 2007-2010

HEI	I-distance 2010 rank	I-distance 2010	I-distance 2009 rank	I-distance 2009	I-distance 2008 rank	I-distance 2008	I-distance 2007 rank	I-distance 2007

As can be seen from Table 1, Harvard University tops the I-distance method list for all 4 years. The correlation between the ranks obtained by the I-distance method for 2007-2010 data is presented in Table 2. As we can see, the year 2007 has the lowest correlations, but still all of them are statistically significant ($p < 0.01$).

Table 2: Correlation between ranks 2007-2010

	Rank 2010	Rank 2009	Rank 2008	Rank 2007
Rank 2010	1			
Rank 2009	0.984**	1		
Rank 2008	0.961**	0.974**	1	
Rank 2007	0.711**	0.694**	0.670**	1

** $p < 0.01$

This data set has been further examined and the correlation coefficients of each variable with the I-distance values have been determined. This is crucial, as it provides information on how significant each of the six input variables is. The results shown in Table 3 demonstrate that the most significant variable for the calculated I-distance values for the 2007-2010 is Score on N&S. By all means this is the most important variable and thus it has to be awarded with the highest relative weight. Score on HiCi, Award, PCP and Alumni are almost equally important. It should be mentioned that in ARWU methodology Alumni and PCP are weighted with 10%, far less than other four variables (20%). Our result clearly indicates that

this must be corrected in following iterations of ARWU rankings. Finally, Score on PUB is the least important variable and thus it's 20% ARWU weighting factor must be dramatically reduced.

Table 3. The Correlation between Input Variables and I-distance Values for 2007-2010

	Correlations			
	I-distance 2010	I-distance 2009	I-distance 2008	I-distance 2007
Score on Award	0.828	0.788	0.840	0.749
Score on Alumni	0.808	0.706	0.948	0.678
Score on N&S	0.976	0.973	0.778	0.979
Score on HiCi	0.908	0.872	0.679	0.882
Score on PUB	0.604	0.651	0.508	0.679
Score on PCP	0.818	0.776	0.748	0.825

4. CONCLUSION

With a growing worldwide interest in university rankings, the academic world is becoming ever more concerned with the assessment of higher education. These rankings are very often used as a marketing tool for universities to show their educational or research excellence (Jeremic, et al., 2011a). This is precisely the reason why it is exceptionally important to provide rankings as accurate as possible. As a remedy to this issue, the analysis presented here has stressed potential weaknesses in the ARWU rankings in regard to the fact that changing the relative weight placed upon each of the six factors significantly alters the ranking. The I-distance method clearly has shown that certain variables are far more important than others for the ranking process. These findings should be incorporated into future research as being weight placed on each variable is crucial for the ranking process. With all of the evidence presented in this paper, it is essential to encourage the debate on how to determine criteria to best conduct and analyse universities' rankings (Leydesdorff & Shin, 2011). Furthermore, this could contribute to the emerging efforts to map regions of academic excellence and scientific output (Bornmann & Leydesdorff, 2011; Bornmann & Waltman, 2011).

Abstract: *Leadership is an important function of management which helps to maximize efficiency and to achieve organizational goals. Leadership and management are of great importance for the survival, development and progress in every field of human organizations and especially in education. The ideal situation would be the one in which management and leadership functions are in synergy. But given the specific system of higher education, this situation is impossible to be achieved. Therefore, the role and importance of a professor as a leader emerges to the fore. However, in the conditions of moral confusion in modern transitional societies, professors-unethical leaders also appear. The management institutions of higher education and their staff are faced with the task to quickly detect and eliminate cases of unethical behavior, and especially cases of unethical leadership. In this context, the authors of this paper made one more effort in the direction of pointing to moral deviant phenomena and their control in the higher education institutions.*

Keywords: management, teacher leadership, ethical leader, unethical leaders.

INTRODUCTION

The education system as a subsystem of a social system is a fundamental factor in the effective and permanent consumption of knowledge of the individual. In the educational process, a key factor for the quality of education is teaching staff which is responsible for their own development and transfer of knowledge to students. Today many factors globally affect the future of education, so that continuing education as a permanent activity sets new demands of society, educational institutions and individuals. Therefore, management education should focus on the application of knowledge to make relevant educational needs, and education should not only be focused on learning as a concept, but should include knowledge about the processes that need to initiate and to apply further development. Leadership, as a function of management, is a process of staff orientation, which influences and motivates them to implement the tasks and achieve goals of higher education institutions.

In modern terms of education there is great competition for getting a higher education institution which may recognize the leader that can engage and, by his influence, trying to maximize the performance of employees and in the same time, rationally to realize its goals. The leadership position of professor in higher education institutions are seen in the creation, organization and successful tasks realization. But the question is: How does the professor act as a leader in its modern environment in many complex situations that are imposed not only by institution, but also by the society.

MANAGEMENT AND LEADERSHIP

To manage means to lead, to run. Manager is a man who manages and leader is somebody who leads. But manager leads and leader manages. Regarding management and leadership, there is a difference, as evidenced by the very words with English translations, but also may not drawn strict limits. Management is seen as a process and describes the management of certain activities, enterprises or systems in order to achieve efficiently the objectives and it includes functions of planning, of organizing, leading and control. Management studies the management of such complex processes and phenomena related to the effective execution of specific tasks and jobs.

An interesting interpretation of the differences between management and leadership gives Maxwell, J., Saying that "the management is process which ensures the implementation of programs and goals of the organization, while leadership deals with creating a vision and motivating people. People do not want to be managed, they want to be guided". But both are necessary for the successful functioning of higher education institutions because there is a synergy between leadership and management. According to Kotelnikov, V., this synergy between leadership and management is reflected in empowerment, achievement, teamwork, innovation and effectiveness of expression.

SYNERGY BETWEEN MANAGEMENT AND LEADERSHIP ROLES		
LEADERS	RESULT OF SINERGY	MANAGERS
Provide vision	Empowerment	Provide resources
Pursue oportunities	Achievements	Reduce risks
Inspire	Teamwork	Coordinate
Lead improvisation	Jazz of Innovation	Providing structure
Do right things	Effectiveness	Do things right

Resource: http://1000advices.com/guru/leadership-management_synergy_vk.html

Regarding higher education institutions, management is always the bearer of authoritarianism, with the power of governments above him and with him, who manage organizations, systems, and who has a power of leadership based on expertise and knowledge that produce ideas and initiatives for progress and improvement of education.

In aim to promote higher education, progressive university institutions are investing in human resources, particularly in the teaching staff. Being a leader in higher education, the educational institution means to have high quality in education, because education is the key matter in creating the conditions and circumstances in which a man finds himself and shapes his personality for the whole life. During the education he pursues his desires, goals, but the realization of these goals is affected by various exogenous factors such as parents, schools, university, which set and guides the direction of the education of the individual. Every person during his life has some idols, or leaders.

There is very much literature written about leadership, so we can say that this term is meant primarily to influence the process of a particular group of people to achieve a particular goal and leader is person who efficiently realizes this process. If we start from Maxwell definition that "the key to success in any business lies in our ability to lead other people and If we form people with this ability, then we get a definition of leadership in higher education because the key to success in higher education institutions lies in the ability of professors who with their skills, knowledge, and personal example markedly affect behavior, thoughts and emotions of other people - his followers.

EDUCATION LEADER - ETHICAL, UNETHICAL

Ethics is the science of morality, and morality is an objective social phenomenon which regulates the behavior of members of a community and includes the regulation of interpersonal relationships with ethical (moral) standards, or putting it more simply-the relationships among people and relationships between individuals and other people in the society prescribed with certain rules and norms. The ethical morality step is required at any level and any subsystem of social organization, but especially and significantly in the field of education. Professor in higher education, his social position and his social role is an example of predisposed leader.

To become a „de facto“leader, his personality should adorn the moral qualities that will serve as role models for their students, which means to have authority. Authority is achieved by positive moral attitudes and qualities, as well as positive attitudes towards work. In this context, the professor is an ethical leader who has influence on ethical values and behavior that comply with social rules and norms, and rules and norms of the institution where he works. His positive attitude towards himself and his followers provides

opportunities for promotion, training and open to positive and negative feedback, recognizing of contributions of others, providing information and having moral standards that emphasize more the interests of groups, organizations and society.

Professors - ethical leaders have an inner vision of long-term goals of educational institutions. They are able to properly consider and choose the ways and means to achieve these goals. Also they are visionaries with a vision that reaches far into the future. Their effective communication with staff members and his followers affect motivation and lead them forward to achieve pre-planned and selected targets.

Leadership requires, above all, a unique and purposeful actions and achieving a unique and important role. This explains a curious paradox: leadership rarely comes only from power, instead it aims to create their own power. (Lester R. Bitell, 1997). Leadership implies an unequal distribution of power between leaders and followers. And followers have power because they can affect the activity of groups in different ways, but certainly the leader has more power than their followers.

Regarding unethical leaders, it must be said that they have the power, but they use their power for their own purposes. These are the people who control their followers and manipulate them, do what is best for themselves and not for the organization, provide only information that is favorable to them, and their moral standards are such that their own interests before the interests of all others. In the following table the differences between ethical and unethical leaders are given.

ETHICAL LEADER	UNETHICAL LEADER
Use power to serve the others.	They use power to dominate or manipulate others for personal gain.
Allow followers to contribute to the development of mission.	They are the only creators of vision, which is used to fulfill their personal goals
Engage in two-way communication and want to learn other people's views on key issues.	Engaged in one-way communication and are not open to others' suggestions.
They are open to feedback and willing to learn from criticism.	They have a pronounced ego, feel their attention and admiration of sycophants and avoid sincere feedbacks.
They want his followers to think and question the status quo, and that the views of leaders.	Do not want their followers to think, but just to uncritically accept the idea of leaders
They focus on training people they work with, to show them the believing in sharing credits with others.	They are insensitive and unresponsive to the needs and aspirations of followers
They follow personal principles that may be contrary to popular conceptions, and have three virtues: courage, sense of fairness or justice and integrity	They follow standards only if they meet their immediate interests, manipulate the impressions that other people thought that they act properly and use communication skills that led others to support their personal aspirations.

Resource: Chuck, W., Principles of Management, 2010

Education is a subsystem of a society system that undergoes a permanent change and innovation. In modern societies of the Balkan countries during the transition period created a serious situation of moral confusion. They leave the old moral values, without creation the news of it. During the pre-transitional time a person was evaluated and appreciated mostly by what he was and then by how much he had. Today the state of affairs is opposite. The man is evaluated by how much hi has, and after it, what he is. The race for money and power pushed people in the moral confusion, there is moral erosion, which leads to a moral deviance. Moral deviation in higher education can be divided into four groups: moral deviation of ruling itself, moral deviation by another person, moral deviation in relation to work and moral deviation of person in the narrow sense.

In this context, unethical leaders in higher education act manipulative with his colleagues and especially with students, they have a flippant approach to teaching, showing selfishness and selfishness which is

followed by calculations, speculations, careerism and corruption. The difference between ethical and unethical teachers is a "public secret". Their behavior is obvious to everyone and is usually expressed in the following moral deviations:

- exposure to the subject matter without a consistent concept,
- no accountability of the establishment and maintenance of interactivity with students,
- pushing and respect for uncritical students,
- pressure on the students to buy their books and additional literature,
- seeking sponsorships and other services from students,
- taking bribes from student for exam
- Abusing the position of teacher for sexual exploitation of students.

Thus, an unethical professor-leader is unfit to perform his profession. So he directly discredits higher education institution. These regressive and dysfunctional social processes entails the undermining of education as one of the most important and crucial public services. The question is: how to stand in the way of these deviant phenomena which leads to low-quality education and destroys the educational systems?

In this context, the following measures need to be introduced:

- Firstly, it is to intensify the management of higher education institutions, which must clearly and unambiguously struggle and make efforts towards promotion and support ethical behavior. Their speeches, promises, interviews and action should be constantly talking about the ethical values of the organization not only professors, but also, above all;
- second, the adoption of formal regulations (codes of ethics), the behavior of teaching staff, management and students in higher education institutions;
- giving a greater importance to the educational function of the teaching staff in relation to educational function;
- organizing seminars, round tables, debates, symposiums and other scientific forms of work which would be indicative of moral deviations in the work of teachers staff in the ways and methods of their elimination;
- public moral condemnation of the deviant behavior of professors and prohibition to carry out educational functions.

CONCLUSIONS

1. The key of success in higher education institutions lies in the quality of teaching staff. Seen from an ethical point of view, high-quality teachers is the one that has a high expertise and above all, high moral standards. These are the basic features which should be characterized by a teacher-leader in higher education. Management of higher education institutions need to recognize these teachers to work in favor and to engage a leadership that stimulates and motivates them to work in order to establish their leadership.

2. In contrast, the management and collective in the higher education institutions should openly condemn every morally deviant behavior of unethical leaders, and to take energetic measures for their elimination. Thus, the detection and sanctioning of unethical professor-leader is a long- term intellectual and academic contribution to the future of higher education and society in general.

3. In the elimination of morally deviant behavior a great significance have precisely defined rules and ethical principles. So the management of higher education institutions should work to define the acts of higher education institutions. First of all, one must adopt codes of ethics with clear and precise ethical standards. Then they should try to introduce the teaching staff and student with these standards and, finally, to be persistent to apply these standards in practice.

Abstract: *Burnout is a widely recognized syndrome of emotional exhaustion, depersonalization or cynicism and reduced personal accomplishment that occurs in a broad spectrum of occupations, and in students as well. The objective of this research was to investigate the risk of burnout among students and to analyze the relationship between gender and grade point average with three dimensions of burnout. Maslach Burnout Inventory – Student Survey, the most common instrument for measuring burnout, was used for this purpose as it was created and validated for student population. The research was conducted on a sample of 376 management and IT students in Serbia of the second to the final year of studies. The results show that 174 (46.3%) of the total sample of students are at risk of burnout, and 78 (20.7%) are at high risk of burnout. There is no significant correlation between gender and risk of burnout. There are higher percentages of students with low grade point average than students with high grade point average in both risk of burnout (54.4%) and high risk of burnout (26.6%) categories.*

Keywords: *risk of burnout, high risk of burnout, students, grade point average (GPA), Maslach Burnout Inventory – Student Survey (MBI – SS)*

1. INTRODUCTION

Burnout is a widely recognized term in theory and practice that caught the attention of researchers almost 40 years ago. First researchers in the field, Freudenberger (1975) and Maslach (1976), based their work on the assumption that burnout occurs due to interaction between providers and receivers in occupations providing services and care (Maslach, Schaufeli, & Leiter, 2001). Later research has shown that burnout relates to other professional activities and occupations as well (Leiter & Schaufeli, 1996). The concept has also been extended to undergraduate and graduate students since studying has some characteristics of a job and students experience pressures while fulfilling academic requirements (Schaufeli, Martinez, Pinto, Salanova, & Bakker, 2002).

Frequently used definition of burnout was offered by Maslach as “a psychological syndrome of emotional exhaustion, depersonalization, and reduced personal accomplishment” that occurs as a response to emotional and interpersonal stressors among individuals (Maslach & Goldberg, 1998). Burnout dimensions defined in such manner reflect the focus on occupations with extensive interactions with people, while slight term modifications - emotional exhaustion, cynicism (a distant attitude toward the job) and reduced professional efficiency, are more appropriate for other occupations (Maslach, Schaufeli, & Leiter, 2001). Emotional exhaustion is the first reaction to the stress of job demands and basic element of the syndrome. Exhausted individuals feel emotionally and physically drained up, and unable to recover. Depersonalization or cynicism reflects negative responses to work and people at work with cold and distant attitude. Final dimension, self evaluation component of burnout – reduced professional efficacy, is a state of ineffectiveness and loss of confidence in own abilities (Maslach & Leiter, 1997, pp. 17-18). All three dimensions respectively correspond to level of energy (e.g. feeling used up), attitude (e.g. being cynical), and self-evaluation (e.g. doubting personal abilities) (Schaufeli, 2003). Burnout dimensions are defined in the same manner for student population and they refer to feeling exhausted because of study demands, having a cynical and detached attitude toward studies, and feeling incompetent and inefficient as a student (Schaufeli, Martinez, Pinto, Salanova, & Bakker, 2002). Moneta conducted a study in which he explored the links between need for achievement, burnout, and intention to leave one's study program in undergraduate university students and concluded that burnout in educational settings has similar characteristics to those it has in occupational settings (Moneta, 2011).

The first scale for burnout - Maslach Burnout Inventory (MBI) - Human Service Survey was developed for a wide range of human service professionals (Maslach & Jackson, 1981). Evolution in burnout research

across different areas brought changes in the widely used scale and development of several modifications: MBI – Educators Survey (for workers in educational occupations), MBI - General Survey (for workers in occupations that are not entirely people-oriented) and MBI - Student Survey (for undergraduate and graduate students). The construct validity of MBI-SS has been acknowledged by previous researchers (Schaufeli, Martinez, Pinto, Salanova, & Bakker, 2002; Schaufeli & Salanova, 2007; Campos, Zucoloto, Bonafe, Jordani, & Maroco, 2011) and the criteria they used to validate the construct was the confirmatory factor analysis. Coefficients of internal consistency (Cronbach's alphas) have values above 0.70, signifying internal consistency, according to Schaufeli et al (2002). In these, previously mentioned research, MBI-SS was validated for following languages: English, Dutch, Spanish and Portuguese. Hu and Shaufeli validated Chinese (Hu & Shaufeli, 2009) version and Shin et al. verified that MBI-SS is appropriate for application on Korean students (Shin, Puig, Lee, Lee, & Lee, 2011).

A lot of studies of student burnout were conducted in the past. Perceived stress was positively correlated with all burnout dimensions (Divaris, Polychronopoulou, Taoufik, Katsaros, & Eliades, 2012). One of the studies investigated the association between gender and burnout subscales where the results showed that the risk of burnout is increasing with the year of study and that there is no significant correlation between gender and any of the subscales of burnout (Galán, Sanmartín, Polo, & Giner, 2011). Results of Adie & Wakefield (2011) suggested that burnout symptoms among students can be reduced by introducing autonomy supportive behaviors in order to facilitate engagement (Adie & Wakefield, 2011). To our knowledge, there were only few studies conducted in Serbia in the field of burnout. Most of them investigated risk of burnout in certain occupations: food industry (Arandelović, Ilić, & Jović, 2010), medical staff (Čurčić & Čurčić, 2009) and military (Dedić, 2005). There was only one study on a student population, with the aim to identify factors that might be associated with health related quality of life, including relationship with depression. Researchers concluded that among the factors that significantly influenced quality of life, depression was the most prominent (Pekmezovic, Popovic, Tepavcevic Kisic, Gazibara, & Paunic, 2011). With respect to previous research and shortage of scientific data for Serbia, the authors of this paper decided to explore three dimensions of burnout on a sample of management and IT students at Faculty of Organizational Sciences, using the MBI–SS construct and analyze the relationship between grade point average and gender with different burnout scales.

2. METHOD

Participants in this survey were 402 management and IT students from Faculty of Organizational Sciences, University of Belgrade in Serbia. Participation was voluntary and students were asked to fill the survey and provide socio-demographic and other characteristics of participants. Each student was assigned numerical code in order to ensure anonymity. From these students, 26 of them did not answer the entire questionnaire and were removed from the study. Convenient final sample of 376 students (93% response rate) consisted from equally distributed students of second to final year of studies. There were 159 male and 217 female participants.

Maslach Burnout Inventory – Student Survey was used for this purpose as it is most widely used construct for assessing burnout. The construct consists of 15 items that represent three scales: exhaustion (5 items), cynicism (4 items), and professional efficacy (6 items). Individual items are scored on a 7-point frequency rating scale ranging from 0 (never) to 6 (always) and students were asked to indicate how often they felt in a certain way (e.g. for exhaustion: "Studying or attending a class is really a strain for me"; for cynicism: "I doubt the significance of my academics"; and for professional efficacy: "I feel stimulated when I achieve my academic goals"). Questionnaires were distributed to participants during the winter term of 2011/12 academic year at the end of lectures. They were informed about the aim of the study, but were not given any particular details. The researchers were not present in the classrooms at the time of filling the questionnaires and they collected them after completion.

Reliability of MBI–SS was estimated through Cronbach alpha coefficient for internal consistency for all three dimensions of burnout. The coefficients were $\alpha=0.814$ for exhaustion, $\alpha=0.868$ for cynicism and $\alpha=0.773$ for efficacy. Since internal reliability is assumed for correlation coefficients greater than 0.7 (Cronbach, 1951), the results point out to a good internal consistency. Descriptive statistics was used to analyze the data (mean scores - M and standard deviation - SD). Afterwards, chi square test was used to identify differences in gender and GPA on the three dimensions of burnout and independence sample t-test was used to determine differences between two group means. Statistical significant results were assumed for $p<0.05$. SPSS version 20.0 was used for all analysis.

3. RESULTS AND DISCUSSION

The mean scores and standard deviation for three dimensions were calculated and they were 2.50 (1.08) for exhaustion, 1.05 (0.97) for cynicism and 3.92 (1.06) for professional efficacy. Scores for each subscale were organized in three groups: low, average and high, according to lower, medium and upper quartile of the score distribution (Galán, Sanmartín, Polo, & Giner, 2011). Therefore, lower and upper quartiles of all dimensions are: low exhaustion ≤ 1.83 , high exhaustion ≥ 3.17 ; low cynicism ≤ 0.33 , high cynicism ≥ 1.67 ; low efficacy ≤ 3.21 , high efficacy ≥ 4.67 . Our research defines burnout as a result of exhaustion, cynicism and efficacy, where high scores on exhaustion and cynicism and low scores on professional efficacy point towards student burnout.

Most researchers (Galán, Sanmartín, Polo, & Giner, 2011; Willcock, Daly, Tennant, & Allard, 2004; Santen, Holt, Kemp, & Hemphill, 2010) identified the existence of burnout risk through at least one subscale of burnout as a sufficient indicator. Taking into consideration Schaufeli et al. (2002), risk of burnout exists when there is a high score on emotional exhaustion or high score on cynicism or low score on efficacy, meaning that high or low score on one dimension is sufficient indicator for risk of burnout. (Schaufeli, Martinez, Pinto, Salanova, & Bakker, 2002). Furthermore, we wanted to identify students with high risk of burnout, and we formed an indicator for high risk of burnout. High risk of burnout represents high scores on emotional exhaustion and high scores on cynicism; or high scores on emotional exhaustion and low scores on efficacy; or high scores on cynicism and low scores on efficacy; or high scores on emotional exhaustion and high scores on cynicism and low scores on efficacy. Therefore, students were grouped into those with risk of burnout (with high/low scores on only one burnout dimension) and those with high risk of burnout (with high/low scores in two or three burnout dimensions).

Table 1 shows that 88 (23.4%) students had high score in exhaustion, 83 (22.1%) had high score in cynicism and 94 (25%) had low score in efficacy. Also, table 1 illustrates that 174 (46.3%) of total sample of students are at risk of burnout, and 78 (20.7%) are at high risk of burnout. There are no data regarding acceptable levels for risk of burnout, but it can be concluded that 46.3% is extremely high percentage, according to which almost every other student is at risk of burnout.

Table 1: Burnout dimensions and number of students at risk of burnout

Subscales	Students	
	Number	%
Exhaustion		
Low	106	28.2
Moderate	182	48.4
High	88	23.4
Cynicism		
Low	125	33.2
Moderate	168	44.7
High	83	22.1
Efficacy		
Low	94	25.0
Moderate	189	50.3
High	93	24.7
Risk of burnout^a	174	46.3
High risk of burnout^b	78	20.7

^a Burnout - high score on emotional exhaustion or high score on cynicism or low score on efficacy

^b Burnout - high score on emotional exhaustion and high score on cynicism; or high score on emotional exhaustion and low score on efficacy; or high score on cynicism and low score on efficacy; or high score on emotional exhaustion and high score cynicism and low score on efficacy

Table 2 shows that 34 (21.4%) out of 88 students who had high score in exhaustion were male and 54 (24.9%) were female. 42 (26.4%) out of 83 students who had high score in cynicism were male and 41 (18.9%) were female. There is no significant difference on a burnout subscale of exhaustion between genders neither in total sample nor in the high scored group. There are significant differences between gender on a cynicism and efficacy subscale. It is interesting that there are no differences between male and female students in a group of students with high risk of burnout.

Previous research showed conflicting results. Some of them showed that there is no significant correlation between gender and any of the subscales of burnout. (Galán, Sanmartín, Polo, & Giner, 2011; Bresó, Salanova, & Schaufeli, 2007). Others showed that there is a difference between genders on a different subscales of burnout (Willcock, Daly, Tennant, & Allard, 2004; Yang, 2004; Weckwerth & Flynn, 2006). Therefore the consensus of researchers on this issue does not exist.

Table 2: Differences in risk of burnout between male and female students

Subscales	Students		p
	Male	Female	
Exhaustion			
Mean (SD)	2.46 (1.06)	2.58 (1.10)	0.487
High score, no (%)	34 (21.4%)	54 (24.9%)	0.554
Cynicism			
Mean (SD)	1.22 (1.02)	0.93 (0.92)	0.004
High score, no (%)	42 (26.4%)	41 (18.9%)	0.004
Efficacy			
Mean (SD)	3.77 (1.11)	4.04 (1.01)	0.018
Low score, no (%)	51 (32.9%)	43 (19.8%)	0.025
Risk of burnout	81 (50.9%)	93 (42.9%)	0.120
High risk of burnout	37 (23.3%)	41 (18.9%)	0.301

For the purposes of this research, we defined low GPA as a grade below 8.00 and high GPA as grades 8.01 or higher (Lowest grade a student can get for passing the exam in Serbia is 6 and highest grade is 10). Table 3 shows that 38 (22.5%) out of 88 students who had high score in exhaustion had a low GPA and 50 (24.2%) had high GPA. 46 (27.2%) out of 83 students who had high score in cynicism had a low GPA and 37 (17.9%) had high GPA. 61 (36.1%) out of 94 students who had low score in efficacy and low GPA and 33 (15.9%) had high GPA. There is no significant difference on a burnout subscale of exhaustion between students with low or high GPA. There is a significant difference between students with low and high GPAs on a cynicism and efficacy subscales. Especially important is the influence of efficiency on a students' GPA for the total sample.

In some of the previous research authors found that students who had highest GPA scores and positive self-esteem didn't experience burnout (Jayoung, Puig, Kim, Shin, Lee, & Lee, 2010). In another research where MBI construct was used, GPA was significantly correlated with emotional exhaustion but not with depersonalization or personal accomplishment (Jacobs & Dodd, 2003). Considering the risk of burnout, it is shown that 54.4% of students with low GPA are at risk of burnout and 26.6% are at high risk of burnout. There is a significant influence of GPA on a risk of burnout and on high risk of burnout.

Table 3: Differences in risk of burnout between students with low and high GPA

Subscales	Students		p
	Low GPA	High GPA	
Exhaustion			
Mean (SD)	2.43 (1.13)	2.56 (1.04)	0.241
High score, no (%)	38 (22.5%)	50 (24.2%)	0.736
Cynicism			
Mean (SD)	1.17 (1.02)	0.96 (0.92)	0.032
High score, no (%)	46 (27.2%)	37 (17.9%)	0.05
Efficacy			
Mean (SD)	3.63 (1.04)	4.16 (1.01)	0.0001
Low score, no (%)	61 (36.1%)	33 (15.9%)	0.011
Risk of burnout	92 (54.4%)	82 (39.6%)	0.004
High risk of burnout	45 (26.6%)	33 (15.9%)	0.011

Detailed examinations of student GPAs found that students in risk of burnout have GPA of 8.11 and those that are not at risk have a GPA of 8.35. Therefore, there is a significant difference in GPAs between two groups of students ($t(374) = 2, 385, p = 0,005$). GPA of students with high risk of burnout is 8.04, while

those who are not in this group have a GPA of 8.29. There is a significant difference between these two groups as well ($t(374) = 2, 426, p = 0.016$).

4. CONCLUSIONS AND FUTURE RESEARCH

Main results from this study show that risk of burnout is widespread in management and IT students in Serbia. Almost 50% of participants are at risk and over 20% of them are at high risk of burnout. There were no differences found between genders. Grade point average was found to be important predictor of risk of burnout.

Data on several other demographic and other characteristics of students were gathered in the course of this research. Some of them were not considered in this paper, but might be significant for risk of burnout in student population. Therefore, authors of this paper will include current year of studies, field of studying (management or IT), source of financing (government budget or self-financing), employment status (unemployed, part-time workers and full-time workers), hometown, and amount of time dedicated to learning activities and class attendance in their future research. Since we concluded there is a significant difference in risk of burnout between students with high and low GPAs, it might be interesting to analyze the relationship between GPA and some other characteristic of students. Likewise it would be useful to conduct a national study on risk of burnout using the entire student population in Serbia, and not just management and IT students at Faculty of Organizational Sciences.

DEBATE – METHOD OF LECTURING AT UNIVERSITY

Svetlana Jovanović¹, Nemanja Dragičević², Marko Ćirović³

¹University of Belgrade, Faculty of Organizational Sciences, jovanovic.svetlana@fon.bg.ac.rs

²University of Belgrade, Faculty of Organizational Sciences, dragicevic.nemanja@fon.bg.ac.rs

³University of Belgrade, Faculty of Organizational Sciences, cirovic.marko@fon.bg.ac.rs

Abstract: Lecturers at the University of Belgrade, Faculty of Organizational Sciences seek to improve the teaching methods they use. This paper examines what set of skills is required in contemporary tuition and how debating skills correlate to them. It also analyzes current methods and paradigms used in tuition to expose the shortcomings of the contemporary approach to the development of tomorrow's workers.

Debating concept fundamentals, basic guidelines on logic and critical thinking are provided in this paper. We explain different formats that may be implemented. Also, comprehensive guidelines are given to lecturers in order to find debatable topics, research and organize discussion. We also include a debating manual in order to help students cope with challenges while performing a debate speech.

This paper seeks to empirically prove that debate advances students themselves, improves their engagement with the topics they encounter in the lectures, develops skills necessary in their future employment, increases their understanding of presented materials and enables the students to analyze the information in a more advanced way. For this purpose, initial research was conducted with students of the University of Belgrade, Faculty of Organizational Sciences. This research examines the differences between the previously described characteristics of students who have participated in the debates, those who have only listened to the debates and those who haven't attended the class when the debates happened. A brief summary of relevant international research in this field is provided.

This paper also provides a framework for further research that was planned to take place over the period of two years, encompassing current debaters, ex-debaters and students new to debate from the entire University and tracking their patterns of thought, their academic and professional success, skill development and overall progress. This framework was formulated in cooperation with The Association of Psychologists of Serbia.

The authors of this paper are aiming to prove that debating is a superior method of teaching, to provide a methodology for the introduction of debating in tuition, to explain the very basics of debate to students, and to provide a platform from which further research and activities are to be done in advancing towards all the previous goals.

1. SHORTCOMINGS OF METHODS OF EDUCATION USED TODAY

When we talk about why it is necessary to improve the system of higher education in Serbia, one of the main often stated reasons is the inefficiency of this system. The proof of this claim lies in the fact that the average duration of the study is almost two times longer than it should be (Ministry of Education and Sport, 2005). In addition, about two-thirds of the students give up entirely on the studies: each year, on average, 33,000 students are enrolled, and only 12,000 graduates (Ministry of Education and Sport, 2003).

The roots of inefficiency in the system of education are very complex, and there is a significant, although unexplored, the impact of various "external" factors: socioeconomic status of students, the general state of society (in economic and social terms), the problems carried over from previous education (mainly secondary) and so on. However, the inefficiency of higher education is partly determined also by the "internal" factors, related to the organization of studies, the regime of the studies, insufficient compliance of curriculums with the exam criteria, the number and volume of study subjects, the mutual compatibility of

study subjects within the same study program, number of students and their readiness to follow the lessons, the number of teachers and their qualifications for teaching, and so on.

Part of these problems should have been solved by adequate implementation of the Law on Higher Education, which entered into force in September 2005, since it envisaged the change of the regime of studies, introduction of the ECTS credits, as well as the definition of the learning outcomes, which was supposed to change the very essence of the current system of education.

Misunderstanding of the essence of the educational process is reflected in the following:

- The teaching methods, within which the *ex cathedra* method is predominant;
- The focus is on the activity of teachers and not on the activity of students;
- The pressure both on teachers and on students is primarily to formally cover the study materials and not to "learn something";
- Often mismatch between what is taught in class and what is asked on the exam;
- Exams are performed in a limited number of ways – periodic tests, written or oral exams conducted through testing, resolving of assignments or oral / written reply to a combination of pre-designed questions - and therefore testing only a limited set of acquired competencies⁴

It is significant to note that, during their education, better part of the students will not acquire, among other things, required practical experience (i.e. how to apply the acquired knowledge in practice). There are only few cases in which the needs of the labor market and consultations with employers are considered during the creation of study programs. In addition, only few of the higher education institutions keep records of employment of its graduates.

Considerable uniformity in terms of teaching methods can also be detected. On most of the study programs, (i.e. in the vast majority of the classes), the only teaching method is *ex cathedra*. Too little room is left for discussion with students, and in the number of cases even for the students' questions related to clarifying the content of lectures. If the goal of higher education is merely for students to develop the ability for sitting and listening, with the eventual development of the ability to keep the notes, then the *ex cathedra* method is the right solution. However, it is impossible for students to develop various skills and abilities by using only one teaching method.

Learning outcomes are the essential element of the curriculum, but their formulation in practice is often reduced to mere satisfaction of forms prescribed by the Bologna Process or by the Law on Higher Education (Verheyde, 2006). However, learning outcomes harbor the potential for a fundamental change in the educational process. Such potential of the learning outcomes stems primarily from a new philosophy of education, which involves changing the focus of education from the process of lecturing / classes to the learning process.

If we agree with the fact that the student and the learning process (rather than the process of teaching) are in the focus of education and curriculum development, the first step in the development of a new kind of curriculum is a departure from the final outcome, i.e. from defining the competencies that a student should possess upon completion of the study program. And here we encounter a problem related to the very notion of competence. The term competencies usually include knowledge, skills and abilities that a person acquires or develops, and which are enabling that person to do something. Educational system in which the focus is on the student *inter alia* aims to provide that students are competent at the end of the educational process, i.e. that students will have certain knowledge, skills and abilities. Competencies in this sense represent a dynamic combination of knowledge and its application, attitudes and responsibilities that reflect the results of educational program.

There are different divisions of competencies. Below are divisions emerged within the Tuning project, with this division primarily dividing the competencies on general (or generic) and professional:

⁴ In accordance with the EU methodology, during 2005 and 2006 the Center for Education Policy AAEN carried out the regional Tuning project related to social and humanistic sciences, entitled "Regional alignment of curriculums - towards the European area of Higher Education."

- Generic competencies should be obtained by ones who finish a certain level of education regardless of science or industry you are dealing with (such as foreign language skills, knowledge application in practice, computer literacy)
- Subject specific competencies are identified for each subject or field of study and they are more specific.

The Tuning project defines three groups of generic competencies - instrumental, interpersonal and systemic. Instrumental competences, among others, include the ability to analyze and synthesize (Gonzales, 2005).

If, for example, the transitional nature of society and recent history of the region are taken into account, the competencies such as social responsibility and critical thinking and reading (developed through the debate as a teaching method) can also be considered as important.

A particular challenge in this regard is the change in attitude and mindset. This change is often considered as “mission impossible”, because the existing attitudes and mindsets are being developed over the long period of time, during which the system of higher education did not change in response to changes in the environment, or did change in a way that it was more isolated from the same environment. What is important to emphasize here is that a change in mindset and approach to higher education as such (as by the academic community and by the students, employers and society as a whole) can come only through broader change in the understanding of the role of education in general. In this context, it is a debate that allows the change in thinking and attitude towards all processes in the society – educational, political, social, economic and other.

2. CHALLENGES FACING EDUCATION TODAY

Information age has reshaped our society, changed the way we acquire information and changed the labour market in the span of a decade. The workplaces we are preparing our students to fill come with a broadband connection, and data has become the realm of hard drives, not humans. Workers are no longer asked to know everything, but to know how to find out quickly. These changes came about through couple of trends brought by the information age, we will examine a few.

Information overload. It is said that more information can be found on the pages of the NY Times than what was available to an average 19th century person during their whole lifetime. The amount of data available on the web is increasing exponentially. As with every information explosion, problems of managing all the new data arise. This means two things:

1. Workers are more productive if they know how to find good information quickly, then if you specialize them they will find out all the information on their own.
2. Once a worker is delegated to find out certain information, it is lucrative for him/her to know how to filter, organize and present that information to others.

The job of University professors is to prepare their students to be as productive and valuable as possible, hence the need to include education in developing these skills.

Persuasion science has advanced to the point where we are bombarded with messages trying to influence us into doing something. Marketing agencies try to sell us their products, paid experts try to convince us into their points of view, trained negotiators try to bully us into concessions at the negotiating table. This trend calls for several things:

1. Critical thinking is beneficial in the workplace. Critical thinkers will represent the company's interests better against competing interests.
2. Persuasion methods are beneficial once the tables turn, as the worker is able to acquire more concessions than the others can.
3. In everyday life, students versed in persuasion skills will be able to see through companies and people trying to influence them, and to preserve their own interests better.

Globalization has brought companies and workers on different continents under the influence of the same forces. The sub-prime mortgage loans bubble in America, and the global economic crisis that

followed it in 2008 are proof of this. This trend brings into light more qualities as beneficial to a today's worker:

1. Knowledge of the world problems, which provides opportunity to foresee those problems spreading locally, and then act accordingly, and
2. Communicating with members of drastically different cultures in a super-cultural context, which enables workers to understand and be understood when cooperating with companies from other cultural frameworks.

New media is quickly replacing the old as the provider of the information. Google, blogs, websites and wikis become the go-to places where people find information. However, most of this new media is agenda driven, not accountable. The trend has become so prevalent that some old media, such as television channels and some newspapers, are abandoning the mantra of objectivity and fact checking, for agenda pushing. Agenda driven media can continue to exist as long as there is no objective confrontation of conflicting agendas to the viewer. As that never happens, it is left to the viewer to cut through the agenda driven propaganda into the core of the issue, whether it is a citizen trying to vote, or an investor trying to find a suitable investment (Snider, 2011)

3. HOW DOES DEBATING AS A TEACHING METHOD RISE TO THE CHALLENGES OF TODAY'S EDUCATION?

Participation in academic debating creates numerous benefits for the students. Some of them we will outline here, as they respond to the exact requirements posed by the previous chapter.

Data analysis is an essential debating tool. Debaters must learn how to find the relevant information on the topic when they're researching possible motions for a tournament, analyze and save or remember their results. After debating for some time, debaters collect a lot of information, but they will always encounter new topics, where they will have to quickly utilize the data they know in a new problem.

Presentation of knowledge is required from debaters in a limited time frame. Debaters learn how to present vast amounts of knowledge briefly, effectively and to the point.

Critical thinking is forced onto debaters, and debaters quickly adopt it. Sides are randomly assigned in a debate, therefore debaters must know how to argue, analyze and assess opposing sides of any argument.

Knowledge of the world problems is necessary in the international debating scene, as the topics must be drawn from a pool of issues which are equally important to all the countries which are participating.

Finding the right information is important because facts count in debate. Most global debates have competing schools of thought, often with competing information. Debaters need to know how to weigh authorities, how to compare sources and spot when information is biased.

Intercultural communication is developed and trained in debate, as judges come from different cultural backgrounds, as well as the opposition teams. That means debaters train to be understood, as well as to understand.

Persuasion is a peripheral skill for debaters. In theory debates should be judged by completely objective judges. As this cannot be the case, advance debating classes cover persuasion methods as a manner of gaining that last bit of competitive edge (Snider, 2011).

4. OUTCOMES OF TEACHING THROUGH DEBATING AS A TEACHING METHOD IN UNIVERSITIES

4.1 International research

After properly defining the outcomes of learning, it is necessary to approach the development of methods of teaching and grading that will enable the fulfillment of those outcomes. Achieving well defined outcomes of learning involves students understanding the teaching as a process in which they question their understanding of concepts and processes and/or create new concepts and understand connections

between them. To make this possible, it is necessary for the lecturer's goal to be more than going over matter, but to accomplish "interactive" teaching, through debating to the topic which is planned to be taught by the curriculum. This chapter highlights the results of research that confirms the importance of introducing debate as a teaching method.

Heads of Urban Debating League in Minnesota found that students who have practiced debate had 36% better results in reading tests than before they had debate training, in addition to showing faster progress than the control group. All the debaters showed increased interest in the curriculum. 87 % of debaters analyzed information better than the control group. Joe Bellon (Bellon, 2000) explains the positive influence of debate training on academic performance was confirmed by Barfield (Barfield, 1989) who found significant increases in cumulative GPAs with students who had debate training. Debaters will also be favoured in certain professions, as proved for jobs in civil service by Pollock (Pollock, 1982), in the legal field by Church (Church, 1975), and educational administrators by Schroeder and Schroeder (Schroeder, 1995). Colbert and Biggers conclude that debate experience is highly valued in the business world and they find unequivocally that debate training will help students get a job.

Debate training requires application of knowledge from a wide array of social sciences, and this is why Robinson in 1956 describes debate as "introduction into social sciences" (Bellon, 2000). In addition to this, Semlak and Shields (Shields, 1997) determined that debaters are significantly better at analysis, delivery and organization of content.

One of the best researched benefits correlated to debate training is critical thinking. Students with debate training are significantly ahead of control group in regards to critical thinking scores (Brembeck, 1949). Colbert and Barfield confirm these conclusions in 1987. These studies were disputed on several grounds, so Allan et al. started a study to remedy the shortcomings. In 1995 they proved that students with debate participation were ahead of the group who listened to lectures on argumentation. A meta-analysis of studies in 1999 proved further the link between communication skills and critical thinking.

People with good communication skills are rated more highly by their peers, as was proved by Pollock (Pollock, 1982). Pollock also makes the connection of forensic activities with developing communication skills, as do Colbert and Biggers (Biggers, 1985) who conclude that debate training improves communication skills, as well as the skill of public speech.

High verbal skills are correlated with decrease in physical aggression by Boone and Montare (Bellon, 2000).

Once someone feels capable of responding verbally they feel less inclined to resort to physical force. On top of that debaters learn to respect the opposite side, because of protocol and because they might be in their spot in the next tournament. Debate training increases argumentativeness without increasing verbal aggression (Colbert, 1994).

Best learning happens when students are asked to organize information and think of alternatives, which is exactly what debating is about. In order to learn, students need to be immersed into an interactive experience that must be rich and real, there must be a personally relevant challenge, and there must be intense analysis in order to present the student with other options and approaches (Caine, 1991). Recommendations of Caine and Caine correlate to debate perfectly: interactive experience is provided through competition with fellow students, even if the grading system doesn't provide a challenge to the student, personal motivation to compete with peers does, and judge's feedback provides exactly the kind of analysis Caine and Caine call for.

In summation we can conclude that debating as a teaching method is supported by scholars who have researched effects of debating training on students, and the scholars who have researched the process of teaching recommend actions that debating fulfils (Bellon, 2000).

4.2. Research at the Faculty of Organizational Sciences

Students of the third year of the Faculty of organizational sciences, majoring Informational Technologies, can choose debating as an activity at their course of Legal Basis for Informational systems. They are introduced to debating for the first time ever in their schooling. They undergo a week of training by the

debaters in the faculty's debate club. The topic is given in advance, and they are prepared for that particular topic.

The goal of the research was to determine whether this method of teaching was successful. In order to measure successfulness certain criteria was set, some of which were how much knowledge of facts in regards to the topic the students attained, how do students cope with opposing opinions, how do they rate their knowledge of the topic, in which degree they felt interested in the topic, how skillful were they in argumenting their positions, and whether they supported this method of teaching.

Legal Basis for informational Systems is taken by some 180 students and they were the sample of the research. These were divided into three groups: **participants** in the debate, **audience** of the debate, and those who **did not attend** the debate. The research set out to determine differences in the quality of the way the topic in question was conveyed to students, through the criteria mentioned above.

Students were distributed a 12 question anonymous questionnaire on the classes that followed the debate. 120 students attended those classes, 60% of which did not attend, 36% were the audience and 4% were the participants in the debate. Debate in question was nationalization of the national telecommunication company.

Students supported debate as a teaching method. 80% of those who participated stated they gained something through debating, of which 60% could explain what it was they thought they gained. The remaining 20% did not have an attitude towards this question. Among the audience only 8% felt they've lost something, and among those were the ones who claimed they lost their time. No students felt disadvantaged because the topic wasn't covered in the traditional teaching method, and 68% claimed they gained something in debate. Those who could explain what they gained mostly claimed it was information on the topic. Majority of those who did not attend did not have a stance, but slightly more (6%) of them said they lamented the fact they did not attend the debate.

Students were asked to say whether they are for or against the sale of the company which was the topic of the debate, and then asked to explain why. Later in the text, the same mechanism was used again with a different issue that was discussed in the debate. Participants did significantly better than the other two groups, on average some 2 points out of 12 ahead of the other groups. The audience and those who did not attend were on par, differentiating only by a couple of tenths of a point per question. This signaled the need to introduce ways of including the audience into a more active role in the debates.

Even though the audience was no better than those who did not attend at explaining their stances, it did not stop them from rating their competence in the issue 0.7 points out of 12 higher on average than those who did not attend. Participants in the debate were even more self confident, on average rating themselves as a whole 4 points out of 12 more competent in the issue than the audience. This signified that debating as a method seemed understandable to students, even though, as we concluded previously they did not engage enough to actually advance their knowledge as audience.

We've discussed that one of proven benefits of debating is learning how to deal with opposing opinions. This research suggests that this trait needs to be nurtured over time, as the participants did not do better than the other group when it comes to displaying aggression towards people with different attitudes. Key group we identified as the problematic in this research were those students who, when asked what they think of those with different stances on the issue, and why might they think differently, replied in an insulting, derogatory manner, and attributed malicious attributes to the people who have opposing stances, not being able to imagine that someone might have a good reason to think differently than them. This group was 15% of those who did not attend, 9% of the audience, and 20% of the participants. The group was reshaped the most over the three categories of students was the group that said they had no interest in people who thought differently, nonexistent in the participants, but larger in the audience than those who did not attend. It seems that, once confronted with people who advocate a view opposed to theirs large portion of those who otherwise would not reply to this question skipped into stating "they don't care about those people category", however this cannot be proven by this research. What we can conclude is that there is no immediate benefit of debating when it comes to confronting people who think opposite to one self.

5. FUTURE GOALS

If there is one thing people who are involved in academic debate love, whether they're judges, debaters, or professors, it's to talk about how transformative experience debate is. Sharing enthusiasm among friends is not enough, and we must seek scientific proof in order to gain backing to introduce institutionalize debate in universities. Research on the Faculty of Organizational Sciences has shown that there are some benefits from introducing even a week of debate training into students curriculum. Further research needs to prove that constant debate training yields even greater benefits and mandates introduction of debate, either across the curriculum, or as an elective.

No research to date suggests what would be the optimal time frame for developing debating skills in an academic setting. It is suggested that debating should be an overreaching method for the entire curriculum, others suggest electives. These two should be rivaled. Comparisons with other methods of teaching should be made. Long term development of students who start debating in earlier years of studies should be researched in comparison to students of same faculties who don't pick up debate. There is no scientific evidence on how well debaters do once they begin their professional carriers, except for anecdotal evidence. The more information we obtain on these issues, the more compelling the case for introduction of debate into universities becomes.

TEACHING ENGLISH AT A TERTIARY LEVEL IN EUROPE AND SERBIA – AN OVERVIEW AND COMPARISON

Gordana Jakić¹, Jelena Plečaš², Marija Novaković³

¹ University of Belgrade, Faculty of Organizational Sciences, gordanam@fon.rs

² University of Belgrade, Faculty of Organizational Sciences, plecasj@fon.bg.ac.rs

³ University of Belgrade, Faculty of Organizational Sciences, marija.novakovic@fon.bg.ac.rs

Abstract: *The paper discusses and compares the current state of foreign (particularly English) language teaching at tertiary level education in the European Union and in our country, points to the similarities and differences between them, and draws our attention to some benefits, drawbacks, and problems. Comparison is made between teaching methodologies and approaches, numbers of contact hours and credits gained, and other relevant criteria. Several strategic documents issued by the EU and the European Commission are also mentioned in terms of their relevance for the issue in hand. The authors conclude by giving recommendations about possible ways of introducing innovations and thus improving foreign language teaching at Belgrade University based on the EU model, with the aim of increasing our students' chances of mobility and employment in an international environment.*

1. INTRODUCTION

One of the most important traits the European Union prides itself on is its multilingualism, as it brings the benefits of cultural, economic and social richness of the continent. With the aim of promoting language diversity, the European Union and the European Commission have issued a number of documents that point to the importance of language learning for improving the relationship and facilitating communication between EU member countries. The documents also emphasize the effects of shortages of foreign language skills on economy, and give a number of recommendations, including the strengthening of foreign language education at all levels, diversifying the range of languages taught and encouraging mobility, especially in tertiary level education. (http://ec.europa.eu/languages/documents/elan-sum_en.pdf).

Another important issue dealt with at the European Union is the consolidation of educational systems of its member countries, and the application of new, common educational policies and programs. Projects such as Erasmus (since 1987) and Tempus (since 1990), both established by the European Commission, aim at developing partnership between European universities and modernizing teaching methodologies and curricula and promoting student mobility, and in such a way indirectly promote multiculturalism, multilingualism and foreign language learning. In order to further enhance cooperation between European universities, EU Commission adopted a common European model of higher education that led to the signing of the Bologna declaration by 29 European countries (including our own) that pledged to reform and coordinate their educational systems to ensure global competitiveness of European universities (<http://ec.europa.eu/education/policies/educ/bologna/bologna.pdf>). Even though the Bologna declaration does not explicitly mention the importance of language learning (Fortanet – Gomez & Raisanen, 2008), the knowledge of languages is implicit in some of its main objectives, such as the mobility of students and teachers. Another document issued by the European Commission, entitled “Promoting Learning and Linguistic Diversity: An Action Plan 2004 – 2006”, urged universities to play a key role in promoting multilingualism (Fortanet – Gomez & Raisanen, 2008) and encouraged projects devoted to increasing language learning among first-cycle higher education students, one of which refers to the use of foreign languages as mediums of instruction, which is to be discussed later.

The fact that English is the most commonly learnt foreign language at European schools and universities does not surprise, having in mind that it has established itself as the language of science, technology and business over the past few decades. English taught at European universities has become increasingly specialized to cater to the specific situations and purposes (Fortanet – Gomez & Raisanen, 2008);

therefore, most of it belongs to the category of English for Specific Purposes (ESP) and several of its sub-categories that are to be defined in the following chapter.

2. DEFINING TERMINOLOGY – ESP, EAP, CLIL, BE

Before providing an overview of the current state of English language teaching at EU universities and comparing it with the state of affairs at Belgrade University, it is necessary to define the kinds of English that are most commonly taught.

English for Specific Purposes (ESP) is the area of English language teaching that caters for the needs of learners in specific disciplines other than arts and languages. ESP focuses on the language, terminology, grammar, and discourse used in the specific academic, professional and occupational domain, rather than on general English. ESP courses are generally aimed at tertiary level students and professionals who already possess some level of general English knowledge. The broad field of ESP includes many specialized sub-fields, such as English for Business Purposes/ Business English (EBP/ BE), English for Academic Purposes (EAP), English for Science and Technology (EST), English for Occupational Purposes (EOP), etc.

English for Academic Purposes (EAP) as a separate field of ESP has gained attention over the last few decades and became a part of curriculum at many European universities. It is generally defined as English language teaching tailored to the needs of students who plan to pursue a career in academic environment. The aim of EAP is to facilitate study or research in English language and the use of scientific materials that are predominantly written in English. EAP courses are based on demands of a particular academic discipline, but generally put an emphasis on teaching academic reading and writing, with the aim of developing academic literacy skills. These skills include conducting research, summarizing their findings, producing formal academic texts in a variety of academic genres (essays, reports, etc.), comparing, classifying, inferring, evaluating, etc.

English for Business Purposes/Business English is an area of ESP aimed at a special interest group of learners – either students or professionals (studying to be) involved in international business. It focuses on the English language skills necessary to communicate in an increasingly global business environment and encompasses a wide variety of topics, such as accounting, commerce, economics, finance, HR, insurance, IT, law, manufacturing, marketing, the stock exchange, trade, transport, etc. The language skills that BE courses focus on include writing e-mails and reports, making presentations, doing negotiations, using the telephone, attending and participating in meetings, etc. English for Business is by far the most common ESP sub-field taught in Europe and in Serbia.

One of the latest approaches in foreign language teaching is **Content and Language Integrated Learning – CLIL**, and, more specifically, **Integrated Content and Language Learning in Higher Education (ICLHE)**. In this approach, teaching of ESP is closely linked to the content classes: ESP teachers use the materials and tasks that the students are assigned in the content courses (Fortanet – Gomez & Raisanen, 2008). Students are expected to possess the adequate level of English for learning through the medium of this language. In theory, the cooperation between a language teacher and a content teacher should be complete, meaning that both of them correct papers and share grading, but in practice this largely depends on individuals. One of the drawbacks of CLIL approach is the fact that it mainly focuses on writing, while oral communication skills are neglected. Apart from that, this approach sometimes relies on the assumption that students already possess good knowledge of English and do not need any special training to follow CLIL courses, which is not always true.

3. FOCUS ON EUROPE

According to the information about top 100 European universities (found at Webometrics website at http://www.webometrics.info/top500_europe.asp), their respective websites, as well as the research results of several authors (Fortanet – Gomez & Raisanen, 2008, and Perovic, Svetlin Gvardijancic., Ignjacevic, 2008.), the authors of this paper have made several conclusions regarding the state of ESP teaching at tertiary level education in Europe. Universities from Great Britain have been excluded from the research since it only focuses on teaching English as a foreign language.

The research was sometimes restricted by the limited amount of information provided by the university websites, and by the absence of its English (or other world language) translation. Due to the limited length

of this paper, the results shown here will refer mostly to faculties of business, economics, and the related fields, i.e. to English for Business as a sub-field of ESP.

European countries and their universities show some similarities, but also significant differences regarding the extent of teaching ESP, levels at which the courses are given, credits gained, the approaches and methodology used in foreign language teaching at tertiary level education.

In most European countries, ESP is taught independently of content classes using specially created ESP material. ESP courses are typically offered in the first cycle of tertiary education, mostly in the first and second year of the bachelor's degree. Unlike Spain, where only a few universities offer English (and other foreign) languages in their study plans (mostly Business, Economics, Tourism, Engineering, and Architecture), in Finland, for example, all higher education institutions offer these programs. This, according to Fortanet – Gomez & Raisanen (2008), makes Finland "the country with the greatest number of ESP programs in the EU" (p. 35). The extent of ESP teaching varies significantly (from one to four semesters on average), depending on the school and the country in question. Generally speaking, faculties of business, administration, economics, and related fields offer at least two mandatory courses in ESP. The number of credits gained per ESP course ranges from 3 to 6.

In countries such as Germany and Finland, as well as at the University of Bologna, for example, universities are affiliated to language centers that teach languages for special purposes. Apart from ESP, there are usually a number of languages offered, as well as the levels of knowledge. At Technical University in Munich (ranked 33rd in Europe by Webometrics), for example, completed foreign language courses are not mandatory, but can each bring 3 credits. One of the benefits that affiliation to language centers bring to university students is that they have a variety of languages and levels to choose from. The drawback, however, is that this arrangement usually means additional cost to students.

North European countries Sweden and the Netherlands, whose citizens are generally well-known for their exceptional English language skills, have gone furthest with the implementation of CLIL (integrated content and language approach). These countries also offer a wide variety of programs in English for international students, too, but those will not be discussed here. At Utrecht University (Faculty of Law, Economics and Governance), there are optional English-taught courses for Dutch students both at bachelor's and master's degree level.

Many European universities, regardless of the country, offer elective courses in English for Academic Purposes either at the end of first-cycle university education or during the master's programs to enable their students to conduct academic research in English.

Apart from the abovementioned approaches to teaching ESP, the authors of this paper have also noticed a growing trend of offering various university courses at all levels (bachelor's, master's and doctoral), and even whole programs (especially Master's) in English. Despite the fact that they bring obvious benefits (both to universities and their students) and encourage student and teaching staff mobility, linguists warn that they promote the ad hoc use of English as medium of instruction, with little attention paid to the educational consequences or to the language-learning objectives. (Fortanet – Gomez & Raisanen, 2008).

The information available proved that universities in all EU members and our surrounding countries share the same general trend of reducing the number of ESP contact hours as well as the number of ESPB credits considerably (Perovic, Svetlin Gvardijancic., Ignjacevic, 2008.), despite the EU multilingualism and foreign language policies. This trend is certainly one of the negative consequences of the Bologna process since it opposes the multilingualism and language learning policies issued by the EU and the EC. An encouraging fact is, however, that European universities have introduced a number of CLIL (more precisely, *ICLHE*) programs, as well as EAP courses.

4. FOCUS ON BELGRADE UNIVERSITY

The state of affairs at the Belgrade University is in many ways different than that of different universities in Europe. Firstly, there is no option of affiliating university courses with language centres and acknowledging such classes as taking regular exams and getting an appropriate number of credits.

Belgrade University consists of a total of 31 faculties organized in four groups: medical sciences, social sciences and humanities, natural sciences and mathematics, and technological sciences. (Arts will not be included in this paper.) Due to the fact that not all Faculty websites provide information on study programmes, not all faculties were included in this analysis. This section of the paper looks at the presence of English language courses at the faculties of the Belgrade Universities, whether they are mandatory or elective, and how many classes are offered and what credits students get (where applicable).

Of the 26 faculties observed, two of them (the Faculty of Architecture and the Faculty of Civil Engineering) have no English language courses included in their study programmes. Those faculties offering English language courses either have them as a mandatory or as an elective course.

In the group of medical sciences and four of the analyzed faculties, the Faculty of Dental Medicine has English as an elective course during the first two years of studies, throughout all four semesters. The Faculties of Veterinary Medicine and the Faculty of Pharmacy have English as a mandatory course only in the first year of studies, and students get from 1.5 to 3 credits for this exam. The best example in this group is the Faculty of Medicine, with English as a mandatory course during the first two years with 3 available at the end of each year, and as an elective course in the third, fourth and fifth year of studies. As far as the authors of the papers had insight into course programmes, the ESP taught at the finishing years of the Faculty of Medicine belongs to the sub-field of English for Academic Purposes. To our knowledge, this is the only EAP course offered at Belgrade University.

In the second group – social sciences and humanities and the six observed faculties, the Faculty of Economics has English as an elective course which brings students 4 credits per the third and fourth semester. Of the faculties where English is mandatory, the Faculty of Law has this subject only in the first semester of the first year. Nevertheless, it brings students 8 credits, which cannot be ignored when stressing the significance of the course. The Faculty of Orthodox Theology, the Faculty of Security, the Faculty of Political Sciences and the Faculty of Philosophy have English as a mandatory course during the both semesters of the first two years, while the Faculty of Political Sciences' students of the Department of International Relations have English thought their graduate studies.

As for the natural sciences and mathematics, the six faculties of this group which were analyzed show a diverse state of affairs. Two of them – the Faculty of Biology and the Faculty of Physics – have English as an elective course; the first has it during the first three semesters, while the second – only during the first semester of the first year. At the Faculty of Mathematics, the faculty for Physical Chemistry and the Faculty of Chemistry, English is mandatory and is held in the first two semesters, the second two semesters and in the second semester of the first year, respectively.

Finally, the fourth group of technical sciences, including the Faculty of Organizational Sciences, is both the most numerous and the group where English language courses are most present. In addition to the two already mentioned faculties offering no English courses whatsoever, another eight faculties were analyzed in this group. Two faculties – the Faculty of Agriculture and the Faculty of Mining and Geology – have English as an elective course, in the second semester and in the third and fourth semester respectively. As for those with English as a mandatory subject, the Faculty of Mechanical Engineering, the Faculty of Technology and Metallurgy and the Faculty of Forestry have the course for two semesters, the Faculty of Transport and Traffic Engineering is the best example of this group with four semesters, and the Faculty of Electrical Engineering and the Faculty of Organizational Sciences have English for three semesters.

Figure 1 Number of Faculties with English as mandatory or elective course

The number of classes per week ranges from two to five, but the majority of faculties have three classes per week on average. The number of ECTS credits these courses bring ranges from 2 to 10.

The prevalent approach to English language learning at the University of Belgrade is English for Specific Purposes (ESP). The majority of the faculties use tailor-made ESP courses and course books written by English language teachers working at these institutions, whereas others use course books published by renown and widely famous publishing houses specializing in the subject (Cambridge University Press, Oxford University Press, Macmillan, etc.)

5. CONCLUSIONS AND RECOMMENDATIONS

This paper attempted to give an overview of the state of English language learning and teaching in Europe and our country. It also defined some important terminology and trends in current studies in the field. Since it was pointed out that English language learning is very important in order to provide students with greater mobility, help them apply for and get scholarships for further education at some of the European universities and gain practical experience which could then be further implemented, it is of utmost importance to continue work on and improvement of the state of English language learning in our country and our universities.

Having seen an overview of how present English is as a course at our faculties, we can see that the majority of them have appropriate and sufficient programmes, but that there is also room for improvement. ESP is the most common approach and should be further implemented, in order to enable students for future efficient work in their field of interest. Also, EAP (English for Academic Purposes) needs to be further developed so as to enable young academics to have a better access to foreign literature and enable them to be able to participate in international academic environments.

The Faculty of Organizational Sciences is among the faculties which have recognized these trends. They also have classes in English language which provide students with sufficient knowledge so that they could be able to participate in international programmes later on during their studies. This aspect of studies could be further improved through a closer cooperation of the English language teachers and the lecturers of respective courses, in order to deliver as better courses as possible. This cooperation could lead to the implementation of CLIL (Content and Language Integrated Learning), which would be the first such case at Belgrade University, and the best possible way of preparing our students for further education abroad and employment in the modern business world.

MAPPING STUDENTS' INFORMAL LEARNING USING PERSONAL LEARNING ENVIRONMENT

Jelena Anđelković Labrović¹, Aleksandar Bijelić², Gordana Milosavljević³

¹University of Belgrade, Faculty of organizational sciences, jeca@fon.bg.ac.rs

²PhD candidate at University of Belgrade, Faculty of organizational sciences, bijelic@fon.bg.ac.rs

³University of Belgrade, Faculty of organizational sciences, gordana@fon.bg.ac.rs

Abstract: *Personal learning environments represent widely spread ways of learning, especially for informal learning process. The aim of this research is to identify the elements of students' personal learning environment and to determine the extent to which students use modern technologies as a part of their non-formal learning. Mapping system for gathering data and analysis of percentages and frequency counts were used for data analysis in the SPSS. The results show that the students' personal learning environment includes the following elements: Wikipedia, Google, You Tube and Facebook in 75% of all cases, and an interesting fact is that all of them belong to a group of Web 2.0 tools and applications.*

Keywords: *Personal learning environment (PLE), informal learning, lifelong learning, students*

INTRODUCTION

In industrial age a person has been educated to be able to work in one type of job, and was expected to work in same conditions and in the same manner during his whole life. In modern world, a person must continuously invest in acquiring new skills and knowledge, and constantly work on improving his value on today's global market. To achieve this requirement person has to be able to learn, adapt and re-learn the things he learned just couple of years ago. Therefore, lifelong learning has become an integral part of our lives and our way of learning. In accordance with requirements of modern working environment, it is necessary to prepare students to adapt to usage of modern information and communication technologies (ICT) in the workplace. Therefore, students need to get used to using ICT more during the studies. The aim of this research is to identify the elements of students' personal learning environment and to identify the extent to which students use modern technologies for learning as a part of their non-formal learning.

1. DEFINITION OF LIFELONG LEARNING

Marick and Vatkis define learning as "the way in which individuals or groups acquire, interpret, reorganize, change or assimilate a related cluster of information, skills and feelings. It is also primary to the way in which people construct meaning in their personal and shared organizational lives". (Marsick & Watkins, 1990, p. 4)

According to Rubenson, European Union, the OECD and the UNESCO proclaimed three fundamental attributes in 1976 that lifelong learning is based on: (Rubenson, 2011)

- it is lifelong and therefore concerns everything from cradle to grave,
- It is life-wide recognizing that learning occurs in many different settings, and
- It focuses on learning rather than limit itself to education.

Lifelong learning is mostly recognized as its one segment - adult education. The contemporary literature does not mention classification of education but in fact the classification of learning, as a base of educational process. The distinction has been made between three categories of settings where purposeful learning activity takes place (European Commission 2000): (Rubenson, 2011)

1. Formal learning. This learning typically takes place in an education or training institution; Formal learning is structured, institutionally sponsored, often classroom-based, with an instructor or trainer planning, implementing and evaluating the learning taking place (Conlon, 2004); it is structured (in terms of learning objectives, learning time, or learning support) and leads to certification. From the learner's perspective, formal learning is intentional. (Rubenson, 2011)

2. Non-formal learning. It is learning that typically does not lead to certification and is not provided by an education or training institution. It is structured (in terms of learning objectives, learning time, or learning support). Non-formal learning could take place in working environment. From the learner's perspective non-formal learning is intentional. (Rubenson, 2011)
3. Informal learning. Informal learning is learning resulting from daily life activities related to work, family or leisure. It is not structured (in terms of learning objectives, learning time, or learning support) and typically does not lead to certification. It may be intentional, but in most cases it is unintentional, incidental or random. (Rubenson, 2011) Other definitions of informal learning by Marsick and Volpe (1999) conclude it is an integration of work with daily routines, triggered by an internal or external jolt, not highly conscious, is often haphazard and influenced by chance, inductively occurs through action and reflection, and is linked to the learning of others. (Conlon, 2004)

Marsick and Watson emphasize that there is a difference between informal and incidental learning. Informal learning is mostly experiential and non-institutional. It differs from formal learning by degree of control exercised by the learner, location (not classroom-based), and predictability of outcomes. The examples of informal learning are self-directed learning, networking, coaching, mentoring, performance planning and trial-and-error. Incidental learning is unintentional, a byproduct of another activity. It differs from formal because it is a subset of informal learning. The examples of incidental learning are: learning from mistakes, assumptions, beliefs, attributions, internalized meaning constructions about the actions of others, hidden curriculum in formal learning. (Marsick & Watkins, 1990, p. 7)

Different researchers use non-formal as informal learning, and informal as incidental learning. It is not possible to state with certainty that during the non-formal and informal learning, incidental learning does not happen. In this paper we address non-formal, informal and incidental, collectively as informal learning. We analyze informal learning as a type of learning that occurs in the learning process using personal learning environment (PLE).

Within this paper we observed the informal learning using contemporary information and communication technologies (ICT), in the Web 2.0 environment. We wanted to assess to what extent particular Web 2.0 learning tools are used in a student's PLE on the course E-Learning at Faculty of Organizational Sciences.

2. PERSONAL LEARNING ENVIRONMENT

Personal Learning Environments (PLE) is term used to define new approach in a way how the learning is transformed through a range of new technologies and Web 2.0 platforms which are currently available to us. It can be best described through the 3P Learning model which encompasses three core elements: Personalization, Participation and Knowledge-Pull (Chatti, Jarke, & Specht, 2010). We could try to define PLE as unique personal digital interface which integrates both personal and professional interest of individual including formal and informal education.

According to V. Teemu and H. Stina the main idea with PLE „is to put students in central position in the learning process by allowing them to design their own learning environments“ (Valtonen, Hacklin, Dillon, Vesisenaho, Kukkonen, & Hietanen, 2012). It is not considered as software application or technical approach to learning „but rather as philosophical, ethical and pedagogic approach“ (Attwell, 2007), which should foster students to exercise their capacities as autonomous learners within a structured context. Through personalization students should be able to handle huge amount of information, while still keeping the „head above the water“, to avoid information overload (Eppler & Mengis, 2004) and efficiently adopt required knowledge.

Starting from definition of PLE we gave at the beginning of this document, concept of PLE will define the environment through which individual learner will be able to search information and adopt knowledge, while at the same time contribute to the others in their own learning environment through sharing research and knowledge.

Web 2.0 platforms allow individual learners to gather information from different sources and chose to adopt them in order which he personally feels is the best way for him. Structured approach to this information gathering is enabling to leave undesired or unnecessary information aside, and only focus on „quality sources“ which are preferred or desired. While individual PLE can exist and be efficient at some point, true value of PLE comes from existing interactions between the individual learners who can form a network of readers and contributors with highly loose network structure.

One of the commonly accepted ways of representing PLE is through visual diagrams also called mappings (Leslie, 2011). They are enabling learner to easily “map” different areas of learning, segmented through different streams of information, that can be further dissolved to different sources of information, in thus way easily documenting structure of data and information which are acquired by learner.

2.1. Characteristics and functions of PLE

Avoiding “holy” debate which is lead around PLE regarding what are the distinguishing characteristics of Personal Learning Environments that should uniquely define PLE, one of the first views on the PLE model we consider today was created by Scott Wilson in 2005 (Wilson, 2006), followed by Stephen Downes (Downes, 2006).

According to the work I. Buchem, G.Attwell and R.Torres we could easily define necessary characteristics of the framework which could be consider as PLE (Buchem, Attwell, & Torres, 2011):

- Support to open interoperability standards of Web 2.0 to receive and share materials from different data's and sources
- Grouping tools to blocks and fundamental groups of elements
- Learner centered – supports establishing rules and learning strategies, based on learners individual preferences and learning needs,
- Controllable and managed - learner chooses level of aggregation, different formal and informal sources,
- Establishing knowledge management – annotations, archiving, searching, filtering,
- Different roles with peers (learner, teacher, expert...)

2.2. Advantages and disadvantages

One of the key advantages that PLE offers is its fully open framework which gives ability to connect to any source of information, and quite quickly have learner receive lots of quality information from all over the world. Span of information sources is limited only by the learners desire to seek new sources, and his ability to fluently understand different languages. As stated by S. Downes in this manner the learning in PLE is about developing capacities (not competencies, skills, etc.) and the outcome of personal learning is engendered through empowerment (S. Downes, 2010).

The main issue however stays how to control the quality level in order to cut through received information and distinguish only the quality one.

While learner can start just by goggling the term and searching for authors in the field to gain quick results, it could easily turn into unstructured learning which in the end will fail to deliver desired outcomes. Because of this it is really important for a learner to approach establishing the PLE in a structured manner.

2.3. Establishing the Personal Learning Environment

The only real requirement for a PLE to function is full and constant access to internet in order to acquire data and information defined inside PLE structure. While there are certain possibilities to establish PLE that uses internet in limited manner (timely limited access, dial up, and firewall closed access), the nature of Web 2.0 with such vivid dynamics of information flow is making this almost impossible. Besides internet access the next required things is to prepare and document goals and areas of interest before learner starts receiving information.

Simple steps to start individual PLE could be identified in three simple steps:

1. **Identify three things which you are required/would like to learn.** In order to avoid information overload and efficiently gather the information, it is important for a learner to specify areas or terms which he would like to learn. Due to the danger to “walk of the path” in an information jungle it is of good advantage to have learner identify maximum three items or areas for which he would like to develop PLE.
2. **Identify three sources which are acceptable for learner.** Based on technologies and connection available, as well as learning habits, learner should identify up to three sources of information for each area. Decision is often influenced by the platforms already provided to learner (company, university, closed club, etc) or learner is supposed to establish on its own. In this step it is important that the learner is not making any concrete steps in establishing sources or access just to identify the sources (e.g. RSS feed, Facebook, Twitter, Slide Share, Netvibes, and Wikipedia, etc).
3. **Document defined PLE.** Documenting the PLE is one of the most crucial parts in establishing the PLE, due to the fact that this will allow learner to see information flow in structured manner, and easily decide if it should be redefined or adjusted. It could be done by handwriting, or through sophisticated visual tools (Mind Manager, Visio, PowerPoint etc), and while the form itself is not so much important, detailing the flow of information is the key element. Lack of documenting could either establish PLE which would flood the learner with too much information, or it would reduce the chances to correctly add new sources of information, which would in long run limit his knowledge environment.

3. RESEARCH

Research objectives:

1. Determining what tools that students use in their everyday life they perceive as learning tools.
2. Identifying key elements of a student's personal learning environment and fundamental groups of elements that student's personal learning environment consists of.
3. Determining the average student's learning environment.

Main research questions:

1. What are the elements that students perceive as part of their PLE?
2. What are the fundamental groups of elements of a students' PLE?
3. What are the key elements of students' PLE?
4. How does an average students' personal learning environment at FOS looks like?

Research method

Students were given an assignment as a part of their “E-learning” module at Faculty of organizational sciences (FOS). For the assignment, each student was required to design his personal learning environment in a form of mapping activity. The students had to submit a document in which they had to draw their PLE diagram. In other words, they had to map all elements which they perceive as part of their learning environment according to examples that were given during the lectures and in the guidelines. Example of students' PLE is presented in Figure 1.

Guidelines were developed to assist students in understanding concepts of personal learning environment and to provide examples of PLE diagrams. In examples of PLE diagrams students were able to see what elements could constitute a PLE. For example, some people identified following as elements of their PLE: Web 2.0 tools such as Wikipedia – for acquiring information, YouTube and SlideShare for sharing videos and presentations and Facebook - for social networking. Other people identified colleagues or television as traditional resources for gathering information.

Classical survey wasn't the first choice, we chose mapping because we wanted to find out not only what elements they actually use, but what of them they perceive as a part of their learning environment. Clark at al. cite that mapping system has much advantages because phenomenographic approach (Marton, 1994; Mavers, Somekh, & Restorick, 2001) “is about ‘variation in the ways people see, experience, think about, understand and conceptualize the phenomena they encounter’ and points to the ‘layering’ of the

individual's awareness as they are called to situate phenomena according to these different 'ways of experiencing' their technological world" (Clark, Logan, Luckin, Mee, & Oliver, 2009).

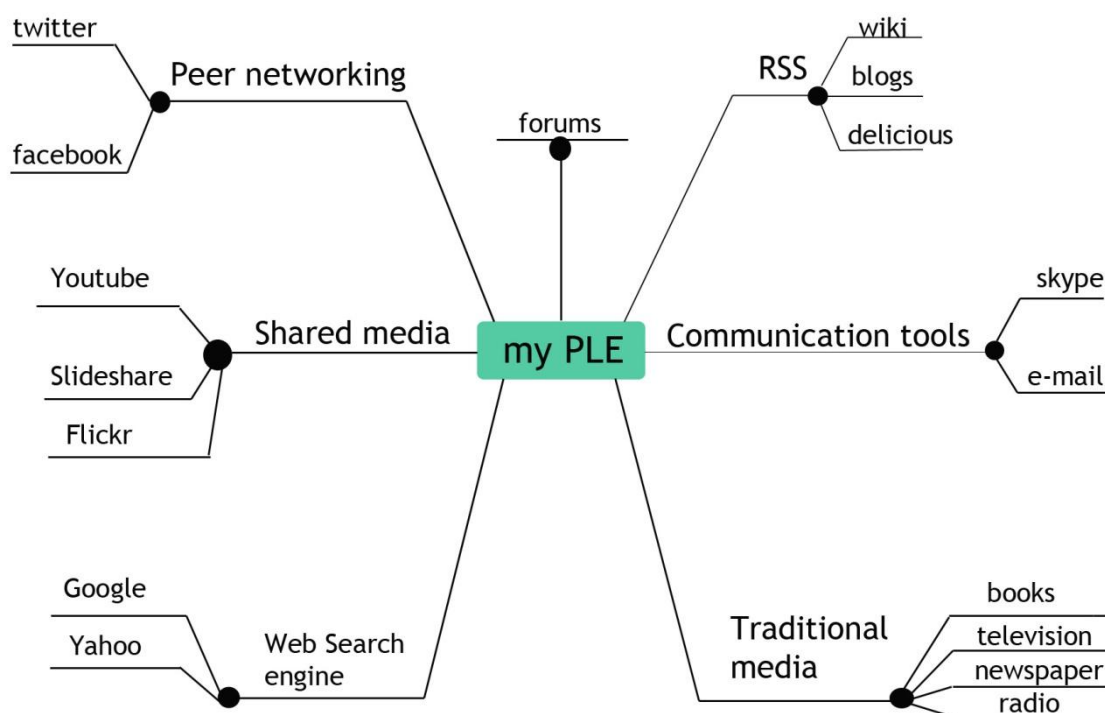

Figure 1: Example of students' PLE

Data Analysis

For further analysis SPSS statistical software was used. Because of the diagram form, data had to be put in form suitable for SPSS. Every element in the diagram was transformed into a YES/NO question.

The example of question design: I use "particular PLE element" for learning. YES/NO.

Example: I use blogs for learning. YES/NO

Collected data were analyzed using percentages and frequency counts for determining the extent in which particular elements, tools or applications are used for learning.

Results

The research was conducted at Faculty of organizational sciences, during "E-learning" module, in the winter semester 2011/2012. The participants were all students of final (4) year of study at a program Information systems and technologies that elected module "E-learning". There were 52 students, 23 male students (44,2%) and 29 female students (55,8%).

The identification of elements that students perceive as part of their PLE is shown in the Table 1. Some students already grouped elements according to their purpose, for example: For Internet search I use..., for communication I use ..., or Traditional tools, Internet tools, etc. According to their grouping system and literature review (Clara & João, 2010), (Tutty & Martin, 2009) (Bartolome, 2008) we identified fundamental groups of elements.

Table 1: Students' PLE: elements and groups of elements

PLE elements	Grouping - phase one		Grouping phase two

TV/Radio	TV/Radio		
Books	Books		
Faculty (teachers/assistants)	People (communication)		
Family and Fiends			
Colleques			

Figure 2: Students' learning tools

After listing all the elements that students perceive as part of their learning environment, we used frequency counts to identify what are the elements that are mostly used among students (Figure 2). As key elements we identified: Blogs, Wiki, Shared Media, Social Networking and Microblogging services, Web Search Engines, Forums, Online communication and Books, because in more than 50% of cases students identified them as elements that they are using for learning.

More than 80% of students use:

1. Wiki – 96,2% of students use Wikipedia.
2. Web Search Engines - 94,2% of students use Web Search Engines: 88,5% use Google, 25% use Yahoo and 15,4% use Google Scholar.
3. Shared Media - 90,4% of students use Shared Media: 84,6% use YouTube, 11,5% use Slide Share, 9,6% use Flickr and 3,8% use Podcasts.
4. Social Networking and Microblogging services - 88,5% of students use Social Networking or Microblogging services: 76,9% use Facebook, 28,8% use Twitter, 13,5% use Google+, 7,7% use LinkedIn and 5,8% use MySpace.

Regarding the question of an average students' personal learning environment, we concluded that in 75% of cases a students' PLE include the following elements: Wikipedia, Google, You Tube and Facebook, and interesting fact is that all of them belong to a group of Web 2.0 tools and applications.

6. CONCLUSION

Throughout this research we concluded that majority of students in everyday life (informal learning process) have not utilised PLE for achieving maximum results even though they have somehow established PLE in certain unstructured form.

After the concluded research we have received positive feedback from students in that they plan to use PLE as a method of supporting their own learning, and that they recognise the value of structuring their PLE.

It would be interesting to conduct further research on faculties which don't have Information Technologies as a major subject area, in order to measure whether there is any impact on accepting and utilising PLE the orientation of students towards technology subjects. It would be interesting to analyze results if the use of PLE and Web 2.0 applications and tools is structured through formal learning at Faculty. Furthermore, it would be interesting to conduct this research at universities in other regions or countries to explore how culture of students, either regional or national, influences the usage and utilisation of PLE.

TAILORING E-LEARNING COURSES USING MECHANISMS FOR ADAPTATION

Dušan Barać¹, Aleksandar Milić², Jovana Dadić³

¹ University of Belgrade, Faculty of Organizational Sciences, dusan@elab.rs

² University of Belgrade, Faculty of Organizational Sciences, milic@elab.rs

³ University of Belgrade, Faculty of Organizational Sciences, jovana@elab.rs

Abstract: *This paper presents an approach to tailoring e-learning courses according to students' characteristics. We introduce sophisticated mechanisms that enable creation, organization and implementation of adaptive courses, based on student model. The main goal of the research is to foster the learning process, as well as students' achievement, by extending Moodle LMS features with services for learning resources and activities adaptation. Business intelligence tools, an expert system and various adaptation techniques were used for developing adaptation services. Adaptation is implemented with respect to three criteria: students' knowledge from the learning domain, students' learning styles and students' interests. The architecture and main features of the adaptation mechanisms are described in the paper. The developed mechanisms for course adaptation were used in the effectuation of the educational process at the Laboratory for E-Business, Faculty of Organizational Sciences.*

Keywords: adaptive e-learning, learning management system, tailoring e-learning courses, mechanisms for adaptation.

1. INTRODUCTION

Systems for e-learning include set of complex processes, different elements, services and users' roles. Users of these systems belongs to heterogenic groups considering their characteristics. At the same time, e-learning systems provide various types of learning resources: tutorials, e-books, scientific articles, etc. Each learning resource is specific and has different way of presentation, content structure, area of study, etc. Number and quantity of education content increases rapidly. In development of an effective e-learning platform one of the most important requirements is to identify users' characteristics and then use the obtained information for creation and realization of educational processes (Aixia & Wang, 2011). Currently, researches show that majority of educational institutions use so called learning management systems (LMS) (Graf, Liu, & Kinshuk, 2010; Graf, 2007). These solutions provide variety of features that enable management of: courses, e-learning activities, e-learning resources, collaboration, etc. LMSs appear to be the best possible solutions for realization of teaching and learning resources (Barać, 2011; Despotovic, Markovic, Bogdanovic, Barac & Krco, 2012; Graf, Liu, & Kinshuk, 2010). LMSs are focused on the support for all processes in e-education (Brusilovsky, 2004; Graf, 2007). Main goal is to enable users to use appropriate services that facilitate organization of teaching and learning processes. At the same time, communication tools such as forums, chats, wikis, etc. improve interaction during courses realization. However, LMSs deliver the same course content to each student, including same course organization, resources and services (Brusilovsky & Millan, 2007; Graf, Kinshuk & Ives, 2010). They do not consider any students' characteristics, such as: knowledge level, motivation, learning styles, expectations, etc. (Essalmia, Ayeda, Jemnia, Kinshuk & Graf, 2010). Managing courses without taking into account these issues very often results in failure (Dekson & Suresh, 2010).

Main goal of the paper is to improve learning process by developing mechanisms for adaptation. These features enable extending Moodle LMS, without need to create new solutions for e-learning. Students should be provided with personalized courses that are adapted to their characteristics.

2. DELIVERING ADAPTIVE E-LEARNING COURSES

Adaptive e-learning courses are emerging issue in the modern e-learning systems (Despotovic et al., 2012). Adaptivity of e-learning courses is reflected in the adaptation of forms of learning materials presentation, methods of communication, interaction, collaboration, organizing pace of courses in accordance with requirements and characteristics of students (Brusilovsky, 2011; Graf, Kinshuk & Liu,

2009; Kock & Paramythis, 2011). Adaptation techniques are (Atif, Benlamri & Berri, 2003; Brusilovsky, 2004, 2011): adaptive interaction, adaptive content delivery, adaptive content discovery and creating, adaptive collaborative support. Two approaches could be noticed in scientific researches within area adaptive of e-learning: developing adaptive web-based systems and extending LMS features. Adaptive web education systems (AWES) have been developed on the basis of theoretical concepts of adaptive hypermedia (Brusilovsky, 2004, 2011; Graf, 2007, Graf & Kinshuk, 2008). However, these systems have a few drawbacks (Brusilovsky, 2004, 2011; Brusilovsky and Millan, 2007; Graf & Kinshuk, 2008). First of all, creation of such systems and their integration into educational process is quite complex and rather expensive process that requires high level of involvement of all users. One of the most common problems is the inability to reuse created learning resources. Basic features of e-education system, such as: administration of courses, learning content, etc., is complex to use in adaptive systems. There are no common services for communication and social interaction among participants in e-education. Second approach, imply using all the advantages of the existing LMSs and enhancing them with personalization features[ref]. This approach is used in the paper. Moodle LMS is one of the most comprehensive solutions that provide numerous functionalities and services (Graf & Kinshuk, 2008, Barać, 2011). Moodle is flexible for implementing new components and integration with other systems and technologies (Graf, 2007).

Personalization parameters

E-learning systems incorporate the concept of adaptivity through the development of a model of a student (Tzouveli, Mylonas & Kolias, 2008). Model of a student includes information about learning objectives, prior knowledge, pace of learning, behaviour, way of interaction and communication (Bruslovsky, 2011; Tzouveli et al., 2008). Student modelling is the process whereby an adaptive learning system creates and updates a student model by collecting data from several sources implicitly (observing user's behaviour) or explicitly (requesting directly from the user) (Bruslovsky, 2011). Most frequent used personalization parameters are presented in figure 1 (Brusilovsky and Millan, 2007).

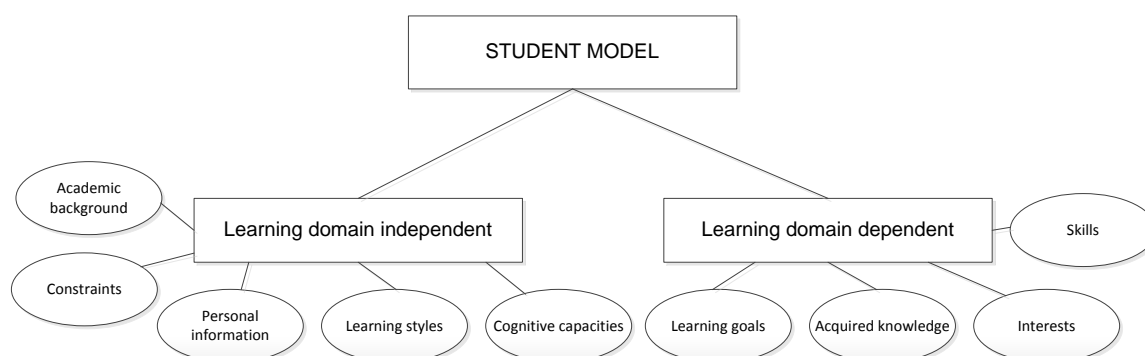

Figure 2: Common characteristics in student model

Four types of the parameters were used for implementing personalized e-learning courses:

- Learning style
- Preknowledge
- Interest and expectation

In order to gather data about these factors, we developed questionnaires and tests. Students' preknowledge is assessed by tests with 20 questions from domain area. Based on test results each student is classified as: beginner, intermediate or advanced. Information about learning goals and expectation are gathered via questionnaire.

There are several different learning style models presented in literature; however, Felder-Silverman Learning Styles Model (FSLSM) is often used for providing adaptability regarding learning styles in e-learning environments (Felder & Silverman, 1988). Felder-Silverman model describes a single student along four dimensions: 1) Active and reflexive learning style; 2) Sensitive and intuitive learning style; 3) Visual and verbal learning style; 4) Sequential and global learning style. Questionnaire to determine learning styles of our students was created by adjusting the Index of Learning Styles Questionnaire (Felder & Silverman, 1988; Mihailović, Despotović-Zrakić, Bogdanović, Barać & Vujin, 2012).

3. DEVELOPING MECHANISMS FOR E-LEARNING COURSES ADAPTATION

Expert system for student modelling

In order to create student model expert system “ELAB” was developed. The system aimed to define attributes that describe each student’s characteristics based on data collected through the knowledge test and questionnaire about learning styles (Buche & Querrec, 2011). Expert system “ELAB” make decision in five steps (Barać, 2011). First four steps are related to four dimension of FSLSM model. Fifth attribute is defined in according to achievement on learning domain knowledge. After selecting student and course, teacher can assign attributes to the student (Figure 2). Firstly, teacher choose a test/questionnaire, i.e learning style dimension and the expert system define the attribute value for chosen criteria.

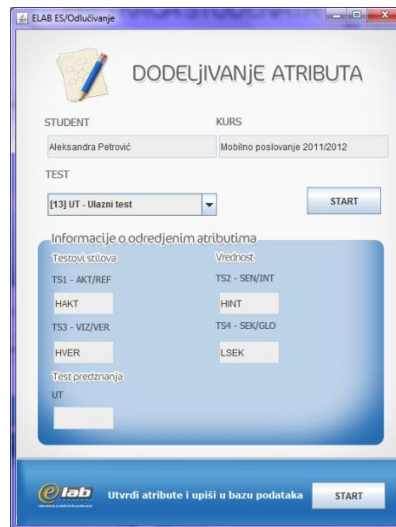

Figure 3: Assigning attributes to a student

Figure 3 presents final output from the system. In the example presented bellow, the expert system concluded that the student is quite active, intuitive, verbal (HAKT, HINT, HVER) and a little bit sequential learner(LSEK). At the same time, the student achieved high result on the knowledge test related to course Internet technologies (id=7).

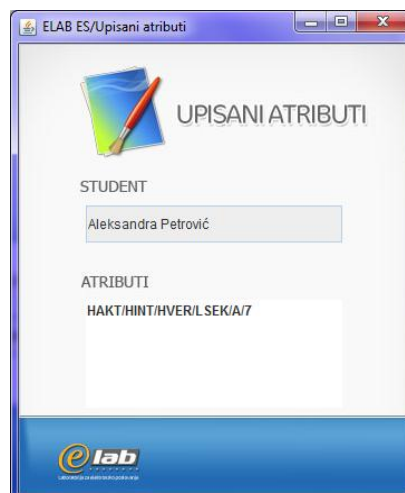

Figure 4: Recorded attributes for a student

Mechanisms for adaptation

When developing the mechanisms for adaptation application, one of the key requirements was not to change Moodle LMS solution core, but to develop application that would be independent of particular LMS. Implementation is realized through following (Barać, Bogdanović, Milić, Jovanić & Radenković, 2011):

- PHP application that implements adaptive mechanism
- New Moodle LMS block and module that would present adapted learning objects and activities
- Extend existing Moodle LMS database by adding new tables

The application was developed using modern programming paradigms. It is flexible, dynamic, service oriented and with rich user interface. Key components are implemented as Moodle modules and blocks and do not require any changes in existing Moodle system. The architecture of the propose solution is presented in figure 4. Within the Moodle LMS, a module and a block for adaptive mode have been created. The module enable adaptation of a: group, student, course, learning resource/activity, collaboration, etc. The application uses existing MySQL database. Adaptation mechanisms get data both from several Moodle tables and student model tables (Expert system outputs). In order to foster adaptive collaboration an SMS service was implemented, as well as an Android application for sending information to students.

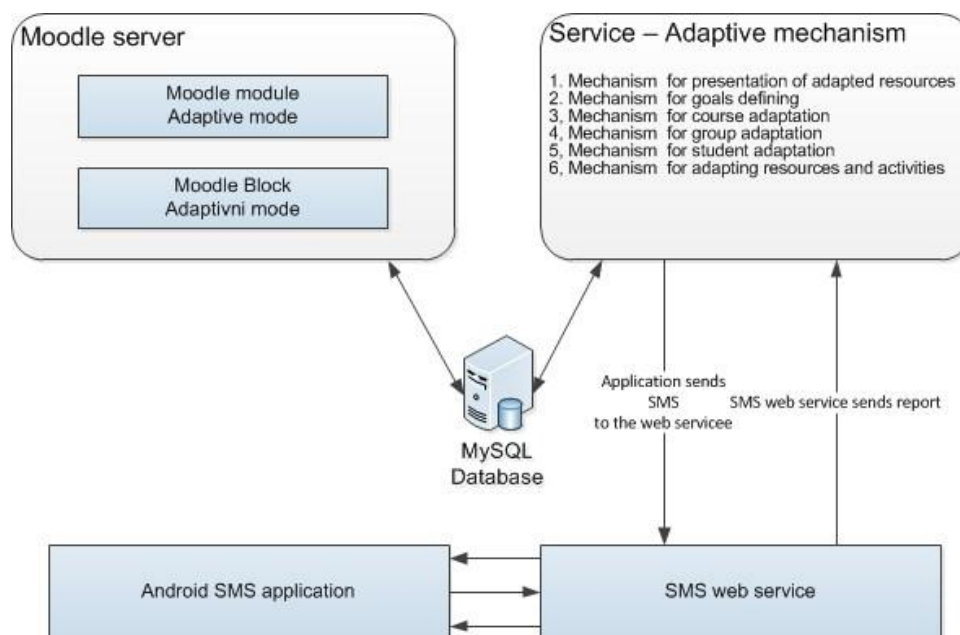

Figure 5: Architecture of the adaptive mechanisms application

Adaptive mode of the course is presented in figure 5. Only learning resources and learning activities that fit student's characteristics are presented to them. In the example, student has low level of knowledge from the area of JavaScript. Therefore, in adaptive mode they are provided by resource „Praktikum“, version adapted to their styles, and introductory test. A student can add Moodle block „Adaptive resources“. Then, only they can see all adapted learning resources and activities within the course.

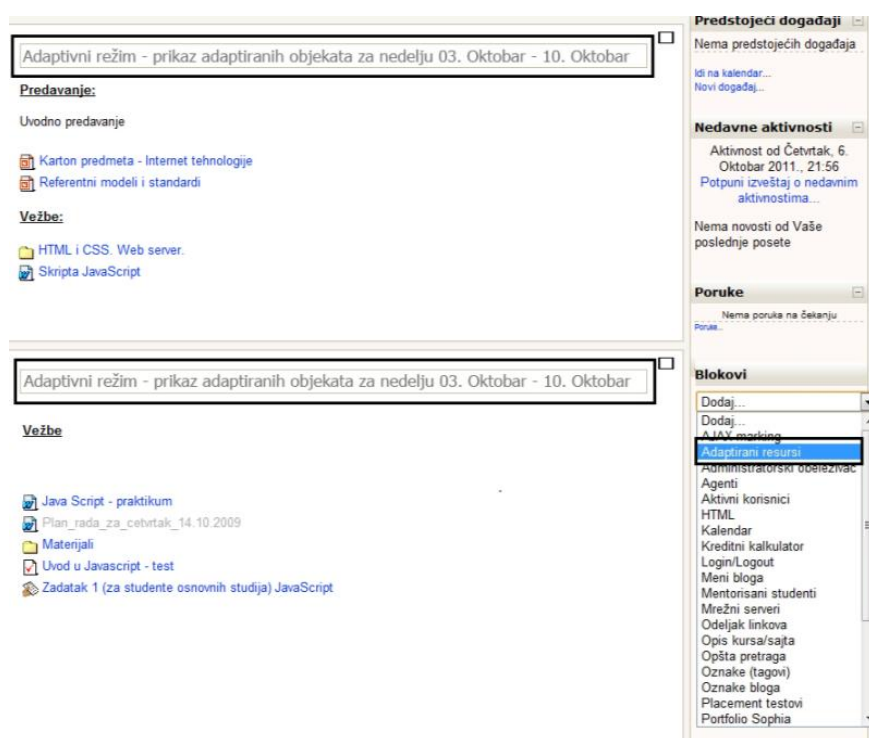

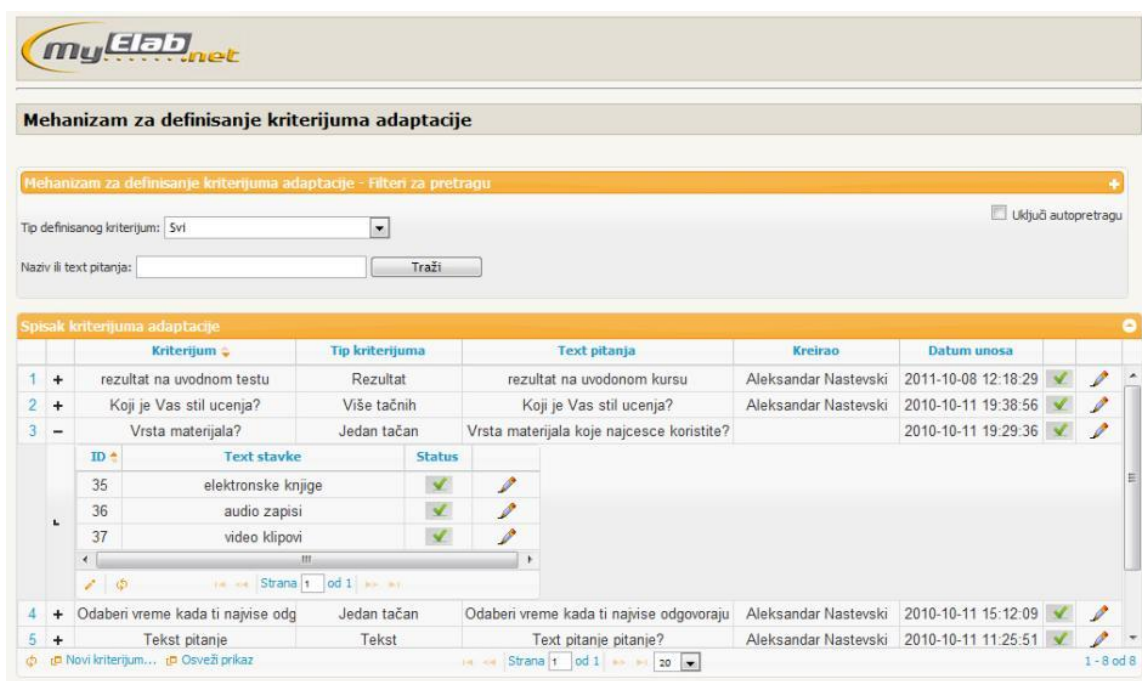

Figure 6: Moodle course “Internet technologies” in adaptive mode

The application enable teachers to add adaptivity to the existing courses. Following features are available to the teachers:

- Creating and defining adaptation criteria
- Adaptation criteria management
- Managing questionnaires and tests
- Learning resource and activity adaptation
- Group personalization
- SMS messages management

Within the application four different type of adaptation criteria could be defined: dynamically created text, number, predefined text, combination of predefined text. Mechanism for adaptation criteria management is shown in figure 6.

Figure 7. Mechanism for defining adaptation criteria

Figure 7 shows an example of defining adaptation criteria that is based on level of knowledge on introductory test. Teacher can set a number of points for each category of knowledge (beginner 0-5, intermediate 5-8, advanced 8-10). When teacher classify learning resources and activities, they can choose for which category of students knowledge it should be presented.

Figure 8. An example of defining adaptation criteria

Further, the mechanisms for adaptation enable group personalization, i.e. learning activities and resources are adapted to the group of students (figure 8.). This type of adaptation can be quite effective and economic when big number of students are enrolled in the course. Teacher can choose criteria that are to be applied in group personalization. For instance, if criteria for group adaptation is FLSM model dimension sequential/global and value of the criteria is GLO, it implies that all the learning resources and activities that are adapted for students with global learning style, will be presented to that particular group of the students.

Figure 9. Group adaptation

Figure 9 shows learning resources and activities adaptation. After selecting course, all the resources and activities from the course are presented to a teacher. The teacher can choose each learning resource/activity and define adaptation criteria to be applied for it. For instance, if adaptation criteria learning style FLSM dimension active/reflexive, value *AKT* is chosen for learning activity *forum*, the forum will be delivered only to student that has active learning style. For each learning resource and activity, more than one criteria can be selected. A learning resource/activity will be delivered to a student only if all the selected criteria are in accordance to the attributes from the student model.

6. CONCLUSION

This paper presented adaptive mechanisms that enable LMSs to generate courses that fit students' characteristics. The adaptation services enable tailoring Moodle courses and features based on data from student model. Adaptation was performed considering three criteria: students' knowledge from the learning domain, students' learning styles and students' interests. Architecture and main features of the adaptation mechanisms were described. Main contribution of the paper is reflected in the fact that proposed mechanisms combine the advantages of LMSs with those of adaptive learning systems by enhancing LMSs with adaptivity.

Evaluation of the system should provide additional information about users' experience in using the system, as well as data about system performances and impact on learning process outcome. Future researches are directed toward improving adaptation mechanisms and automation of adaptation process, as well as complete integration of all processes in adaptive e-learning system. Mechanisms for adaptation could be improved by introducing ontologies and concepts of semantic web. Integration of social networks and developing services for social interaction should improve students' loyalty and motivation for learning

Abstract: *A new vision of higher education system in which the student is the central subject opens up new learning opportunities that include customization and adaptation to students' needs and preferences. Student satisfaction can be increased in this way, and mutual trust will remain intense after graduation as well. Student Relationship Management (SRM) is often applied in order to improve the quality of the administrative process in educational institutions. However, SRM can also significantly improve the teaching and learning process. This paper focuses on these aspects of SRM. In this paper, we present SRM opportunities for the improvement process of e-education. For student relationship we use SugarCRM. We present the teaching and learning process implemented in the described system, the metrics for the evaluation of system performance and the results of using the SRM system within regular activities.*

Keywords: CRM, SRM, ERM, social CRM, e-education

1. INTRODUCTION

Customer relationship management (CRM) has been defined as the management approach that involves identifying, attracting, developing and maintaining successful customer relationships over time in order to increase the retention of profitable customers. The CRM introduction into e-learning is a long and demanding process because students' demands are increasing simultaneously with the growth of technology capability. The steps in the CRM implementation in e-learning field are as follows defining the CRM goal and strategies, adaptation and implementation. From the perspective of the student, the CRM strategy allows interaction with the educational institutions from a single entity that has a complete understanding of their unique status. From the perspective of the educational institutions, the CRM strategy provides a clear and complete picture of each individual and all the activities pertaining to the individual.

A model of improving CRM concept for applying in develop the electron system of education is shown in this paper. The major goal is to improve the current system of e-education by development of methods for managing relationships with students (SRM-Student Relationship Management) based on previously identified needs of the Laboratory for e-business (Faculty of organizational sciences). Application of the developed solutions in the real system of e-education is described in detail in a practical part of this paper.

2. THEORETICAL BACKGROUND

Customer relationship management (CRM) is a coherent and complete set of processes and technologies for managing relationships with current and potential customers and associates of the company, using the marketing, sales and service departments, regardless of the channel of communication (Chen, & Popovich, 2003). CRM is a highly fragmented environment and has different meanings for different people (Sohrabi, Haghighi, & Khanlari, 2010). CRM is endorsed to generate and administer bonds with clients more efficiently through the itemized and precise analysis of customer information utilizing distinctive information technologies (Peppers, & Rogers, 2011). To assess future customer behavior and offer the best possible care, it is necessary to exploit, evaluate and regularly update the company's knowledge about the customer (Wilde, 2011). CRM is therefore understood as a customer-oriented management approach where information systems provide information to support operational, analytical and collaborative CRM processes and thus contribute to customer profitability and retention (King, & Burgess, 2008).

Just as CRM strives to build long-term relationships with customers, employee relationship management (ERM) strives to build long-term relationships with employees. ERM's two main internal user groups are

employees and managers. ERM enables managers to communicate with their teams, align employees with the overall goals of the business, share information and build a common understanding. ERM also offers support to employees through workflow modelling that depicts how tasks should be performed, provision of job-related information and collaboration with colleagues (Buttle, 2009).

Educational institutions are becoming aware that education belongs to the service industry. Students' demands and desires have to be met. Independent learning and teaching is an educational system and consists of sub-systems: a learner, a teacher and a method of communication (Moore, 1973). The integration of CRM into e-learning is a long and demanding process because students' demands are increasing simultaneously with the growth of technology capability. Student relationship management (SRM) is the systematic care of a business relationship between the university and students, where service quality is becoming an ever more interesting question. Student satisfaction can be increased in this way, and mutual trust will remain intense after graduation as well. SRM is a new vision of higher education system in which the student is the central subject of the teaching process opens up learning opportunities that include customization to the student and teaching methods, modes of communication, both between teachers and students and among students themselves (Kumar, 2008).

The steps in the CRM implementation in e-learning field are defining the CRM goal and strategies, adaptation and implementation. From the perspective of the student, the CRM strategy allows interaction with the educational institutions from a single entity that has a complete understanding of their unique status. From the perspective of the educational institutions, the CRM business strategy provides a clear and complete picture of each individual and all the activities pertaining to the individual. Data related to students characteristics and interaction are substantial for SRM. Data should be acquired, stored, analyzed, distributed and applied throughout the educational institution in a timely manner. Educational institutions should consider what data about students are required to support analytics and operational processes. SRM technologies form a fundamental part of any educational institution's application portfolio and architecture. SRM application requirements should be considered as the provision of integrated functionality that supports seamless student-centric processes across all areas of the learning.

Performance measurement is one of the key aspects of managing the SRM system. It's very hard to effectively manage SRM system, if educational institutions don't have insight in functionality of the system. Well defined SRM system metrics increases chances for success through synchronization of processes in an educational institution. This affects on increase of quality of the educational process. The absence of appropriate SRM metrics has bad influence on students' results, communication and satisfaction of their demands. Techniques of performance measurement and system metrics that are described in the literature, put focus on key performance indicators. Some of the authors indicate need of measuring global performances, but they don't offer framework or methods for designing metrics. Additional research is necessary for identification of SRM metrics and overcoming barriers of implementation. Bigger part of literature focuses on analysis and classification of system for performance management, and smaller part to SRM metrics.

SRM must be observed as one entity and system for performance measurement must have global character. Goal is development of system metrics that enables identification of fields for improvement SRM system performance. In this way, educational institution can focus their efforts and achieve better performance. With considering all specificity of SRM system, system metrics should satisfy following criteria: metrics is based on processes, metrics is defined on all levels (strategic, operative), metrics is synchronized with the strategy of educational institutions, and metrics cover all relevant processes.

Customer or student interactions, conversations, and relationships are what transform CRM into social CRM. Social CRM is a philosophy and a business strategy, supported by a system and a technology, designed to engage the customer in a collaborative interaction that provides mutually beneficial value in a trusted and transparent business environment. Social CRM can provide the tools and strategies for meaningful, accurate customer insight (Greenberg, 2010a). Social CRM is based on the ability of a company to meet the personal agendas of their customers while at the same time meeting the objectives of their own business plan (Garcia-Crespo, Colomo-Palacios, Gomez-Berbis, & Ruiz-Mezcua, 2010). The characteristics of social CRM are (Greenberg, 2010b):

- fully integrated into an enterprise value chain and that includes the customer as part of it,
- customer interactions are encouraged through authenticity and transparency,

- knowledge is utilized in context to create meaningful conversations,
- the company processes are modeled from the customer point of view,
- both information-seeking and information-contributing behaviour are encompassed into the customer business ecosystem,
- resides in a customer ecosystem,
- creating conversation with customer - engaging customer in activity and discussion – observing and redirecting conversations among customers are activities done in the marketing frontline,
- business is an aggregator of experiences, products, services, tools and knowledge for the customer,
- the intellectual property that is created with the customer, partner, supplier, problem solver is also owned together,
- the business is focused on environments and experiences that engage the customer,
- focus of technology is on both, operational and social/collaborative areas and customer is integrated into the value chain.

Success factors have received increasing attention within the literature of CRM. CRM success factors in e-education are (Almotairi, 2009):

- communication of CRM strategy,
- willingness to share data,
- student orientation,
- motivate staff,
- education schedule and plan,
- connectivity,
- monitoring and feedback,
- software customization,
- teacher and student involvement,
- creating of multi disciplinary team,
- student information management,
- student contact management.

3. IMPLEMENTATION OF CRM SYSTEM IN E-EDUCATION

3.1 Model of CRM in e-education

A new vision of higher education system in which the student is the central subject of the teaching process opens up learning opportunities that include customization to the student and teaching methods, modes of communication, both between teachers and students and among students themselves (Kumar, 2008). The advantages of modern information and communication technologies allow to connect students with teachers, as well as students and colleagues in many manners: from communicating via electronic mail (e-mail), talking over the Internet (chat), maintenance of electronic conferences (forum), teaching in an electronic classroom (e-classroom).

SRM aims to build mutually beneficial relationships with student at segment, cohort or individual level. A fundamental approach to achieving this goal is to customize the value proposition in order to attract and retain targeted students. SRM aims to fit the offer to the requirements of the student. Customization has both cost and revenue implications. It may make strategic sense because it generates competitive advantage and is appealing to students, but there may be serious reservations because of the costs of customization. Educational institutions need to ask whether investment in customization will generate a return higher than they could achieve through other strategies carrying a similar amount of risk (Buttle, 2009).

The following figure shows the influence of CRM in an educational institution (David, 2005).

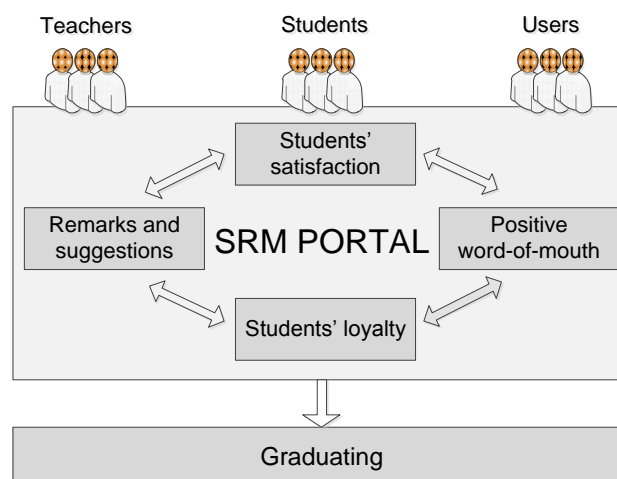

Figure 12: Influence of CRM in an educational institution

Figure 1 shows significant of good communication between educational institution and teaching staff with students. Node of communication processes in an educational institution represents a portal which access is enabled for teachers and students, and other users. Students' satisfaction with educational system of the institution where they study, positively affect on their attitude toward that institution. Students' loyalty toward educational institution decreases/disappears if they decide not to continue their further education at the institution (postgraduate study). The dissatisfaction of students and lack of loyalty toward educational institution may arise as a result of not taking into account their suggestions and opinions on possible improvements of the educational process, by the teaching staff and the management of educational institutions.

The educational institution must take proactive approach in creating a student relationship management. The SRM vision should be used as the guide to the creation of a SRM strategy which is all about how to build and develop a valuable asset: the student base. It must set objectives and metrics for attaining that goal. It directs the objectives of other operational strategies and the SRM implementation strategy. The student experience must be designed in line with the SRM vision and must be constantly refined, based on actively sought student feedback. The relationship with the students needs to be viewed and managed in terms of the student life cycle and formalized processes must exist to manage that life cycle. Collecting data is important for good relationship and adjustment educational system to the needs of each student, and personalization of educational services.

Successful e-education process should create processes that not only meet students' expectations and support the student value proposal, but also provide competitive differentiation and contribute to a designed student experience. In order to define an adequate set of metrics, we need to identify key processes within the e-education system.

3.2 CRM implementation in e-education

Implementation of CRM concept for improvement system of e-education of the Laboratory for e-business on Faculty of organizational sciences is described in this paper. Large number of courses for undergraduate and postgraduate studies is applied in the Laboratory for e-business. Work of the Laboratory is based on using of modern methods and technologies. Blended learning is practiced, and that is a combination of classic type of teaching in a classroom and teaching using the information and communication technologies. The major idea of work is based on improvement of existing system for communication with students in a system for e-education. A system should provide support for realization postgraduate studies (Master and PhD) as well as monitoring projects where the Laboratory participates.

Software solution SugarCRM is chosen for implementation of CRM concept because the solution is free, open source, easy for using and allows adjustment of functionalities of a system to needs of the Laboratory. Customization and adaptation the system environment to the activities of the Laboratory on Master and PhD studies is performed after installation.

Figure 2 shows schematic presentation of connections between created modules (Courses, Teachers, Master students, PhD students) and existed modules (Accounts, Projects).

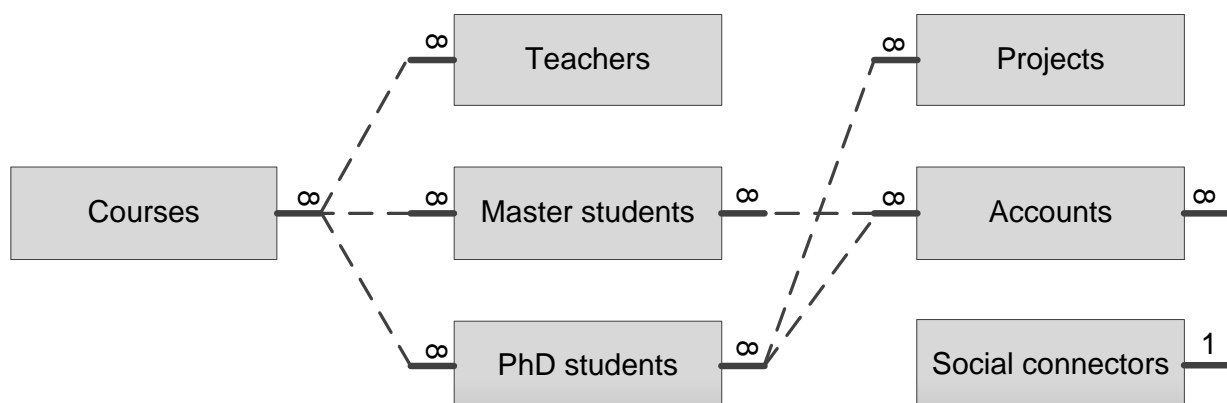

Figure 13: e-Lab's CRM modules

Module for improvement of activities of students on Master studies (Figure 3) contains major information about student - name and surname, ID number, department, e-mail, phone number, address and the module enables writing additional comments (remarks, suggestions, topics of final paper, notes, etc.). It is possible to get information about employment status of students and a company where they work on the social network LinkedIn through the module (Figure 4).

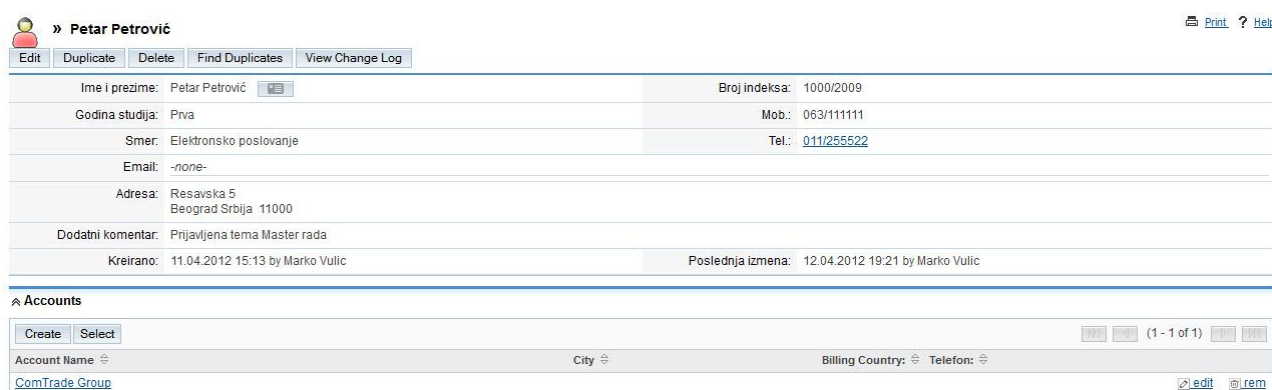

Figure 14: Master studies module

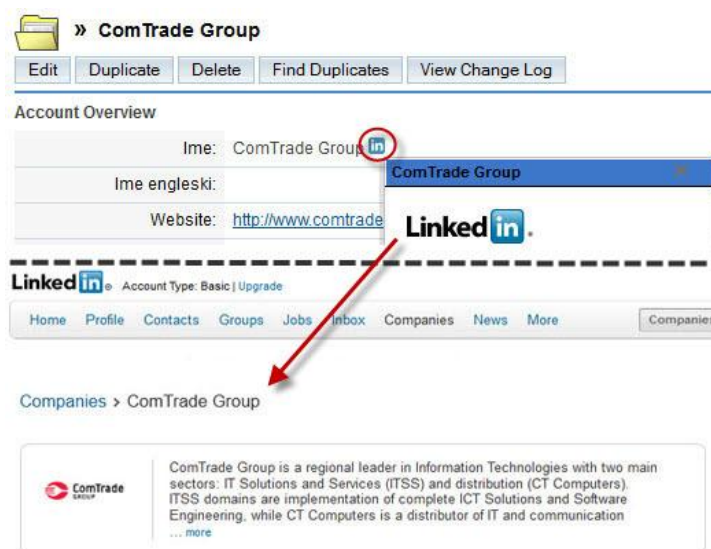

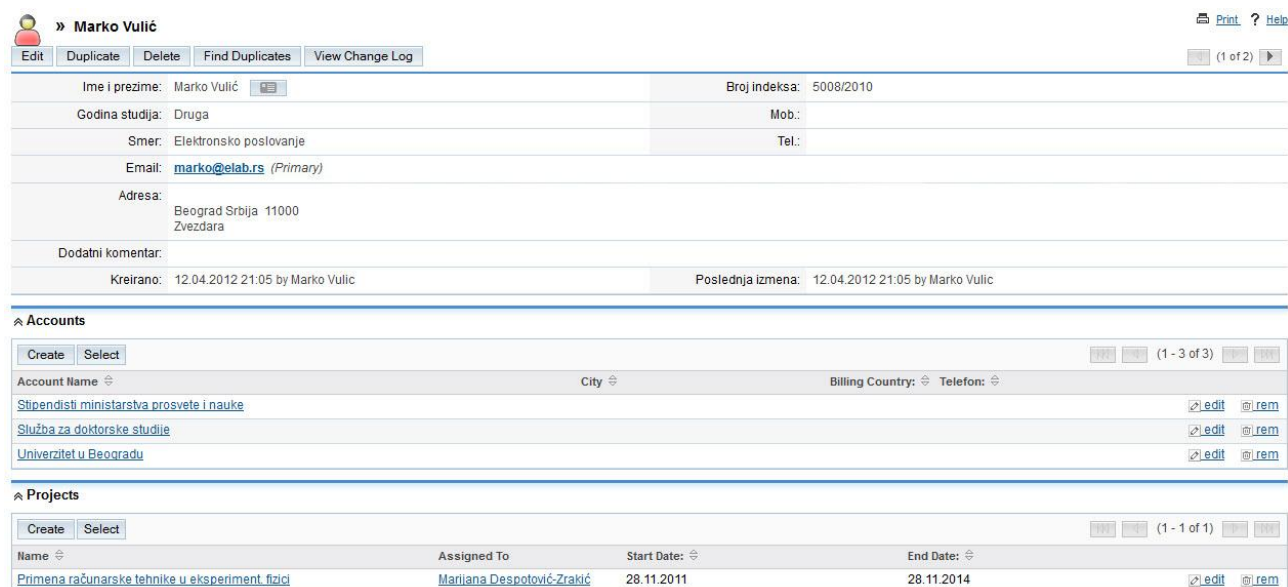

Figure 15: Company profile in LinkedIn

Figure 5 provides major information about a PhD student (department, years of study, e-mail, etc.) and thanks to the synergy with other modules, we get detailed information about a student from CRM data base of a student's service such as Ministry of Education and Science Republic of Serbia. CRM student profile enables viewing the data about activities related to project financed by the Ministry. The student's progress in activities is tracked by a mentor assigned by the Laboratory. CRM student profile also informs about educational meetings where the Laboratory participates.

Figure 17: Projects module

A module (Figure 7) was created in order to planning, organizing and implementation educational activities, i.e. courses. It provides information about subject teachers besides general information about courses. The goal is to raise a relationship management system between students and educational institutions on a higher level in a simple and quick way by availability and exchange of information to students.

4. CONCLUSION

The customer relationship management system is seen by educational institutions as a tool for more effective management of communication. The educational institutions that use the CRM are able to automate activities such as generating and sending e-mails, responding to student requests for a particular type of information, etc. The system based on maintaining relationships with students, the prospective students and the graduates represents the imperatives of competitiveness.

CRM metrics not only gauge the level of success, but also provide the feedback mechanism for continuous development of strategy and tactics. CRM metrics must follow and measure the enterprise's own CRM strategy. A hierarchy of metrics is required, depending on their purpose and who is using them.

We used SugarCRM in order to improve the development of higher education institution. The main goal was to emphasize the advantages and constraints of applying CRM in education. The future research directions include the further development of CRM infrastructure for student relationship management that can be shared, and organized for educational, scientific and research purposes.

Abstract: *The subject of this paper is the application of mobile services to working with distributed learning resources in the cloud. The goal of this paper is to introduce new services to students which will enable more convenient learning in the cloud computing environment. We have developed an Android application which enables the usage of cloud computing resources by students, who can make reservations of desired learning resources. The developed application is integrated with previously developed web services and with Moodle. The application is deployed within the e-learning infrastructure of the Laboratory for E-Business at the Faculty of Organizational Sciences in Belgrade.*

Keywords: *e-learning, cloud computing, mobile application, virtual machine, Android*

1. INTRODUCTION

Using information and communication technologies in the teaching process is inevitable nowadays. A large number of universities all around the globe use systems for e-learning. A number of users and quantity of available teaching materials in these systems are increasing and distance-learning systems are becoming more complex, thus it is needed to provide more advanced and more scalable IT infrastructure. The second issue is providing virtual machines for heterogeneous software running on different operating systems. For exceeding these problems, introducing cloud computing infrastructure is one possible solution.

Cloud computing infrastructure management is a problem which can be solved by developing an application. Laboratory for E-business at the Faculty of Organizational Sciences in Belgrade developed an application ELABCloud for cloud management. The application is designed for administrators of cloud computing infrastructure as well as to students which represent end-users of the system. The application consists of two main parts, which are web application and mobile application. In this paper, the mobile application will be described in detail.

2. TECHNOLOGIES USED FOR DEVELOPING THE APPLICATION

Mobile technologies are handheld IT artefacts that encompass hardware (devices), software (interface, applications), and communication (network services) (Jarvenpaa & Lang, 2005). By the end of 2011, it is estimated that there are more than 86 mobile subscribers per 100 inhabitants in the world (Free Statistics, 2011).

Service-oriented architecture represents a set of principles which permit developing of distributed applications (Vescoukis, Doulamis, & Karagiorgou, 2012). It includes all aspects of creating and using of business services (Yang, Sun, & Lai, 2011). Service oriented architecture (SOA) delivers application platform which connects business processes with operating resources. It provides interfaces for a new service based on the enterprise semantic and functional demands which are mapped into existing systems.

Web service is software which enables interoperable interaction between devices which are connected to network. Web services can be realized using different technologies. One of possible approaches is using REST architectural style. REST (REpresentational State Transfer) is an architectural style for distributed systems such as World Wide Web (Hamad, Saad, & Abed, 2010). This architectural principle is first defined by Roy Thomas Fielding in his PhD thesis (Fielding, 2000). In REST, all objects are resources with unique identifications. Data can be represented using XML, JSON, HTML or other technology (Wang, Mao, & Cai, 2009).

Realized web services should be scalable and reliable because they need to serve a large number of users simultaneously, which can be achieved by introducing the cloud computing infrastructure. This infrastructure enables working with distributed resources.

Cloud computing is a part of computer science and it enables providing Internet services to external customers via very scalable computing capacities (Sultan, 2010). It is abstracted, high-scalable and controlled computer infrastructure which hosts applications for end-users. Data and services are located in shared, dynamic and scalable set of resources based on technologies of virtualization and scalable application environments (Srinivasa, Nageswara, & Kumar, November 2009).

Cloud computing represents an infrastructure which is able to provide a high value to the distance-learning system, due to its ability to deliver computer resources as a service. One of the most important features of cloud computing is scalability which is enabled thanks to virtualization (Dong, Zheng, Yang, Li, & Qiao, 2009).

There are four types of cloud computing models: private cloud, public cloud, hybrid cloud and community cloud. Roles in the cloud computing are: cloud computing vendor, cloud computing provider and cloud computing customer. There are several approaches, depending on the way of delivering technology to the end-user (Costanzo, Assuncao, & Buyya, 2009): infrastructure as a service (IaaS), platform as a service (PaaS) and software as a service (SaaS).

3. CLOUD COMPUTING INFRASTRUCTURE OF THE LABORATORY FOR E-BUSINESS

Laboratory for E-business at the Faculty of Organizational Sciences in Belgrade conducts a large number of courses for undergraduate and postgraduate studies. These courses include E-business, Internet Technologies, M-business, Concurrent Programming, Internet Marketing and other courses. The Laboratory has been using e-learning concepts since 2001 and the concept of blended learning, which represents a combination of traditional learning and distance learning, is applied at the Laboratory.

Model of implemented cloud computing infrastructure at the Laboratory is presented in the Figure 1.

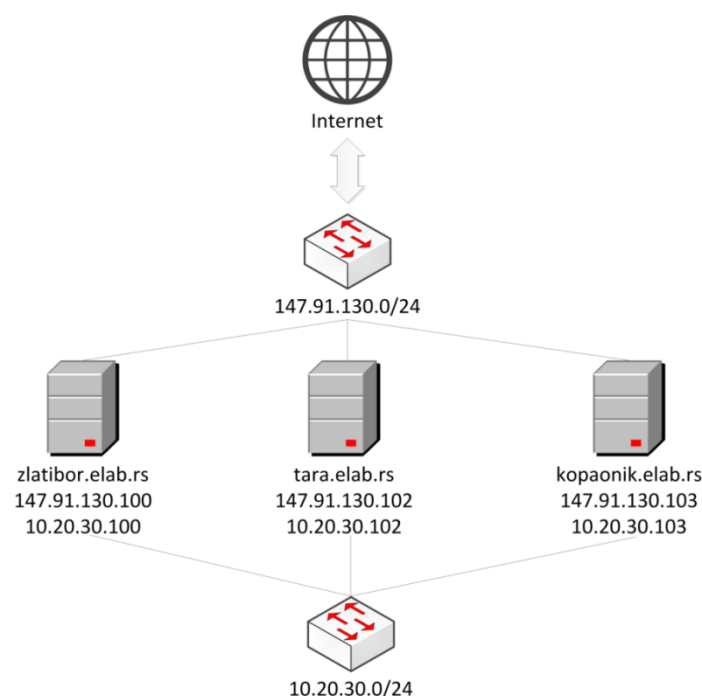

Figure 1: Model of cloud computing infrastructure

Moodle Learning Management System (LMS) is software which has been used in the Laboratory for several years. It permits managing the courses and it is used by schools, universities and individual teachers. Moodle enables publishing courses, teaching materials and assignments to web and tracking the progress of students. It is the core of the IT infrastructure of the Laboratory.

Apache is open source web server software which is used for running Moodle, as well as other web application at the Laboratory. For database management, MySQL server is used.

Subjects which are conducted at the Laboratory require very heterogeneous software packages running on different operating systems. Cloud computing infrastructure provides a scalable environment and it permits running different virtual machines simultaneously. Different system and application software is installed on these virtual machines.

Software OpenNebula is used for deploying cloud computing infrastructure. Currently, the infrastructure consists of three nodes. OpenNebula FrontEnd which controls the infrastructure is installed on one of these nodes. The non-shared storage subsystem is used for managing image repositories. Images are stored on the same server where the OpenNebula FrontEnd is installed.

Each node has a public and a private network interface. Public network interface uses public range of IP addresses assigned to the Faculty of Organizational Sciences (147.91.130.0/24). Private network interface uses private IP addresses (10.20.30.0/24). The main purpose of introducing private network interface is obtaining higher speeds for transferring large images between FrontEnd (where the image repository is located) and cloud nodes.

For delivering SMS services to students, Ozeki SMS Gateway is used. By using web services, it is integrated with other services provided by the Laboratory.

For user management, the Laboratory uses OpenLDAP server. It is an open source implementation of LDAP protocol which enables defining user accounts and roles. Using LDAP is convenient for users because they need to have only one account for accessing to all services which the Laboratory provides.

4. DESIGN AND IMPLEMENTATION

4.1. User request

It is needed to develop an application which is able to manage the cloud computing infrastructure powered by OpenNebula. The application should use OpenLDAP user accounts for authentication. Administrator prepares virtual machines with needed system and application software for taught courses. By using the application, administrator should be able to associate virtual machines to corresponding courses. All students which are enrolled to a specific course should be able to make a reservation for desired virtual machines. During the process of making a reservation, students should be able to choose a virtual machine they need as well as date and time when they want to use the virtual machine. Students should be able to make a reservation using their web browser or Android-based mobile devices. When previously reserved virtual machines are ready, students should receive SMS notifications. Remote access to virtual machines should be provided only by using a web browser.

4.2. Architecture of the application

The architecture of the application is shown in the Figure 2.

Figure 2: The architecture of the application

Administrators can access the application only by using their web browsers. End-users (students) can access the application using either their Android-based mobile devices or web browsers. End-users can also be notified about their learning progress via SMS messages. The application is based on REST web services. This approach permits developing mobile and web applications simultaneously, using the same infrastructure and the same data sets.

Web service enables integration of heterogeneous components, which are OpenNebula, Moodle LMS, MySQL database, OpenLDAP and Ozeki SMS Gateway. The main part of the web service is integration with OpenNebula software, which is responsible for managing the cloud computing infrastructure. OpenNebula provides its own application programming interface (API), which permits managing the cloud computing infrastructure from any other application. OpenNebula API uses XML-RPC based web services which can be used for invoking remote methods. Our web service uses OpenNebula's functionalities related to displaying all images for virtual machines in the cloud, as well as starting and stopping virtual machines.

The other principal functionality of web service is integration with Moodle LMS. Web service communicates with Moodle LMS using its built-in web services based on REST architectural style. This kind of integration enables fetching the list of students which are enrolled to the specific Moodle course.

User authentication subsystem is realized by using the LDAP protocol. User accounts are stored on the OpenLDAP server. LDAP authentication enables having a unique username-password combination for accessing all services. Same authentication data can be used for logging into Moodle LMS, this application and any other future services provided by the Laboratory.

MySQL server is used as a database server. Different data needed for the application are stored into the database, including the data related to reservations of virtual machines and data related to virtual machines that were previously enabled by administrators.

Web service is also integrated with Ozeki SMS Gateway, which permits sending SMS notifications to students. The computer where Ozeki SMS Gateway is installed is connected to GSM modem, which permits sending the messages.

4.3. Designing and deploying web application

There are two user roles in the web application: administrator and student (end-user). Use cases for administrator are following: displaying main settings, displaying running instances and modifying available virtual machines. Use cases for students are following: displaying available virtual machines, making

reservation of a virtual machine, displaying previously made reservations, displaying running instances, remote access to an instance and displaying Moodle courses.

After successful authentication, administrator can view system settings.

Other features related to administrator include displaying all running instances of virtual machines and displaying and modifying virtual machines.

Administrators make a choice which course they want to change available virtual machines for.

System displays a form for modification of enabled virtual machines for selected course (Figure 3). Administrator chooses which virtual machines are going to be available for desired course and confirms the entry.

Figure 3: Enabled virtual machines

System informs the administrator about the change.

Similarly, if students are logged in, they can choose an option for making a reservation for a virtual machine. After choosing a desired virtual machine, they should choose a date and time when they want to use virtual machine and a period of duration in hours.

Finally, if a student is logged into the application at the time defined for a previously made reservation, it is possible to invoke a remote access to a virtual machine choosing an appropriate option (Figure 4).

Figure 4: Remote access to a running virtual machine

4.4. Designing and deploying mobile application

After the analysis of user's requirements, following use cases were identified for a user of mobile application: login, making a reservation of virtual machine, making a reservation of virtual machine by scanning a QR code from Moodle LMS, displaying previously made reservations and log out. In addition to the use cases related to the mobile application, it is needed to implement SMS mobile services which are able to send a reminder to students at the time when reserved virtual machines are scheduled to run.

Mobile ELABCloud is developed for Android platform 2.2 or later. Main menu of the mobile application is displayed after successful authentication (Figure 5). Using the mobile ELABCloud application, student can make a reservation of any available virtual machine and it is also possible to view previously made reservations. This application uses same web services as the web application, thus the integration with Moodle LMS platform is supported as well. Currently, it is not supported to invoke remote access to a virtual machine by using a mobile device.

Figure 5: Main menu of the mobile ELABCloud application

The procedure of making a reservation is very similar to the web application's procedure. After a successful login, the student needs to select an appropriate option from the main menu and then it is needed to select a virtual machine, date and time of availability and duration (Figure 6). The system then informs the student about a successful reservation.

Figure 6: Making a virtual machine reservation via ELABCloud mobile application

The mobile application also permits another way for reserving virtual machines. In each Moodle course where the administrator enabled using of prepared virtual machines, there is a specialized resource in the form of web page (Figure 7). This page displays a list of virtual machines enabled for the current course. For each virtual machine, a corresponding QR code is displayed. QR code represents an ID number stored in the database for that virtual machine. QR code can be scanned using Android mobile devices by choosing an appropriate option in the main menu of the mobile ELABCloud application. After scanning the code, it is necessary to choose date, time and duration for reserved instance of the selected virtual machine.

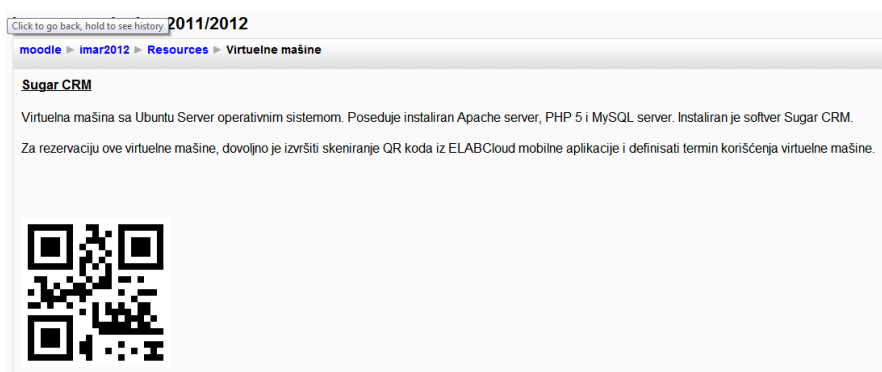

Figure 7: List of virtual machines at a Moodle course

Ozeki SMS platform provides a possibility of sending SMS notifications to students. It is integrated with ELABCloud web services which enable fetching the data about reserved virtual machines and users which made these reservations. OpenLDAP memorizes all data related to users, including their mobile phone numbers. These numbers are used for sending SMS reminders to students. SMS reminder is sent at the time which was scheduled for initiating a virtual machine during the reservation process. The content of a SMS is following: "The reserved virtual machine is now running. Please login to the ELABCloud application to use it."

6. CONCLUSION

Applications of mobile technologies, service-oriented architecture and cloud computing in e-learning were presented in this paper. Application ELABCloud which permits cloud computing resource management using web and mobile access was described. The application integrates OpenNebula, OpenLDAP, Moodle LMS and Ozeki SMS Gateway. REST architectural approach was used for developing web services. Target users of ELABCloud application are students and teaching stuff of the Laboratory for E-business. This application can be applied in other institutions as well. In the future, the application can be improved in several ways:

- Developing mobile applications for other mobile platforms;
- Improving of the integration of application with Moodle LMS and other components;
- Improving of the virtual machine reservation algorithm;
- Developing of a single-sign-on service which uses LDAP directory;
- Creating a module for analytics and statistics.

SOFTWARE SOLUTIONS FOR CLASSROOM-PERIOD SCHEDULE REOPTIMIZATION USING FF AND FFD LOGIC

Zanin Vejzović¹, Aida Brkan-Vejzović²

¹Software Engineering; zanin.vejzovic@unmo.ba

²Operational Research; aida.brkan@unmo.ba

Abstract: *This paper presents software solutions for the mathematical model which deals with university's teaching schedule defragmentation problem. According to the appropriate procedure, the following databases were formed: a database of all coded university courses and a database of the teaching schedule for each university classroom on a weekly basis. Based on the two previous steps the university temporal-spatial matrix is formulated. Then, the flowcharts are defined. Their main subroutines are calculation of a daily occupation parameter for each classroom at the university level, and reoptimization which consists of repositioning period fragments following FF and FFD approximation algorithm procedures. The programs written in C++ were tested at the University "Džemal Bijedić" of Mostar, B&H (56 classrooms, 12 periods and 6 working days per week).*

Keywords: *reoptimization, daily temporal – spatial matrix, bin packing approximation algorithms*

1. INTRODUCTION

School schedule is form of the general scheduling problem. It is defined as a description of movement and grouping of resources in time to achieve appropriate goals that are constrained by a set of conditions. In the general case, there is a set of resources and a set of processes which has to be performed for each of these resources. The resources include students, teachers, classrooms, periods, etc., while processes are lectures carried out by teachers, attended by certain group of students in the classroom of the appropriate type and capacity, in such a way that none of the participants is required to attend two lectures in the same time. Usually, on this basic problem many other constraints are added, such as periods allocated to lectures must be divided by working days of the week, number of lecture attended by students is defined by curriculum, teachers' working hours must not be exceeded, etc. Therefore, it is said that school schedule is feasible if and only if it satisfied its associated set of constraints.

On the other hand, one often deals with cases of improvement (optimization) of existing solution, called reoptimization. In this way, the timetable problem of University "Džemal Bijedić" can be considered. Each faculty for themselves makes lectures' timetable at the beginning of the semester for their classrooms. Exceptions are four university classrooms. Also, there are few cases when certain faculty cedes free periods in their classrooms to another one. So, it is obvious that the main disadvantage is drastically low level of classrooms' utilization at the University level.

However, the classrooms' utilization can be significantly improved if faculty lectures' timetable are considered at the University level. This means, the unification of all faculty timetables in University one, which can be further reoptimized, so, the number of used classrooms at the University level can be reduced. Reduction of the number of used classrooms means less cost to their maintenance as well as maintenance of equipment in them, while on the other hand opens up the possibility of their lease (additional revenue). So, University gets more effective management of available space. Another objective could be better planning for future investments in physical capacity.

In order to reach the goals, a mathematical model already presented in (Humo, & Vejzović, 2007), modified by first fit (FF) and first fit decreasing (FFD) bin packing (BP) approximation algorithms, is used in this paper. Applying it leads to the development of software and its application at the University "Džemal Bijedić" of Mostar.

2. INPUT DATA

In order to study temporal-spatial interaction it is necessary to define a subset of a basic period set on a daily basis for higher education H_d (Humo, 2005). In a concrete case this subset for observed University has been defined as follows: $H_d = \{08.15 - 09.00; 09.15 - 10.00; 10.15 - 11.00; 11.15 - 12.00; 12.15 - 13.00; 13.15 - 14.00; 14.15 - 15.00; 15.15 - 16.00; 16.15 - 17.00; 17.15 - 18.00; 18.15 - 19.00; 19.15 - 20.00\}$.

Temporal-spatial interactions are presented through daily schedules of teaching activities. For University "Džemal Bijedić" of Mostar it is represented by daily temporal-spatial matrix $M(I,J)$. One dimension of this matrix (columns) consists of the elements of subset H_d ($n(H_d)=bd$), while another dimension (rows) consists of the classrooms at the University. So, the row of university spatial-temporal matrix is 56×12 (56 classrooms in which the teaching is performed, 12 elements of H_d subset – bd).

The elements of university matrix f_{ij} ; $i=1, 2, \dots, 56$; $j=1, 2, \dots, 12$, are the course codes with a specific teaching activity performed in a given classroom in a given period.

The above course code consists of six figures. The first digit refers to a department. The following three figures refer to the course of the given department. The fifth figure of the code refers to the type of teaching activity. The last figure indicates the presence of different groups of students having the same type of teaching activity in a given course, but in different time periods. For example, code 800422 indicates the exercises for the second group attending the course Roman Law studied at the Department of Law, as shown in Figure 1.

Figure 1: Course code

It is important to notice that one part of the code – its first digit – refers to a given department (element of the basic set: *departments*), while the following – second, third and fourth figures – refer to a concrete course (element of the basic set: *courses*), for which a specific teaching activity is performed (Humo, 2005). So, the university matrix is not two-dimensional, but four-dimensional, because its elements represent the interaction among elements of the basic sets: classrooms, periods, departments and courses. Introducing teachers (elements of the basic set: *professors*) and students (elements of the basic set: *students*), in a given model (course code), it could even be observed as a six-dimensional mathematical space.

A daily university spatial-temporal matrix, defined in this way, represents the input data for a software solution of its reoptimization, and it is shown by Figure 2.

As far as the proposed mathematical model is concerned, the difference is that the values of its elements are not binary. The values of its elements are 0 if there is no teaching activity in a given period in a given classroom, or they have the value defined by a code if there is a determined teaching activity performed. After loading the university spatial-temporal matrix it is necessary to calculate number of periods q_i for which classroom r_j is occupied and then to form the sequence $QR(I)$; $I = 1, 2, \dots, 56$; where the q_i elements refer to occupation of each single classroom for the working day under consideration.

Additionally, it is necessary to form resulting matrix of daily students' number $SA(I,J)$ (56×12) whose each element $sa(i,j)$ refers to how many students attend lecture given by f_{ij} . Furthermore, it is important to form following sequences: $TU(I)$; $I = 1, 2, \dots, 56$; where the t_i elements refer to type of each single considered classroom (general or special usage, laboratory, etc.), and $RM(I)$; $I = 1, 2, \dots, 56$; whose elements represent number of seats in each of considered classrooms.

Figure 2: University matrix for Monday before reoptimization

3. FF AND FFD REOPTIMIZATION CONCEPT

Usually, the university (school) calendar is used as a base for the time-school problem analysis. First of all, this calendar with opening and closing data, allows comparing educational systems and their capacity and flexibility to meet the needs of students, as well as the other sectors of society. In this context, school time flexibility means a better use of available time, rather than asking for more time. Spatial dynamics of teaching is basically related to the distribution in space of different teaching activities. The greater the variety of these activities exists, the more specialized spaces are required.

Temporal and spatial coordination of different academic activities could be expressed as interactions among the elements of periods and classrooms sets on one side with the elements of the departments, courses, professors and students sets on the other side. Classes, in any given classroom, are scheduled in the course's fragments consisting of one, two, three or more periods. This means that every classroom is occupied during certain fragments of course periods, while in the others it is empty. Therefore, each classroom's daily occupation consists of occupied and empty fragments distributed in a determined way. In general, this distribution is different for each of the classrooms considered.

It is now reasonable to develop the reoptimization (defragmentation) procedure for the occupied fragments which will enable better usage of the classrooms available while maintaining the current time schedule. In order to do this, after identifying the status of all periods (occupied or empty) as well as the occupied fragments (clusters of periods), it is useful to calculate the q_i of each single classroom for the working day under consideration. When q_i are calculated for all the classrooms, the defragmentation procedure or fragments repositioning may start. The course fragments of the classroom with minor values of the q_i should be moved from their original position to the corresponding empty fragments of the classroom with major values of the q_i . When moving fragments from one classroom to another, additional conditions such as classroom size (number of seats) and teaching facilities installed (classroom type) must be respected. In addition, if there are more alternatives (classrooms) satisfying the above conditions, additional criteria, such as location vicinity, curricular similarity, etc. may be introduced.

Now, after main concept of defragmentation is shown, it is reasonable to introduce BP procedures. It was proved that BP approximation algorithms never differ from optimal packing by significantly more than 70 percent and they can on occasion be essentially this bad (Garey, & Johnson, 1990). The classroom's course fragments should be moved from their original position to the corresponding empty fragments of

the classroom with major values of the q_i , considered as objects of BP. This means that object size represents fragment of course periods size which we are trying to move to the corresponding empty fragments of the classroom with major values of the q_i . Meanwhile, other classrooms are considered as bins whose size is equal to number of elements of H_d subset (for University "Džemal Bijedić" it is equal to 12).

After these transformations it is reasonable to use approximation algorithms FF and FFD for defragmentation of spatial-temporal dynamics at university.

FF algorithm starts with classroom r_1 (first row of daily temporal-spatial matrix). First step is to determine first classroom's course fragment size. If it is one-period fragment, then: $f_{1j} \neq 0 \wedge f_{1j-1} \neq f_{1j} \neq f_{1j+1}$. For two-period fragment: $f_{1j} \neq 0 \wedge f_{1j-1} \neq f_{1j} = f_{1j+1} \neq f_{1j+2}$, and for n-period fragment:

$$f_{1j} \neq 0 \wedge f_{1j-1} \neq f_{1j} = f_{1j+1} = f_{1j+2} = \dots = f_{1j+n-1} \neq f_{1j+n}; j+n \leq b_d$$

In general case, for any classroom r_i and any n-period, fragment relation must be satisfied:

$$f_{ij} \neq 0 \wedge f_{ij-1} \neq f_{ij} = f_{ij+1} = f_{ij+2} = \dots = f_{ij+n-1} \neq f_{ij+n}; j+n \leq b_d \quad (1)$$

When relation (1) is satisfied, next step is seeking for "suitable classroom" $r_i \neq 1$, starting with r_2 , in which classroom's r_1 n-period fragment can be allocated. Classroom r_i is suitable if classroom type and number of seats are matched with same parameters for classroom r_1 , r_i must have corresponding empty fragments where classroom r_1 n-period fragment can be allocated, and q_i is greater than or equal to q_1 . So, suitable classroom r_i must meet:

$$tu_1 = tu_i \wedge q_1 \leq q_i \wedge sa_{1j} \leq m_i \wedge f_{ij} = f_{ij+1} = f_{ij+2} = \dots = f_{ij+n-1} = 0; i \neq 1$$

In general, above conditions are:

$$tu_p = tu_i \wedge q_p \leq q_i \wedge sa_{pj} \leq m_i \wedge f_{ij} = f_{ij+1} = f_{ij+2} = \dots = f_{ij+n-1} = 0; i \neq p \wedge j+n \leq b_d \quad (2)$$

Index p in relation (2) refers to classroom whose period fragments are trying to be allocated to the classroom r_i that meets relation (2). In case when relation (2) is not satisfied, next classroom is investigated, and so on. If there is no suitable classroom, same procedure is repeated for next classroom's r_1 occupied period fragment. After classroom r_1 , algorithm shifts to r_2 , then r_3 , and so on to the last classroom r_k , repeating above described procedure.

Of course, if classroom r_i is empty ($q_i=0$) or its all periods are occupied ($q_i=b_d$), algorithm is avoiding it. But, if relation (2) is matched, algorithm allocates classroom's r_1 n-period fragment to r_i , q_i is increasing for n , while q_1 is decreasing for n . After relocation, FF defragmentation is repeated for all period fragments of observed classroom, and for all remaining university classrooms.

FFD procedure begins with sorting classroom's r_1 n-period fragments in decreasing manner. Classroom's r_1 biggest n-period fragment (n_{max}) has a priority for allocating following FF procedure. After it, same procedure is repeating for the next biggest n-period fragment of classroom r_1 , to the last (the smallest) one. When application of FFD algorithm for classroom r_1 is finished, it is applied for all other university classrooms respecting their order in daily temporal-spatial matrix $M(I,J)$. Of course, relations (1) and (2) must be matched for allocation.

4. SOFTWARE SOLUTIONS

Figure 3 shows flow chart diagram for FF algorithm. So, routine begins with classroom r_1 . If it is empty or occupied all day then it has to be excluded ("if $QRI=0$ " or "if $QRI=12$ ").

Counter $BVZB$ follows classroom's occupied period fragment size which is trying to be allocated. It is increased by one when element of matrix M for observed classroom is not equal to zero, and when two contiguous elements are opposite to zero and equal (they have same course codes).

When occupied period fragment is found ($BVZB \neq 0$), subroutine "relokacija FF" (rFF) is seeking for classroom where observed period fragment can be relocated. This means that relations (1) and (2) must

be matched ($QR(K) \geq QR(I)$, $TU(K) \geq TU(I)$, and $RM(K) \geq SA(I, J)$). If these inequalities are satisfied, then time terms compatibility is investigated using variable L . Further on, if these inequalities are met together with $BVZB = BVSB$, relocation counter BR is increased by one, subroutine rFF decreases classroom's q_i whose period fragment is relocated by period fragment size. In the same time, rFF increases occupation of classroom where observed period fragment is relocated for the same value. But, if only one of above conditions is not met, rFF is seeking for suitable free time terms in other classrooms respecting there matrix order. After finishing rFF, above procedure is repeated for other period fragments of observed classroom. When these relocations are finished, routine FF is applied for other university classrooms respecting there matrix order.

In the end, it is necessary to investigate if any relocation was made ($BR=0$). If this is met, FF routine ends, but if it is not, routine goes to beginning and repeats procedure. This is necessary because of the following simplified case: let's take three contiguous classrooms $r-1$, r , $r+1$ (generally, they don't need to be contiguous) which meet these conditions $QR(r-1) \leq QR(r)-1$, $QR(r+1) \geq QR(r)$, $TU(r-1)=TU(r)=TU(r+1)$, $SA(r-1) \leq RM(r)$ and $SA(r) \leq RM(r+1)$. Figure 4 shows that in first step relocation of classroom's r_{i-1} period fragment at position t_{j-1} , t_j , t_{j+1} is not possible. But, in second step, after relocating t_{j+1} period from classroom r_i to r_{i+1} , it is obvious that procedure must be repeated, because period fragment relocation at position t_{j-1} , t_j , t_{j+1} in r_{i-1} classroom is possible to r_i . This is reason why it is necessary to repeat routine rFF until $BR=0$.

Counter *BZL* determines how many occupied period fragments are in observed classroom. *BVZB* counter has same role as in rFF. This means that it determines each occupied period fragment size, and they are elements of *NVZB(I)*. So, observed classroom whose occupied period fragments are trying to be allocated, has *BZL* occupied period fragments that have *BVZB* sizes. It is also necessary to create *NILZ(I)* sequence. Its elements represent matrix *M* column index for observed classroom, where each occupied period fragment starts presented by *NVZB(I)* elements. Now, following FFD algorithm, sequence *NVZB(I)* has to be sorted. In programming, there is lot of different sorting procedures. One of them is used here, and it will not be explained. *SNVZB(I)* is sorted *NVZB(I)* sequence. As *NILZ(I)* elements follow occupied period fragment's positions (presented by *NVZB(I)* elements in matrix *M*), it has to be sorted too. Result is *SNILZ(I)*, which is sorted *NILZ(I)* sequence. Subroutine zFFd is finished, and subroutine "relokacija FFD" (rFFD) starts (right flow chart diagram on Figure 6).

Subroutine rFFD requires seeking for suitable classroom where *SNILZ(I)* elements are trying to be allocated, so that the last element *SNILZ(BZL)* is trying to be allocated (because *NILZ(I)* is sorted ascending), starting with first matrix row *M(1,J)*, to classroom satisfying four conditions: $QR(T) \neq 12$, $QR(T) \geq QR(I)$, $TU(T) = TU(I)$, and $RM(T) \geq SA(I, SNILZ(K))$. If at least one of these conditions is not satisfied, rFFD repeats procedure with next classroom.

In the case that all four conditions are met, it is necessary to determine if classroom *T* is free for period fragment that is trying to be allocated. So, to do relocation, matrix elements *M(T,L)* must be zeros for $\forall L \in [SNILZ(K), SNILZ(K) + SNVZB(K) - 1]$, which means that *BVSB* = *SNVZB(K)* (counter *BVSB* determines free period fragment size in *T* classroom). *QR(T)* is increasing for period fragment size while *QR(I)* is decreasing for the same value, matrix elements *M(I,L)* become zeros and *M(T,L)* becomes course code whose period fragment is relocated for $\forall L \in [SNILZ(K), SNILZ(K) + SNVZB(K) - 1]$, allocation counter *BR* is increasing by one, number of students who attend course is relocated from *SA(I,L)* to *SA(T,L)* after what *SA(I,L)* becomes zero for $\forall L \in [SNILZ(K), SNILZ(K) + SNVZB(K) - 1]$. But, if *BVSB* \neq *SNVZB(K)*, procedure is repeated for (*T*+1) classroom. Subroutine rFFD is repeated for all *SNVZB(I)* sequence's elements (*BZL* times).

When one classroom is finished, rFFD, zFFD and rFFD are repeated for all other matrix classrooms. After all classrooms are investigated, it is necessary to determine if *BR* \neq 0, for the same reason explained by Figure 4. When *BR* = 0, rFFD ends. C++ code for FFD procedure is given by Figure 7.

Figure 7: C++ code for FFD procedure

Figure 8 a and b shows matrix *M* after applying FF and FFD procedures, respectively.

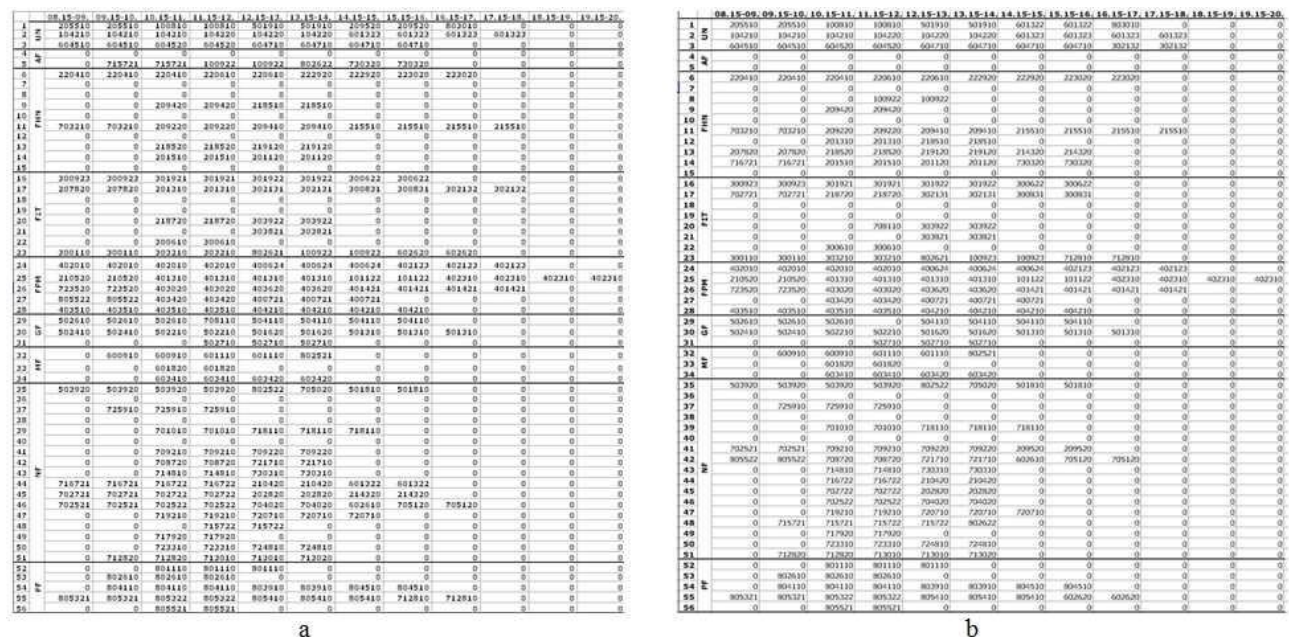

Figure 8: Matrix M after applying FF (a) and FFD (b) procedures

FF and FFD procedures applied in university time table reoptimization are upgraded software solutions of (Vejzović, Humo, 2007).

5. DISCUSSIONS

Now, it is reasonable to make comparison between input and output matrix M (Figures 2 and 8). As a result of school timetable reoptimization the number of empty classrooms is increased: from 5 in input matrix M to 12 using FF, and 10 for FFD solution.

Very interesting comparison of classrooms with maximum of six occupied periods, where empty classrooms are not taken into account, can be done. In that case, 33 of those classrooms were reduced to 23 for FF, and 25 for FFD. Similar situation is for all other working days, which can be seen in Table 1.

Further analysis could be done comparing mornings' and afternoons' periods, where solutions are not helpful due to human factor, because general tendency at University is to complete all teachings to 14.00. So, reoptimized school timetable by FF and FFD solutions can offer more efficiently usage of university classrooms. At the same, it was shown that solutions have practical value.

Table 1: Comparison between input and output matrix M for other working days

STATE	TUE.	WED.	THU.	FRI.
INPUT	≤6	30	28	37
	=0	5	8	8
FF OUTPUT	≤6	17	17	24
	=0	12	16	16
FFD OUTPUT	≤6	17	16	24
	=0	12	16	16

6. CONCLUSION

Today, requests for more time are very frequent in every human activity. These requests are often an insurmountable obstacle. However, the solution lies in better time flexibility, and its better utilization. Furthermore, more regular spatial arrangement of planned instructional activities, can considerable diminish the problem of lack of time. The proper time-space dynamics, not only in the system of higher education, but also in other spheres of human labor such as ports, airports, railways, even in manufacturing, does not represent only saving. It is representing (re)optimization, too. In the general sense, optimization is a way to improve the economic effects of human work.

Further on, presented software solutions have shown that it is possible to increase the flexibility of pre-defined temporal and spatial dynamics of real system of higher education such as University "Džemal Bijedić" of Mostar. Increasing the flexibility of scheduling classes (increasing the number of empty classrooms) at the university, which includes its heuristic optimization with respect to realistic constraints, is also a concrete example of practical application and relevance of these solutions. Thus, solutions are practically applicable, with respect of the real limitations concerning the type of classrooms in which teaching is conducted, their capacity (number of seats), and the size of the group of students (their number) who attend a given class.

Abstract: This paper presents an information system whose task is to improve the quality of teaching and educational and administrative work systems in schools. The advantages of applying an information system based on information and communication technologies in education are: improving the quality of teaching, objectivity in the evaluation of students' knowledge, and transparency, which is reflected in the viewing and access to data and other documents by students, parents, school management, school teachers, sectors in the Ministry of Education and other factors directly or indirectly involved in the teaching process. Another advantage is the mobility of data from the database which is used for statistical analysis and serves to improve the teaching and educational process by increasing the overall quality of educational and training efficiency.

Keywords: education, process, information, system, transparency, objectivity, teaching, quality, statistics

1. INTRODUCTION

The educational process in Bosnia and Herzegovina (BiH) and its surrounding countries is still stagnating on its traditional method which is based on frontal work with students using a piece chalk and a black-board with the lack of use of ICT. The reason for this is inefficient engagement of state sectors, schools' management and teachers themselves. In this type of constellation in the education process it is very hard to lift the level of quality of lecturing, with that the knowledge of students. To improve the education process it is vital to start using an information system in phases. First phase: convince the proficient state sectors in investing in education, second phase: training the teaching staff to use ICT in lectures, and phase three: use of the information system which will in a very short time enhance the quality of teaching.

2. PREPARATION OF A TEACHER FOR CLASS-ENTRY DATA

The preparation for class of the teaching unit which will be covered is very important so that the lecture reaches its peak. Preparation as a guide, for the teacher through the lecture is important as well as other elements. Educational tools, in this case it would be a computer with a 60 inch (152 cm) LCD monitor. The computer that the teacher uses would have to be connected to all the other computers that the students use. The teacher would than use software to enter data for the lecture structure with all elements of the preparation. The data is stored in a knowledge base and database with all the additions (documents, instructions, presentations, software and other that the teacher used during the preparation of the given teaching unit). All data of this lecture preparation is visible to a new teacher who will come as a substitute to the one that made this lecture preparation and will with new innovations upgrade and leave for the next teacher to come. Apart from the new teacher, the preparation (with all its documents) can be seen by students' parents that prepare their child for evaluation and view all material the teacher used for preparation.

Photo No. 1. Data distribution

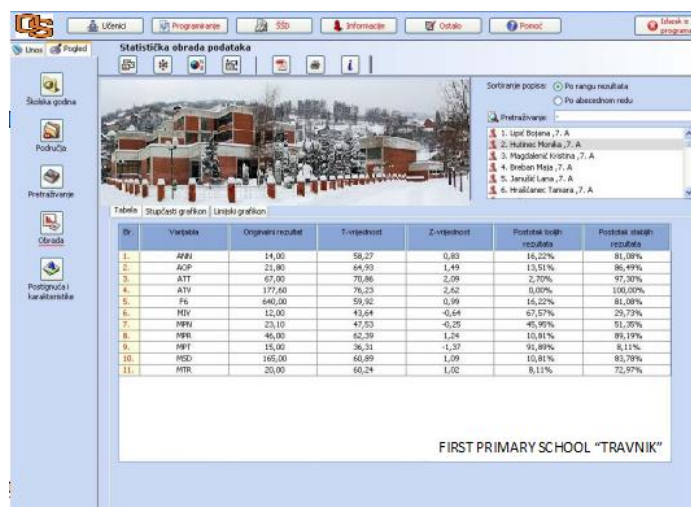

Photo No. 2. Preparations for one class and one subject

The web server can store statistics data of teachers' reports (students' accomplishments and behaviour), students' statistics, classes, school generations, statistics of absences and other information (financial, goods and materials and other) which are needed by Ministry sectors. This data is entered by school sectors. Data that is crucial for the upbringing of the student is entered by the school psychologist, data that is related to the accomplishment and behaviour of students is entered by the class teachers and the financial, goods and materials data is entered by the school secretary. The full overview is done by the school director. What should be pointed out is that the view inside a certain subject can only be done by the teacher that teaches that subject and not into any other module. The secretary has access to only his/her module (bookkeeping), the school psychologist has access only to data that is related to him/her. It is important that only students' parents have access to their own data while others do not.

3. THE INFORMATION SYSTEM MODULES

The information has nine modules:

- **Lecture preparation module** – the teacher enters the lecture preparation (lecture structure) and other information that is important for the lecture realization,
- **Teaching diary module** – teachers enter accomplishments and behaviour of students, attendance and other information related to the teaching process,
- **School secretary module** – entry of materials and financial data and other reports and information,
- **School psychologist module** – entry of all inclusion data and all other information related to the upbringing of students,
- **Parents module** – view of students' accomplishments,
- **Ministry module** – view of statistics data on request, sending information and instructions toward schools,
- **School director module** – view of all data on request. There are as many computers as there are students in a classroom (student-computer),
- **Moodle module** – transfer system of documents and other files needed by teachers and students. Entry to this module is protected by a LOG-IN password system. Each student or teacher has their own LOG-IN password.
- **Student evaluation module** – students in this module receive a test by random choice of questions and are required to complete it in a certain amount of time (45 min.). After the test, students are allowed to view their results. The test is electronically sent to a database where it stays visible to all factors of the teaching process.

4. THE INFORMATION SYSTEM INFRASTRUCTURE

The computers are linked to a local (LAN) network with one server and LCD monitor which is placed above and behind the teacher, visible to all students in the classroom. The computer that the teacher uses is connected to the LCD monitor mounted on the wall facing the students. Everything being done on the teachers' computer can be seen on the monitor. The network of computers is linked to a global network-internet. Students' computers are equipped with the same programs as the teachers' (same version), the only difference is in the access to the programs, maps and documents. The teacher has access to all programs on the computers being used by the students.

All computers in the school are connected to a network. The main database and knowledge base are on the web server. Every user has his/her LOG-IN password and access to only their module. Access to data can be established by any computer linked to the internet. Each student is given his/her own (always the same) computer. For work with documents we have chosen the Moodle system that gives each student a subject on whose module includes all documents and additions for the given subject.

Photo No. 3. Blueprint of computers in a local network, classroom with one monitor (152cm.)

5. DESCRIPTION OF A LECTURE

Instead of a teaching diary a teacher has a computer in front of him. The work schedule in modules is as follows:

1. Opens the **Teachers' diary module**:
Enters the students' attendance data (present and absent). This module is constantly open during the lecture and any data relating to it can be entered at any time (credit for students' activities ect.).

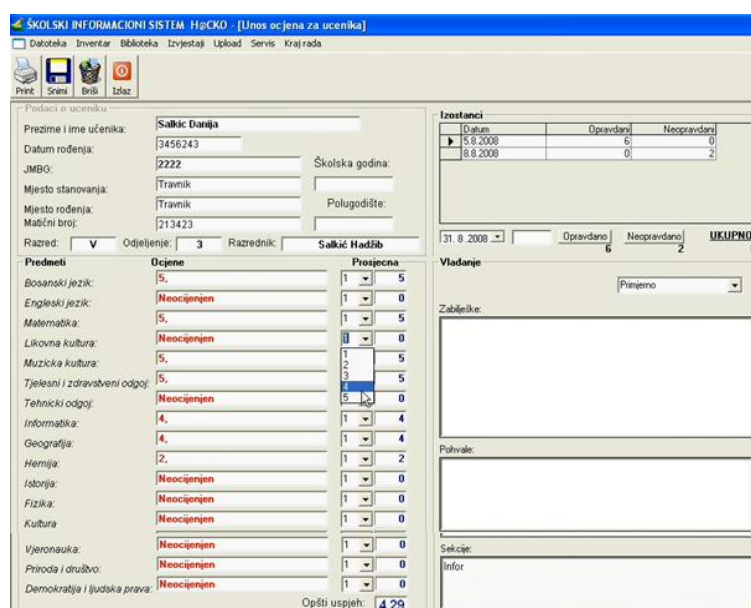

Photo No. 4. Score of students

2. Opens the **Lecture preparation module**:
Lecture preparation (lecture structure) leads the teacher through the teaching unit with all additions (presentation, links, and all other needed documents) which are crucial for the teaching unit to be as successful as possible. Of course, the work of the teacher is followed on the LCD monitor visible to all students, above the teachers' desk.
3. The teacher **starts one of the programs** on the computer in he/she wishes to work in. At the same time the students follow the teachers' instructions and work independently unless the teacher has assigned a group assignment. Teachers usually use the internet to show the students how to explore and solve the given assignment. The students can use only those programs on the computer which are pointed out by the teacher. After finishing an assignment students transfer the document into a subject map where it stays and a copy is sent to the teacher.
4. **Moodle system**:
Consists of all necessary documents, presentations and other additions related to the teaching unit.

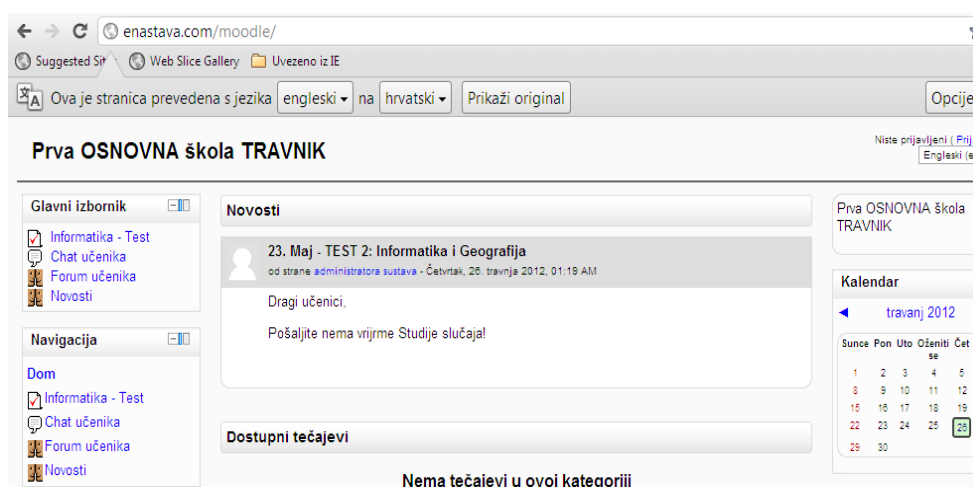

Photo No. 5. Moodle system Web interface

Everyone has access to the Moodle system; according to privileges (student, teacher, moderator, administrator) so that others without a LOG-IN password do not have access. This is one kind of privacy protection and exchange of information, documents and other additions between students, teachers and

others in the teaching process, so others who are not in the teaching process are unable to access and violate the work system.

It is very important to emphasise that apart from documents, presentations, additions and such, a live-stream link is installed into the Moodle system which enables following of lectures (which are taking place) through this channel as well. Registration is free but for the complete version with a price (on www.Livestream.com), that also enables additions that were used during the lecture. They are usually instructions which are made in Camtasia studio as a video clip. After the finished instruction (video clip) it is uploaded onto a live-stream channel (www.livestream.com/prva-os-travnik). This way all video clips are found on one address and numbered according to the teaching unit. Students within 24 hours can start and watch any of the video clips. Apart from the video clips there is a possibility of following parts of the lecture live (online), for example, in a case of a weather storm or scheduling a special conference period. This type of communication enables students with special needs to listen to the lecture more than once and for those that have problems reaching school. In this case students are able to listen to the lecture from their homes and also the teacher to teach it from home. Also, lectures can be set in a way so that chosen students are given a LOG-IN password so they are able to defend their seminar papers. This type of communication through live-stream breaks the monotony of the lectures. There is also a possibility to make a debate club or quiz, and make two channels: www.livesream.com/ost-dk-1 and www.livesream.com/ost-dk-2 which would be posted on the webpage. One group of students would log on to one channel (or one class) with one assignment and the other to a second one (or other class). The teacher would be the mediator, while other students would follow what is happening from their homes on the webpage (www.is-nastava.ba/livestream-kanal). Comments would be able to be posted on the chat page of the live-stream channel. Presence to this event is reported by registration onto the chat channel, and under the channel video picture the number of persons present in this event is visible.

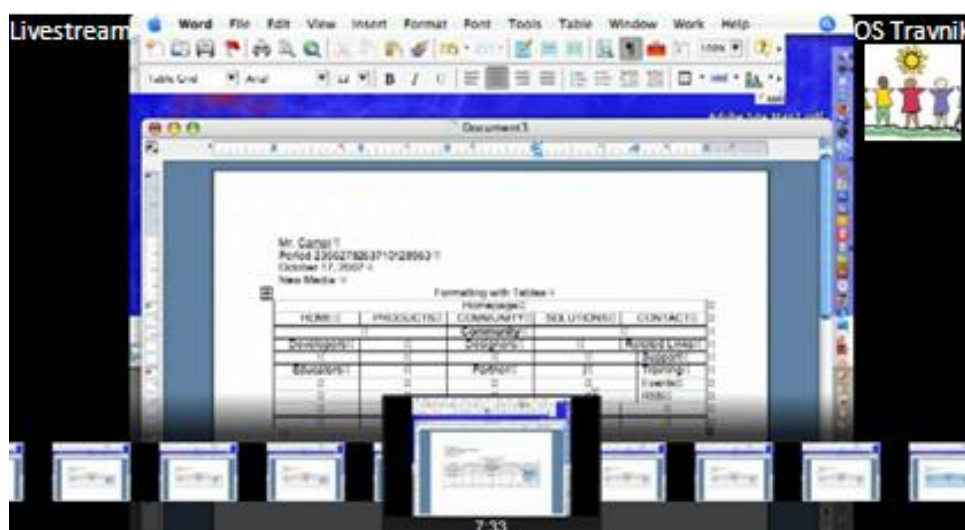

Photo No. 6. Livestream channel

6. STUDENT EVALUATION

After a certain teaching cycle, students are required to take a test. The test is done on a computer by a random choice of questions from a given subject. The teacher prepares questions and answers and enters them into this module. After the finished test, the students can see the results of their achievement. The test is electronically sent to a database and stays visible to all factors in the teaching process.

8. CONCLUSIONS

Education of students in the best way possible can be achieved by a wider use of information and communication technologies. Learning and teaching with the help of information and communication technologies we named e-learning, not eliminating the existing (traditional) methods of learning and technology, but enriching them when used adequately. It is not rare that institutions which believe that with creating a web page and posting a text on it that they created a platform for e-learning. We do not believe so. Our long-term experience in use of information systems supported by information and communication technologies gave us the basis for the next conclusions with positive and affective use of information and communication technologies in education (I) the role of the teacher is highly reduced, because the student with the help of technology has a greater source of information; (II) with video, the student receives an audio and text presentation of information; (III) digital information can be accessed at any time, so that lectures in school are more effective and used by students, and the way they are presented is more efficient and made easier on the teacher. Besides (IV) students' parents have the possibility to oversee and control responsibilities and results of the education of their dearest and (V) allows the school management to oversee and control the whole education process, work efficiency of teachers and other school staff.

Abstract: *The subject of this paper was prompted by the importance of Suitable Structure of Support (SSS) determination, as one of the support actions that the environment provides to the SME sector – in the case of SMEs in Serbia. (Support can be viewed as a type of service, with a significant share of material resources in that service, i.e. in a specific form of support. Therefore, Structure of Support (SS) is the primary issue in this paper. If support is viewed as a service, it is also important to follow the process of providing that service). It is recognized that structure support planning is the root of successful support to the SME sector, so the subject of this paper is the improvement of the SMEs structure support planning process based on new structure determination (which, therefore, contributes to the suitability of structure support). **Problem:** Weak effect of the environment support to SMEs (not only in Serbia) at the beginning of the 21st century is the problem whose solution this paper is dedicated to. The conducted survey has identified the cause of the problem: the environment provides Low Suitability of Structure Support in relation to SMEs' support needs. Therefore, the ways of structure support planning and, consequently, an inappropriate process of planning and providing support has been recognized as a real problem of insufficient effectiveness of support provided to SMEs. The need for the improvement of the existing SMEs support planning process, as well as the need for innovation in the way support structure is determined, have been identified. **Idea:** (H0): If the planning of structure support that the environment provides to the SME sector achieves higher suitability with the structure envisaged by the owners/management of SMEs, better results of that support are achieved (and also higher SMEs' business performance). Of course, such structured support should and can be incorporated into support plans and, thus, support could be more effective and "supported" SMEs more successful. The presented idea has been tested in the case of providing support to the SME sector in Serbia. **The intention** is to show that the SMEs structure support can be improved (made more suitable for the one needed, or at least for the one that the owners/managers of SMEs want), and that this leads to the improvement of the planning and the overall management of providing support to SMEs, as well as of SMEs' successfulness. **Purpose:** This paper is intended for those who are planning and/or providing support to the SME sector. They are proposed to improve the "Structure of Support" performance (especially the "Suitability of Structure Support" indicator). This would, as an innovation, improve the process (as well as the system) of planning and the overall management of providing support and make it more effective. **Result of the survey/Contribution of the paper:** Based on the "Research on the conditions, needs and problems of SMEs and entrepreneurs" (conducted in 2010 and 2011), it is shown that better results are achieved by those who apply the here proposed method of designing structure support while planning support for the SME sector. This conclusion is derived from the observation that SMEs support is more effective if it is more in accordance with the objective needs of SMEs, or at least with the ones desired by the owners/managers of SMEs. Therefore, the conclusion is that the first step should be to determine the required/desired SMEs structure of support from the environment, and then to plan other support characteristics (such as details on types of support, scopes, periods, methods of delivery, etc.). It is concluded that the new way of designing structure of support and the proposed planning process of providing support leads to the improvement of the SMEs environmental support, which should be "kept permanently open" for improvement.*

Keywords: Small and Medium Enterprises (SME), Support for SMEs, Structure of SMEs support, Suitability of SMEs support, Planning the environmental support for SMEs.

1. INTRODUCTION

Subject of the paper is in the scientific field of Entrepreneurship and SME management. It refers to the improvement of the planning of SMEs' support system (more specifically: the process of planning the Structure of Support - SS). Identification of the actors involved in the support system should be the first step in defining of the suitable SMEs' support. There are two types of actors: the actors who are demanding for support (small and medium enterprises and entrepreneurs - SMEs) and the actors who are providing the support (government and its institutions, international institutions and other organizations that provide

support). The actors who are demanding for support (SMEs) have their needs and form their own expectations (rarely: requirements) for support (which is usually done by the managers/owners of SMEs, but the help of experts would be more reliable). It is shown in practice that the actors who are providing the support are actually trying to help the SMEs. The problem occurs because the SMEs' support that these organizations design is usually independent from the actual needs of the SME sector (but is designed according to their own competence/interest), so the delivered support is not suitable enough with the needs/requirements of SMEs. Support usually doesn't have the suitable structure and other performances.

The authors of the paper provide an answer to the research question: Does the support whose structure is more suitable with the one expected by the managers/owners of SMEs (related to solving problems and satisfying the needs of SMEs) achieve better effects (that have an impact on the overall business of SMEs)? The authors give an answer to the research question in accordance to analysis of the data collected by the Survey¹.

After reminding of the: a) Basic concepts of SMEs, their characteristics, problems and needs and b) SMEs' environment that provide support to the SME sector through the structure, institutions and resources of support (in case of Serbia), it is proceeded to the idea of improvement of the planning SMEs' support (so that SS is in accordance with the desired one). The concept of planning support, presented in this paper, can contribute to higher suitability of the SS with the one required, resulting in increased performance of providing support.

2. SMALL AND MEDIUM ENTERPRISES

Small and medium enterprises - SMEs is the phrase used for special type of enterprises that are becoming very important in the last decades of the 20th century. SMEs are recognized as: the engine of national economies' growth; the biggest potential of (self-) employment; the new job generator; companies that have great influence in the national, regional and local development (as a "tool" for prevention of the migration of people from some passive geographical areas) and as companies that obtained international character (because of their business in the global market). SMEs are a key source of national economies' growth (Spicer & Sadler-Smith, 2006, p. 134). SMEs are determined – using the criteria defined by the European Commission – as companies with up to 250 employees, whose annual turnover does not exceed 50 million [€] and/or whose total capital does not exceed 43 million [€] (The New SME definition, p. 5).

SMEs, as the largest category of companies (99.8 [%] of total enterprises in the EU and Serbia are SMEs) have many common features, despite the diversity and specificity of each of them. Attention of this paper is drawn to only one relevant characteristic: shortage of SMEs' resources. That characteristic of SMEs is the main constraint. It reflects to the other characteristics of SMEs: a) Integration of ownership and management; b) SMEs' small capacity; c) Specialized (niche) market; d) Lack of standard use, etc.

According to Barney (1991, p. 106), the necessary condition for developing competitive advantage and reaching company's strategic goal is the availability of resources. He notes that sustainable competitive advantages of a company come from its resources that are valuable, irreplaceable and difficult to imitate. Due to the limitation of SMEs' resource potential, it is obvious that SMEs need extra help.

Shortage of financial resources (as a universal resource) is one of the most commonly used justification² for the problems and failures of SMEs. SMEs' owners have difficulties with finance because they invest their personal savings and assets and the funds borrowed from family and friends into their business (Irwin, 1998, p. 162). Based on the characteristics of SMEs (in particular - on the basis of modest resource capacities) and the problems they face, it can be concluded that the SME sector needs the help and support. SMEs' environment is a potential source of help and support.

SMEs' environment is an important factor, viewed from the aspect of SMEs' support that is explored in this paper. The business environment is the business potential and resource of SMEs (Lazic-Rašović & Omerbegović-Bijelović, 2006, p. 5). According to Porter (1990, r. 73) "root of companies' competitiveness is in the nature of their business environment". Actors of SMEs' business environment are its stakeholders: customers, suppliers, competitors, banks and investors, educational and research institutions, the

¹ "Survey of conditions, needs and problems of SMEs and entrepreneurs", organized by the Regional Center for Development of SMEs and Entrepreneurship - Belgrade, conducted in 2010 – 2011, on a sample of 310 SMEs in Serbia (from cities: Belgrade, Kragujevac, Vranje, Jagodina, Arandelovac and Sombor).

² Research conducted in 2006 – 2008, during the preparation of a doctoral dissertation: "The contribution to application research of contemporary metamanagerial tools in small and medium enterprises with unbalancedly developed resources" (2008), M.Sc. Brankica Ljamić-Ivanović (under supervision of prof. dr J. Omerbegović-Bijelović), showed that the most important resource for the success of SMEs is the owner's competence.

government and its institutions, local communities, environmentally oriented organizations, media, organizations and agencies that provide support to the SME sector (Omerbegović-Bijelović, 2006, p. 5). SMEs can benefit and receive help and support from its stakeholders (whether in money or in other resources - material resources, knowledge, information, etc.). The rule is that each stakeholder has an interest to observe (and also to help and support) the existence and development of a specific SME.

The state that the SME sector needs help and that it expects the environmental support is justified by the analyzed data from the Survey - which shows that every SME from the sample had at least one problem in its business. The average number of problems per SME was 3.87 [problem/SME]. (Some of the main problems in the survey were: Shortage of financial resources (86.4 [%] of respondents), Lack of business ISO standard certifications (92.7 [%]), Inability of doing business on the international market (86 [%]), Inadequate legislation (34.3 [%]), Lack of information about the market trends and situation (29 [%]), Lack of trained personnel (12.5 [%]).)

In the Survey, SMEs were also asked about the types of support which they believe would assist in overcoming their problems. Survey has shown that every company in the sample reported at least one missing/desirable form of support. The average number was 2.88 [types of support/SME]. (Some of the most demanded forms of support are: Easy access to financial resources (82.9 [%] of respondents), Help in the promotion (54.8 [%]), Procurement of the missing equipment or replacement of the existing equipment (41.6 [%]), Professional support through training, consulting and mentoring (40.5 [%]). Therefore, based on the presented data, it can be concluded that the SMEs have a strong need for help and support from the environment.

3. SMEs SUPPORT

Term of SMEs support refers to any form of financial or non-financial help to SMEs that is provided from the environment (by other individuals, companies, institutions, state or some supra-system). The sources of various forms of SMEs support can be: Supply chain participants (customers, suppliers), banks, agencies (accountants, lawyers and consultants), business associations, government organizations, media, family, friends and others. Bennett and Robson (1999, p. 161) explain how buyers and suppliers can be a good source of information and help: a) Customers of a company may provide a good signal of product's market success; b) Suppliers are the sources of information about new technologies, opportunities and chances for innovation and cost reduction.

Usage of external support is strongly associated with successful business growth (Bennett & Robson, 1999, p. 155). Chrisman and McMullan (2004) have shown that small businesses that use the support services of public agencies have a higher rate of survival and growth than the firms that do not use these types of services. Therefore, the conclusion is that support is very important and that, consequently, the improvement of the environmental support can help the SME sector more effectively.

According to the basic categories of resources, the help/support that can be provided to SMEs is divided into **two main types**: financial and non-financial support.

Financial support – money is the key resource of this type of SMEs support. More precisely, it refers to the financial help of various institutions and organizations to start new business (start-up loans) or to improve the business of existing SMEs (loans to finance current operations). In many cases, money that is given to support SMEs is not a help itself, but a resource for the achievement of specific objectives, so it must be spent on planned activities. (For example, the support institutions provide funds to SMEs for: purchase equipment, employee trainings, export activities and innovation of products/ services/ processes/ management).

Financial resource, as a form of support, is necessary for the development of new business ventures. Patzelt and Shepherd (2009, p. 322) claim that entrepreneurs can achieve their strategic goals only if they have sufficient funds and available sources of funds.

Non-financial support refers to support that does not include money as a resource of support. It is some kind of service: consulting, mentoring, training and seminars in various educational fields (e.g. legal aspects of operations, business planning, marketing, finance, human resource management, change management, innovation), intended for "managers" of SMEs (owners, entrepreneurs and managers). The main objectives of non-financial support are knowledge and competence improvement of the SMEs' owners, management and employees. The non-financial form of support may also include: the transfer of technology, help with business networking (entrance into clusters and other associations), contribution to the SMEs' reputation and

promotion, reduced administrative barriers and increase of tax incentives, but also a platform for business development - such as business incubators and technology parks.

Non-financial support includes provision of resources and activities combination. The most important are: a) Technology transfer is very important for the development of the enterprises in many countries, so support measures for this process are created (such as: Technology Transfer Agencies and Technology Transfer Offices); b) Entrepreneurial networking - an important form of non-financial support, which refers to the formal and informal links of entrepreneurs and SMEs with other individuals and organizations, through which they do economic transactions. Those networks can provide access to important knowledge and improve the visibility and reputation of a new business ventures. Support creators use them for placing numerous support program this type of support (entrepreneurial networking) for numerous support program (e.g. for formation of clusters); c) Knowledge - a very important resource for the development of every company and one of the most important sources of competitive advantage (Spicer & Sadler-Smith, 2006, p.133). According to the Knowledge based theory, it is a basic asset/resource for any company. All other resources depend on it (Chirico, 2008, p. 434). There are three very important types of knowledge: 1 - knowledge about management and development of existing business or newly established company; 2 - knowledge about processes of products and services development and production; 3 - knowledge about market, where the new company will operate; d) Removal or reduction of administrative barriers allow entrepreneurs to focus on daily operations and finding new business opportunities in their environment (because high levels of bureaucracy and administrative barriers have a negative impact on new business ventures development, according to Patzelt & Shepherd, 2009, p. 326); e) Tax incentives - they can be an excellent form of support, so the governments of many European countries provide large number of them (e.g. reduction of tax rates and respite in tax payment).

The existing forms of support which are provided to SMEs in Serbia are presented in Table 1. It is obtained by research on forms of support intended for SMEs in Serbia (Support for Success, 2012).

Table 1: Institutions and type of support for the SME sector in Serbia

Institution	Support intended for:	Type of support
Ministry of Economy and Regional Development	Fast growing SMEs ("gazelles")	The funds for financing activities for encouragement of SMEs' competitiveness.
	SMEs	The funds for financing activities for strengthening of SMEs' innovativeness.
		Free services provided by the regional development agencies (consulting, training, promotion).
National Employment Service	Potential Entrepreneurs	Subsidies for self-employment.
		Mentoring and specialized training for entrepreneurs who have received subsidies for self-employment.
	SMEs	Subsidies for new job creation.
		Subsidies for employment of persons with disabilities.
		Professional practice - financial subsidies for training of unemployed persons without work experience.
National Agency for Regional Development	Potential Entrepreneurs	Non-financial and financial support to the business starters who are returning to their cities (underdeveloped municipalities).
	SMEs	Support programs for co-financing (up to 50 [%]) of project costs for the development of SMEs' competitiveness.
		Mentoring for start-ups and existing SMEs.
	SME clusters	Support programs for co-financing innovative project activities (up to 50 [%])
Innovation fund	SMEs	European Network of Entrepreneurship Program: Information about conditions for entering into the EU market, export opportunities, new technologies, potential partners, etc.
		Program of early development of start-up and spin-off companies that have the technological innovation with potential of creating new intellectual property.
Serbia Investment and Export Promotion Agency	SMEs	Grants for financing export activities and the international promotion.
Export Credit and Insurance	SMEs	Short-term loans for financing export activities.
		Guarantees issuance

Agency of the Republic of Serbia		Receivables insurance Factoring (assignment of receivables)
	SME/Entrepreneurs	Consulting for potential exporters.
Development fund	SME/Entrepreneurs	Loans for arts and old crafts.
		Credit support for beginners (newly established SMEs and entrepreneurs, women entrepreneurship).
		Guarantees for SMEs' and entrepreneurs' loans.
		Short-term loans for encouragement of competitiveness and liquidity, investment loans
		Low interest loans for development of SMEs/entrepreneurs in underdeveloped regions
National Bank of Serbia	SMEs	European Investment Bank, the Government of Italy and the European Agency for Reconstruction loans for SMEs
The Intellectual Property Office of the Republic of Serbia	SMEs	SMEs' intellectual property diagnostics
		Education of SMEs about intellectual property

Therefore, the Structure of SMEs Support (SS), as a set of individual environmental support components that are designed for solving SMEs' problems has next characteristics:

- **Type of support** - complex characteristic that indicates on: its form, nature of resources that are provided to SMEs, specific purpose;
- **Volume of support** - the number of different support types that are integrated into the SS that is provided to SMEs. If the SS, consists of several types, the volume of support is higher;
- **The intensity of support** - characteristic that involves introduction of indicators (and measuring unit of the indicator expression intensity) which may be: period of providing support, financial value of support, number of participants who provide support to SMEs (mentors, consultants, listeners). Intensity of one support type refers to the amount of certain type of resource that is used in the implementation of a specific form of support;
- **Process of providing support** - an essential part of the structure of environmental support (because processes "justified" structure). It also refers to the cost, time and risk that are appearing in support;
- **Support recipient satisfaction** – refers to the level of SMEs' managers/owners satisfaction with received support. It can be measured as a level of fulfillment of expectations for support;
- **Support provider satisfaction** – an indicator of fulfillment of their intentions and expectations;
- **The quality of support** – measure of fulfillment of the SMEs' support expectations (and also of the involved stakeholders expectations), which is usually expressed as the effectiveness and efficiency of SMEs support. The authors of this paper suggest that the quality of support can be determined through the other two characteristics: Suitability of support and Successfulness of support;
- **Suitability of support** - it can be defined as an indicator of compatibility of support provided to SMEs with the SMEs' problems recognized by competent individuals or organizations (experts, SMEs' owners/managers, specialized consulting organizations). According to Chrisman & McMullan (2004, p. 231) support should be conceptualized and organized so that, in terms of its structure, it corresponds to the particular problems and requirements/expectations of SMEs. They are drawing attention to the suitability of support: "It is preferable that advisors (who provide support to SMEs) rely on the ideas that are given by the owners/managers of SMEs, than to rely on prefabricated solutions to the SMEs' problems", because "the SMEs' owners/managers expect support that is suitable with their needs, that are numerous and that vary according to the activities, firm's sectors, firm's development phase and also according to the ambitions from the owner/manager "(Audet, Berger-Douce & St-Jean, 2007, p. 30);
- **Successfulness of support** – it refers to the effect of support on the problem solving and SMEs' performance indicators. It can be measured by different (direct or indirect) indicators: the degree to which problems in the company are solved, i.e. the effects on company performance (an increase of: revenue, profit, number of employees, market share, etc). Possibility of measuring the successfulness of support through the integral objective function, that will satisfy more stakeholders at the same time, is particularly interesting;

The main hypothesis of this paper refers to the connection of support suitability with the support successfulness (and therefore SMEs' successfulness): If the planning of SS that environment provides to the SME sector achieve higher suitability (SSS - as a performance indicator of SS) with the structure expected

by the owners/management of SMEs, better results of that support are achieved (and also higher SMEs' business performance).

For the purpose of proving the main hypothesis, 310 SMEs were surveyed. Two different things were analyzed - SMEs' requests for support (requests for solving problems that are identified by the SMEs' managers/owners), on one side, and the specific forms of support (that are provided to SMEs), on the one side. The level of agreement between the support SMEs are looking for and the support that is provided to SMEs is recorded as a variable - suitability of support. That variable could take integer value of how many times used SMEs support is suitable with the requirements of the manager/owner. An indicator/variable "Direct growth of total SMEs revenues", expressed in [%], was used for support success measuring.

Correlation analysis of these two variables gave the following result: Pearson Correlation ρ (suitability; increase in revenue) = 0.422 was statistically significant ($\text{sig} = 0.002$). The obtained coefficient of correlation is in the category of medium correlation. Dependence between suitability and successfulness of support (precisely, in this paper it refers to one successfulness indicator: direct increase of revenue as a result of the environmental support to SMEs) can be established on the basis of that correlation. (The authors believe that the reason why the relationship between two variables is not stronger ($\rho > 0.5$), is in the answer to the question "Are the owners/managers of SMEs competent enough to identify what is the problem of their SMEs?").

Since the statistical test confirmed a statistically significant relationship, it can be concluded that the hypothesis is true, i.e. that if support achieve higher suitability of structures (SS) with the structure expected by the SMEs' managers/owners, the better SMEs' business score will be achieved.

(The next conclusion is that if more competent experts define SMEs' needs, the more suitable structure of support will be given. That will lead to even higher improvement of planning/plans of support to SMEs). Based on this conclusion, the suggestion for improvement of the planning support process (and also the whole support system) should be defined by including the innovated ways of defining and designing structure of SMEs support. This can help the improvement of SMEs support and the success of their business.

4. IMPROVING THE PLANNING SUPPORT PROCESS TO SMEs

The purpose of planning model, that is proposed in this paper, is to help in directing always limited resources to the forms or activities of SMEs support that is "most promising", i.e. support that will have the biggest positive effect on the success of SME sector and, consequently, on the economy and quality of life. The initial hypothesis is defined to indicate that there is regularity in the designing of SMEs structure of support. Stakeholders are advised how to improve the system of SMEs support and how to participate in it.

Support planning is part of a more complex process which occurs in the support management system. Therefore, the complex management process of providing SMEs support can be presented in two phases (Omerbegović-Bijelović J. et al., 2010, p. 141 and p. 245):

F1. Planning – creation of plans for SMEs support where the highest goal(s) are decomposed into:

a) hierarchically-organized (and time-synchronized) goals' tree-structure, and b) A set of appropriate actions (up to the level of work assignments for the direct objects of work transformation) for achievement of the planning goals, c) Resource defined by type and quantity (planned activities should be implemented over them) s and d) Specifying of the ways for providing resources to SMEs support;

F2. Execution of providing support plans, where other three classical phases of management could be found:

a) Organization for plans execution - where the decomposed goals and other elements of plans (like: information about planned activities and the authority for managing necessary quantity of planned resources for planned activities perform) are assigned to individuals or groups (organizational units); b) Realizations of SMEs support plans where the availability of necessary recourses is provided through purchasing and supplying (at the each relevant (work) place and at all planned horizons). In this phase planned resources are used to obtain the output - planned support (with planned quality, planned costs, in planned moment, with optimized values of output characteristics, for planned users); c) Controlling the execution of support plans through all goals and tasks, time horizons, management objects (resources, processes, functions) and indicators of the quality/ success of business operations, through the stages: 1) Identification of conditions of SMEs support management entity, 2) Determination of deviations between the real condition and planned values, 3a) Discovering of the deviations causes in parallel with, 3b) Operative removal of achieving goals obstacles and 4) recording of experience and recommendation for next cycle of management improvement.

SMEs support planning system in Serbia (as an illustration for possible of SMEs structure of support innovation and as an improvement object for planning process of the motioned support) is concretized with *"The Development Strategy of Competitive and Innovative Small and Medium Sized Enterprises for the*

period 2008-2013". The strategy is adapted every five years, and it includes the defined aims for SMEs support. More precisely, it is a strategic plan that is defined by the Serbian Government, which includes the aims that should be achieved by the government institutions and organizations through their activities in the planned period. The Strategy is document for SMEs policy development. That document defines the main priorities (goals) and ways (actions) for their realization in planned period. The main goal of Strategy is to develop Serbian entrepreneurial economy based on knowledge and innovation. It needs to create a strong, competitive and export-oriented SME sector and to significantly contribute the improvement of life standards in Serbia. The general goal of the Strategy is further decomposed into the five most important objectives – "pillars":

- Promotion and support to entrepreneurship and the development of new enterprises
- Human resources for competitive SME sector
- Financing and taxation of SMEs
- Competitive advantages of SMEs in export markets
- Legal, institutional and business environment for SMEs

For the purposes of meeting the defined five "pillars" or the main aims of the Strategy, the particularly activities are defined. Therefore, the strategy was defined according to the "top-down" principle - from the main goal at the state level towards specific objectives and activities designed for the SME sector.

Authors of this paper think that another complementary approach (a "bottom-up" approach that is based on concrete problems and needs of SME sector) is missing in defining Strategy. Based on the hypothesis conceptualized and proven dependence between the results of provided support (the success of SMEs) and its suitability with the problems and needs of SMEs, the authors present the concept (proposed methodology) to improve the planning of support system (as part of SMEs management support system), so that each individual support, meets demands and needs of SME in the best way. Additional contribution of this concept would be a better definition of support strategy for SME sector.

Support planning process should be initiated with "call for help" - that the owners/ managers of SMEs send to the particular SME support institution. However, in many cases, owners/managers of SMEs are not able to identify when they have problem, what is the problem and even does the problem really exist in their company. SMEs' owners/managers are also not informed well enough about the capabilities of many support institutions. Therefore, the support institutions often encourage SMEs' support demands with a numerous proactive programs and activities. It can be said that the institutions start the planning process for SME support. So, the beginning of the SMEs support planning process can have two sources of "impulses": Particular SMEs or institutions that provide support to them).

During the designing of SMEs support planning process, next things must be taken into considerations:

- *Structure of support* that is provided to the SME, which is in accordance to their problems and need. This element of support planning can include all important aspects of support (type, scope, intensity, quality, suitability and desired successfulness);
- *Resources* required for realization of support (money, people, knowledge, information, time, etc.). where care should be taken about their availability in different time-planning period;
- *Time period* in which the support is implemented. It must be in accordance with the SMEs support needs in the observed period, and with the resource availability of organization that provides support;
- *Institution* or organization that has task to implement support, because the organizations that planned support to SME, are often not the ones that implement support.

SMEs support planning process (stages S1-S9) cannot be regarded as isolated, but in the context of integral planning, and also in entire support management process (or at least on the level of operational management - in stage S7). Therefore **SMEs support planning process** can be conducted through the following stages:

S1) Investigate the problem of SMEs – i.e. do an accurate diagnosis of the SMEs' condition, problems and needs. It is necessary to define the SMEs' problems, because incorrectly defined problems can lead to inefficiency of the whole support system). Therefore, this phase is crucial for the further support planning and support realization process;

S2) Define the goal that will be achieved through the support. Well-defined SMEs' problems (in previous stage), may determine the purpose and goals of providing support to SMEs. While considering the goals the expectations of many stakeholders should be take into consideration;

S3) Define suitable structure of support which meets goal identified in stage 2. At this stage, with respect to the support suitability, structure of support that is intended to SMEs is precisely defined;

S4) **Define the necessary resources** by types and quantities and specify the dynamics of resource needs (which may be the major constraint to achieve support goals) for implementation of support. The goal is to make the greatest support effect with rational use of always limited resources;

S5) **Define the support intensity** in accordance to the SMEs' needs and support providers resource constraints;

S6) **Define indicators for monitoring the support results** – while support planning, the indicators that will monitor the achievement of planned support and successfulness of realized support forms are also defined. Those measurable indicators could be: a) degree of plan achievement, b) degree of resources utilization, c) degree of support needs satisfaction and g) degree of particularly stakeholders' satisfaction;

S7) **Implement the support** – according to strict classification it is not included in the planning stage because it is a realization phase. However one part of realization stage (transformation, i.e. direct providing support activities), cannot be separated from operational preparation of support planning, and even less from the operational preparation of providing support. They are so close that they are not even separate from the operational management of SMEs support activities realization. Information about validity of the applied planning process, and ideas for SMEs support planning process improvement come from this stage;

S8) **Analyze the performance indicators** of the provided support structure. Indicators for measuring success of planning and support providing are analyzed after the execution of support. If the results meet expectations, it can be concluded that the support was successful and that the plan achieved the goal. According to Omerbegović-Bijelović et al. (2010, p. 151) "measure or degree of planning objectives fulfillment is the quality of planning. It can be defined as: effectiveness - an indicator that measure the achievement of planning purpose and efficiency - as the ratio between the benefits and cost of planning process", Otherwise, it is necessary to work on further improvement of the planning system of SMEs support (primarily, here observed structure of support);

S9) **Define further actions** – SMEs support planning process usually does not end after the successful or unsuccessful completion of the planning and plans executing cycle,. New cycles of providing support are defined and planned towards a further SMEs problem solving and improvement of their success. Continual improvement activities of the system for monitoring SMEs' needs, problem solving and successfulness, are defined through the following: measurement, analysis of the results, determining deviations, further planning of improvement and implementation of SMEs support activities. After one cycle of improvement, next cycles should be repeated.

An important characteristic of the SMEs support planning system is the structure of that system, in addition to the process of providing support. Organizational structure for SMEs support planning objectives achievement is defined in accordance to the decomposition of those objectives. Theoretically, that process goes through: 1) Delegation of (planning) goal's components to individuals and/or to organizational entities of the complex SMEs support planning system (i.e. assignment of specific goals to groups and individuals) 2) Allocation of authorizations for: a) use of necessary resources to achieve assigned planning goals and b) initiating and managing the activities of planning goals. Although the organization of planning is just one phase of SMEs support planning management, it is necessary to consider the time horizon, and to synchronize the organization ("activities assignment") with that aspect of planning (and the entire management) SMEs support. However, this topic will further be discussed in another paper.

5. CONCLUSION

Providing support to SMEs is a serious social and professional task. The role of science is to make decisions in this area be based on the facts. The result of the survey of the relationship between the suitability of SMEs structure support (SSS) and the effects of providing that support (in case of SMEs support in the Republic of Serbia) is presented in this paper. It was found that the effect of the support depends on its suitability with and the actual needs for environmental support (at least as the owners/managers of SMEs saw those needs). It is shown that the success in providing support to SMEs (including the SMEs' business success) is higher if the provided support is more suitable with the one needed.

Based on the proven hypothesis and the innovated way of SMEs structure of support (SS) designing, the authors made an improved concept of SMEs support planning process. Through this new concept, the authors want to direct the institutions and organizations that provide support to SMEs towards the real needs of practice – that during the process of SS planning and providing support they have to consider the real needs and problems of SMEs, in order to achieve greater success.

The concept of SMEs support planning has many benefits. It can serve as a guide to:

- *Small and medium enterprises* – for better planning of their own support needs and learning about the available support forms from their environment;

- *Government and its institutions* – for better understanding of the SMEs' problems and their needs for support (with the aim of defining more adequate forms of support provided/coordinated by the Government of RS);
- *Institutions and organizations that provide support to SMEs* - for better planning of: support, necessary resources and support activities.

Abstract: *The transition period of the society has left us richer for certain immediate experiences that will not remain without influence on future generations. The transition from the old paradigm (socialist society) to the new one (entrepreneurial society), is an uncertain and a long-lasting process, merely due to its radicalism. Thus, this study aims at determining the quantity of entrepreneurial resources for those who manage and operate organizations, institutions, and companies in the Republic of Macedonia, through determining the extent of some of their personal characteristics that are considered part of the profile of any successful entrepreneur. Inventive and creative potential, reliability, attitude toward change, attitude toward risk-taking are the personal traits, in which we are interested in terms of management of human resources. It is said that they broadly represent, but not fully cover the entrepreneurial personality. The research comprises a sample of 132 respondents from different levels and activities in the Republic of Macedonia and the conclusions have been reached according to their results on the TTS test by Eugene Rodsep, the test for determining confidence, the MI 1 test for measuring the attitude toward changes, and the questionnaire assessing the level and attitude toward risk-taking. The results of the research have shown that the managers in the Republic of Macedonia possess, more or less, the tested characteristics, but they are very unevenly distributed among individuals. In conclusion, this research aims to help managers of different organizations to become aware of their "entrepreneurial spirit", to help HR managers and the state authorities to develop it and give directions for further development of entrepreneurship.*

Keywords: Entrepreneurship, entrepreneur's profile, inventive- creative potential.

1. INTRODUCTION

The period of transition of the society has left us richer for certain immediate experiences that will not remain without influence on future generations. The transition from the old paradigm (socialistic society) into the new one (entrepreneurial society), is uncertain and long lasting process, by the mere fact of its radicalism. Collectivism, averaging, closeness, redistributive ethic, rigidity, maintaining of certain social justice, require to be replaced with the values of the modern times. Market economy, pluralism of ideas and opportunities, private initiative, entrepreneurship promotion, etc., are the clear objectives that we have targeted. From here, the context of all contemporary developments, as much it seems hard to understand and accept, represents confrontation of the individual with reality and often means certain discontinuity of living. Thus, on the one hand, a process of rejection of the negative baggage occurs from the past, which is a measure of convergence towards the new. And on the other hand, it becomes more clearly that this change requires time - but not empty and unorganized, but filled with thought-out steps that will mean success. Hence, it is understandable that the period in which we live is a challenge to professional profiles of different facets of human activity. All of them from their own aspect are trying to observe and explore the entrepreneurship.

2. THEORETICAL FRAMEWORK AND DEFINITION OF THE KEY VARIABLES

Inventiveness and entrepreneurship are part of the key concepts, determinants of the development of any society. They can be understood if presented as interconnected elements, characteristic for those individuals who make change. Entrepreneurs are basically innovators, and innovation is the core of entrepreneurship. Hence, the determination of entrepreneurship inevitably will lead by setting the remaining terms, which constitute its essence. We start with innovation.

Innovation is a process of creating something new and as a phenomenon is a key determinant of the development of any society. Certain need that appears in a certain area of the human life can become a problem, inevitably requires adequate innovation (content, product, service).

“The term innovation under the proposed definition of the OECD include transforming an idea into a market product or service, new or improved production or distribution process, i.e. new way of social service.” (Petkovski, K. & Sulejmani, N., 2001:11)

“The innovativeness would mean:

- Renewal or expansion of the assortment of products and services, as well as, connecting the markets;
- Establishing new ways of production, supply and distribution;
- Introduction of changes in management, organization of work, working conditions and skills of the workforce.” (Krale, T., 2001:32)

Previous determinations of the innovation put the emphasis on the outcome of the process. In another words, they focus on the consequences of it, while listing to what the innovativeness has led and where it is needed. However, we think that for practical reasons that would function in a certain meaningful treatment of the field of innovativeness fostering and development, in the determination of this term it is necessary to include some other more fundamental determinants (processes, capabilities, features) that will allow more accurate and bigger understanding of the innovativeness. Explaining the scheme of “the process of creative problem solving” by defining the characteristics of the person who does it - creatively solve certain problem, is the essence of the innovativeness, which, as was told, is the core of the entrepreneurship. (Figure 1)

Figure 1: Process of creative problem solving (Gruevski, D., 2010: 119)

Hence, the phenomenon of creativity is not reduced only to a divergent production of ideas, but the process of creative problem solving fully and very concretely explains the essence which may have practical implications. As the professor Lj. Madzhar says: “In fact, the entrepreneurship by definition is capability and current practice of solving completely new, very nonstandard problems on which from the previous experience can be drawn only poor or no lessons.” (www.yuorpe.com / Republic, Sources of entrepreneurship in transformed Serbia, pg.1)

Thus, is started from some emerging unmet needs, which by themselves represent a particular problem whose solving through a creative process answers the following questions: “why”, “what” and “how to”, in a certain constellation of structural elements of a particular creative person, acting in suitable conditions, leads to innovation that he or someone else, the market, may valorize. In fact, **entrepreneurship is only applied and market valorized innovativeness - creativity.**

Actually, if we recall the development of scientific thought and aspects that were crucial in explaining the concept of entrepreneurship, given in the review made by professor Petkovski, we will get to the following: “the risk taking”, as the main determinant of the entrepreneurs: “the ‘entrepreneur is one who takes risk, unlike the person who provides the capital.’; “development carriers”, not only about “risk carriers”: “the entrepreneur is an innovator and instigator of growth.”; “The entrepreneur has the ability for creation and situation assessment.”; “The entrepreneur takes initiative, organizes social and economic mechanisms and

assumes the risk of losses in the activity that he realizes.”; “The entrepreneur is one who sees the opportunity for gaining a profit.” etc. At the end we will come to the determination which is most acceptable and understanding to us – the explanation of Peter Drucker, who emphasizes “the economic valorization of creativity”, as crucial: “Entrepreneurship is based on recognition of the opportunities for innovation and their fastest market and economic evaluation.” (Petkovski, K. & Jankulovska, P., 2001)

Of course, what is not completely clear is the answer to the question whether the process of creativity and the process of its economic valorization is identical and is present as personal category in the same person to call him entrepreneur or it is about two processes - one of generating creative ideas that later someone else manages until their economic valorization? Or, we can speak about the entrepreneur only when the two abilities (creating and management until the economic valorization of the creation), are clearly expressed?

Thereby, the answers to this question are probably already given by some authors. Yet according to us, they are not clearly defined. For example, according to Ljubomir Madzhar: “Entrepreneurship is very heterogeneous and complex mixture of ingenuity, the ability to predict or even presentiment about future events, the ability to accept unusual and unconventional ideas, courage, persistence and other natural gifts, and on the other hand it is the result of some favorable ambient conditions largely related to factors and constellations that reduce the uncertainty.” (www.yuope.com / Republic, Sources of entrepreneurship in transformed Serbia, pg.1)

On the other hand, indeed there are many ambiguities and misconceptions regarding the determination of the essence of the matter, which have negative practical implications for the attempts to systematically encourage and develop, reminds professor Vlado Petkovic, who summarizing the various definitions and understandings of entrepreneurship talks about misconceptions about the term:

First delusion: Entrepreneurship is not just forming a new company, but also introducing a new activity, creating a new product or service. Entrepreneurial may be even those enterprises established in the past century, if in their work are introducing major innovations which are of general importance and interest.

Second delusion: Relating of entrepreneurship to small commercial ventures. The large firms, even the largest state enterprises, may be entrepreneurial. It is about making something new, unknown or not used in the practice.

Third delusion: Refers to the ownership of the entrepreneur. The entrepreneurship can be developed in all enterprises regardless of their ownership status.

Fourth delusion: It refers to the relating of entrepreneurship only to commercial enterprises. The entrepreneurship also exists in the non-profit activities (science, education, health, information, etc.). (www.ekof.bg.ac.yu / Economic chronicles, Entrepreneurship and entrepreneurs, pg. 1-2)

Besides the economic and social aspects in defining of the entrepreneurship, retention to the characteristics of personality and behavior of typical entrepreneurs would mean special approach and contribution. Through the literature can found lists of characteristics of individual entrepreneurs (profiles). They highlight various characteristics among which dominate the following: high level of motive for achievement, small fear of failure; strongly expressed sense of self-control and self-criticism; capability of dealing with uncertain situations, great confidence, optimism, determination - commitment, great energy, emphasized individualism, etc.

This, it can be said that for the entrepreneurial person is characteristic a certain set of manifesto and recognizable behavior, which would amount to: orientation to goals setting, commitment to those goals, persistence in their achievement; constantly decision making, calculated risk, acceptance of responsibility, innovativeness.

Quite understandably, besides defining of the concept, the next crucial question that arises and which is of special interest for each country refers to the possibility of a systematic approach to any organized attempt to **encourage the development of entrepreneurial consciousness and culture**.

Namely, if we know that the development of entrepreneurship is an essential factor for acceleration of the economy and rapid development of every country, every state must to encourage its development with various measures. The factors - determinants that affect the development of entrepreneurship, various authors divided into: “objective - subjective, internal - external, personal factors of the environment. Some have divided them into: economic, psychological, sociological, legal, information, technical - technological.” (Ibid, pg. 1-2)

According to Professor V. Petkovic, it is more useful to elaborate the basic conditions for development of entrepreneurship, which are exhausted by the existence of a) Free market; b) State deregulation in the economy; c) Innovative culture, climate, tradition. Also other authors listed factors, activities that can be placed in the previously mentioned, conditions.

“There are various forms of state aid for development of entrepreneurship. These include: providing legal certainty to entrepreneurs, infrastructure and above all, stability of the economic system and democracy. Also, one of the forms of state aid is the promotion of entrepreneurship and stimulating of young talents to pursue a career in small business, the establishment of institutes and special forums, which should contribute to removing barriers that hinder the development of entrepreneurship. Particularly, the state should help in creating of a stable and reliable framework for managing.” (Ibid, pg. 4)

“It is necessary first to create conditions for competition in the economy, which represents the most favorable climate for entrepreneurship development. That would mean building a market infrastructure, institutional and public infrastructure, which includes primarily agencies and funds for development of entrepreneurship and running a stable economic policy.” (Ibid, pg. 5)

On the other hand, the professor Lj. Madzhar lists the as well the international sanctions and the economic blockade, as appropriate mechanisms and environment for entrepreneurship development. Of course, not forgetting this phenomenon to be named as “often mistakenly targeted and exploited entrepreneurial energy and resources”, characteristic for him is that he does not believe in the possibility of systematic development of entrepreneurship through the forms of any formal education: “Unlike the management in the business and other organizations, the entrepreneurship is not a factor that would thoughtfully and meaningfully grew through learning and educational activities, least through some formal education, where courses in the area of entrepreneurship would have a central place.” (www.yuorpe.com / Republic, Sources of entrepreneurship in transformed Serbia, pg.4)

Of course, this attitude is extremely questionable and calls into question concepts and theories of education and socialization. And precisely this dilemma opens the question that we have set as a problem. Namely, who is an entrepreneur, those who are creative, or those who successfully and quickly manages a creative idea to its economic valorization, or both? It seems interesting because both of them through education and socialization processes surely can be systematically developed and encouraged.

3. PROBLEM – SUBJECT FRAMEWORK OF THE RESEARCH

The fact that all proposed activities, concepts, strategies, methods of development of entrepreneurship are based on the assumption of the existence of individuals with their personal characteristics apart from others and who can properly use such opportunities given and constructed, leads to the question of personality of the entrepreneur and the possibilities for systematic action in the direction of fostering, encouraging and developing certain abilities, traits, values, attitudes and beliefs from their early age through the education system and families.

Because, the inventiveness, creativity is defined as the core of entrepreneurship, for which we said that it is nothing else than “applied creativity found its market valuation”, we think that nurturing, encouraging and maintaining the inventive-creative potential through thoughtful treatment represents a form of support and development of entrepreneurship. On the other hand, also the confidence of the person, as characteristic of the image for himself, the “self concept”, over which can be directly acted and it can be shaped through the process of socialization and by imitation and which is mentioned as characteristic of the entrepreneurs, represents a point of interest in this study.

The support and attitude toward change is another important dimension which is different for entrepreneurs (initiators, leaders, innovators, non-conformists, flexible) and the others that hinder, and prevent the development, and that is the goal of this research. Hence, it is focused on: determining the extent and certain diagnosis of the inventive-creative potential, reliability, attitude to change and the attitude toward risk taking of those who successfully manage, operate with organizations, institutions, companies in Republic of Macedonia and for who exist indicators of their entrepreneurial trait, with the main goals:

- To verify which of the personal traits that make “the entrepreneur profile” given in the literature are present in individuals who manage their own business or manage with other organizations in Republic of Macedonia;
- To set the foundation for building of an experimental model - system for encouraging and developing of the inventive-creative entrepreneurial potential in children and adolescents of school and adolescent age;
- To test the use value and validity of some psychometric instruments and procedures used in this research.

4. METHODOLOGY OF THE RESEARCH PROCEDURE AND INSTRUMENTS

In terms of methodology, the research can be placed in the group of preliminary researches with the main objective to verify, determine the level, to diagnose the situation and as such it is part of a wider activity towards trying to establish a system to encourage and develop entrepreneurial awareness and culture where the values obtained will be useful for certain profiling of the local entrepreneurs as the basis for future recommendations and analysis.

In the research was used the test procedure by using validated instruments such as: the TTS test of Eugene Rodsep (test for determining the confidence), the MI 1 test for measuring the attitude toward the changes, and the questionnaire referring the level and attitude toward risk taking.

The test for measuring the **attitude towards creativity – TTS** is authorship of Eugene Rodsep and it has been already used in research on creativity in Republic of Macedonia. It is quite extensive with 50 offered attitudes and a few words that are chosen through several alternatives. The processing and scoring is made according to a key on the given scale of creativity: from 21 to 14 / uncreative, from 15 to 29 / under average creative, from 30 to 55 / average creative, from 56 to 84 / above average creative, from 85 to 109 / highly creative, from 110 to 140 / extremely highly creative.

The test for measuring the **confidence CC/C** is adapted to the needs of some researchers in Macedonia (K.Petkovski, 2001). Its metric features are not fully tested on our soil. It contains list of given statements with which the respondent may agree or not, the test is easy to check and evaluate by elaborated key. It provides rough indicators on the extent of one's confidence – non confidence on the confidence scale: from 0 to 15 / unconfident, from 16 to 24 / confident, from 25 and more / very confident.

The test for measuring the **reaction towards change - MI-1 (RTCI)** is proposed as a simple and fast tool for identifying the degree of acceptance / repulsion towards change (Smilevski, C., 2000: pg. 529). It contains 30 words referring the change. The preference of certain words that are most often associated with some changes, allows using prepared key and scoring system, to calculate the certain score which then is seen on a scale of acceptance of change: 40 and over / strong support, from 20 to 30 / moderate support; from 10 to -10 / subjection to change, from -20 to -30 / moderate resistance to change; of -40 and less / strong resistance to change.

The **attitude towards risk taking** recognized through direct response to the question “To what extent do you take risk?” on a scale from 1-7, where the rounded answer no. 1 means: “I often take risks by exceeding the positions that are previously defined, set out, agreed”. And the other extreme under no.7 means: “I almost never take risks by not going beyond what I had previously scheduled, planned, conceived”.

5. DYNAMIC AND STREAM OF THE RESEARCH

As previously mentioned, the study is focused on sizing the entrepreneurial resource of those who manage, operate with organizations, institutions in the Southwest region in the Republic of Macedonia (municipalities of Bitola, Prilep, Demir Hisar, Krusevo, Resen), through determining the extent of some of their personal characteristics that are considered part of the profile of every successful entrepreneur. Hence, the sample consists of 132 managers, owners of private companies and a number of heads of public sector organizations. The choice has been made based on several criteria: a) persons who started and run their own business (in any area); b) persons who applied and participated in the realization of projects connected with the promotion and development of entrepreneurship; c) people who were / are customers of business start - up centers or other development foundations, associations, NGOs working in the area.

Given the nature of the research, the type of research procedures, the usual closure of the business world for the researchers - especially with this type of research, the field work of the research was done on several occasions and it is mainly done in part of the free sessions at several training, seminars, in whose realization we participated. Hence, the overall process of collecting data, with certain interruptions, lasted several months in 2010 and 2011.

6. RESULTS FROM THE RESEARCH

This research focuses on sizing the entrepreneurial resource for those who represent certain example of successful individuals who manage, through determining the levels of their inventive - creative and confidence dimension, as well as the attitude towards risk taking and acceptance of change.

After the conducted research, the results obtained are presented qualitatively and quantitatively, and is used a statistical methodology for concluding by calculating the indicators of the descriptive statistics (measures of central tendency and measures of variability and dispersion) (Table 1). These indicators clearly show the extent to which each of the examined entrepreneurial characteristics is present among managers from private and public sector in Macedonia, which actually is the aim of the study.

After processing of the results a ranking of the respondents was made, separately for each test and for all tests together, collecting the achieved scores for each respondent. The results indicate that there are certain variations in the range of respondents on different tests. Given the deviations in the scores we consider that they are significant and show that very few (about 15% of the total number of respondents) are those who achieved high scores on all tests. In others there is variation in matter that on some tests they achieved extremely high, and on others - extremely low scores.

Table 1 Descriptive statistics' indicators of the examined variables

	TTS	SS/S	MI 1	Risk
Measures of central tendency				
\bar{Y} - Arithmetic mean	60.64	15.13	17.42	4.09
Me - Median	60.00	15.00	20.00	4.00
Mo - Mode	59.00	17.00	30.00	6.00
Measures of variability and dispersion				
Min. - Minimum	29.00	5.00	- 30.00	1.00
Max. - Maximum	95.00	24.00	50.00	7.00
Range	66.00	19.00	80.00	6.00
σ^2 - Empirical dispersion	122.03	16.04	381.10	3.43
σ - Standard deviation	11.05	4.00	19.52	1.85
Kv - Coefficient of variation	18.22	26.47	112.04	45.25
Ka - Coefficient of asymmetry	0.41	- 0.09	- 0.34	- 0.11
n - Sample size	132	132	132	132

From table 1 is obvious that when speaking of the first variable - the **attitude towards creativity (TTS)** the largest part of the respondents fall into the category of "creative above average" ($\bar{Y} = 60.64$). It is confirmed by the graph (figure 2) in which 64% of respondents fall into this category. The relatively high value of standard deviation, however, is a sign that the scores of the most respondents are different i.e. have major deviations from the arithmetic mean value.

In the results for the variable - **confidence (CC / C)** the average score achieved $\bar{Y} = 15.13$ indicates that most respondents are on the limit between "unconfident" and "confident". Most respondents, 53%, were unconfident. As for variability and dispersion can be said that exists pretty high variability, especially considering the values of standard deviation, variance and the empirical coefficient of variation.

As for the **reaction towards change (MI 1)**, the average achieved score $\bar{Y} = 17.42$ indicates "moderate support for change" as characteristic of most respondents. Majority of the - 46% have that attitude towards change. From the range of sores it is evident that with respect to this variable there are big differences from "strong support", to "strong resistance" to change, confirmed by the fairly high value of standard deviation.

The indicators for the fourth investigated variable - **the attitude towards risk taking** - indicate that the most respondents have average willingness to take risk ($\bar{Y} = 4.09$) on a scale from 1 - 7. Here, respondents are fairly divided by "often taking risk" to "not taking risk at all", for which speak the indicators of variability.

All this is concisely presented in the following graphs:

Figure 2 Distribution of "Creativity"

Figure 3 Distribution of "Confidence"

Figure 4 Distribution of "Reaction towards change"

Figure 5 Distribution of "Attitude towards risk taking"

7. CONCLUSION

Given the fact that in Republic of Macedonia do not exist similar researches aimed at determining the levels of these delicate personal parameters, our discussion will remain focused on the indications of some authors from which indirectly can be drawn certain conclusions.

In addition, although it was not subject of this research, however lacking in other studies related to other parameters that we measured, we intentionally focus on the exploration of "the achievement motive" realized in our country. We say intentionally because:

- It is a subject that is of scientific interest since the time of socialism and offers certain comparison;
- It is known that it is a gained motive which is subjected to development and change;
- It is a key of the entrepreneurial profile and
- Its structure includes the attitude towards risk taking and towards change which are variables of our interest. (McClelland according N.Rot, 1987).

Namely, the research conducted in the former Yugoslavia pointed to its low level, compared with levels in the population of developed countries. (Havelka & Lazarevic, 1981) and (Nikolovski, 1991). But its more recent measurements suggest that living in the transition has not remained without influence on the socialization of new generations. Specifically, it is claimed that it has an upward growth and tend to be equalized with the same levels set in the same population of the Western countries. (Donevska, 2010)

Hence, it appears that the issue regarding the risk taking, based on our results, as it was expected, the propensity to take risk is average - $\bar{Y} = 4.09$.

Finally, we can conclude that:

- The results indicate that it is necessary every eventual strategy for encouragement and development of the entrepreneurial potential to contain adequate, adjusted contents and activities which will be implemented under the supervision and guidance of specially selected and trained individuals - synergists, mentors, especially in the structure of values and attitudes (attitude towards change and risk taking). Even more, given the model and structure of the human capital in which, among other, are distinguished the values for which the famous author and researcher in this field M.Rokic spoke as for "cognitive represent of the connotative." (according Kolevski, N. & Kotevska, M., 1992: 331)
- There are individual cases in the group of respondents who possess personal characteristics regarding all investigated parameters, which can be considered as positive role models that might try to establish certain future cooperation, and the modeling system to encourage and development of the inventive - creative and entrepreneurial potential in our environment.
- By registering of the relatively high score in the attitude towards creativity, in Republic of Macedonia is reinforced the conviction that entrepreneurship is nothing but "market valorized creativity" and is easily explainable with some contemporary concepts and models of the relationship of creativity with other variables (Renzuli) .

Taking into consideration the opinions of the authors Petkovic and Madzar, regarding the definition of the concept and its differential separation from something it is not, which is summarized in the text as "delusions about the concept " we consider that the criteria " successful business " and even more "wealthy boss" often used in the context of determining the level, development, directions, tendencies, etc. of the entrepreneurship, are not fully appropriate in situations when is needed to identify or distinguish models of people - entrepreneurs. Of course, this is due to the existence of many other intervening variables that is obviously difficult controllable in an attempt to define "success, wealth," and ways of getting them. Hence, we believe that our attempt: the models of successful entrepreneurs with who in the future we would like to cooperate, on the way of fostering and development of the entrepreneurial awareness and culture, to choose the group of those who meet a certain level of characteristics described throughout the literature is entirely justified and appropriate. Of course, the variables emphasized in this research are one of the key in that profile.

Abstract: *The paper elaborates on the current situation in the field of financing entrepreneurial venture in Serbia in times of crisis. The global financial crisis significantly hit the SME sector in Serbia, reduced the liquidity and solvency of the enterprises, reduced the amount of available funding and loans for SMEs, increased the cost of capital and generally made existing financing problems even more difficult. The number of registered enterprises and entrepreneurs is constantly dropping, while the number of those ceasing to work has been going up since 2008. In times of crisis, SMEs are more vulnerable, since it is very difficult for them to downsize. Also, their weak financial structure is heavily dependent on external financing.*

Financing entrepreneurial ventures became one of the key challenges entrepreneurs are facing today and one of the major barriers to the rapid development of SMEs. Therefore, this paper aims to give an overview of available instruments of financing in Serbia, as well as to emphasize missing options. Regarding debt financing, since costs of credits and banking services in general are relatively high, SMEs are not profitable enough to be able to afford significant levels of debt financing at the existing interest rates in Serbia. Collateral requirements are still high, the procedures for obtaining guarantees and loan approval are too long, and loan amounts limited. Loans, although available, are not accessible to SMEs. Equity financing is in the initial stage of development. Venture capital companies are generally focused on large companies, while the segment of informal investors (business angels), who can substitute bank financing or venture capital at the early stage of a firm's life cycle in particular, is the missing piece of the puzzle. Serbian entrepreneurs are not quite familiar with the advantages and disadvantages of equity financing, and more training and education are necessary in order to introduce this kind of financing. Investment readiness programs could be an excellent opportunity to clarify business angels' expectations and entrepreneurs' perception of investors' requirements. Confronted with this gap and realizing that the existing market failure inhibits the provision of appropriate financing for SMEs, the Serbian government plays a very active role in providing subsidized loans and grants.

The analysis was mainly based on existing surveys conducted by Serbian and international institutions. The problems were analyzed from different perspectives using available statistics and we tried to provide relevant inputs of value to Serbian SME policy makers, entrepreneurs, banks and potential investors. The development of new financial instruments, especially in times of crisis, in order to support innovative SMEs and provide access to equity-based investments, has been envisaged as the priority of SME policy in Serbia. It is necessary to develop regulatory and funding mechanisms for encouraging formal and informal venture capital investments in SMEs.

Keywords: entrepreneur, SME, bank, debt financing, equity financing

1. THE LATEST DEVELOPMENTS IN SME SECTOR IN SERBIA

Since 2000 significant progress has been made in creating an institutional and legislative framework for business development in Serbia. The SME sector became the most efficient segment of the Serbian economy and the key generator of income and employment. In terms of SME developments, Serbia has managed to catch up with other countries in transition.

Table 1: Key development indicators of the SME sector in Serbia

	SME sector		Share of SME sector	
	2009	2010	2009	2010
No. of enterprises	314.827	318.540	99,8	99,8
No. of employees	872.540	814.585	66,7	66,4
Turnover (mil. RSD)	4.380.545	4.677.933	67,8	65,3
GVA (mil. RSD)	778.108	817.417	57,1	55,9
Export (mil. RSD)	275.378	339.845	50,5	46,4
Import (mil. RSD)	627.147	680.549	60,9	54,3
Investments (mil. RSD)	259.796	...	52,6	...

Source: MoERD, NARD: Report on SMEs and entrepreneurship development (2011), adapted by authors

Number of SMEs and number of employees generally has the positive trends in the period 2006-2009. It is worth mentioning that the *number of new jobs created in the SME sector in the period 2005 – 2008 was higher than the number of jobs lost due to the restructuring of large enterprises (MoERD, RDB, RASMEE, 2009)*. In 2010 the SMEE sector accounted for more than 99% of total number of enterprises, 66.4% of the employment, 65.3% of the total turnover and 55.6% of the gross added value of Serbian economy (MoERD, NARD, 2011). Micro business entities - entrepreneurs and micro enterprises account for the highest share in the number of SME sector entities, whereas small and medium-sized enterprises are dominant according to number of employees, total turnover and GVA, total export and import.

Decrease of foreign and national demand and investments had a negative impact on the business operations and the overall entrepreneurial climate. Slower development dynamics of the SMEE sector in 2009 and 2010, made the development problems of the sector more visible. The structure of SMEE, due to dominant share of micro enterprises and entrepreneurs and insufficient number of medium-sized enterprises (which are the key drivers in all developed countries), is unfavorable in a longer period of time and reflects pretty slow transition of micro into small and especially small into medium-sized enterprises. Secondly, prevailing position of low-tech industries is evident within the manufacturing sector (64% of all SMEs, 59% of total number of employees and 55% of GVA were realized in low-tech industries) while, medium-high-technology industries and high-technology industries encompass only 10% of all SMEs, 17% of number of employees and generate 21% of GVA.

Table 2: Indicators of SME sector in manufacturing industry in 2010 by technological structure (%)

Industries	No. of enterprises	No. of persons employed	Turnover	GVA	Export	Import
Manufacturing industry – SMEs	100,0	100,0	100,0	100,0	100,0	100,0
Low tech industries	63,6	59,0	55,6	54,4	54,6	40,6
Medium-low-tech industries	26,4	24,1	23,5	25,3	24,8	24,9
Medium-high-tech industries	6,6	12,8	13,2	14,1	15,8	17,6
High-tech industries	3,4	4,1	7,7	6,3	4,8	16,8

Source: MoERD, NARD: Report on SMEs and entrepreneurship development (2011), adapted by authors

Relatively low level of competitiveness is crucial problem of SMEE sector in Serbia which generates significant trade deficit. Low level of production and financial capacities produced increased investment dependency of this sector on the external sources of financing. Preliminary results from the *Business Environment and Enterprise Performance Survey (EBRD, 2008)* clearly showed increased reliance of SMEs in Serbia on bank borrowing as compared to the findings of the same survey run in 2005. Bank loans are the most important external source of financing SMEs (40%), whereas significantly less important sources are loans from friends, relatives or partners, leasing, government funds, foreign loans, guarantees and donors' support.

2. IMPACT OF FINANCIAL CRISIS ON SME SECTOR

At the present time, SMEs have been especially hard hit by the global crisis. *These firms are more vulnerable now for many reasons: not only has the traditional challenge of accessing finance continued to apply, but new, particularly supply-side, difficulties are currently apparent (OECD Centre for Entrepreneurship, SMEs and Local Development, 2009)*. There is the evidence that since 2008 SMEs in Serbia are being constantly faced with a clear decline in demand for goods and services. In this context, it is very difficult for micro and small enterprises as well as entrepreneurs, which are the dominant segment of SME sector, to downsize business operations as they are already small. Two related factors were of special importance for the SME sector: increased payment delays (which produced the decrease in liquidity) and increased insolvency and bankruptcy rates (due to weaker financial structure, lower or no credit rating and inability of SMEs to obtain short-term financing).

The number of registered enterprises and entrepreneurs has been constantly dropping, and the number of business entities ceasing to work has been going up since 2008. The ratio of established and closed enterprises, has been declining every year indicating less newly established enterprises compared to

number of closed enterprises. In this context, constant negative trends can be found in decrease of birth rates and increase of death rates of enterprises.

Table 3: Established/closed ratio and birth rate vs. death rate

	Established/closed ratio		Total	
	enterprises	sole traders	Birth rate	Death rate
2006	7,5	1,7	22,3	10,6
2007	5,9	1,5	20,7	12,1
2008	3,7	1,3	18,0	13,2
2009	2,8	1,1	15,7	12,7
2010	1,0	0,9	14,2	14,9

Source: MoERD,NARD: Report on SMEs and entrepreneurship development (2011), adapted by authors

According to Survey of small and medium-sized enterprises and entrepreneurs (*Republic Statistical Office, 2011*), 60% of respondents are coping with challenges of the current economic crisis, among which there is a small number of enterprises that do not feel the effect of the crisis (14%). There are 21% of respondents faced with decisions on dismissal of employees, and as much as 19% of them are faced with uncertain perspective in terms of further survival. Share of surveyed enterprises that feel stronger impact of the economic crises was reduced compared to the findings of the surveys in the previous years (40% compared to 51% in 2010, and 48% in 2009). Most of enterprises in 2011 intend to continue working with the increased (44%) or the same scope of business activities (48%) in the following three years. Negative outcome was considered by 8% of respondents, where 4% is related to reducing business activities, 3% to closing the business and 1% to transferring the business to somebody else.

Table 4: Orientation and plans of SMEs in times of crisis

	Business expansion	The same workload	Reduced workload	Closing the business	Transfer business to others
Micro	32,2%	55,6%	6,1%	4,7%	1,5%
Small	45,9%	47,2%	3,8%	2,0%	1,1%
Medium	58,7%	37,6%	2,4%	0,9%	0,5%
Entrepreneurs	29,1%	59,1%	4,6%	5,3%	2,0%
Total SME	43,6%	48,5%	3,8%	2,9%	1,2%

Source: MoERD,NARD: Report on SMEs and entrepreneurship development (2011)

In the similar survey conducted in 2006, there was much more enthusiasm among entrepreneurs: 66% of respondents intended to expand their business, and 26% planned to keep the existing level.

Governments generally responded on financial crisis by three types of measures aimed at: *supporting sales and preventing depletion of SMEs' working capital, enhancing SME's access to liquidity and helping SMEs to maintain their investment level* (OECD Centre for Entrepreneurship, *SMEs and Local Development*, 2009). Serbian Ministry of Economy and Regional Development in 2009 initiated the scheme and put in place anti-crisis packages, through the Serbian Development Fund in cooperation with the commercial banks, which enables subsidized loans for businesses covering investments, liquidity maintenance, financing of long-term working capital, export activities and financial leasing.

3. FINANCING ENTREPRENEURSHIP IN SERBIA

3.1 Debt financing

SME sector has become an important segment of interest of banking sector and an increasingly attractive customer group although the banks in Serbia have been traditionally cautious with lending to SMEs due to high risks associated with the sector. Consisting of 33 banks with network of 2.432 organizational units at the end of 2011, the banking sector in Serbia provides the range of both standardized as well as specially tailored banking products/services. Banks became more aware of the importance of the SME sector in Serbia and majority of them have separate departments dealing with SMEs. In this context, banks that are a part of international banking groups have changed the terms of access, the risk analysis and risk

management practices for SMEs. Concerning banks' operational management, the small enterprises became the part of retail lending while the medium enterprises became the part of corporate lending. The existence of financial infrastructure, such as credit Bureau of the Banking Association and the Solvency Centre in the NBS, have been of major importance to allow introduction of modern credit risk appraisal techniques.

Serbian banking system operates under very strict and tight legislations and regulations. Although the bank lending conditions have significantly tightened, growth rate of credit potential of banking sector in Serbia had increasing trend in 2008 and 2009, but slower than in the period 2005-2007, indicating the direct impact of financial crisis. Deposit potential had a negative growth only in 2008 as a direct consequence of the first wave of financial crisis.

Table 5: Indicators of banking sector in Serbia

	2005	2006	2007	2008	2009
Number of banks	40	37	35	34	34
Growth rates of credit potential (in %)	40.0	26.2	38.7	21.4	7.2
Growth rate of deposit potential (in %)	35.2	52.2	45.4	-2.7	14.2

Source: NBS and ECB, 2010

From the bank's perspective, profit potential from SME lending is high, but some obstacles, basically policy related, were identified (<http://siteresources.worldbank.org>). The most serious obstacle is the legal and contractual environment (including weak protection of creditors and property rights, problems with contract and collateral enforcement, judiciary inefficiency and slow and costly bankruptcy procedures). Banks in Serbia are trying to deal with these inefficiencies by demanding high levels of collateral for practically all types of credit products. Macroeconomic factors related to regulations were also recognized as obstacle to SME finance. Due to very tight monetary policy implemented by National Bank of Serbia and high cost of compliance, the cost of credit and of banking services generally in Serbia has significantly increased. It is widely recognized that SMEs are not profitable enough to be able to afford significant level of debt financing at the existing interest rates in Serbia. In the field of bank's policy, they frequently try to avoid providing loans to certain types of SMEs particularly start ups and very young firms without track records that typically lack sufficient collateral, or firms whose activities offer the possibility of high returns but at a substantial risk of loss (OECD, 2006). In this context, loans although available are not accessible for SMEs in Serbia.

On the other side, SMEs' perspectives elaborated in the Survey on current situation, *problems, and needs of the SMEE (MoERD, RASMEE, SSO, 2009)*, conducted on a sample of 3,000 enterprises, provided insight into the existing situation and problems encountered by the SMEE sector. Entrepreneurs found very limited possibilities and poor assortment of sources of finance on the domestic financial market. Commercial banks' offer is still not stimulatory enough and unreachable for the majority of SMEs. High interest rates are the main problem regarding loan arrangements of small enterprises, banking costs as well as collateral required are still high, the procedures of obtaining guarantees and approving loans are complicated and too long, and loan amounts limited. Serbian Business Registration Agency and the Serbian Development Fund have a fully operative system for the registration of movable assets allowing firms to use movable assets as collateral in their efforts to access bank finance. Additionally, it should be emphasized that some opportunities for reduction of collateral requirements through credit guarantee schemes exist in Serbia. The Serbian Guarantee Fund and Vojvodina Guarantee Fund issue guarantees for SMEs, entrepreneurs, start-ups and agricultural producers. Export credit and Insurance Agency is focused on export oriented sectors and provides credit guarantee schemes. There is an idea that credit guarantee schemes should be privately managed in order to achieve efficient allocation of resources through the incentive schemes.

3.2 Government intervention

Due to existing market failure that inhibits the provision of appropriate financing suitable for the SMEs, Serbian government still plays an important role in supporting the SME sector. There is a number of government-sponsored programs aiming to stimulate the SME development. Existing financial infrastructure at the national level that directly or indirectly provides financial support to SMEs and entrepreneurs from government sources consists of several institutions.

Table 6: Government support

	Institution	Types of support
1.	Ministry of Economy and Regional Development	<ul style="list-style-type: none"> • Subsidies for quality certification, cluster development, entrepreneurship development and innovations • Subsidies within Program for stimulating investment in innovations in Serbian companies • Loans for development of enterprises and entrepreneurship in under developed municipalities • Loans for improvement of the quality of tourist products in SMEs • Low interest rate loans for start-ups
2.	Ministry of Science and Technological Development	<ul style="list-style-type: none"> • Subsidies for innovation projects
3.	Ministry of Agriculture	<ul style="list-style-type: none"> • Financial support to entrepreneurs and NGOs in the field of agriculture for developing safety and quality systems for agro products in 2009 as well as for providing consultancy work.
4.	Development Fund of Serbia	<ul style="list-style-type: none"> • Low interest rate loans in order to facilitate SME start up and development (including investments in new programs/innovations, reconstruction and modernizing, and in working capital)
5.	Development Fund of Vojvodina	<ul style="list-style-type: none"> • Long term and short term loans for SME development and export finance
6.	Guarantee Fund of the Republic of Serbia	<ul style="list-style-type: none"> • Approves and guarantees for company loans parts approved by the banks and other financial institutions. Guarantee Fund approves 30% and the banks 70% of the loan.
7.	Guarantee Fund of Vojvodina	<ul style="list-style-type: none"> • Issuance of guarantees to banks as the collateral of regular bank loans repayment by individual farmers, private entrepreneurs, small and medium enterprises
8.	National Agency for Regional Development (former Republic Agency for SME Development)	<ul style="list-style-type: none"> • Low interest rate loans for start-ups (as implementing institution within the government program) • Subsidies for quality certification, entrepreneurship development and innovations (as implementing institution within the government program)
9.	Export Credit and Insurance Agency of Serbia (AOFI)	<ul style="list-style-type: none"> • Short –term financing, export credit insurance, factoring, foreign buyer financing, refinancing of a foreign buyer via commercial bank and financing from other sources.
10.	Serbia Investment and Export Promotion Agency (SIEPA)	<ul style="list-style-type: none"> • Subsidies for the participation of Serbian companies at international fairs, creation of business linkages as well as organization of trade missions for the foreign companies interested in doing business with Serbian companies
11.	National Employment Service (NES).	<ul style="list-style-type: none"> • Subsidies for job creation – mostly for the ones listed in the NES's database as unemployed and other incentives for job creation.

As far as state-funded credits are concerned, the Development Fund of the Republic of Serbia is the principal channel, providing (subsidized) financing for different programs related to economic, regional and SME development, increasing competitiveness and related activities. This Fund has a number of credit products including: Long term credits up to five years at an annual interest rate of one per cent, funded by the Ministry of Economy and Regional Development; Short-term credits (6 months), with annual interest rate of 3.5% from Fund own resources; Long-term credits of up to five years at 4.5% annual interest and with a grace period of one year; Credits for financing development of production trades (craftwork) and services – entrepreneurial credits (4 years) with 1-year grace period and annual interest rate of 1-3%.

Banks were very positive about the need for the Government to take an active role in trying to facilitate lending to SMEs (<http://siteresources.worldbank.org>). Although the subsidized programs have provided interest rates that were significantly smaller than that of banks, when asked to evaluate the Government-sponsored credit programs, banks responded that the programs have little or no real impact on the market or the SME development. One explanation for such an opinion can be that the total volume of funding available from the government-sponsored sources is actually rather small to affect the market rates, which is partially true. More importantly, there is no reliable impact assessment of the incentives to SMEs put in place by Serbian government. It should be the very clear indicator of efficiency of SME policy in the context of financing entrepreneurship. Therefore, it is necessary to design clear monitoring processes for all government-sponsored programs aiming to finance and stimulate the SME development.

3.3. External equity financing – the missing piece of the puzzle

Financial markets in Serbia are generally underdeveloped and there are limits for SMEs to use other financial instruments coming from the capital market and corresponding financial organizations. The Law on Investment Funds (2006) was a first step towards allowing the establishment of private equity funds in Serbia. The *OECD report "Progress in the Implementation of the European Charter for Small Enterprises in the Western Balkans: 2009 SME Policy Index"* (2009) states that several private equity funds are operating in Serbia. But, these funds confine their investments to the acquisitions of stakes in larger Serbian enterprises. Existing Law on Investment Fund does not impact substantially on innovative SMEs nor venture capital companies investing in them.

Despite the importance of innovative SMEs, having in mind that they represent higher risk than traditional SMEs or large firms, they face particular problems when attempting to access traditional bank loans. On the other hand, SMEs are also disadvantaged having in mind that investors (who provide risk capital in return for the equity share in the company), are generally focused on large companies. Financing innovative SMEs is additionally complicated by the fact that these firms require different financing at different stages of their development.

Business angels can be a substitute for bank financing or venture capital which can be difficult to attract at the early stage of a company's life. In contrast to bank finance, venture capital companies and business angels do not seek scheduled repayment, but for a minority stake in the share capital of a company in return for cash. Business angel, as private investor who brings not only capital but also experience and know-how in company management at the early stage, is generally interested in the high-risk and high-reward business opportunities that the venture creation offered. Business angel tends to operate on a smaller scale than formal venture capital companies and probably concentrates more on start-ups than in expanding enterprises. For these reasons venture capital companies and business angels are usually regarded as separate categories.

Although, there is no formal representative association of business angels in Serbia, in the end of 2009, the first informal network of business angels was established in Serbia, called "Serbian Business Angels Network" (SBAN). SBAN provides an opportunity for entrepreneurs, through the web portal that serves as a type of matchmaking platform, to place their business ideas and to search for potential investors. Investors, business angels, members of the network, can see all the projects and browse through projects according to their field of interest or value of capital needed as investment. SBAN also allows the investors a potential joint investment. It is of vital importance for entrepreneurs in Serbia, through attending trainings, conferences, workshops and lectures, to improve knowledge on designing business plans, project documentation, marketing and finance as well as to improve their communication and negotiation skills in order to prepare themselves for the business meetings and negotiations with potential investors. Investment readiness programs will be an opportunity to eliminate some misunderstandings and to clarify business angels' expectations and entrepreneurs' perception of investors' requirements. Also, it is necessary to promote the equity financing and to develop regulatory and funding mechanisms for encouragement of formal and informal venture capital investment in SMEs.

4. CONCLUSION

Slower development dynamics of the SMEE sector in the times of crisis, made the development problems of the sector in the fields of financing entrepreneurship venture more visible. Weak financial structure of SMEs is heavily dependent on external financing and due to lower or no credit rating (especially in case of start-up firms) they have limited external financing options.

Existing scope of financial support to SME sector in Serbia, although significantly improved, is not enough specially in times of crisis to contribute to faster growth and development of SMEs and entrepreneurship.

Regarding the debt financing, the cost of credit and of banking services generally increased. Although available, loans are not accessible for SMEs in Serbia having in mind the SMEs are not profitable enough to be able to afford significant level of debt financing at the existing interest rates in Serbia. Start-up businesses are in particularly difficult position. Banks frequently hesitate or try to avoid providing loans to them because they have no track records or sufficient collateral.

External equity financing in Serbia is in the initial stage of development. Venture capital companies are generally focused on large companies, while the existing Law on Investment Fund does not impact substantially on innovative SMEs nor venture capital companies investing in them. Informal investors (business angels) can be the substitute for bank financing or venture capital especially at the early stage of a company's life. But, in Serbia this is the missing piece of the puzzle, and more training and education is necessary in order to promote and introduce the essence of this kind of financing. Very first initiative to establish the network of business angels in Serbia was implemented via SBAN web portal enabling entrepreneurs to present their business ideas and projects on one side and investors to better allocate their investment decisions in the area of their interest.

Development of new financial instruments which will support primarily innovative SMEs and provide access to equity-based investments, was envisaged as the priority of SME policy in the area of financing SMEs in Serbia by the Strategy for Development of Competitive and Innovative SMEs 2008-2013. Besides providing direct financial support to SME sector, it is also necessary, in the conditions of a financial crisis, to work more actively on improving the knowledge of SME owners and entrepreneurs in the field of availability of funding, information on how to access these sources as well as how to manage them efficiently.

²Faculty of Economics Subotica, University of Novi Sad, bojan.lekovic@ef.uns.ac.rs

Abstract: *One of the main goals of this paper is to define formal management practices, as well as to define success, i.e. good performance of small businesses. Current dilemmas in the cited triangle are of immediate interest because of different research results on this subject. Initiating critical thought on the subject creates necessary conditions for further research within the framework of the defined field, increases the understanding of the research problem and contributes to better dissemination and usefulness of future research results. Considered from the aspect of future research intentions, this paper is a necessary step on a defined path, that is, a necessary condition for further research.*

Keywords: management practice, success, good performance, small business

1. INTRODUCTION

Numerous works published in academic publications, as professional journals, including research results on management practice and success and/or good performance appeared about 50 years ago. At the beginning, significant part of this sort of researches related to large enterprises, therefore, most management practice was founded on methods and procedures developed for large enterprises, where operative and financial goals were very precise and clear and could be very easily turn into concrete actions (Simpson M., Padmore J., Frecknall-Hughes J., 2007). Recently, the realized balance and part of attention have been paid to small business. This change of behavior relationships have been caused by the opinion and a very logical attitude that **management practice is the principal culprit for success/failure of large companies and everything good for large companies is also good for small ones**. This attitude is confirmed by many researches where managerial practice was on the top as a critical factor for the success of small business. Significant research space within the framework of this subject after five decades of current importance has been present for opposite results of authors when researching in this field. The previous statement should be accepted very carefully. Results of the cited researches can be hardly compared because there is some dose of relativism when determining how an author understands the key variables of researches as managerial practice, success, performance and indices for indicating these variables. The work, as part of a wider research project will enable the adequate starting points and the realization of planned researches to determine the interdependence of management practice and success/performance of small business. The main result, the practical result, of these attempts should be the managerial framework in the form of managerial recommendations for success, i.e. good performance of small business, as well as the adequate way to disseminate these results with a view of advancing practice in the field of researching. It is also very important to emphasize the necessity of clearing up the starting points and complete understanding of some categories so the results of this research can be definite, unambiguous and completely useful. This means, firstly, that we must determine precisely the categories of formal management practice, as well as to limit the categories of success and good performance; these will be some of the key variables in the research.

2. EXISTANCE OF MANAGEMENT PRACTICE

As the beginning phase in the life cycle of an enterprise, i.e. development, considered from the aspect of its size, small business, as the social-legal entity – societies have a significant distance in relation to medium enterprises, when speaking on management practice and the level of its application. Management and intention for the long-term existence, as well as the realization of its own mission make small business an officially accepted entity of the economic activity. The existence of management orientation clearly divides small business from the entrepreneurial undertakings, as visually explained in Figure 1. In the same way, starting management practice, largely, qualitatively divides small business from medium enterprises, as the next phase in development, where management is present at one higher, professional level.

Figure 1. Differences between entrepreneurial investments and small business management

Source: Wickham, P, 2004.: «Strategic entrepreneurship», Prentice Hall, p. 103.

Therefore, small businesses divided from the segments of medium ones, where the category of micro enterprises is turned off, represent one homogeneous entirety, i.e. one qualitatively precise and clearly limited field of researching. As seen in the previous part of the work, as selected research field appears a subgroup of small businesses where the category of micro enterprises numbering until ten enterprises is excluded. Reasons are exclusively of the substantial character and they significantly exert influence on the quality of researching. The basic set of small businesses without micro enterprises, defined in this way, is completely compatible and comparable with the same segment of economic societies as defined in EU and the surrounding countries. It is not the case in our country. In the analysis of interpreting and usability of research results based on the realized compatibility of the research field, we get the broader field, in the time and space sense, for medium enterprises dissemination. Except micro enterprises, the sub-segment of medium enterprises is also excluded because small businesses have specific features in relation to the medium ones, as for the attained level of management practice. As obliging in the next part is the precise determination of key research variables in order to interpret causes, relationships and connections of some results with a dose of reliability and usability. One of the main independent variables in this research is certainly management practice in small businesses. There are different approaches and determinations in the scope of this part of the research field. According to Wickham and the model illustrated in Figure 1, the existence of small business management within entrepreneurial undertakings is confirmed with the strategic orientation and it represents the basic indicator of management practice in small business (Wickham P., 2004, p. 41). The substantial strategic orientation means the existence of the long-term determination with small business for realizing business activities materialized in strategic goals, defined mission and business vision. The presence of formal small business management is mostly identified with planned activities. The dominant activity within the framework of strategic management is planning. Planning as the first phase of management process is definitely the key subject of small business and management practice. Some authors connect planning with the advancement of performance, others treat planning as the key factor of success. Connecting management practice for planned activities exclusively points to some indications that it is about the beginning phases of management system and its development in small businesses according to the level of business activities of economic entities as small businesses. The following citations speak about the importance of business planning for small business. If the beginner entrepreneur asks for advices to advance business, the most often answer is "Start with planning" (Brinckmann et al, 2010). In addition, most university in the U.S. A. having study entrepreneurship programs, teach students on the importance and carrying out business plans (Brinckmann et al, 2010). Seventy-seven schools of 100 business schools in the U.S.A. have courses for carrying out business plans (Honig, 2004). Many leading professors of entrepreneurship consider business plan development as the most methodical unit in entrepreneurship

instruction (Hills, 1988). In many countries, business plan is one of the leading instruments for entrepreneurship development and regional development (Russell et al, 2008; Lange et al, 2007). In addition, in many countries, hundreds of people participate every year in the government instruction programs for carrying out business plans (Brinckmann et al, 2010). Citing these attitudes in detail, we have not yet defined precisely how we understand management practice in small businesses. According to the previous question, there are two opposite schools: the planning school as opposed to the learning school (Wiltbank et al, 2010). Supporters of the planning school emphasize that learning generally advances efficiency, therefore the performance of small business (Ansoff, 1991). As the main components of business planning, they cite strategic goals, strategies, evaluation and decision-making as part of control implementation (Armstrong, 1982; Porter, 1985). Supporters of the learning school focus dominantly on learning, strategic flexibility and resource control, not on the predefined behavior in the form of formal plans (Mosakowski, 1997; Mintzberg, 1994; Waters, 1985). In addition, one of the researchers who connect management practice of small business with the survival and good performance is Johan Maes et al (2005). He cites, in his work, the following activities proving the existence of management practice and their influence on financial performances in small business.

The list of business activities is illustrated in Figure 2, being identified as the form of management practice, unambiguously points to the beginning steps in building the management structure, which is typical of enterprises in the beginning phases of development as small businesses. The cited activities in this research cause the interdependence with financial performances and are very important for the survival of small business. From our standpoint, only their presence and the form in which they appear are interesting. In this way owners/managers confirm the thesis about intentions and efforts on the long-term survival, building the organized business system; all this has the characteristics of strategic orientation.

2. SUCCESS AND/OR GOOD PERFORMANCE

In all the fields of social and economic engagement, participants try to realize success. Success is not always the end goal in undertaking some activities, but it becomes the resource for realizing many other goals. Success is something to which owners/managers/beginners of small businesses also gravitate. For economic activity and enterprise management, success can be measured and expressed by a large number

of indicators, but an overall expression of success is realized by means of synthetic indicator called profit. Besides this representative indicator, success can be considered in different business segments where success can be presented in different ways as productivity increase in production, winning a new part of the market, sale volume increase, introducing a new product on the market, increasing the number of employees, production increase, etc. Most attitudes, presented in the literature considering success, define successful enterprise in the following way: to be considered as successful, the enterprise must realize at least average profit of its economic branch. However, as for small business, is it the same? For success in an entrepreneurial undertaking, it is necessary to satisfy all the conditions so business activities can result in successful business results. These conditions relate to knowledge, skills and capabilities of the entrepreneur who, as a person, should have them, then good business ideas, as well as conditions ruling in the business environment. There is no guarantee for entrepreneurs. Simply, there is no way to eliminate all risks connected with starting small businesses, but the chances for success can be increased by good planning, preparations, evaluation of strengths and weaknesses of potential owners/managers of small businesses. Except of all these usual legalities, there are exceptions as many successful owners of small businesses are who, in the age of adolescence, were team players, athletes, leaders at school, excellent students, never considering status quo. However, it is quite usual to meet many successful entrepreneurs inclined to be rebellious people, and inclined to taking risk, as well as those having tendency to be "off beat" and it is considered as necessary for successful carrying out an entrepreneurial undertaking. Obviously, there is not a well-known formula for success, but there are numerous open questions and dilemmas what it represents and how to measure it in small businesses. To treat the problem of performance categories and success of small business represents one of the key points in this work. There is not firm determination what the previously cited categories mean, as there is a wide range of variables for measuring performance/success. Most management practice is based on methods and procedures being developed for large companies, where operative and financial goals are very precise and clear and which can be easily transformed into concrete actions (Simpson M., Padmore J., Frecknall-Hughes J., p. 1). As for small businesses and the relationship between management practice and success/performance (Rue and Ibrahim, 1998; Perry, 2001; Gibson and Cassar, 2006; Simpson et al, 2007; Wiesner et al, 2007), there are some difficulties mostly relating to objective measurement. But, in most researches, a significant part of success/performance of small businesses is connected with management practice, illustrated in Figure 3. According to some authors, success is interpreted as a specific aspect of performance (Brush and Wanderwerf et al, 1992, p. 159); others equalize success with high performance (Brooksbank et al, 2003), while some authors bring it in touch growth and profitability (Perren, 2000).

Figure 3. Relative importance of the factor of small business failure

Causes	%
Lack of management skills	29.1
High interest rates	15.6
Economic recession – inflation/unemployment	11.4
Taxes	10.1
Competition	5.8
Money flows	5.8
Laws and other bylaws	5.0
High business costs	3.6

Source: Peterson, R., Kozmetsky, G., Ridgway, N.: « Perceived Causes of Small Business Failures », *American Journal of Small Business*, 2003., p. 15

Some authors connect small business success with the survival itself, i.e. avoiding failure. As for **defining small business failure**, it may be the simplest way when it equalizes with its **formal bankruptcy** (Cochran, 1991). Using different sources of information on small business failure, there is a possibility to widen the previous definition by the category of conscious retreat from business, including here small businesses that stop working because of the loss financial resources, which also means bankruptcy, as well as conscious retreat, leaving nonpaid liabilities to creditors (Dun & Bradstreet, 1999).

Because of different understanding of success and performance, and the way of measurement, there is the necessity of precise limitations and defining. As for owners/entrepreneurs/managers of small businesses and the wide spectrum of their goals, as quality independence and life style (Jennings and Beaver, 1997, p. 63)

speaks enough about the complexity of problems. The illustration of success by means of financial indicators, as the total income per employee, profit per employee or the period of investment return is not enough to apply in the context of small businesses, disregarding they are easy to measure because they ignore the alternative criteria of success based on personal goals of owners/entrepreneurs/managers. Personal goals of owners/entrepreneurs/managers should not be harmonized with business goals, financial indicators do not often state them, and it additionally complicates the current situation. Some financial categories, total income, profit, property, as quantitative statements are differently calculated because they, in their structure, include different elements, and it makes the category of financial indicators and their values relativistic. According to Frecknall-Hughes et al (2007), the main shortages of accounting and financial indicators of performance are:

- Ratios give meaningless figures if the company has generated a loss;
- There is no absolute definition as to what constitutes a “correct” ratio;
- Given (ii), they may be calculated almost as one likes, which means that they are capable of manipulation;
- Compounding (ii) and (iii), ratios are often just presented as figures, without any supporting calculations or definitions;
- Ratio analysis deals only with financial numbers and does not take account of other factors which may affect company performance; and
- If they are calculated over a period of years to provide longitudinal data, then the value of currency in later years will not be the same as that of earlier years, owing to the effect of inflation, etc.

For the concept of small business success, i.e. owners/entrepreneurs/managers, we can say that it is a subjective-absolute category as a measure in realizing the set goals of the company, which can be simple and having one meaning; therefore, they can reflect individual, personal aspirations and motives. *Performance represents the relative-objective dimension of success as a multi-dimensional, qualitative and quantitative, the expression of success compared to other enterprises or relevant groups of enterprises.* Performance itself represents the attained level of realization, i.e. the principal result of business activities of the company, in this case, small business. Such defined limited categories of success and performance point to the fact that the company can be successful in realizing the set goals, but also it finds itself in an unsatisfactory level of performance- good, high, optimal), for instance , regarding to growth and development, as a multi-dimensional term of success (Jennings and Beaver, 1997, p. 68). When the analysis is oriented toward small businesses, as the pattern and the basic set defined within the framework of this research, the main resource of mutual comparison to the dimension of relative success is certainly performance expressed by selected indicators, which unambiguously represent this category. The selection of indicators for stating the level of performance is certainly the key factor of success of all the efforts expressed in this and similar researches, which have performance as an independent variable. Lumpkin and Dess are very precise when researching the multi-dimensional nature of performance, deciding for traditional indicators of growth, market participation, profitability, stakeholders’ satisfaction, etc. (Lumpkin and Dess, 1996, p. 153). In this research, indicators of survival, growth, development and profitability are selected with a view of measuring small business performance. The cited selection represents one consensus on the subject of performance indicators, and it is seen in the research carried out by Murphy with authors within the framework of 51 works, where he identified 71 different performance measures, classifying them into nine principal groups, where growth and profitability are the most frequent (Murphy, Trailer and Hill, 1966, p. 16).

3. CONCLUSION

Based on the previous attitudes, determinations within the framework of this research are as follow. Documented business plans do not represent strategically oriented management practice in small businesses, but the formal planning is part of a strategic management process. Learning a lesson from the previous sentence, for management practice, we mean planning and documented business plans, as well as management activities in all the phases of management processes with formal documentation.

As for measuring and business result statements in small businesses, there is a significant distinction between the categories of success and performance. For the category of small and medium enterprises, we can say that it is a specific aspect of performance characterized by subjectivity and the personal dimension of owners/managers/entrepreneurs, which should not be in accordance with realized business results, i.e. performance. As a qualitative statement, it is very hard to express it by means of numerical indicators, and it represents the basic shortage of financial success indicators, when talking about small business. Performance measuring, as an objective statement of business success, does not point to the level of

realized business goals of owners/entrepreneurs/managers and it points to the need of inclusion of qualitative indicators of the entrepreneur's business success. If we want performance indicators to express the real measure of business success and realized results in the form of selected financial indicators, some mutual comparisons within the framework of some related groups of companies in the same economic branch are necessary. It is also necessary that financial indicators are uniform to relative relationship of selected categories and being compared and in this way; they make a comparable ratio structure. In any case, the volume of management activities, according to all the phases of management process and the degree of its formality in the form of written documents, is connected with success, i.e. small business performance. The former researches partly and contradictorily covered such a defined problematic orientation, opening the space for intentions set in this research.

Abstract: *This paper describes the role of owners of small or medium sized businesses as the main pillars of business functioning, and outlines potential impacts (positive or negative) on owners of SMEs. The objective of this research is theoretical understanding of the problems SME owners face every day, and possible identification of local SME owners (in Serbia) with foreign or domestic problems abroad. Specific methods used in writing this paper were confrontation of views of various authors on the same issue, and the synthesis of the authors' own findings, or the findings of others. The authors have gained insight into the quantity and quality of problems and factors affecting owners of SMEs, and the daily amount of tasks which an owner has to deal with. The limitation of this study may be a lack of practical research, but it can certainly be a good impetus for further work. The paper has revealed a strong correlation between owners of SMEs and ways in which they are introduced to problems, or whether they will succeed in minimizing side effects. This theoretical study may serve to existing or future entrepreneurs and researchers, to elaborate on the topic.*

Key Words: *small, enterprise, owner, influence, business*

1. INTRODUCTION

Concept of entrepreneurship now basically covers the design and organization of business activities with the ultimate goal of profit making. An entrepreneur is a person who is constantly looking for changes, and responses to changes in the environment, using them as an opportunity for further development. Entrepreneurs innovate constantly in order to keep up with market conditions. Within-entrepreneur (intrapreneur) is a person working in a company apart from other activities, and the company is actively involved in innovation, as well as in revitalization / diversification of business. Entrepreneur has to feel the freedom of action in order to explore and implement ideas, although the outcome effect of that work will be greater than the whole company can withstand, but also the entire company has to take over the risk that comes with such actions. Entrepreneurs usually play a major role in developing the economy of a country, or to increase the GDP of a country. Social development of a country or region is also marked by the influence of entrepreneurial activity.

2. THE ROLE OF A SME OWNER

In business there are no guarantees. There is simply no way to eliminate all risks associated with start-up businesses - but it is possible to increase the chances of success with good planning, preparation and close examination of business conditions. The owner must have a good idea to assess the strengths and weaknesses of his small business. It must be carefully considered including all concerns, such as:

- Do you venture into everything yourself (i.e., whether each project, organizing, monitoring, just go through the owner or someone else),
- How well is the owner getting along with the environment (the owners have to develop working relationships with a variety of people including customers, vendors, bankers, lawyers, consultants, etc...)
- How well and how does the owner plan to organize a business (a good finance organization, storage, distribution, production can help avoid many downfalls),
- Is the urge to own a business strong enough (business management can significantly emotionally downfall on owners, so many owners burn out quickly, precisely in order to submit all the pressure, all liability for (non) success of their business).
- How will the business affect the family of the owner (the first few years can be very difficult for the family life of the owner, so it is important for family members of owners to know what to expect, but for the

owner it is very important to know that they will have the support of family members when it comes to difficulties in business) (Morgan, 2007.).

Picture 1 (Saroj and Mehndiratta, 2009.)

Ideas to the new business owner can come from various sources. Some owners run the business and develop existing ones, according to some of their personal interests. Any specialized knowledge or skill may be the owners to indicate, and the possibility of turning it into a business. Through time, as companies reduce, or require more external services (outsource), so the opportunities for entrepreneurs are born. Any task or responsibility that large companies do not want, or do not have time to do it, can be the basis of the owner of an SME to be involved in cooperation (and Saroj Mehndiratta, 2009.).

The role of the SME owner is to learn all aspects of his business potential, to make such a good knowledge that could lead to good functional and business decisions. There are entrepreneurs who are very inventive in their work, including developing new or improving existing products which can interfere with much larger "players" in the market. There are some advantages in developing your own business. Again, the owner is the main pillar of that development. It is less costly to start and develop their own business, rather than to buy someone else's which already had numerous disadvantages encountered. Most people who start their own business are good at what they do, so it is easier for their colleagues to rely on them in the process of developing a business (and Saroj Mehndiratta, 2009.).

When owner family members are involved in the whole story, then it is possible to develop their own management style and approach, their own policies, ways of treating the problem (and of course there are risks that cannot stop the realization of the process of business development) (Saroj and Mehndiratta, 2009.).

The characteristics that a SME owner has (at least most of them) to meet are:

- Ability to take initiative - an entrepreneur is a person that identifies an opportunity, trying to extract the best outcome from it, if he doesn't have this capability, the entrepreneur cannot continue to progress,
- Self-confidence,
- Possession of leadership quality- an entrepreneur would have to be able to influence the behavior of his employees so that they achieve the objectives of the organization,
- Ability to assume the risk- an entrepreneur would have to be able to analyze the opportunities and calculate risk factors before taking the next step,
- Originality,
- The ability to predict- an entrepreneur must try to understand future trends and to plan for their outbreak,
- Creativity- an entrepreneur must be able to generate new ideas and designs, to depart from ordinary products, and to open new markets,
- The inner drive to succeed- entrepreneurs set big goals in front of them, they tend to behave very ambitious, removing obstacles to success,
- Dynamics- entrepreneurs recognize the importance of coming and staying "on top", and the only way to achieve this is to change and grow depending on the situation in the region,
- High Motivation- high standards and objectives that need to be achieved by looking for entrepreneurs to be motivated and to motivate their employees,
- Acceptance of constructive criticism-good entrepreneurs must know how to receive criticism, hurdling obstacles are a part of the picture in business conduct, so they have to be treated, with analyticity,
- Good interpersonal relations-Entrepreneurs with good interpersonal relationships can more easily find their way to market, to develop a network with its suppliers, etc. retailers. Good relationships help them work more efficiently,
- Appropriate strategic planning-, medium-term and operational planning must be present to access business opportunities in the best possible way, to be implemented (and Saroj Mehndiratta, 2009.).

3. SME OWNER PROBLEMS

The work and the type of work performed, the fear of job loss or employment, fatigue, short deadlines, lack of parent support, a sense that he cannot manage their time or work performance, inability to influence the way or work organization, sense of alienation other employees of the company, a sense or feeling excessive exploitiveness unused in connection with work tasks set before the owner, any gap in the work, monotony, and numerous physical, biological, or chemical influences at work - these are all potential problems that arise in entrepreneurial life.

On the other hand, Brixia (2011.) defines several key limitations that owners of a major problem and obstacle to the initiation and maintenance of entrepreneurial ventures, including its:

- High tax rates;
- The inefficiency of tax administration;
- Advanced obtaining permits and licenses;
- Corruption;
- Poor infrastructure.

Stress is a daily companion, a certain feature of organizational life and largely associated with the execution of duties and tasks at work, daily routine, relationships with other people, control and performance management processes, as well as a variety of unplanned and unforeseen circumstances which business owners face with, during their company's life cycle.

While between all the employees in any organization exists a normal, natural, level of stress, the business owner's situation is slightly different (Lovelace et al., 2004.). Directors of large systems generally are under increasing pressure over the short-term problems, while the main stress of SME owners are about the long-term planning, financial investment, job security, as well as the status of their business (Fassin et al., 2011.).

Leaders of organizations are more prone to experiencing different problems because of the position and level of responsibility demands that are expected of them to meet. In order to create a healthy and motivating work environment, the owner is the one who needs to develop leadership skills and autonomy of thinking of other employees.

The practice of „self-leadership“ is the development of personal motivation and desire for achievement of organizational goals, but in a way that will help reduce stress and increase job satisfaction or easier coping with problems (Lovelace et al., 2004.). .

The biggest motivation for almost every owner of a SME is a possibility of prosperity and growth of his small business. According to Ward (2004)., owners of small and medium businesses cited six major problems for long-term development of their business, which in some way motivate them in a positive (or negative) direction:

- Maturation of business life cycle and increasing competitiveness;
- Limited capital for business growth;
- Next generation of business owners (if inheritance is between family members);
- Ownership changes dependently and inflexibility;
- Conflicts between the heirs;
- Incompatible goals of family values and needs.

4. INFLUENCE FACTORS ON SME OWNERS

The authors believe that the owners of large businesses seek to achieve the highest possible profit, while the owners of small businesses do not think that way. The main fact is that the profit level is satisfactory and constant, to maintain their business, and to preserve the pleasure of owning their own business (Sarasvathy et al., 2011.).

What can spoil the plans is a bad tax system, and the inability to find and retain good employees and loyal customers. The advantage of entrepreneurs is primarily in that they are doing what they love, and to affect

their satisfaction is knowing that they are independent, free to create their own money (Alstom, 2009.). On the other hand, risk and responsibility is often a big negative impact on entrepreneurs. All this with long working hours, or the lack of working time leads to stress.

What is not discussed here, that there are some very important reasons why entrepreneurs of the enumerated factors of influence haven't seen as something negative, but in spite of them engage in creating their own business. For this it would primarily be required a study of the psychological characteristics of entrepreneurs and the way of thinking where you might be concluded that these entrepreneurs are simply people who love challenges and do not like to be a self-controlled part of the organizational hierarchy.

Lussier and Halabi (2010). Cited several factors as reasons for failure of a family business, of which the most important are:

- Planning-companies that do not have a business plan are more likely to fail than those that have (a business plan),
- Parents (owners) whose parents had had a family business are less likely to experience failure of their business,
- The age-young people who start businesses are more likely to experience failure than older colleagues,
- Management-owners who have no experience in management are more prone to failure than colleagues who have managerial experience.

As for relations in firm size and success of entrepreneurship is the only association seen in the influence of the duration of a company. Entrepreneurship has a stronger and better impact on the longevity of small businesses, while the major factor in the company is weaker and negative (Ha-Brookshire, 2009.).

The family business firms can be improved and some of the factors that influence is not directly related to the job. This is primarily done to reduce tension among family members, living in families with two or three generations, devoting more time to the detriment of business and holiday hiring temporary help, during a turbulent period. The family has a stronger impact on business than on the family business (Olson et al., 2003.).

Threats, such destabilization operations, which follow from the specific personalities owners of SMEs, can be activated by the subjective, knowledge, personal values and beliefs, perceptions and experiences of the owner as an individual who cannot easily be replicated, and are therefore an important factor (un) successful business (Kor et al., 2007).

Factors threats coming from outside are often unable to reach owners and small businesses would usually resort to strategies of avoidance, is often faced with insufficient institutional support their enterprise. But also, too little capacity resources is an important factor that may determine the success of an SME (Welter and Smallbone, 2011.).

So often employed in an MSA does not really look favorably on new employees who come right out of college in business, since they are a potential threat due to a higher level of education. Employees of SMEs, if they are employed because of nepotism, additional pressure will be done by the owner to not only recruit graduates (Gao et al., 2011.). SME owners need to further fight against it, because otherwise it could not be expected to increase the capacity of its business.

A Portuguese study has proved the claim that the slowdown in the rate of growth of SMEs is under the increasing influence of the economic crisis, but because it affects the growth of large companies (Amorim Varum and Rocha, 2011.), and therefore the economic crisis should be appreciated as an important factor impact on SMEs also.

Companies that do not invest in R&D projects will inevitably experience a nearly complete or total slowing growth rates. As an additional factor appears the lack of quality human resources to participate in such R&D projects, while larger firms have such capital (Macas Nunes et al., 2011.)

There are several major factors that influence the barrier to a stable rate of growth of SMEs, such as the inability of entrepreneurs to establish an appropriate organizational model in the company. This organizational model would imply a professionalized management system and development of methods, techniques and processes to support development (Barbero et al., 2011.)

Several factors influence the operations of an SME should be further explored in other papers, as well as their role in everyday relations in such organizations. Factors which influence the following (below), can in some cases represent a barrier to normal functioning and development of SMEs, but also can contribute to stimulating the owners of SMEs in certain situations for the sake of achieving greater efficiency.

Motivation is any influence that causes, or maintains a direct human behavior. In the management of family SMEs, motivation plays an important role because with a higher level of owner motivation they are trying to meet the desires of their business environment, so that it contributes to the realization of various benefits for the owner.

There are various emotional (psychological) factors affecting the owner of small or medium businesses, which will certainly affect his motivation for running the business. They can be classified into:

- Autonomy in work;
- The power of decision making;
- Challenges;
- Continuity of operations (Zellweger and Astrachan, 2008.).

For the owner of an SME, he may be affected by the three environments:

- Home;
- Business;
- Personal career flow.

Considering the first environment, it is related to marital status, number of working hours, responsibilities towards children, living expenses, work at home. The business environment influences the owner through the available resources, employee behavior and performance of employees. The third environment that may affect the owners of SMEs is reflected in the transition from economic inactivity into entrepreneurship, family business management experience, and age (Jayawarna et al., 2011.)

5. CONCLUSION

It is difficult to choose what problems most affect a small business owner. That is, each owner is dealing during his career in the SME sector, with various problems, never (or seldom) repeating the same problem. What is really possible to show, that's the way the owners can deal with these problems. There is no universal pattern, but there is a certain mindset, that can overcome most of the risks and problems. As for the impact, the implications are too many and it would be pointless to compare them, or even by a classified order. But what can be concluded, it is that any "attack" on the company, each factor of instability-is surely preventable, or at least can be mitigated so it makes no major problems. This story can be repeated in circle until the owner of the company, as the main pillar of the link between all sectors of the company, can fit in and integrate the parts into a whole so that external influences are not the reason for the decrease in profits, or business-shutdown.

Abstract: *When starting a new venture, entrepreneurs usually select founding team members with skills and expertise closely matching their own. In choosing cofounders it is wise to focus on complementary aspects when it comes to the knowledge base, but on similarity in terms of personal characteristics and attributes. Once the appropriate founding team is assembled, these individuals must work together effectively if their venture is to succeed. The main research focus of this paper is to analyze principles of building effective business relations within a new venture along with establishing an optimal team structure and size. As a new venture grows and the number of employees rises, new skills and capabilities enhance performance. Founding team diversity is prerequisite to innovativeness and creativity that result in a successful new venture.*

Keywords: *entrepreneurship, team, new venture, management*

1. INTRODUCTION

People tend to feel more comfortable to work and cooperate with persons who are similar to themselves in various ways, and therefore, entrepreneurs usually select cofounders with skills and expertise closely matching their own. Nevertheless, since variety and diversity of knowledge, experience and training is significant advantage to new venture, it is reasonable to select members of founding team on the basis of complementarities rather than similarities. In other words, in choosing cofounders it is wise to focus on complementary aspects when it comes to knowledge base, but to similarity with respect to personal characteristic and attributes. In order to choose excellent cofounders, entrepreneurs must perform the task of social perception well, which is not an easy task since others don't portray themselves accurately, but engage in various tactics designed to impress and present them in favorable light. Therefore, entrepreneurs should be careful when choosing cofounders and double check information provided by other contacts. They often confront deception, or other efforts by others to actively mislead them, and if they make wrong decision when choosing founding team, that can lead to disastrous results.

Once the appropriate founding team is assembled, these individuals must work together effectively if their venture is to succeed. One of the key ingredients in establishing strong working relations is development of clearly defined roles, responsibilities and jurisdiction. Because of the self-serving bias and other factors, individuals often perceive that they are not being treated fairly by others – that they are not receiving a share of rewards according to their contributions. Reactions to such perceived unfairness range from demanding more or doing less. Because of potential problems that may arise, entrepreneur should take active steps to assure that all the members of the founding team feel that they are being treated fairly. Another ingredient in strong working relationships is effective communication. Entrepreneurs should deliver constructive criticism, or otherwise he will face atmosphere of conflict and hostility (Baron & Shane, 2005, pp. 107-128).

As new venture grow, requirements for additional human resources increase. Often these new employees are hired through the founding team's social network. Evidence suggests that the greater the number of employees in new venture, the greater success, due to the quality of the opportunity being exploited. The choice between hiring temporary and permanent employees is a complex one, since both offer advantages and disadvantages. Ultimately, this decision must depend on the situation and specific circumstances.

2. THE ROLE OF OPTIMAL HUMAN RESOURCE COMPOSITION IN THE NEW VENTURE CREATION

The beginning of new millennium brought knowledge economy, globalization of competition and increasing expectations of Internet commercial use. During the last decade initial *dot.com* enthusiasm has dwindled and investors realized that there is much more sense to invest in industries where intellectual property rights are legally protected and consequently new ventures based on radical entrepreneurial ideas came to the spot of

the light. The most prospective ventures are in the field of high technologies since they bring investors multiple returns on investment, either through acquisition or initial public offering (Stojanović Aleksić, Šapić, & Erić, 2010).

Schumpeter was the first one who described *new venture* concept in 1934. arguing that “entrepreneurs have need to compete; they are overwhelmed with activities providing encouragement for launching radical innovation that cause irreversible turn of events and structural market change” (Busenitz, 2007, pp: 183-185). *Entrepreneurial new venture creates added value through innovation of products, services, markets, technology, distribution channels or business strategy* (Allen, 2009, p. 9). Ventures can have legal form of independent enterprise or they can be incorporated in organizational structure as dependent business unit, established as a result of corporate entrepreneurship process (Babic, Eric & Nikolic, 2010). Entrepreneurial venture and small enterprise are two related concepts, but are not synonymous. Entrepreneurs tend to disrupt the existing market equilibrium and present new products or processes that change the way business works, while small business owners are focused to provide their own existence and lifestyle. The latter should not be neglected because they are the backbone of any national economy. Those entrepreneurs are emotionally involved with their company survival and growth, but only to the point of meeting personal needs. The most successful new ventures were initially founded as a small business.

Employees create innovative ideas, overcome rigid organizational hierarchy, make necessary modifications and strive to obtain key resources and support for their implementation (Stojanovic Aleksic & Eric, 2011). The success of a new business venture depends on the quality of human resources: knowledge, experience, skills, capabilities and the network of business relations of not only the founder but the team of his or her associates as well. Although the largest number of ventures is started by teams, there are relatively few attempts to explain the process of their effective creation and management. The team consists of two or more individuals who jointly create a venture they have a business interest in. (Kamm, Shuman, Seeger, & Nurick, 1990). There are two reasons for which they are the subject of research; the first one is that new ventures are much more frequently led by teams rather than individuals, and the second one is that their performance is determined by the successfulness of the venture.

Several significant researches conducted in the 1990's showed that 55-80% of the analyzed ventures had been founded by teams (Kamm, Shuman, Seeger, & Nurick, 1990). The key reason lies in the fact that, in high-technology activities, it is not probable that an individual has all the knowledge needed for a venture to succeed. Recent researches (Davidsson, P., 2006, pp. 33-36), conducted by Ruef, Aldrich and Carter have accounted for the fact that 52% of new ventures are started by teams. In the largest number of cases, 74%, teams consist of two members, and in less than 5% of the cases, they consist of five members. Even 53% of teams of two members are spouses or partners, 18% are family members and only 15% of the ventures were founded by partners only related to each other through business. The conclusion of this research was that it is much more probable that a new venture will be started by a team rather than an individual. A similar research was conducted by Chandler, Honig and Wiklund, and they came to a conclusion that there is reverse proportionality between the number of new members joining a team and the time needed for a new venture to reach the desired profitability rate. The offered explanation is based on two theses: first, when a new member joins a team, it is a disturbing factor for the venture's functioning, and second, the venture has already been facing difficulties since it needs a new member, so, for that reason, profitability also suffers.

Teams have a much greater chance for success than solo efforts for a variety of reasons (Allen, p.154):

- The intense effort required of a start-up can be shared;
- Should any one team member leave, it is less likely to result in the abandonment of the start-up;
- Founding team covers major functional areas (marketing, finance, operations);
- A skilled founding team lends credibility to the new venture in the eyes of lenders, investors, and others;
- The entrepreneur's ability to analyze information and make decision is improved because she or he benefits from the varied expertise of the team, and ideas might be viewed from several perspectives;

In psychology, an individual is known to tend to feel the most comfortable when being with people similar to him- or herself. Such a tendency when the starting of a new business venture is concerned can have its negative side. If people are similar, that means their knowledge, experience and attitudes significantly overlap. Furthermore, this means that they lack the same or almost the same skills. The optimizing of the

personnel structure imposes a need for achieving complementarity by means of harmonizing various personal and business capabilities of all participants in a venture.

Finding partners with complementary skills means making sure that the team is not overloaded with people who all have the same expertise. A team of three engineers or three finance analysts is generally less attractive than a team with more diverse skills. Teams with more diverse skills make better strategic choices that lead to higher performance. In terms of skills sets, heterogeneous teams also tend to handle the complexity of new ventures better. Five factors that have great significance in team composition are: a) homogeneity, or similarity; b) functionality, or skills diversity; c) status expectations, or cultural bias; d) network constraints, or social contacts; e) ecological constraints, or geographic distribution (Allen, pp. 155-157).

When the start-up effort is collective, with a team that displays diverse capabilities, the new venture is more likely to be innovative. Evidence suggests that firms founded by heterogeneous teams are more successful than those founded by individuals (Bird, 1989). Lead entrepreneurs drive the development of new venture and serve as guardian of their vision. They have the ability to see what others cannot see and to identify ways to change marketplace rather than simply recognize an opportunity.

To make a perfect match between an entrepreneur as the initiator of a new business venture and right co-workers is a huge challenge. There are several activities (Baron, & Shane, 2005, pp. 107-127) which he or she must carry out to create the optimal personnel structure for the venture. First, they must consider if they are in need of partners to start their venture and which characteristics and knowledge they should possess. Second, they must start the process of searching for partners, which is a very complex process. Third, they must establish effective communication between their partners and other employees, based on clearly demarcated authorities and responsibilities and the principle of impartiality in awarding as well. Four, they must make a decision if and on which principles they will seek external consultants' help.

An entrepreneur must have the skill of *social perception*, i.e. assessment of one's personality, because only then can they recognize other people's potential and capabilities they need. That would not be difficult unless people had a tendency to show themselves in their best light, which usually does not coincide with their real capabilities. They hide their feelings and motives with an aim to impress their collocutor. For that reason, an entrepreneur must separate the external impression a potential partner has made on them and its essence. To be able to know what to expect from other team members, an entrepreneur must reconsider personal values and capabilities they are bringing to the venture. There are two reasons for this to be a challenging task. First, it is not always clear why an entrepreneur behaves the way they do. He may want to include someone in the team because he or she feels attracted to that person because of his or her personality, but could not provide a precise answer to what it is he or she exactly feels attracted to in that person. So, there are factors that have an influence on the behaviour of an entrepreneur which he or she is not fully aware of, which makes the self-evaluation process more difficult. The second reason is that an entrepreneur can become aware of his or her characteristics only through interaction with other people. An entrepreneur as leader should focus him- or herself on complementarity when his members' knowledge, skills and experience are concerned, and on similarity when their motives and personal characteristics are in question. The effectiveness of every type of leader behaviour directly depends on the nature of the situation and factors such as characteristics of the task, organization and employees (Stojanović Aleksić, Erić, Šapić, 2010).

3. CREATING THE FOUNDING TEAM

The manner in which an entrepreneur creates a team is an interesting piece of information for potential investors (Allen, 2009, pp. 153-158). New ventures are analyzed by investors from the aspect of their personnel structure. From their viewpoint, the team whose members have already had an opportunity to cooperate is of a better quality than it is the one being formed for the first time. An entrepreneur tends to achieve a high degree of business control and is worried about a possibility that he or she might employ a wrong person in the key position, so, for that reason, they are frequently not ready to employ staff who have experience in management positions. There are also those who are aware of their shortcomings and tend to form their team so that it consists of individuals complementary with each other with respect to their skills. The venture must have a strong management team, dedicated, competent, dynamic, and persistent, with relevant experience and highly flexible (McAleese, 2004, pp. 182-183). The investor would rather invest in a worse idea implemented by first-class management team, than vice versa (Eric & Nikolic, 2010). If team lacks certain competencies, investor provides assistance in overcoming difficulties (Gladstone & Gladstone, 2002, pp. 54-55).

Some authors (Franke, Gruber, Harhoff, & Henker, 2006), came to a conclusion that, when they are supposed to make a decision whether to invest their capital in a concrete venture, investors are significantly influenced by the so-called *similarity hypothesis*, defined by psychologist Burne in 1971. In brief, it says that the bigger the similarity, both professional and personal, between the founding team's members and the investor, the bigger a probability that a favorable decision on investing in a new venture. That means that the process of accessing external sources of financing has its psychological dimension as well, and an entrepreneur should have *the* dimension in view.

When creating a team, two sorts of problems appear: first, there is a possibility of a collision and conflicts, and second, a problem can arise with a need to define the formal organizational structure and hierarchy of decision-making. This process is additionally complicated when several partners found a venture. There are several factors that determine the quality of a team (Barringer & Ireland, 2006, pp. 127-129) on the basis of which differences between founding teams are possible to identify according to several different dimensions: their scope, the type of the venture, the pace of accession and the individual members' contribution.

A more recent research (Beckman, 2006) accounted for the fact that the composition of a team has an influence on whether exploitative or explorative behavior will be favored within the framework of a venture. Team members who previously worked together in another company know and understand each other well and have routine performance schemes, and for that reason they prefer a rather passive *exploitative* style of behavior. Contrary to that, team members who did not previously directly cooperate with each other on a business basis bring fresh ideas in a venture, force creativity and promote the *explorative* type of behavior. It can be concluded that there is a strong correlation between team members' previous experience and the degree of innovativeness promoted by organizational culture, so that a higher degree of knowledge and unique competences dispersion contribute to the creation of the ambience of innovativeness and change.

Analysis 161 of a high-technology company from the Silicone Valley (Beckman, Burton, & O'Reilly, 2007) only corroborated these statements, proving that higher efficiency is achieved by teams composed of members who used to work for a larger number of employers and have more diverse working experience. These differences lead to stimulating constructive discussions amongst the members reducing the probability of rash decision-making without considering relevant alternatives. Apart from that, the research suggests that the structure of the founding team has an influence on the capability of carrying out critical activities, such as the acquisition of the venture capital.

Although for a long time an attitude prevailed that, due to a high level of turbulences, a team in high-technology ventures should have the organic structure characterized by the adaptability and a low degree of formalization, a more recent research (Sine, Mitsushashi, & Kirsh, 2006) proved the superiority of teams characterized by a formal structure and high specialization in the venture founding stage. The shortcoming of the theory laid down by authors Burns and Stalker in 1961 is reflected in that they did not analyze ventures in their emergence stage, but in their mature stage, which significantly influenced giving advantage to the organic organizational design.

Choosing partners to start new venture is one of the most critically important tasks that an entrepreneur must undertake. It is a difficult task because it is often not possible to understand a person's character until that person has spent some time working in the company. The stressful environment of a start-up may bring out traits and responses that were not apparent when the person was originally selected. Everyone from investors to bankers to potential customers looks at the founding team of the new venture to determine whether its members have the ability to execute their plans. Thus it is vital to choose partners who have complementary skills and experience and who do not have a history that might be detrimental to the company.

There is another advantage to forming a team. Because members of an entrepreneurial team often invest not only their time but also their money, the burden of gathering resources is shared. The lead entrepreneur also gains access to the network of contacts of the other members. This vastly increases the information and resources available to the new venture and enables it to grow more rapidly. Of course, it isn't always possible or necessary to put together the perfect team from the start. The right person to fill a particular need may not have been determined, or the right person may be too expensive to bring on board during start-up.

3.1 Building effective business relations amongst team members

One of the latest researches (Eden, Hitt, & Ireland, 2008) led us to interesting conclusions when interpersonal relations within the framework of a venture are concerned. They suggest that the entrepreneur prefers to cooperate within a venture with his or her friends who he or she trusts; however, if that is not possible, due to a lack of trust, they establish business relations with absolute strangers rather than superficial acquaintances. These conclusions do, to a certain extent, coincide with the results of the research conducted by Fracis and Sendberg (2000), where they suggested that stronger interpersonal relations amongst the team members lead to more efficient decision-making, a higher level of participation, as well as the domination of cognitive rather than affective conflicts. Besides, top management teams characterized by unique dynamics and interpersonal relatedness, family ties among other relations, lead to a higher cohesion and a stronger strategic consensus in view of the future of the venture (Nordqvist, 2005, pp. 285-290).

Although there is no universal recipe how to build a team who will operate successfully, yet there are several aspects (Barringer & Ireland, 2006, pp. 129-131) which, in that view, can represent a stimulating but also limiting factor:

- a) *The demarcation of authority and responsibility* – the main source of conflicts amongst employees is a lack of clear authorizations. If it is not clear who has the decision-making authority, then probably there will be conflicts. When founding a new venture, partners should share responsibility according to their competences and skills, which means they must stick to the complementarity principle.
- b) *Showing respect for the principle of impartiality* – psychology has proved that every individual has a tendency to give themselves credits for work done successfully, and fault others for a failure or attribute it to external factors which could not be influenced. So, he concludes, their performance is not adequately valued comparing with the results of other employees. The entrepreneur must seriously approach this problem and promote the principle of *distributive impartiality* reflected in that the employee's contribution/award for performance ratio must be the same for all. A balance among different interests must be found and clear rules for all must be established.
- c) *Effective communication* – this is the key factor in the creating and maintaining harmonious business relations. Constructive criticizing other people, based on respecting their feelings and dignities, deprived of aggression and antagonisms, subjecting no one to condemnation and offering concrete proposals for improvement are always beneficial for all team members. A functional conflict is desirable because it brings to surface different ideas, motivates employees to observe things from another person's viewpoint and leads to more quality business decisions.

Although there are no perfect founding teams and no fail-safe rules for forming them, effective founding teams tend to display the following characteristic (Allen, 2009, p. 157):

- The lead entrepreneur and the team share the same vision of the new venture;
- The team members are passionate about the business concept and will work as hard as the lead entrepreneur to make it happen;
- One or more members of the founding team have experience in the industry in which the venture is being launched;
- The team has solid industry contacts with sources of capital;
- The team's expertise covers the key functional areas of the business: finance, marketing and operations;
- The team members have good credit ratings, which will be important when the firms seeking financing;
- The team is free to spend the time a start-up demands and can endure the financial constraints of a typical start-up.

3.2 Founding team extension

The entrepreneur and his or her team make maximal efforts, use their maximal knowledge and capabilities to provide the functioning of their business venture. However, it is impossible to create a team capable of having all necessary knowledge and information at any moment, which means that, sooner or later, the team will need services provided by experts and external consultants (Hisrich, Peters, & Shepherd, 2008, p. 282).

New ventures have significant difficulties when engaging quality personnel is concerned. They are unknown to a broader public, they have not built their business image and credibility yet, which is the case with

existing enterprises. It is a big shortcoming of theirs in the labor market, so entrepreneurs are forced to use their own business contacts to come to quality personnel. There are two basic reasons why entrepreneurs employ new personnel (Forbes, Borchert, Zellmer-Bruhn, & Sapienza, 2006): they either possess knowledge their venture is in need of or personal traits perceived as desirable by the entrepreneur. They employ people who they know in person or who have been recommended by another person, and, in that way, they save their time, energy and resources. Besides, it is easier for them to persuade people they know of the quality of ideas and their ideas' potential.

One of the key issues the entrepreneur has to deal with is the number of employees needed for the functioning of a new business venture. Although a larger number of employees has obvious advantages, brings new energy, ideas and information, there are certain negative sides as well, reflected for the most part in high fixed costs from salaries. The engagement of new personnel is a sword that cuts both ways; in the majority of cases, however, positive effects prevail. Neither is there any doubt about advantages from engaging a team because the team has a plethora of various skills, experiences and talented people with numerous professional contacts supporting and helping each other. There is general agreement about positive correlation between the number of the employed and a probability that a new business venture will be successful; however, it should not be taken for granted because it has not yet been proved empirically beyond any reasonable doubt.

The entrepreneur has a right of discretion to make decisions on the optimal size of a team. Sometimes it happens that a team is too small for the creation of a complex venture; however, it is more frequently the case that entrepreneurs make an even more dangerous mistake when creating too big a team. With the number of team members, the number of problems related to the functioning and interpersonal relations also increases. One question is asked: if a smaller team is better, why do entrepreneurs make this mistake? The uncritical application of the *the-more-the-better* way of thinking (Baron, & Shane, 2005, pp. 124-126) is one part of the answer; the main reason, however, is of psychological nature and lies in any individual's need to share their responsibility with as large a number of people as possible. In that manner the team becomes over capacitated and neither is capable of efficient operations nor does it demonstrate the necessary originality and inventiveness in managing a new venture.

Additional question which the entrepreneur must answer is: which employees should be engaged permanently and which ones from time to time? Both alternatives have their advantages and disadvantages. To engage personnel from time to time is, from the viewpoint of the project principle, more profitable and provides greater flexibility; on the other hand, of course, those employees are usually insufficiently motivated and are not loyal, which may be a problem, especially if they have access to the venture-related sensitive information competitors would like to learn about and are prepared to pay for. Permanently employed people are much more dedicated and more loyal to the venture; however, their engagement is a bigger cost. So, a choice the venture founder has to make is everything but easy. It is recommended that, in activities where flexibility and the fastness of response are important, the entrepreneur should engage personnel he or she needs at the moment, whereas in those branches where the environment is more stable, it is rather advisable that they should employ people on a permanent basis.

When the new firm is in its infancy, it generally doesn't have the resources to hire professional help such as an attorney or accountant. Instead, it must rely on building relationships with professionals on an *as-needed* basis. These professionals provide services and information not normally within the scope of expertise of most entrepreneurs, pointing out potential flaws in the business concept. There is hardly any aspect of starting a new venture that is not touched by the law. Attorneys are professionals who typically specialize in one area of the law – taxes, real estate, business or intellectual property. Within their area of expertise attorneys can: advise the entrepreneur in selecting appropriate organization structure and in preparation for acquisition of intellectual property rights and licensing agreements; negotiate and prepare contracts; advise the entrepreneur on compliance with regulations related to financing, etc. Another type of expert help entrepreneur can get from an accountant. The accountant may set up the company's books and maintain them on the periodic basis, or may hire a bookkeeper to perform the day-to-day recoding of transactions. Bankers, insurance agents, and other specialist today, more than ever will put the new venture in better position to compete on the market (Allen, 2009, pp. 160-163).

A growing number of start-ups are forming advisory boards to provide them direction and guidance. An advisory board is a panel of experts who are asked by a firm's managers to provide counsel on the daily bases. Unlike board of directors, an advisory board possesses no legal responsibility for the firm and gives

nonbinding advice. Some firms have advisory boards for specific issue or need, such as to help identify new products ideas or dealing with an emerging challenge (Baron & Shane, 2005, pp.134-137).

4. CONCLUSIONS

In organizations, there is never ending tension between need for stability, which implies effective performance of current business activities as prerequisite for maintaining current competitive position, and constant quest for new products and business activities that would provide superior competitiveness in the future. Entrepreneurs in their quest for independence often attempted a new venture as soloist. In this way they could retain sole ownership, make key decisions and not have to share profits. This approach is still common in small lifestyle businesses and among craftspeople.

However, in today's global and complex environment, most entrepreneurs find it necessary to start their venture with a team. It is rare for an entrepreneur to conclude that she or he has all the expertise and access to resources that are needed by the new venture. It is very important for entrepreneur to identify the essential participants for the initial launch. Not everyone involved with the new venture has to be an owner or employee. It is not uncommon to find that one or more members of an otherwise cohesive team had different expectations for the outcomes of the business or their role in it. These differences must be discussed and agreed upon before moving forward as a team. It will be far more costly in time and money, not to mention relationships, if these differences are ignored and cause problem later when the business is growing.

Creating optimal team structure is still huge challenge, and relevant research studies are yet to be done. Researchers must focus their attention more on how to manage heterogeneity and diversity within entrepreneurial teams, but in a way that will not jeopardize innovativeness, creativity and lateral thinking. How to select not best individuals, but individuals that will fit the best, remains the main issue and dilemma entrepreneur will face in the future.

Abstract: *The focus of this paper is the analysis of the most important factors for SME performance, survival and growth in the EU.*

The main objective is to consider what determines potential failure of young companies to innovate and grow. The importance of innovations and growth for new, young and thus often still small firms is commonly claimed. Therefore, factors that would inhibit these small, young companies from achieving their goals can have a huge public impact.

The research results show that the age of the firm (which reflects its reputation) is important to the degree to which the firm feels financially constrained. Also, finance barriers can be associated with market failure. Risk and informational asymmetries create capital market imperfections and a firm's lack of reputation and collateral become crucial elements.

Conclusions reveal that the ability of SMEs to grow depends highly on their potential to invest in restructuring, innovation and qualification. All of these investments require capital and, therefore, access to finance. Recent policy initiatives aim at improving the financial environment for European entrepreneurial activity and, more specifically, supporting newly-founded innovative firms in order to increase their global competitiveness and spur innovation.

Key words: *SMEs, financing, innovation, growth.*

1. INTRODUCTION

We are living a period of financial and economic crisis. It is accompanied by widespread pessimism and lack of confidence and trust. Under these circumstances the focus on long run growth and innovation may appear out of place. This paper is an argue against such a perspective. It is important to take a long run perspective precisely in moments of crisis and turmoil. From the earliest period on record up to the eighteenth century, the standards of living have been quite stable over the long run. Sharp variations in standards of living were associated with disease, famine and war. Nevertheless, they would not persist over the very long run. The Malthus / Ricardo model was able to reconcile long run stable standards of living with technological progress over time (Lucas, 2002).

The engine of growth is a capitalist society based on competition and change. Joseph Schumpeter characterizes economic development as: "The spontaneous and discontinuous change [...] which forever disturbs the equilibrium state that previously existed".

Nobel Prize winner Robert Solow showed that for a sustained economic growth technological progress is more important than factor accumulation. For Schumpeter behind innovation (i.e. the economic application of technological improvements) lies entrepreneurship. Innovation involves the industrial or commercial use of something new: a new good or service, a new production method, a new market or source of supply, a new form of organization or a new method of financial organization. For Schumpeter innovation is fraught with difficulties. One of them stems from the need for external financing (Levine, 2005).

2. A SCHUMPETERIAN LOOK AT THE GROWTH PERFORMANCE OF THE EU

After a long period of technological catch-up since the WWII, the productivity gap between Europe and the US began widening again in 1995. Structural conditions necessary for Europe to catch-up with the productivity leader, the US, were present from the end of the war to the first oil shock and afterwards. However, conditions needed for creation, innovation and leadership in a knowledge economy worked against Europe (relative to the US).

The recovery of the US productivity growth in the post-1995 period and the corresponding decline in the EU reflects the influence of key technology and policy factors. Below are discussed three interrelated determinants: ICT (information and communication technology), innovation and firm dynamics.

2.1 The role of ICT as a general purpose in EU productivity growth

Sectional data suggest that the divergence in productivity growth between the US and the EU in the post-1995 period is primarily explained by differences in the pattern of production and use of ICT.

- Labor productivity growth in *ICT producing manufacturing* industries has been particularly high in both the US and the EU. However, the US benefited from a leading initial position and an increasing growth in the post-1995 period in high-tech industries such as office machinery, electronic valves & tubes, telecom equipment, TVs, and scientific instruments.
- *ICT using services* have been the focus of the most profound technological gap with the US, particularly in the retail and wholesale sectors and in banking and finance. On the other hand, more restrictive regulatory barriers in European countries have been detrimental to the diffusion of ICT.

More recent firm level evidence (Bloom, 2007) confirms that the US productivity advantage is not only related to a higher ICT spending by US firms (in ICT using sectors), but US firms as well as their subsidiaries operating outside the US-specific conditions reap a higher return from their ICT investments. This suggests that other firm-specific advantages are important, such as the quality of management practices.

2.2 The importance of knowledge production and diffusion

In the present context, we need to define the extent to which the example of ICT is an isolated case or is likely to be replicated in other high-growth, high-tech industries. This is a pertinent question if one accepts that the US's lead in ICT is not an isolated case.

Assuming that a failure of EU enterprises to recapture the full potential and benefits related to ICT is a credible risk, the following key questions arise: 1. Does the EU have specific problems regarding its innovation infrastructure?; 2. Does the US have specific features/framework conditions which make it more likely to be the locus for the next future breakthroughs in technology?; 3. Why is the EU less apt to creating and exploiting new technologies in general? In order to better understand the EU-US innovation deficit, discussion beyond ICT importance is needed.

Figure 1: EU's overall innovation performance relative to the US

Source: EIS 2006.

Despite some signs of catching-up, Figure 1 confirms the presence of persistent innovation deficit in the EU. As this innovation indicator comprises several innovation input and output measures, the EU innovation gap goes beyond the deficit in R&D spending. The R&D deficit is a symptom rather than a cause of a weakness in the EU's capacity to innovate; the cause is rooted in the structure and dynamics of industry and enterprise (O'Sullivan, 2007).

A comparison of innovation inputs shows that SMEs represent a larger share of *R&D expenditures* in the EU than in the US and Japan. On the other hand, EU SMEs are less R&D intensive than in the US, although the SME gap is similar to the overall gap in R&D spending. The average R&D intensity of SMEs in Europe is 0.34% versus 0.53% in the US. This compares to an overall average R&D intensity in Europe of 1.17% versus 1.57% in the US (Results are based on DG RTD, 2007).

However, specific contribution of SMEs to innovation goes beyond the share of SMEs in R&D expenditures or in innovation output. SMEs have a very important indirect effect. Usually young small innovating firms create radical new technologies and markets, whose further developments are completed by large players. Baumol (2002) recognizes the complementarity between small and large firms, but at the same time notes the importance of small firms in large innovations. In 1994 the Small Business Administration Office of Advocacy prepared a list of breakthrough innovations made by small firms during the 20th century. It is impressive going literally from A (airplane) to Z (zipper) with many innovations that have been crucial to the economy. Other studies on the distribution of innovations certified as “significant” by industry experts, confirmed that small (as well as large) firms outperform medium-sized firms for the US (see OECD (2006) for an overview).

According to Baumol, private sector innovations in the US come from two distinct sources, firstly from the activities of large firms and secondly from the efforts of independent inventors and their entrepreneurial partners. Baumol asserts that the active presence of both groups enhances the overall innovation process since their activities are complementary. Independent inventors/entrepreneurs specialize in breakthrough innovations while R&D departments of the larger firms enhance these breakthroughs and add to their overall usefulness.

2.3 Firm demography and the creative destruction process in Europe

EU-US productivity growth differences can be additionally explained by (a change in) the firm’s demography. The *churning process* has substantial effects on labor productivity growth because large part of it results from reallocations from less productive to more productive firms. Industries and/or countries where the churning process is inhibited, exhibit lower productivity and employment rates.

All European industries exhibit a greater number of small firms and also a higher share in total employment than in the US. American manufacturing firms are larger and they display wider size dispersion, particularly in high-tech sectors and in wholesale and retail.

Figure 2 on aggregate entry, exit and net entry rates from the research work of Cincera and Galgau (2005) shows that although both *entry and exit rates* are lower in the EU than in the US, the differences in exit rates are substantially larger. The average *size of entrants* is much smaller in the US. Lower entry as well as lower exit (firing) costs in the US allow benefiting from the experimentation process supplied by the market. While there is a high positive correlation between the entry and exit in the US, correlation is insignificant in the EU and even negative in France, Italy and Portugal. A positive correlation reflects churning of firms within sectors as a part of the creative destruction process. A negative correlation reflects more traditional sectoral shocks (positive for entry, negative for exit).

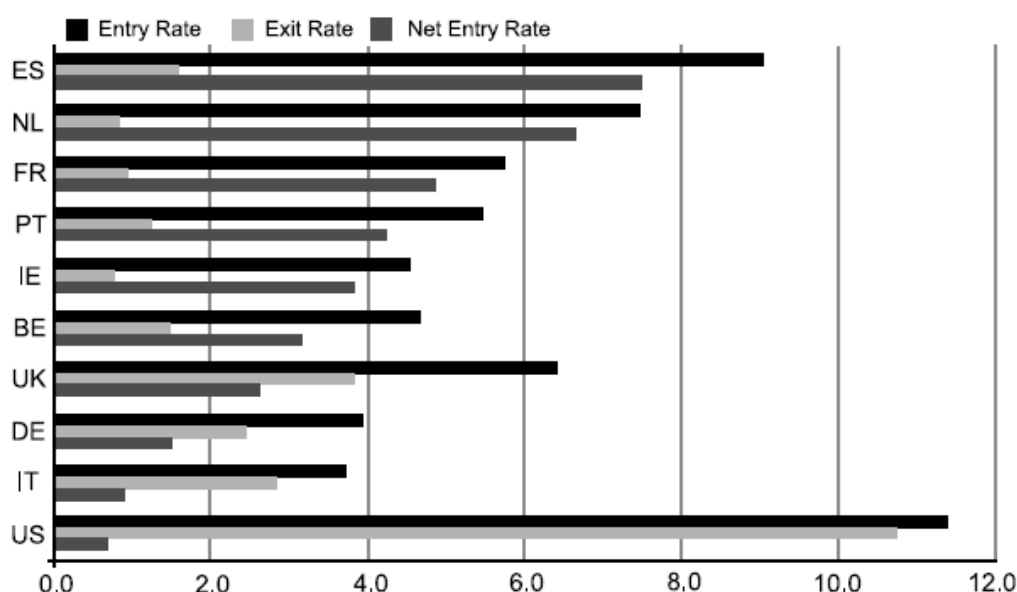

Figure 2: Aggregate entry, exit and net entry rates (in %) by country (1997–2003)

Source: M. Cincera and O. Galgau (2005), “Impact of Market Entry and Exit on EU Productivity Growth Performance”, EC Economic Papers p. 222

Post entry performance also differs between Europe and the US as shown in Figure 3: net employment gains amongst surviving firms at different limits, from the empirical research of Bartelsman et al. (2004). The short term survival rate (2 years) for American entrants is very low, but after this market experimentation period, the conditional survival rate of successful firms becomes high. In addition, the growth for firms that survive for 7 years is higher in the US than in Europe. These results are a clear indication that there are also higher barriers to growth for SMEs in Europe.

Figure 3: Net employment gains among surviving firms at different lifetimes (net gains as a ratio of initial employment)

Source: Excerpt from Bartelsman et al. (2004).

2.4 The impact of the creative process on productivity growth

The overall labor productivity growth originates mainly in growth of incumbent firms, both in the US and the European manufacturing sector. However, the EU-US differential growth performance can be explained by the reallocation effect between firms and the net entry component. This seems to be a clear indication that creative destruction process is less effective in European countries than in the US in both low and high tech industries.

- The *exit effect* is always positive, both in the US and the EU, which means that exiting firms are the least productive firms.
- The *long-run effect of entry* on aggregate manufacturing productivity growth has a smaller magnitude in the EU than in the US. Furthermore, the effect of entry depends on the industry's distance to the technology frontier. The positive effect of entry on productivity growth is more significant the closer a country or sector is to the technological frontier.
- In high-tech sectors, the entry effect is positive in all countries and this suggests an important role for new firms in more *technology intensive industries*. In these industries, the entry effect is much stronger in the US than in the European countries. Similar observations apply to exit barriers.
- New and small firms contribute to aggregate productivity growth directly through their own growth performance, and indirectly by affecting growth of large incumbents. Thus, the US firms' post-entry growth and productivity performance is higher. Moreover, beneficial interactions between small and large firms, especially in sectors where technical ideas and innovations are an important ingredient of growth, could be at the heart of different effects that entry has on aggregate productivity growth.

In summary, Europe's growth gap results partly from an inappropriate industrial structure in which small and new firms, occupying the main part of total employment, fail to play a significant role in the dynamics of the industry, especially in the high-tech intensive sectors. This is illustrated by their inability to enter, but most importantly, for the most efficient innovative entrants, to grow. The churning that characterizes the creative destruction process in a knowledge based economy encounters significant obstacles in the EU, suggesting barriers to growth for small innovating firms which ultimately weakens Europe's growth potential.

Economic analysis suggests the following "problem drivers" for the insufficient exit and low post-entry growth:

- weaker product market competition (e.g. barriers to cross-border trade in services, national regulations, etc);

- protection of inefficient firms through subsidies, bail-outs, etc.;
- labor market and other regulations that kick in when a firm grows beyond a certain size threshold;
- financial market developments.

3. FINANCING OF SMALL AND YOUNG INNOVATIVE COMPANIES

The literature generally supports the importance of new, young and therefore often still small firms for innovations and growth, even if they are small in number. Therefore, factors that would inhibit these small, young companies to innovate and grow can have a huge public impact.

In the analysis of the (failing) contribution of small and young firms to innovation and growth, *access to finance* is a priority issue. Survey data for the EU confirm the importance of access to finance. Excessively high economic risks are the major hampering factors for innovation for all types of firms, but somewhat more for small than for large firms. A second tier of barriers is formed by the *access to skills*, which again impedes both small as well as large firms. *Regulatory burden* is also included in the second tier of barriers. The empirical evidence suggests that this burden is somewhat stronger for small firms.

Table 1: Proportion of enterprises that regard selected hampering factors as highly important (% of all enterprises); by size class

	Excessive perceived economic risks	Innovation costs too high	Lack of appropriate sources of finance	Organisational rigidities within the enterprise	Lack of qualified personnel	Lack of information on technology	Lack of information on markets	Insufficient flexibility of regulations or standards	Lack of customer responsiveness to new goods or services
Small	16	21	16	6	13	5	5	10	8
Medium-sized	13	19	13	5	14	4	4	8	6
Large	18	21	10	6	13	3	4	7	5

Source: Eurostat (2004).

Analysis of survey data on firms' financial constraints perceptions show that the age of the firm, which reflects its reputation, is more important than its size in determining the degree to which the firm feels financially constrained. A possible interpretation of this result is that age might reflect reputation of the firm which, in turn, significantly affects access to finance.

The access to finance barrier can be associated with the *market failure*. Risk and informational asymmetries create capital market imperfections and a firm's lack of reputation and collateral become crucial elements. Existing literature demonstrates substantial differences between small and large firms in this respect. Hall (2005) shows that imperfections in capital markets usually affect small firms more than large ones which can rely on internal financing. Young firms are even more likely to be constrained than other small firms as reputation and collateral are important to mitigate capital market imperfections. More radical investment projects further exacerbate the imperfect, incomplete and asymmetric information problem. Thus, young innovative companies, which combine the disadvantages of a small scale, a short history, less retained earnings and more risky innovative projects, are even more likely to be financially constrained than other small, young and/or innovating firms.

Along with this financial market failure, particular for the EU, stands the highly fragmented nature of its venture capital market with 27 different operating environments adversely affecting both fundraising and investing. Complexity in operating across borders means that some funds have difficulties in expanding, growing and reaching a critical mass. This makes access to financing even more difficult and more expensive in the EU.

3.1 Characterizing YICs

Young Innovative Companies (YICs) are defined in the EU State Aid Rules as small enterprises, less than 6 years old, being "certified" by external experts on the basis of a business plan as capable of

developing products or processes which are technologically new or substantially improved and which carry a risk of technological or commercial failure, or have R&D intensity of at least 15% in the last three years or currently (for start-ups). The YIC dummy takes a value of 1 if an innovation active company is less than 6 years old, has less than 250 employees and spends at least 15% of its revenues on R&D.

Out of the sample of 1342 German innovation-active companies (A research done by the Catholic University of Leuven, 2006), only 51 companies qualify for YIC status, using the EU State Aid definition. This confirms the “rareness” of YICs, representing only 3.8% of all innovation-active companies in West-Germany in 2006. Even within the group of small innovators or young innovators, YICs are rare (4.3% and 24%, respectively).

A “typical” YIC has a micro size, with about 20 employees. This is considerably smaller than other innovating SMEs, as well as young innovators. Also on R&D intensity and basicness of its R&D profile, a “typical” YIC scores much higher than any of these reference categories. These statistics confirm that it is a combination of age, size and R&D profile that composes the particularity of YICs. YICs are not the same as innovative SMEs or young innovators. Finally, YICs are overrepresented in knowledge-intensive, technological sectors, specifically services (ICT and R&D engineering) while they are absent in more traditional manufacturing industries.

3.2 YICs and barriers to innovation

Table 2 presents the results on whether YICs perceive differently obstacles to innovation. Respondents were asked to give a score to each (potential) hampering factor on a scale going from zero (not relevant) to three (high). The first column indicates the share of firms that considered this factor to be relevant (i.e. firms that scored one or more), while the second column reports the mean score.

Table 2: Obstacles to innovation

	YICs		Other Innovators		
Barriers to innovation	%	mean score	%	Mean score	mean diff. with YICs
External financial constraints	95.65%	2.283	75.75%	1.234	−1.049***
Internal financial constraints	93.30%	2.457	66.42%	1.382	−1.074***
Innovation costs too high	93.33%	2.356	87.71%	1.862	−0.493***

Source: Schneider and Veugelers (2008)

As expected, YICs face, on average, higher obstacles to innovation than other innovating firms. When comparing across barriers, results confirm the presumption that financial constraints (both internal and external) are the most important barriers to innovation for YICs. Although this ranking also holds for other innovating firms, the YIC-differential is the largest and strongly statistically significant on both financial constraints. The evidence presented by Schneider and Veugelers (2008) show that young innovative companies, combining newness, smallness and high R&D intensity are rare in the sample of innovative firms. They view financial constraints, both internal and external, as an important factor hampering their innovation activities, significantly more so than other innovation active firms.

4. CONCLUSION

We have argued that innovation is an important determinant of competitiveness and important to address global challenges, such as sustainable development. The importance of innovation has been reinforced by a fast development of new technologies (ICTs in particular), which enabled new forms of competition and opened new markets for creation of innovative products. Nevertheless, despite importance of innovation, as well as new opportunities offered by globalization and new technologies, improvement in productivity in the EU, the EU seems to be lagging behind the US in this area.

We try to document the importance of SMEs and young innovative companies (YICs) for the innovation process. Both of them are source of dynamism and in particular, YICs are directly related with research activities and are a key component of the innovation system, facilitating the emergence of new products and

markets. However, evidence shows that in Europe small and new firms fail to play a significant role in the dynamics of the industry, although they account for a majority of employment. Not only they face significant entry barriers, but also successful entrants face difficulties to grow.

However, the ability of SMEs to grow depends highly on their potential to invest in restructuring, innovation and qualification. All of these investments require capital and therefore access to finance. Recent policy initiatives, such as the creation of the YICs status at the European level, aim at improving the financial environment for European entrepreneurial activity and more specifically to support newly-founded innovative firms in order to increase their global competitiveness and spur innovation.

Empirical research on access to finance for SMEs and young innovative companies has been limited, however, a recent analysis confirms the presumption that young, small, innovation-intensive firms are a very small but distinct segment in the group of innovative companies. Furthermore, access to finance is the most important factor that hampers YICs' innovation activities, significantly more than other innovating firms.

THE IMPACT OF PUBLIC PROCUREMENT ON THE IMPLEMENTATION OF PUBLIC-PRIVATE PARTNERSHIPS

Nevenka Žarkić Joksimović¹, Slađana Benković¹, Predrag Jovanović²

¹ Faculty of Organizational Sciences, University of Belgrade

² Public Procurement Office, Republic of Serbia

Abstract: Increasingly evident is the public sector's interest in introducing new financial instruments intended for the financing of infrastructure projects and facilities. This conditions the need for the creation and improvement of the political, economic and legal framework that makes this possible. At the same time, private investors are becoming increasingly interested in the creation of conditions that allow for efficient and more regulated implementation of the public-private partnership concept. The paper aims to point out potential opportunities brought about by the new Law on Public-Private Partnerships in Serbia, relying on the guidelines established in the Law on Public Procurement. In essence, our wish was to point to the need for establishing institutions that would make the implementation process of a public-private partnership transparent and reliable for all of those interested in private sector investment. Improvements in communication between the local and central government authorities are also necessary, in terms of opportunities and potentials of the implementation of the public-private partnership concept, as a modality of financing infrastructure projects.

Keywords: Public-private partnership, public procurement, infrastructure financing, projects, Serbia

1. INTRODUCTION

The public-private partnership concept has a great number of interpretations and ways in which it is defined. Perhaps Winer (2012) gave the most precise definition when he said that "a public-private partnership represents a relationship between the public and private sectors, in which the risk is shared based on joint efforts to achieve a desirable result of the public policies". It is a form of cooperation that allows for the financing, construction, renovation, operation and maintenance of infrastructure works and/or provision of services (Commission of the European Communities, 2008). Therefore, a public-private partnership represents a contractual relationship signed between government authorities and private enterprises, whose subject is the realization of a project of public interest in which both parties contribute with certain resources, according to their abilities, and participate in the planning and decision making. The goal of a public-private partnership is the achievement of greater efficiency, easier access to capital in order to share the financial risks and risks related to deadlines, while at the same time respecting high standards of environmental protection and employee safety.

Private partners find public-private partnerships attractive from the commercial aspect (profits and investment opportunities on new markets), while the public sector finds them attractive because they create a better end product/service (for the same level of investment, the same level of quality is created at a lower cost). Financing, tasks, as well as the responsibilities and risks of the project, are allocated between the parties in various ways, but the contribution of each contracting party is for every project accurately determined. The basis of the public-private partnership concept is the idea that both the public and private sector need to gain potential benefits.

As an infrastructure development concept, public-private partnerships are at a different level of development and implementation within the EU countries, but as an infrastructure financing concept they have especially found their place in the sectors of transport infrastructure, public construction works, the construction and equipping of schools, hospitals, prisons, as well as conservation of the environment. In Serbia, for now, there is significant participation of the private sector in the financing of infrastructure development in the sectors of energy and telecommunications, where commercial interests provide sufficient incentives for the private sector. However, the full contribution of this concept of financing infrastructure projects and facilities is yet expected in the years to come.

2. THE SELECTION OF PRIVATE PARTNERS THROUGH PUBLIC PROCUREMENT

Public procurement within a public-private partnership implies a process in which a public authority enters into a contractual relationship with a private partner. Yescombe (2007) states that the public procurement phase is the period during which:

- Offers are requested and received, and a supplier is selected,
- A special-purpose project company is established in whose name the public-private contract is negotiated, as well as the various sub-contractors that are to be used during the construction, delivery of services, management, etc., i.e. all that is together known as the „project agreement“,
- due-diligence is completed (review and evaluation of the project company and its related risks, by the public authority and the creditor, independently of each other) by the public authority,
- equity is invested by the investor, and funds are borrowed from financiers.

It is important for public authorities that they are able to generate an efficient procedure for public procurement based on real competition in an open and transparent process. The public procurement process is governed by the law, and its respect and implementation are practically unavoidable when the financing or guarantees are provided by multinational banks, such as the European Investment Bank.

The World Trade Organization (WTO), whose members include most of the developed countries, has provided a framework for public procurement procedures in the Agreement on Government Procurement. The WTO allows three types of public procurement (Yescombe, 2007):

- **“Open procedure”**. This procedure allows anyone to submit an offer,
- **“Selective procedure”**. This procedure allows public authorities to reduce the number of prospective bidders through prequalification,
- **“Restricted procedure”**. In this procedure, the public authorities directly approach prospective bidders, without issuing a tender (with or without prequalification).

On the other hand, the Law on Public Procurement of the Republic of Serbia (Public Procurement Law, 2008) recognizes the following procedures: 1) open procedure, 2) restricted procedure, 3) negotiated procedure with publication of a public notice, 4) negotiated procedure without publication of a public notice; 5) design contest, and 6) public procurement procedure of low value. The most widely applied, however, are the restricted procedure and the negotiated procedure with prior publication of a public notice. Regardless of the type of public procurement procedure, all bidders must be provided with the same information, i.e. the principle of transparency and equality of bidders must be satisfied. The Law on Public Procurement of the Republic of Serbia stipulates that the contracting authority is obligated to provide an equal position to all of the bidders during all phases of the public procurement procedure.

Prior to making a decision on the best bidder, the public authority performs a comparison of the offers by: comparing the prices, contract terms, the level of support by the public authorities in the event that it is known that the service fees would not generate enough income to cover the costs of the project; by selecting the “economically best” offer by scoring various aspects of the offer (points for design, speed or project completion deadlines, reliability, service quality, prices, etc.). The completion of the public procurement phase is known as “financial closure”, which represents the moment in which the conditions are met to allow for the construction of the object to begin.

3. THE ROLE OF PUBLIC PROCUREMENT IN THE IMPLEMENTATION OF THE PUBLIC-PRIVATE PARTNERSHIP CONCEPT

The main reasons for the development of public-private partnerships are discontent with the traditional methods of public procurement as a result of the development of the financial market and project financing, as well as the introduction of the private partnership concept as a new form of management.

Under the existing Law on public-private partnerships and concessions (2011), these partnerships represent a long-term cooperation between a public and private partner that serves to provide for the financing, construction, reconstruction, management or maintenance of infrastructure and other objects of public importance, as well as the provision of services of public interest. Public-private partnerships can be contractual (i.e. a partnership in which the relationship between the public and private sectors is based solely

on contractual relationships) or institutional (a partnership that involves cooperation between the public and private sectors within special institutional bodies) (Prijić, Ristić & Šteković, 2011).

Contractual and institutional partnerships are different in their structure. In an institutional public-private partnership, the private partner enters into a partnership with mixed capital (local government and the private partner) in order to carry out the tasks assigned to him by the public partner through a public contract or concession. In a contractual public-private partnership the mutual relations, rights and obligations of the local authorities and the private partner are defined by a public contract, which is concluded for a definite period of time. Contractual public-private partnerships are most often seen in the construction of infrastructure and public facilities, because they (Prijić, Ristić & Šteković, 2011):

- can be contracted for a period of up to 50 years,
- define the responsibilities of the partners during all phases of realization of the project: planning, financing, construction, maintenance, use and closure of the project,
- define the output performance of the project and services, and
- transfer most of the project risk onto the private partner, except risks that the private partner cannot manage appropriately and which are taken on by the public sector.

Although these two approaches differ, their common characteristic is that the public-private partnership concept contains a segment of short term political attractiveness, which is sometimes so significant that it represents the main motive in the decision process of establishing a partnership with the private sector. Furthermore, the common attitude is that the provision of infrastructure goods and services would be more effective if handed over to the private sector rather than the public, where the public sector would have a role in monitoring and evaluating the development of the project, as well as the role of the only guarantee for the quality and availability of the infrastructure. The benefits of public-private partnerships are reflected in the better management of resources, and not in an increase of funds intended for the financing of infrastructure. Projects that are implemented through public-private partnerships can play an important role in enhancing the efficiency of procurement of goods and services that had formerly been primarily under the jurisdiction of the public sector.

A public-private partnership represents a more complex form of public procurement (The European PPP Expertise Centre, 2011), i.e. the key difference between the concepts of public procurement and public-private partnerships is the fact that the construction and management of business operations after construction are assigned to a contractor from the private sector. In the traditional methods of financing the construction of infrastructure through the public procurement concept, these used to be separate activities. The argument that stems from the above, which goes in favour of a public-private partnership as a concept of financing infrastructure, derives from the fact that, when a single legal entity is responsible for both the construction of a facility as well as its operation and maintenance after its construction, then the legal entity is likely to be more interested in investing in the project during its construction, seeing as how, in this way, it reduces the cost of conducting business in the exploitation phase (Grimsey & Lewis, 2004).

However, we should also acknowledge the argument that goes in favor of understanding and respecting all that the Law on public procurement implies, in order to implement a “transparent” and “equal treatment” that will contribute to the legitimacy and legal validity of the public-private partnership procedure, as well as its acceptance of by all of the stakeholders (The European PPP Expertise Centre, 2011). Well established and legally validly implemented principles of public procurement must be implemented from the moment that a tender is issued on the participation of private investors. All informal contacts and negotiations with potential private participants in a public-private partnership must be performed prior to the announcement of a tender. This ensures equal treatment for all of the participants that are involved in the bidding.

4. CONTRACTS ON PUBLIC-PRIVATE PARTNERSHIP IN INFRASTRUCTURE FINANCING

The development of public-private partnerships has accompanied a renewal of the public sector by the adoption of a new management culture (Pavlova, V, 2009). Public-private partnerships include numerous participants, and therefore an appropriate number of contractual arrangements that regulate the relationships among the participants in the project financing, distribution of rights and obligations, as well as risk allocation. Finance contracts follow the planning, construction and management of the infrastructure project, as well as its financial aspects.

Public-private partnership contracts belong to the category of 'incomplete contracts', since it is impossible for the contract to predict all the possible events in the future. The more complex the contract is, and the longer its duration, the less complete the Contract itself is (Petrović & Stanković, 2009). That means that only the projects which are expected to be long-term and stable, such as the construction of roads and road infrastructure, are suitable for the implementation of a public-private partnership as a concept of financing. In accordance with that, analysis of the legislation that monitors public-private partnership contracts is based on the analysis and study of individual contracts with the immanent project finance concept, as well as the elements that are essential for closing the contract.

The most important is the Project Contract, which defines the framework of the project. According to Yescombe (2002) there are two main models of this contract:

- contracts with predetermined buying conditions for project products/services, and
- concession contracts.

Contracts in which the buying conditions for project products/services are predetermined are contracts signed between a project company and the buyer of the project's final product, and they define the conditions of buying a product/service. According to this contract, the private partner designs, constructs, finances and manages the investment project, and, after that, sells the product/service (e. g. electric energy) to the buyer (e. g. the company that distributes electric energy) under the conditions in the contract. With this contract, the buyer ensures the supply of the needed product, and the private investor in the public sector ensures the sale of his products in advance, which enables him to plan his income more easily and, in that way, it significantly decreases possible risks in the sale of his products.

A concession, in the sense of this law, is the right to use natural resources and goods in general use or conduct business of general concern which the grantor cedes to a domestic or foreign person (concessionaire) for a period of time, under the conditions defined by law, for a concession fee. A concession contract is signed by the Government in the name and on behalf of the state, and the concessionaire. If the concession was granted to multiple persons, the concession contract is signed by each of the concessionaires or the person authorized by the concessionaires, with special proxy. When the subject of the concession is the construction of municipal facilities for municipal activities, the contract is signed by the concessionaire and the authorized government body in the name and benefit of the local government, with previous written consent by the Government (2011). The contract identifies project risks that are allocated between the grantor and concessionaire, and specifies the role of the state, as well as the supervision and procedure in the case of unforeseen circumstances.

Concessions are used more in the service sector than the product sector. A concession contract can be signed between a project company and the Government of the host country, local government, government agencies, public companies or special companies founded for the needs of the concession.

5. THE IMPLEMENTATION AND EXPECTATIONS OF THE LAW ON PUBLIC-PRIVATE PARTNERSHIPS IN SERBIA

In the countries of the Western Balkans, the capacities for successful implementation of public-private partnerships are still in the phase of establishment. Bearing in mind the current concept of financing infrastructure in many countries of Southeast Europe, which includes Serbia, the best approach to implementation of projects of public-private partnerships would be through the implementation of small-scale projects at the level of local government, rather than large-scale projects at the national level. In addition, experience has shown that the application of this form of financing must be organized, and not left to the market and the conditions that dominate it.

A public-private partnership enables local authorities, the business sector and civil society, to take responsibility for the development of their environment, and undertake joint action for its improvement. The need for the private sector to assume greater responsibility in the fight against poverty, and improve the quality of life of local communities, is widely recognized (United Nations Development Program, 2012). The Law on public-private partnerships and concessions, passed in November of 2011, is meant to encourage partnerships between the private and public sectors, attract domestic and foreign investors, and encourage financial institutions to participate in the financing of projects of common interest. Involvement of the private sector, however, can only be expected if the public tender is issued by the highest levels of public authority, and if it has a clearly defined legal framework that ensures transparency and equality for all of the

participants in the bidding, which is supported by the Law on public procurement. This is particularly suitable when it comes to smaller projects, which are of importance for the development of local government.

The Law in Serbia that regulates the question of public-private partnerships has to this date not yet fully provided the expected results in its practical application, thus it is necessary to do much more in the field of institutional improvements. This primarily relates to the securing of criteria for transparency and equality for all participants in the bidding process, which represents the basis of the Law on public procurement. However, the implementation of the law governing public-private partnerships itself is not the only condition that would make the development of infrastructure projects and facilities better. It also requires other preconditions such as the provision of: developed and modern corporate governance in the country, a more developed securities market and insurance market, regulated property right relationships within the public sector, a clearly defined division of institutional responsibilities, etc.

It can be concluded that, although the benefits of a partnership with the private sector are undoubted, the concept of public-private partnerships should not be taken lightly, bearing in mind the complexity of the procedure itself, its design, realization and management. This type of partnership must therefore be carefully evaluated in the context of the project, public benefits, as well as the relative gains that could be achieved by using different approaches. Showing to be the most serious in implementation of the concept of public-private partnerships in Serbia, at the local level, is the City Administration of Belgrade, which has with the support of international institutions and consultants decided to establish a public-private partnership model in public transportation, solid waste management, and the city's water-sewage system. Other local authorities have most often made investment decisions by applying the public-private partnership concept based on the expected value of the investment of the private partner, without additional analyses of the existing conditions of utility services, i.e. the financial and economic effects of the public-private partnership on municipal property.

It is expected, in the period ahead, that this financing concept has yet to gain on importance in the field of development of services and reconstruction of infrastructure. However, it should be noted that this will also imply solving an array of administrative and practical problems, as well as solving problems related to structural economic transformation, the volatility of market conditions, and growing competition.

6. CONCLUSION

The term public-private partnership covers various contractual forms of transactions, where the private sector is given the right to conduct operations over an extended period of time, and at the same time bear the responsibility that had traditionally fallen on the public sector. A partnership between the public and private sectors is based on best practices defined by the Law on Public Procurement, which implies transparency and equality of the participants in the bidding. Nevertheless, the evaluation of bids for a project through implementation of the public-private partnership concept is different from the evaluation of tenders in a conventional procurement. Here we evaluate the solution offered by the private partner in order to achieve ultimate performance of the facility and/or services, which are contained in the output specification of the project of a public-private partnership within the tender documentation.

This is why the phenomenon of public-private partnerships represents one of the most important modalities of funding and improving public services, infrastructure, as well as an array of other project activities related to the realization and improvement of transport, health, education, safety, and waste and water management in the countries of the EU. It is expected that its full contribution is yet to be provided to Serbia. However, this implies that, in Serbia, it will be necessary to establish institutions that will make the process of implementation of a public-private partnership transparent and reliable for all the interested investors from the private sector. At the same time, it will be necessary to improve communication between regional (local) and central government, in terms of the opportunities and potentials of implementation of the public-private partnership concept as a modality of financing infrastructure projects.

POSSIBILITIES OF REAL OPTIONS APPLICATIONS TO MERGERS AND ACQUISITIONS

Vesna Bogojevic Arsic

University of Belgrade, Faculty of Organizational Sciences, bogojevic@fon.bg.ac.rs

Abstract: *The increasing volume, as well as the complexity of domestic and international mergers and acquisitions, has influenced the real option valuation method application. Traditional valuation methods of merger and acquisition analysis (such as the discounted cash flow method) these days are not enough because of uncertainties related to the time period determination, cash flow estimation and adequate risk-adjusted discount rate determination.*

The aim of the paper is to point out different real options applications to mergers and acquisitions. Real option analysis allows for explicit consideration of value-enhancing factors. In this way, decision makers can value the opportunity to alter their decisions further into the future and to actively search such opportunities.

Keywords: *mergers and acquisitions, real option, valuation, embedded option, acquisition, models.*

1. INTRODUCTION

An option is the derivative instrument which gives (provides) its holder the right, but not the obligation to buy or sell underlying asset at predefined price (i.e. exercise price) during the predefined future period of time or at the specified date (i.e. expiration date). In this way defined option is financial option. Besides this, there are (or may exist) options on real assets, or so-called real options. The real assets can be valued as call options if their current value exceeds the asset's current value and some predetermined level. On the other hand, real asset can be valued as a put option if its value increases as the value of the underlying asset falls below a predetermined level. In either instance, the option holder can choose to exercise (or not exercise) the option now or at some time in the future.

The term real option refers to management's ability to adopt and later revise corporate investment decisions. Since management's ability to adopt and subsequently change investment decisions can greatly alter the value of a project, it should be considered in capital budgeting methodology. If we view a merger or acquisition as a single project, real options should be considered as an integral part of merger and acquisition (M&A) valuation.

Traditional discounted cash flow techniques fail to account for management's ability to react to new information and make decisions that affect the outcome of a project. However, real options can be costly to obtain, complex to value, and dependent on highly problematic assumptions. They should not be considered unless they are clearly identifiable, management has the time and resources to exploit them, and they would add significantly to the value of the underlying investment decision.

Investment decisions, including M&As, often contain certain so-called "embedded options," such as the ability to accelerate growth by adding to the initial investment (i.e., expand), delay the timing of the initial investment (i.e., delay), or walk away from the project (i.e., abandon). Frequently, the existence of the real option increases the value of the expected net present value (NPV) of an investment. For example, the NPV of an acquisition of a manufacturer may have a lower value than if the NPV is adjusted for a decision made at a later date to expand capacity. If the additional capacity is fully utilized, the resulting higher level of future cash flows may increase the acquisition's NPV. In this instance, the value of the real option to expand is the difference between the NPV with and without expansion. An option to abandon an investment (i.e., divest or liquidate) often increases the NPV because of its effect on reducing risk. By exiting the business, the acquirer may be able to recover a portion of its original investment and truncate projected negative cash flows associated with the acquisition. Similarly, an acquirer may be able to increase the expected NPV by delaying the decision to acquire 100% of the target firm until the acquirer can be more certain about projected cash flows.

All these options exist in period prior to closing an acquisition, as well as in period post closing an acquisition.

In recent years the volume of M&A and the complexity of M&A activity have increased as financial systems have become more open with firms expanding not only domestically but also globally. Cross border mergers in particular tend to be much more complex, and the valuation of such M&As is more involved with additional elements of risk exposure. The analysis of any M&A goes far beyond the simple stand-alone value of the target firm, given that the acquirer now has many decisions that can be modelled using real options.

Traditionally, M&A valuation closely followed capital budgeting methodology, predominantly the discounted cash flow method with the focus on free cash flow. The cash flows are developed for a forecast period for the target firm, and then a terminal value is calculated at whatever is considered a reasonable time period. The valuation process involves parameters which are uncertain (the appropriate time horizon determination, free cash flow estimation, growth opportunities consideration and an appropriate risk-adjusted rate specification). Furthermore, many other factors influence the parameters (i.e. the timing of the M&A, competitor action, the flexibility of exploiting a target firm's resources, the leverage factor etc.).

Traditional capital budgeting techniques, such as NPV, fail to adequately consider uncertainties in future time periods with regard to decisions that management may undertake (Trigeorgis (1996)). In other words, firms typically have many opportunities to make other decisions based on the original M&A such as expanding into (or abandoning) new product or geographic markets. Also, the embedded options in an acquisition can have different risk levels. Theory suggests that the greater the number of adjustment opportunities in terms of management decisions, the more value can be added (Dixit and Pindyck (1994)). Through real option analysis, managers can more explicitly consider any added value a result of these future decision opportunities. Such knowledge can enable both the bidder and the target firm management to negotiate and capture more value in the transaction.

In this regard, real option analysis allows for the explicit consideration of a number of value-enhancing factors. Clearly, the ability to identify and evaluate options associated with M&As can be of great value to corporate decision makers. Decision makers have many options including timing of the acquisition, entry and exit options, growth options, options on managerial flexibility, and options involving the merger terms. Managers value the opportunity to alter decisions further into the future and actively seek such opportunities.

2. REAL OPTION ANALYSIS FOR M&As

Since the end of 1970s, there has been extensive growth in real options research in the standard financial option framework, as well as in Bayesian and game theoretic (competitive and cooperative) valuation frameworks. The earliest models include direct applications of standard financial options, such as the Black-Scholes model, but since then, models have evolved into more complex options, such as compound real options and other complex exotic options. These also include Bayesian learning models and game theoretic models with incentives and agency features. Real options applications are seen in various industries and business circumstances including forestry, oil and gas, M&As, pharmaceutical research and development valuation, information technology, and manufacturing, among others. More recent articles have investigated the deviation from all equity-financed firms and projects to those that have both debt and equity (Lambrecht and Myers (2007), (2008)).

Theoretically, real options have proven to be a powerful technique for analyzing investments under uncertainty. Researchers find the expected net present value criterion is inadequate in capturing the managerial flexibility to delay, grow, scale down, or abandon projects, exchange resource inputs, and incorporate learning or uncertainty resolution (when underlying asset values are uncertain). Thus, real options that combine strategy with valuation have increasingly attracted attention in the corporate finance literature.

Financial economists use various real option modeling techniques depending upon the problem structure. These techniques include continuous time models, multinomial (lattice) and finite difference techniques, and simulation.

3. M&A PROCESS AND REAL OPTION VALUATION

Typical M&A investments are embedded real options, which may include additional investment or growth (expansion) options, abandonment options, and wait-and-see (timing) options. Real option models can be classified as:

- (1) Standard M&A real option models,
- (2) Game theoretic M&A real option models and
- (3) Collaborative models.

3.1. Standard M&A real option models

Standard M&A real option models are used when the exercise decision does not directly depend on the actions of competitors or collaborators. These models have different focus. There are models which are focused on stock-for-stock M&A transactions, exchange ratios in M&A transactions, model oriented to strategic option valuation, model focuses on entry and exit possibilities etc.

In one of the earliest studies, Kogut (1991) presented the perspective that joint ventures are created as real options to expand in response to future technological and market developments. The exercise of the real option to expand accompanies the acquisition of the venture. The author provides counter evidence to the prevailing assumption in organizational theories that firms engage in cooperative ventures as buffers against uncertainty. He provides a real option perspective that joint ventures are designed to exploit the upside and not simply to buffer uncertainty.

Several researchers have developed models that investigate real option features in stock-for-stock exchanges. Stock-for-stock M&A transactions generally take more time to complete than transactions that are cash based (Gaughan (1999)). If a buying firm's and a selling firm's stock volatilities are high, the value of respective shares may fluctuate widely between the time a fixed exchange ratio is determined and the actual acquisition date. When a fixed exchange ratio is applied to determine a target's compensation, an acquiring firm would overpay when its stock price is higher on the merger date than on the agreement date or when a target's stock price is lower on the merger date than on the agreement date. Alternatively, a target would lose if an acquiring firm's stock price is lower on the merger date than on the agreement date or when a target's stock price has risen on the merger date.

Models focused M&A transactions have investigated how to exploit the fluctuations in the exchange ratios to increase the M&A deal value. These real option models provide more elaborate methods for structuring an M&A deal.

Herath and Jahera (2001) argued that explicit valuation of managerial flexibility in setting the final terms of an acquisition may enhance the M&A deal value in the process. Accordingly, the deal may be optimally structured to benefit an acquiring firm if the stock prices are highly volatile between the announcement date and the closing date. In a deal where the stock exchange ratio is fixed, the shareholders of an acquiring firm may have to pay a premium for the net assets of the target firm. This will happen if the acquirer's stock appreciates in value over this period because the deal value would increase. As a result, authors model the right of an acquiring firm to optimally switch between alternate purchase considerations: either swap stock or pay the target's fair market value (of the net assets) as a switching option. The premium is a hidden loss to the shareholders of the acquiring firm. They show that the value of managerial flexibility in deal optimization, which is traditionally ignored, can be significant and could increase the deal value to both parties.

The same authors (Herath and Jahera (2002)) developed an extension of their originally model and demonstrate how an M&A deal may be optimally structured as a real options swap. They argue that consideration of both buyer and seller expectations often results in fairer deals. Authors use real option analysis to model a stock-for-stock transaction as an exchange ratio swap when both the buyer's and the seller's stock prices are volatile. Hence, they show how to structure an acquisition to minimize the purchase price paid by a bidding firm and to maximize the deal value to a target. The theoretical value of an acquisition is defined as the deal value based on a fixed exchange ratio but dependent on the acquiring firm's stock price at consummation. Accordingly, in order to minimize the value of a deal, the authors suggest that an acquiring firm buy a call option or hold a cap, which guarantees a minimum deal value. On the other hand, a target should consider a put option or a floor, which ensures that the holder will receive the maximum deal

value. Consequently, when stock prices are volatile, the flexibility available to management of both parties can be valued as an exchange ratio swap—holding a cap and selling a floor with an identical strike price. Two years later the same authors (Herath and Jahera (2004)) investigated how to provide price protection to both acquiring and target firm shareholders by setting conditions for active risk management by managers. The authors investigate the contingency effects of managerial flexibility to renegotiate the deal and hedge the market price risk by specifying a range within which the deal is allowed to fluctuate as in a collar-type arrangement. To minimize the value of a deal, an acquiring firm could buy a call option or a cap, which guarantees a minimum deal value. On the other hand, a target could consider a put option or a floor, which ensures that the holder would receive the maximum deal value. Since the cap and the floor have different strike prices, the managerial flexibility to both parties can be structured as a collar arrangement, in essence going long on a cap and shorting a floor. Herath and Jahera argue that in addition to the valuation effects, the contingency effects also enforce favorable managerial behaviors.

More recently, Giacomello (2008) analyzed how M&A exchange ratios can be assessed when a firm's economic capital valuation is carried out within a stochastic framework. He develops a quantitative model for exchange ratio accounting. Assets and liabilities with stochastic cash flows represent embedded real options such as minimum guarantees that have incremental value over traditional deterministic balance sheet values. Hence, Giacomello introduced important differences in exchange ratios. When stochastic cash flows are assumed to be contingent claims on underlying traded securities, the author shows that the no-arbitrage conditions hold. In the absence of liabilities, stochastic capital reserves are shown to be equivalent to a portfolio of European call options with a guaranteed and call component. In multi-period settings, the options embedded in the merger contracts have multiple options such as ratchet or cliquet options. A ratchet or cliquet option includes a series of consecutive forward start options. The first option is active immediately and then the second becomes active after the expiration of the first option. The above stream of literature primarily focuses on the exchange ratios in M&A transactions.

Model oriented to strategic option valuation (Smith and Triantis (1995)) considered three types of real options that arise in strategic acquisitions and influence overall value. The first refers to growth options. Through acquisitions, firms can exploit strategic synergies, which, in the long term, may affect the combined growth options of the acquiring and target firms by lowering exercise prices, thus increasing upside potential and improving exercise timing. More specifically, a firm, through a series of strategic acquisitions over time, can change the acquirer's competitive position through development of growth options, which traditional DCF cash flow analysis tends to overlook in restructuring deals. Second type of real option refers to firms that have substantial flexibility in organization, marketing, manufacturing, and financing can benefit from acquisitions. The third type of real options is the divestiture (abandonment) option, which conventional acquisition analysis ignores. These divestiture options limit the downside losses to the acquiring firm. Although there may be an opportunity to divest assets soon after an acquisition, firms may decide to hold these divestiture options in hopes of a more optimal time.

Model focuses on entry and exit possibilities (Arzac (2008)) considered the application of real options to the entry and exit issue as well as to the foothold issue. That is, the timing of when to undertake a venture can be modeled in the context of real options. Delaying entry until a more favorable time can at first appear to be valuable, but this may increase risk exposure by allowing competitors time to enter the market. Likewise, the optimal time to exit a venture or project can be modeled as a real option. The foothold issue refers to the entry with subsequent opportunities to expand, including both geographically and in terms of production.

Besides these models, researchers considered the possibilities of real option application to accounting aspect of goodwill impairment as well as to explanation why information and communication technology firms might acquire early, as well as which of those firms are likely to do so (Baldi and Trigeorgis (2009), Warner and Fairbank (2008))

3.2. Game theoretic M&A real option models

Game theoretic M&A real option models or the models of strategic M&A interactions in a real option setting consider competition between parties. These models investigate how combining real options analysis and game theory can help resolve valuation problems that involve strategic interaction among firms. In this regard, various authors investigate the strategic interaction in research and development, the competitive interaction in real option valuation of M&As and, the early preemptive investment by giving up the option premium to wait (of a wait-and-see approach).

Smit and Trigeorgis (2001) modeled strategic real option interactions in research and development as a two-person game in which the growth option value depends on exogenous competitive reactions. That is, the firms invest in research and development to develop a more cost-efficient production process and then commercialize the product. This idea can be used in M&A valuation if the target and acquiring firms can combine resources to mitigate exogenous competitive reactions.

Toxvaerd (2008) developed a theory to explain the merger waves based on interaction between competitive pressure, irreversibility of mergers, and uncertainty when targets are scarce. Its real options game model is based on three elements: there is a relative scarcity of desirable targets; mergers can be viewed as irreversible investments containing considerable uncertainty (there is an embedded delay option or an option value of waiting to acquire a target); and imperfect competition for the target exists. Author derived a complete information model which has showed that waiting versus the preemption trade-off leads to a continuum of sub game perfect equilibrium. Furthermore, the author introduced noisy private information about merger profitability leading to a dynamic global model in a Bayesian setting.

Morellec and Zhdanov (2005) developed a dynamic real option model that jointly determines the timing and terms of takeovers by solving option exercise games between bidding and target firm shareholders. They examined the role of multiple bidders in the presence of competition and imperfect information on takeover activity. The authors based their model on the analogy between exchange options and takeover opportunities (takeover can be compared to an option to exchange one asset) and on the imperfect information. Firms have complete information but outside investors have incomplete information. Starting from this, the authors made certain predictions: returns to target shareholders are higher than bidding shareholders; returns to bidding shareholders are negative if competition exists for the acquisition; and competition affects returns on takeover deals and speeds up the acquisition process. These predictions are consistent with the empirical evidence.

Because of formal models inability to deal with takeover incentives, Lambrecht and Myers (2007) considered takeovers in declining markets. They develop a real option-based theory of takeovers and divestment for M&As and conclude that a firm can abandon a business voluntarily or be forced to do so by a takeover when product demand falls to a low threshold level. The same authors extended their research by developing a dynamic infinite horizon model that incorporates the option to abandon the firm and release the assets to investors. In this model, the managers decide when to exercise the real abandonment options either voluntarily or when forced by a takeover. The authors provide new theoretical results and testable predictions on the optimal payout policy, the role of golden parachutes, and the link between debt and takeovers. They show that debt service can reduce managerial rents and force managers to close the firm early. Thus, they claimed that debt financing plays an important role in hostile takeovers.

Almost immediately, another group of authors (Magsiri, Mello, and Rukes (2008)) has developed a model in which the acquisition price is endogenously determined as the outcome of a bargaining game between the acquirer and the seller. The authors analyzed the fundamental trade-off between internal growth and growth via acquisition. The opportunity to grow internally affects the price of an acquisition because it is a fallback option in the event negotiations fail due to lower price and other factors. If the negotiations fail, the acquirer has the opportunity to grow internally through investments, which is a real option to expand (which assumes that the acquirer has the flexibility to decide if and when to undertake the investment). Assuming that an acquisition investment and an internal investment represent mutually exclusive strategies, the option's value to grow internally at the time of negotiations becomes a bargaining game option. This model complements the findings of Morellec and Zhdanov (2005) and shows that competition is unnecessary to generate negative earnings announcements. Inclusion of the internal growth opportunity is shown to force early acquisitions (rather than at a socially optimal time), which contrasts the finding in Morellec and Zhdanov.

3.3. Collaborative M&A real option models

Collaborative or joint action M&A real option models deals with cooperative options. Unlike Smit and Trigeorgis, group of authors (Savva and Scholtes (2005)) distinguish between cooperative and competitive options. Cooperative options are exercised jointly to maximize the total deal value, while competitive options are exercised unilaterally to increase the payoff for individual parties. These collaborative real options fall within the boundaries of risk-sharing contracts. The authors considered cooperative options, which are partnership deals such as joint ventures with future flexibility. Cooperative options allow better understanding of real options in partnership deals with regard to fair splits of risks and return of a partnership. In partnership deals, the idea is to develop synergies by combining core competencies to form unique offerings that neither

party alone can provide. Thus, the exercise decisions are taken jointly with a view to maximizing the total value of the deal.

On the other hand, Thijssen (2008) examined a situation in which both parties in a transaction can make bids for each other. Assuming some agreement is reached, the firms then merge. Author considered a takeover to be different from a merger, with the role of both parties being endogenous in a merger. He concluded that any value associated with options in the merger is eliminated if the actions of each party are endogenous. Beside this, the author further developed a theoretical model to support its finding.

The presence of specific antitakeover defenses can create new options, many antitakeover measures are triggered by certain events with the intent of deterring a hostile takeover. In reality, defensive measures may not actually prevent a takeover, but they do have the effect of increasing the cost of a takeover. Hence, an acquirer could use the real option framework to incorporate the activation of various antitakeover measures a target would invoke if the attempt is hostile, that is, without board approval. A target could also apply real options to the valuation from its point of view in the context of activation of antitakeover provisions. Such an analysis may facilitate negotiations and result in a friendly rather than hostile takeover. The reality is that most takeovers are the result of negotiation between the boards of the acquirer and the target firm, even if the initial offer was a hostile offer.

4. REAL OPTIONS IN PRACTICE

The actual implementation of real option analysis into the corporate decision-making framework has been somewhat difficult. Triantis and Borison (2001) took a survey approach to gauge the actual use of real option methodology. They categorize the use of real options into three broad groups. The first is the qualitative use of options methodology as a thought process. Managers have long recognized that options or future decisions exist in almost any long-term investment opportunity. The second category is the analytical use of real options, while the third one is the use of real options in the context of much broader company planning. Based on their survey, they noted that some respondents had viewed the use of real options primarily as an endeavor of academic researchers while the other responses had indicated that the use of real options evolved as managers seek to make better decisions. The authors concluded that the acceptance of real option analysis in corporate decision making in general would depend upon its perceived value in terms of better financial outcomes.

Beside this, Damodaran (2005) provided an overview of the actual implementation of real option analysis in corporate decision making. According to Damodaran, many managers believe that accurately placing a value on the many potential embedded options involved in a corporation is impossible. He noted that others perceive that it is indeed possible to determine a quantitative value. The author attempted to examine various options that arise in business decisions and then to develop a methodology to use the appropriate inputs and develop a true value. With regards to investment considerations (including M&A), he focused on the timing option, expansion option, and termination option. The parameters for determining the option value include the cost, the variance, the exercise price, and the expiration period. While these seem straightforward, Damodaran pointed out that, in practice, developing these parameters is more difficult. In this regard, he argued that the investment may or may not be traded, meaning that obtaining a true variance may be difficult. The same issues he applied to expansion decision. Regarding the abandonment, the author argued that applying option models is complicated because abandonment value can change over time. Regardless of the difficulties, the inclusion of option values may transform a negative NPV acquisition into a value additive acquisition.

Barnett and Dunbar (2007) went one step further. They offered a different perspective by examining what they call real options reasoning. They discuss how this reasoning can lead firms to undertake many investments because each has some option involved for future decisions. Accordingly, firms may be motivated to assume many investments, given multiple options associated with each. They discussed how real option reasoning can lead firms to undertake many investments because each has some option involved for future decision. The authors concluded that this would result in abandoning many such investments.

5. CONCLUSION

Real option analysis can enhance the value of M&A because it takes into account the managerial flexibility. It enables managers to include the value of different options such as expansion, abandonment, optimal timing and resource flexibility. Furthermore, managers may use real option analysis in preparing the terms of

an offer. That means that the bidding firm's managerial flexibility should enhance value for the firm. Similarly, the managers of the target firm can consider managerial flexibility in order to increase a target's value. In this way, all parties in a transaction can potentially benefit from the identification and valuation of any embedded options, which may differ between the acquirer and the target firm. The present literature in this field shows that the number of papers and researches has increased in recent ten years, but they are still largely theoretical. Practical real options use in M&A process are partly limited because of their valuation complexity, which is related to option identification difficulties and the resources and time they require. This does not mean that the real options are not used. On the contrary, real options had been applied in different industries (pharmaceuticals, IT, oil, banking etc.).

The literature suggests that real option use in M&A valuation can raise the value of M&A. The main issue that still has not been resolved is the gap between the research and actual practice. Another issue that waits for solution is how to encourage managers to use real options. According to recent researches, we can expect the further use of real options in M&As, especially in decisions related to M&As timing, spin-off, divestiture etc. Practice has shown that although many managers realize the importance of applying real options in M&A, many of them are not capable to quantify the real option value in acquisition valuation process as a whole.

Further research is needed, so it could be expected the researches related to better option identification as well as real option valuation methodology creation.

Abstract: *In the last decade, financial turmoil has triggered a need for more effective and efficient working capital management (WCM) in companies. A popular measure of WCM is the cash conversion cycle (CCC), i.e. the time lag between the expenditure for the purchases of raw materials and the collection of sales of finished goods. The longer this time lag, the larger the investment in working capital. That implies that companies with efficient working capital management have a relatively short CCC. This study aims to explore the relation between liquidity measures and profitability of Serbian companies. In particular, the survey addresses relation between CCC and return on assets, assuming these performance indicators as the most representative for liquidity and profitability. The survey of this kind has never been conducted among Serbian companies. Empirical data analysis is based on 51 Serbian publicly traded companies. Our findings show some inconsistencies with the WCM theory. Specifically, number of days accounts receivable is negatively correlated with return on assets, which may be of particular interest for both corporate managers and academics.*

Keywords: *working capital, cash conversion cycle, account receivables, accounts payables, inventory, profitability*

1. INTRODUCTION

In the last decade special attention is given to the issue of working capital management. Evidently, many authors suggest that the optimum level of working capital depends on the industry and the nature of its transactions (Walker, 1964; Outram, 1997; Ozbayrak, 2006). According to Johnson and Soenen (2003), in order for company to be able to achieve its aim of shareholder value creation, effective working capital management should be integral part of its corporate strategy. Net working capital is defined as the difference between firms' current assets (including accounts receivable, inventories, and cash) and current liabilities (including accounts payable and short term debt). These elements significantly influence company's liquidity and that is the reason why working capital is often used to evaluate liquidity of a company.

According to Deloof (2003) working capital management will have a significant impact on the profitability of companies and consequently WCM is a very important element of financial management. In order for working capital management to enhance value of a company, adequate balance between liquidity and profitability must be maintained. Same author also states that a popular measure of WCM is the cash conversion cycle (CCC), i.e. the time lag between the expenditure for the purchases of raw materials and the collection of sales of finished goods. The longer this time lag, the larger the investment in working capital. That implies that companies with efficient working capital management have relative short cash conversion cycles.

Taking all this into consideration, determining the optimum level of working capital in a company is not an easy task. It raises questions regarding appropriate amount of current assets as well as questions regarding financing these assets. Garcia-Teruel and Martinez-Solano (2007) point out that working capital investment involves a trade-off between profitability and risk i.e. decisions that tend to increase profitability tend to increase risk, and, on the other hand, decisions that concentrate on risk reduction will tend to decrease potential profitability.

This study aims to explore the correlation between liquidity measures and profitability of Serbian companies. In particular, the survey addresses correlation between various liquidity measures and return on assets. The relation between liquidity and profitability measures has widely been explored in the extant literature. This relates to corporations in both developed (Wang, 2002; Deloof, 2003; Lyroudi and Lazaridis, 2000; Garcia-Teruel and Martinez-Solano, 2007), and emerging markets (Luo, et al., 2006; Zariyawati, et al., 2006; Afza

and Nazir, 2007; Raheman and Nasr, 2007; Samiloglu and Demirgunes, 2007; Afza and Nazir, 2008; Sharma and Kumar, 2011).

However, to the best of authors' knowledge, the survey of this kind has never been conducted among Serbian companies. Serbian corporations have evolved in a different economic and political setting compared to other, both developed and emerging economies. The most important differences can be found in general economic conditions, the development of Serbian financial markets, managerial style of Serbian corporate leaders, corporate culture and leadership, managerial attitudes towards the risk, expectations from shareholders etc. Thereafter, the relationship between liquidity and profitability may prove to be interesting for management, shareholders, and other various stakeholders in Serbian corporate sector.

2. THEORETICAL BACKGROUND

The theoretical foundation for this paper derives from numerous research papers and surveys performed both in developed and emerging markets. Deloof (2003) conducted a survey among 2,000 Belgian corporations in order to determine what kind of effects working capital management has on firms' profitability. Deloof (2003) found that there is a significant negative relation between profitability of the firms, measured by gross operating income, and the number of days accounts receivable, inventories and accounts payable. He concluded that profitability could be enhanced by reducing the number of day's accounts receivable and inventories to some acceptable minimum level.

Wang (2002) studied relationship that liquidity management has with both operating performance and corporate value. This study is based on data for Japanese and Taiwanese firms. His results suggest that aggressive liquidity management will increase both operating performance and corporate value.

Lyrodi and Lazaridis (2000) examined liquidity of food and beverage industry in Greece and connected it to profitability, indebtedness and company size. They found that there is a significant positive relationship between the cash conversion cycle and quick and current ratios. Furthermore, there is a positive relationship between cash conversion cycle and both ROA and net profit margin. Hence, there was no linear relationship between cash conversion cycle and leverage ratios. According to Lyrodi and Lazaridis (2000), current and quick ratio had negative relationship with debt to equity ratio. Yet there is a positive relation of these ratios to times interest earned ratio. They found no statistical evidence of difference between liquidity ratios of different sized companies.

The study of Afza and Nazir (2007) examines the relationship between the aggressive/conservative working capital policies with profitability and risk. Sample consists of 208 public limited companies listed on Karachi Stock Exchange for the period of 1998-2005. Their results show that there is a negative relationship between working capital policies and profitability, and they also found no significant relationship between the level of current assets and liabilities with risk of the firms.

Garcia-Teruel and Martinez-Solano (2007) provide empirical evidence of the effects of working capital management on the profitability based on a sample of small and medium-sized enterprises (SMEs) in Spain. The research has been performed on a panel data of 8,872 SMEs covering the six year period. Their study showed that profitability can be achieved by reducing inventories and the number of days for which their accounts are outstanding. Also, their study proved that shortening the cash conversion cycle also increases firm's profitability.

Consistent findings can be found in research of Samiloglu and Demirgunes (2008) performed on manufacturing firms listed on Istanbul Stock Exchange for the period of 1998-2007. The results showed that accounts receivables period, inventory period and leverage influence profitability negatively, while growth in sales has reverse affect.

By examining different manufacturing, retail and wholesale companies from 1980 to 2006, Luo, et al. (2006) found that the efficiency of a firm's working capital management has lasting impact on firm performance. The future earnings increase follow improvements in working capital management. The same authors reveal that the firm value tends to increase when cash conversion cycle decreases. The consistent results can be found in Zariyawati et al. (2006). Covering similar period and using panel data of 1,628 Malaysian firms, these scholars found high negative correlation between cash conversion cycle and profitability.

Nevertheless, Sharma and Kumar (2011) reported inconsistent results obtained from similar study conducted in India. By examining 263 non-financial firms listed at the Bombay Stock Exchange, they find that working capital management and profitability is positively correlated. In particular, inventory and number of days accounts payable are negatively correlated with profitability, whereas number of days accounts receivables and cash conversion cycle exhibit a positive relation with companies profitability.

3. METHODOLOGY

3.1. Sampling procedure and data

Aim of this study is to test whether there is a correlation between liquidity and profitability of companies in Serbia. In order to properly determine significance of such a relationship, we have selected Serbian corporations that list on Belgrade Stock Exchange and that are included in Belexline broad market index. This index is chosen because it represents capital market movements. Our sample consists of 51 corporations. Index is based on price movements of 70 Serbian corporations. However, because of specific nature of their activities we have excluded banks and financial corporations from our sample. Also, corporations that have not yet submitted last year's financial reports have not been taken into consideration. Likewise, one corporation that has missing data for the year 2010, due to the fact that is founded in 2011, has been removed from the sample.

Our findings are based on liquidity and profitability measures, obtained from last year's financial statements that are publically available. Sample is described with descriptive statistics, more specifically: means, minimums, maximums and standard deviations. Interdependence of variables was examined using correlation analysis (Spearman's rho two-tailed correlation), conducted in SPSS 17.0.

3.2. Research variables

The basic objective of the study was to examine and explore the relationship between indicators of profitability and liquidity. Therefore, as a profitability measure the study used return on assets (ROA), defined as the ratio of earnings before interest and tax to total operating assets. This ratio was used in numerous studies (Afza and Nazir, 2007; Garcia-Teruel and Martinez-Solano, 2007; Uyar, 2009; Sharma and Kumar, 2011) as it provides the best insight into corporate profitability.

Liquidity and other performance measures employed in this study are number of days accounting payables (AP), number of days inventory turnover (INV), number of days accounting receivables turnover (AR), cash conversion cycle (CCC), size of the company (SIZE), and the sales growth of the company (GROWTH). Similar set of variables was used to examine the relation to profitability in numerous studies (see: Lyroutdi and Lazaridis, 2000; Deelof, 2003; Garcia-Teruel and Martinez-Solano, 2005; Nazir and Afza, 2009).

The effectiveness of working capital management was measured by number of days accounts receivable (AR), number of days of inventory (INV) and number of days accounts payable (AP). Number of days accounts receivables, inventory and accounts payable was calculated as 365 times accounts receivables, inventory and payables, respectively. Number of days accounts receivables indicates number of days that passes from selling the products and services to collecting the cash from debtors. Number of days inventory shows the period of time that passes from receiving raw materials and services from suppliers to the sales of goods. Number of days accounts payables denotes the duration from receiving raw materials and goods from suppliers to the payment time. Finally, the cash conversion cycle (CCC) is an additive measure of the number of days funds are committed to inventories and receivables less the number of days payments are deferred to suppliers (Johnson and Soenen, 2003). The size of the company (SIZE) was measured as the natural logarithm of the actual book value of assets. The logarithm approach was used as the original large value of companies might have disturbed the analysis (Nazir and Afza, 2009). The sales growth (GROWTH) was measured as the relative growth in sales $[(sales_{n+1} - sales_n)/sales_n]$.

3.3. Descriptive statistics

The descriptive statistics for both profitability and controlling variables is displayed in Table 1. The mean for return on assets was 6.7%, whilst minimum and maximum values for ROA are -7.8% and 62.6%, respectively. Hence, profitability is very volatile [standard deviation is approximately .1162]. The average cash conversion cycle of sampled companies was approximately 318 days. This means that in average it takes 318 days from paying suppliers to collecting the cash from buyers. This was affected by accounts

receivables of 364 days, inventory of 130 days and accounts payables of 175 days in average. This indicates that the average observed company in this study face myriad of problems with liquidity.

The mean growth of examined companies was nearly 10,3%, but the standard deviation indicates large differences between the sales growth among observed companies. Average leverage is 39,52%. It is noteworthy to notice that the maximum leverage is 123,9%, which means that some of the observed companies have losses in excess of equity. Finally, current ratio was in average 2,45, with minimum and maximum values ranging from 0,168 to 11,894.

Table 1: Descriptive statistics for profitability and liquidity measures

	N	Minimum	Maximum	Mean	Std. Deviation
ROA	51	-,078	,626	,06703	,113346

Valid N (listwise)	51				

4. RESULTS AND DISCUSSION

As the objective of the study was to analyse the correlation between liquidity and profitability indicators, the results displayed in Table 2 represent the correlation matrix. Results show that there is a statistically significant correlation between return on assets and number of days in accounts receivable, number of days in accounts payable, growth, size and current ratio.

The weak negative correlation exists between ROA and number of days accounts receivable and ROA and number of days accounts payable. These findings suggest that if number of days accounts receivable and number of days accounts payable is reduced profitability of a company will increase. Therefore, the companies which more frequently collect cash from costumers tend to be more profitable. The working capital management theory suggests the same. However, negative correlation of number of days accounting payables and profitability is highly inconsistent with a working capital management theory. The theory suggests that delays the payments increases the profitability of the company. However, similar inconsistencies could be found in other empirical studies (Deloof, 2003; Garcia-Teruel and Martinez-Solano, 2007). These findings emphasise the fact that more profitable companies in Serbia more frequently respond to their commercial liabilities. Nevertheless, the shortcoming of Spearman's rho, or any other correlation test, does not allow identifying causes and consequences.

Study results also reveal a positive correlation between current ratio and return on assets (.389). With regard to other performance measures, relatively high values for correlation could be found between return on assets and both growth (.428) and size (.310) of corporation. Profitability is positively associated with growth in sales, as well as with size. Hence, larger companies tend to have higher profitability, which could also be found in Garcia-Teruel and Martinez-Solano (2007).

5. CONCLUSIONS

Extant literature provides a profound insight into effects of working capital management on corporate profitability in both developed and emerging economies. Different authors present contrasting findings of the relationship that exists between liquidity measures and ROA. This study analyzed profitability-liquidity relationship within Serbian companies listed at the Belgrade Stock Exchange. Our findings suggest that Serbian corporations suffer from severe illiquidity. Cash conversion cycle, as the most frequently used dynamic liquidity measure, tends to be too lengthy, and it does not have statistically significant relationship with ROA.

Our study reveals a negative correlation between ROA, and both number of days accounts receivable and number of days accounts payable. There is a positive correlation between return on assets and current ratio, and ROA and sales growth. Based on these results management can increase profitability by reducing number of days accounts receivable. On the other hand, delays in payments to suppliers are not necessarily a driver of profitability. However, it cannot be stated as a fact that liquidity affects profitability and not the other way around.

This survey did not explore all profitability drivers and also did not determine real nature of the relationship that exists between liquidity performance measures and various indicators of profitability, which could be suggested for further research.

Abstract: *Modern enterprises of XXI century should be characterized by the ability to adequately use their intangible resources that have become much more significant in relation to material resources. With the spread of market uncertainty is greater, technologies are more sophisticated, competition is stronger, the lifetime of products is shorter. Therefore, successful companies need to be able to distinguish the continual creation of new knowledge and its dissemination to all parts of the company, building them into all processes, new technologies, new effects. Adequate knowledge management leads to improved performance of employees and becomes an important factor to parry competition. Knowledge is an indispensable strategic resource for companies, because it contributes to the achievement of its basic objectives. Use of adequate knowledge creates intellectual capital of a company that provides objective reports with additional financial reporting and is an important factor in parrying the fierce competition.*

Keywords: *intellectual capital, knowledge, financial statements, measurement, enterprise, International Accounting Standard 38*

1. INTRODUCTION

The present time is characterized by global competition, political turmoil, turbulent environment, uncertainty, marked fluctuation of qualified personnel, development of technology and others. Being surrounded with this kind of environment a company can hardly survive in the market without professional management and staff who possess modern knowledge, intelligence and ability to knowledge sharing in teams to improve company performance and to parry competition. Rapid technological and market changes that would require the company more flexible operations in order to adapt to this environment. Competitive advantage can only be held if the company has adequate experts from various fields whose knowledge is transformed into a intellectual capital as a pillar of defence against competitors. Therefore, the advantage can be maintained by adequate investment and motivating employees, because they are headquarter that is key factor of intellectual capital as a resource base for survival, growth and enterprise development, and increasing value of it. Company's ability to properly activate their intangible resources has become more important in relation to the management of material resources. The official financial statements present only part of the intangible assets, and only tangible part of it (research, patents, trademarks, licenses - governed by the International Accounting Standard 38 - Intangible assets), intangible and impalpably (i.e. intellectual capital) is not in the official financial statements but is in the additional company financial statements in some developed countries.

2. KNOWLEDGE AS A BASE OF INTELLECTUAL CAPITAL IN FUNCTION OF COMPETITIVE ADVANTAGES OF COMPANY

In the new economy based on the information technology knowledge gets a great importance in relation to the past. It became a crucial strategic factor for the development of enterprises, and thus society. The modern corporation operates in a knowledge society - it Peter Drucker recognized in his researches. Therefore, in the XXI century - century of knowledge, real information is not invested in the material factors, but in the knowledge of employees. Companies in the new economy have realized that their advantage toward competition is reflected through what it knows, how it to uses, what it knows and how fast it can learn something new.

Adaptation and learning skills is associated with enterprise intellectual capital. Intellectual capital can be defined as a combination of three integral segments, namely: human capital (skills, knowledge, skills, staff and management experience, the dynamic action of an intelligent enterprise in competitive conditions), structural capital (infrastructure support human capital including information technology, the company's

image, proprietary databases, organizational concepts, documents, patents and licenses) and customer capital (the ratio of companies and their clients) (Puloć & Sundać, 2008.).

The combination of qualitative and quantitative human, structural and customer capital merge into intellectual capital that is a source of competitive advantage. In fact, the intellectual capital comprises the knowledge involved in a dynamic process and transformed into added value for the company.

In order to gain insight into the intellectual capital and its various structural components one of the first was a Swedish insurance company "Skandia" in 1995. get down measuring the performance of intellectual capital. They added the intellectual capital report to traditional (official) financial statement. They made a pioneering step in terms of more comprehensive financial reporting. An additional report called new reporting model is made to provide a balanced picture of the intellectual and financial capital. This model is a step beyond traditional accounting presentation of value added.

One should not misunderstand their model. Skandia's intellectual capital measurement model is not a replacement of traditional accounting, nor it is complete. Regardless the above, it represents an important step forward compared to the traditional way of displacing of accounting the value added. It is in fact incentive, the driving force for the development of other methods, techniques and models of monitoring measurement and management of intellectual capital.

Numerous studies and analyzes show that knowledge and its externalization in many companies are not shown in the financial statements, and also is present insufficient attention in the management of these resources. It also means that the intellectual capital is under-utilized in these companies because they own success, or failure, calculated using the old principles and methods.

For modern enterprises sources of competitive advantage are related to information, the process of organization and relations with external stakeholders. Infrastructure of companies, relationships with customers and business partners, innovation efforts initially incorporate intellectual capital.

The sum of knowledge of all individuals in the company, as well as the practical translation of this knowledge in a competitive process, trademarks, masks of products, actually makes intellectual capital. More detailed studies relating to intellectual capital are tied for second half of the nineties of last century and the beginning of the XXI century.

The intellectual capital of the company is really focused an increase in competitiveness in the future, a development of options, opportunities to make use of the environment and the future operations of the company. Therefore, the real value of the company is estimated over its potential for future opportunities and the ability to increase profitability, and therefore competitiveness. Intellectual capital is knowledge that can be transformed into profit. From this point of view in the focus are investment, approaches, processes, ideas and know-how.

Intellectual capital marks a new knowledge-based economy and become the most important factor of production, which drives all other production factors. The synergy of the components of intellectual capital is the basis of creating value-added company, positioning the company in the market creating competitive advantage.

The role of knowledge in achieving competitive advantage is a challenge to management. It is a fluid mix of experience, information, intuition of experts. Sveiby believes that knowledge has four characteristics (Sveiby, 1998).

- Knowledge is tacit
- Knowledge is directed to action
- Knowledge is supported by the rules
- Knowledge is constantly changing

To create innovative enterprise by transformation processes immanent is prominent place of the knowledge without which is impossible involvement in the contemporary development trends. Therefore, the knowledge,

skill, creativity and innovation are becoming the main generators of human intellectual capital of employees, which increasingly require new types of production.

Intellectual capital is intended to explain the origin of the differences between book and market values of companies. This way value of the companies is more precisely determined and is of great importance not only for the company, but also for investors. Intellectual capital is the knowledge included in the dynamic process transformed into a value-added of enterprises.

International Accounting Standards 38 - Intangible Assets prescribes the accounting treatment of intangible assets that are not dealt with other accounting standards. This standard defines the criteria for recognition of intangible assets, as well as way of the measuring of the book value of these and requires certain disclosures about intangible assets. Some intangible assets may have a physical form (for example a prototype, CD-ROM, documentation of patents or licenses, or film) and is considered to be tangible intangible assets of its definition, recognition, initial measurement, the measurement after recognition is regulated by this standard. Intangible immaterial assets are not regulated by acts of professional regulations and also are not integral components of the official financial statements on, but are integral components of the additional financial reports from some companies of countries with developed market economies. The company chooses its accounting policy that it will use the cost model or revaluation model.

Intangible immaterial property i.e. investments are not regulated by the International Accounting Standards / International Financial Reporting Standards to the financial statements show a true picture of the property, financial and profitability position. We should as soon as possible incorporate as the official position of the financial statements, which implies the adoption of new standard that will govern the quantification of the so-called intangible immaterial property so called intellectual capital. Or will complement the existing International Accounting Standard 38 with the necessary elements related to the intangible asset that is intangible immaterial property i.e. investment. The pointed will require a change of the Accounting and Auditing Law and Company Law and accompanying documents.

3. MEASUREMENT OF INTELLECTUAL CAPITAL

Company after setting up knowledge management strategy of its employees faced a new challenge i.e. the question is how to measure the effects of complex activities. Some companies (Skandia, Dowchemical, Buckman Laboratories, Canon, etc.) twenty years ago made a pioneering step and began measuring intellectual capital, and were deeply convinced that the growth of intellectual capital leads to a positive financial result of the company, and contrary - his fall is a sign for the future problems.

Present are the following methods for measuring intellectual capital, namely: (Šijan, 2007).

1. Market to Book ratio
2. Tobin's Q
3. Calculated Intangible value

1. Relation of the market and book value is based on calculating the difference between the market capitalization of the company and its book value. This method is simple to use, but it is difficult to embrace complexity. Of the multitude of economic indicators and speculation in the markets in which the company cannot influence with the results of its operations depends the market value of companies. Therefore, in order to implementation of this method provided adequate results it is very important to anticipatory define the criteria of determining and quantifying the market value of the company, which is not an easy task.

2. Tobin's Q was initially developed for the analysis of financial markets by James Tobin. This method uses the value of the reproduction costs of corporate assets in order to predict investment decisions independent of interest rates. Tobin's Q is the ratio of enterprise value and reproduction cost of its assets. Market value is the most probable price that would be provided a means to achieve a competitive and open market under conditions necessary for a fair sale.

If the Q ratio is greater than 1 (if the reproduction costs of corporate assets is lower than its market value), then the company earns monopoly profits and, conversely, if the coefficient of Q is less than 1 (if the reproduction costs of corporate assets is higher than its market value) then achieved a normal return on their investment.

This method provides insight into the current market and financial situation of enterprises. Important is dynamic approach to management of skills (knowledge) performances of employees who will point out the

positive activities to highlight and the negative to be avoided or minimized. It is an important indicator that the company should focus on creating new value and achievement of competitive advantages continuously.

3. Method Accrued intangible value developed by NCI Research Illinois, to calculate the fair value of intangible assets of companies. This method calculates the excess return on fixed assets and use this figure as a base for a certain proportion of return attributable to intangible assets.

A prerequisite for calculating intellectual capital makes the availability of data of the profit of entire capital within their own business. Intellectual capital is calculated in relation to the achievements of the average competitor, compared with an average that type of industry to which it belongs. For a period of time is necessary to average company revenues divided by the average of its material resources. Then this result (which is repayable funds) compared with the average in the industry.

There is a need for linking intellectual capital with the objectives of the company that will be manifested through competitive advantage, which is why many companies are experimenting with the management of intellectual capital in order to achieve this. Because of it appeared many methods of measuring and managing intellectual capital. One of the models of intellectual capital developed together Leif Edvinsson, Hubert St. Onge, Charles Armstrong and Gordon Petrash and called it a platform of values. Platform values (see Picture 1) describes the intellectual capital through three main components that are interconnected to form a value that is created in the cross section of these three components, i.e. human, structural and relational capital. In the framework of human capital considered to be people's ability and capacity to learn. Structural capital is the infrastructure, intellectual structures and cultures. The relational capital are among customers, brands, and contracts.

Picture 1: Platform of values

1. INTELLECTUAL CAPITAL MANAGEMENT USING THE MAGIC PROJECT

QPR software developed by the European MAGIC Consortium (measurement reporting on intellectual capital) has created a technology that supports the methodology and model for measuring intellectual capital. This project is funded by the European Commission.

Many companies have realized the importance of creating a measurement system to monitor the most important resource of the company so called intellectual capital. Seen from this aspect intellectual capital can be defined as:

- Proportional value added to all intangible resources of company and
- Dominant knowledge necessary to provide the competitive advantage

If we measure the intellectual capital by methodology MAGIC project, its structure consists of human capital (which includes all the skills, competencies, expertise, so that he can react to market demand and customer needs, including leadership and management decisions and skills), organizational capital (including ability of the company, its infrastructure and organizational processes related to creating products and services for the market), market equity (the company's ability to communicate with the external environment, customers, suppliers and other stakeholders), and innovation capital (referring to the company power to innovate, improve and develop the untapped potential and create wealth in the long run).

Development of methodology of measurement system for determining the intellectual capital was actually the goal of this project. QPR Software from Finland, Institute for Human Factors Technology, Management IAT from Germany were partners MAGIC project.

5. CONCLUSION

Continuous adjustment of the market, technological and organizational changes in the century based on knowledge and intellectual capital the focus is adequate management skills of employees, i.e. intellectual capital. Only satisfied and adequately motivated employees are essential and primary resource of companies to innovate and achieve competitive advantage. Presented methods focus on measuring intellectual capital as a whole or its parts. The classical financial indicators are not able to cover all the results of knowledge management and intellectual capital. It is necessary to strive to develop new, more adequate methods for monitoring the economic effects in order to achieve competitive advantages. The invention enough precise methods will allow quantification of intellectual capital not only in the supplementary financial statements, but also in official statements, which represents a major challenge for theorists and for practitioners, and policy makers for acts of professional accounting regulations.

Abstract: *The first wave of the global economic and financial crisis in the U.S. spread to the European Union and worldwide. Very quickly, the crisis from the mortgage market spread to stock markets, government bonds, the labor force. The crisis has brought with it the decline of economic activity, insolvency and losses, primarily in the financial sector and then in the real sectors of economy. Problems in credit and savings that were accumulated in the past have reached the peak with the collapse of over a thousand banks. Those were the first signs of emergence of the current crisis, but they were ignored. A few years later, company corporate scandals followed (for example Enron, WorldCom, Adelphia, Global Crossing), which realized the suspect accounting procedures, participated in accounting and financial fraud schemes for deceiving the public and illegal acquisition of large gains by individuals.*

Keywords: *prime mortgage loans, sub-prime mortgage loans, U.S. housing bubble, crisis, loss*

1. INTRODUCTION

Until the mortgage market crisis, the U.S. is considered to be one of the safest and most developed markets, which almost certainly guaranteed profits with little risk. In the frantic race for profits in the U.S. mortgage market, global financial markets lost ground.

Globalization has contributed to the spread of the crisis of global proportions, but its occurrence did not signalled. The cause of the crisis was irrational consumption without taking into account the traditional business models. The cause of the boom in the mortgage market, which is the cause of occurrence of the current financial crisis, was a seemingly easy access to affordable mortgages. Boom was not based on fraud, as the overvaluation of stocks and excessive speculation.

This paper will tell about sub-prime mortgage loans, compensation of lenders risk, U.S. housing bubble and its burst, possible culprits and collapse of the financial system, the help from outside, crisis spreading, and protecting the financial system.

2. SUB-PRIME MORTGAGE LOANS

At the beginning of the millennium two types of mortgage loans appeared in the market. Prime mortgage loans were offered by lenders to their best customers who are creditworthy to make a repayment of a mortgage loan and sub-prime mortgage loans were offered by lenders to customers who did not meet the requirements for obtaining this type of loans. Believing in the idea that the value of homes in America never fall, the U.S. bankers developed this system of high-risk loans, known as "sub-prime" mortgages which characteristics are that the housing loan is offered and approved without much checking of property of the borrower. Many of these instruments let families purchase homes without documenting their income, putting little down, and with potentially high loan-payment-to-income ratios if interest rates rose. Banks have been easily approving these types of loans because the growth of housing prices in the U.S. was constantly rising every year extending the value of collateral so after a few years the value of mortgage loans exceeded the amount taken. Many of the borrowers could now easily get mortgage loans from banks and that led to an increase in demand for housing due to a limited supply and an increase in property prices in the U.S. The financial institutions that where lenders of this loans where know working in a field of low liquidity and high leverage.

3. COMPENSATION OF LENDERS RISK

Being attracted by the low initial interest rates on "sub-prime" loans lower-paying Americans did not pay lot of attention to the clauses in loan agreements. There should be no doubt that lenders were at least somewhat aware of the risks they were taking. Therefore, in order to ensure against loss, the U.S. mortgage banks have put a clauses that in the case of irregular borrowers' payments their interest exponentially increase. Although it seems that the lenders did not take into account the riskiness of their given loans, they have already made this step with interest increase in order to compensate

the taken risk (Spiegel, 2011). On the other hand, U.S. lenders have started to repack mortgage loans into complex financial arrangements and resell them to investors around the world. Many central banks around the world had difficulties to monitor this whole process and they long had almost no insight into the rules of buying and selling these loans (Vujić, 2008)

4. U.S. HOUSING BUBBLE AND ITS BURST

This type of loan has directly influenced the increase in demand, and indirectly on the growth of housing prices, so many started to buy the property from the speculative purpose - to sell for higher prices, giving further speed to price rising. This phenomenon is called as a U.S. housing bubble, which is characterized by rapid growth in the value of real assets such as property until it reaches an almost unbearable level, compared with earnings and other economic factors. This was followed by bank securitization of subprime loans where they sold their debts on the market. Thus, unwittingly endanger the entire financial system. Of course, the price of a balloon at one point had to burst that happened in July-August 2007. Home prices had increased by an average of 124% from 1997 to 2006 (Kjelleren, 2008.). Real estate prices have started to fall rapidly so that the debtors faced with the situation that they owe more than their property really worth. Many who bought the property were not able to repay taken loans, and their number was growing rapidly and the entire financial system was potentially insolvent. When the U.S. housing bubble fully burst in 2007 and home prices dropped, 1.25 million subprime mortgages foreclosed, up 80% from 2006. In Phoenix, Miami, greater Los Angeles and Las Vegas, home prices declined by over 25% in 2008. and the national average declined 17%, with around 10 million families having negative equity in their homes (Kjelleren, 2008.).

Borrowers were not able to carry out their obligation and they were announcing bankruptcy. Banks unwillingly became owners of great amount of mortgages. Banks have tried to sell mortgages in the amount of debt but prices were constantly falling, so even if the property was sold it was not enough to service the debt.

5. POSSIBLE CULPRITS AND COLLAPSE OF THE FINANCIAL SYSTEM

Some authors suggest that the blame modern practice of securitizing loans, but some disagree with this opinion mentioning 1930s and the fact that there were no securitized mortgages then. It is also very hard to say that modern institutions are solely responsible for currently observed modification rates (Spiegel, 2011).

Going back to 1977 and Community Reinvestment Act it can be seen that the Government as one of its well-intentioned policies intentionally encouraged home ownership by low-income families and intentionally contributed to weakening of the whole financial system. In order to meet this Act, banks began to give loans in low- and moderate-income areas, softening credit policy with not so rigid requirements what automatically led to higher rates for those borrowers as assuring themselves from the taken credit risk. Lower and lower credit standards followed (Spiegel, 2011).

Consequences arisen

- Unrecorded wave seizure overpriced houses owned by the impoverished Americans
- drop in U.S. consumer confidence in their purchasing power,
- increase the local unemployment and inflation,
- Slowdown of economic growth,
- Balance of costs of too expensive war in Iraq

Running away of investors

- bad assets in banks' balance sheets
- withdrawal due to rising investor risk
- due to the low liquidity, financial institutions were forced to sell their property
- due to the crisis there is a lack of investors willing to buy property
- due to low demand prices decreased, and banks are forced to sell assets at a price that is lower than the purchase price which leads to the realization of loss
- Crises leads to deterioration of the balance sheets of banks, which represents an additional incentive for investors to withdraw funds

The disappearance of capital

- bad assets on the balance sheet of banks
- due to large creditor investments and the absence of regulation the banks have little capital ratio and a high leverage
- due to the crisis, banks are forced to sell assets (decrease leverage)
- due to the crises there is lack of investors wishing to buy property
- a decline in property prices influenced banks to sell real estate below price
- As the property was sold below price that led to deteriorated of capital ratio, which is an additional incentive to sell the property (Petković, 2009).

"The collapse of the U.S. mortgage market has caused a great financial crisis and all the big companies that played a key role in the process of securitization (the five investment banks - "Goldman Sachs", "Morgan Stanley", "Lehman Brothers", "Merrill Lynch", "Bear Stearns "; two financial conglomerates - "City Group", "JP Morgan Chase"; three companies dealing with insurance - AIG, MBIA, AMBAC, three rating agencies for risk assessment - "Moody's", "Standard & Poor's" "Fitch" and two big mortgage corporations - "Fannie Mae", "Freddie Mac") found themselves facing bankruptcy. But not only them, because the vast mass of "toxic" securities spread throughout the world. Banks in many countries around the world in their portfolios had higher or lower mass "toxic" securities, and was threatened with bankruptcy. Therefore, the crisis in the United States quickly passed on to the whole world. It should be noted that the crisis in the housing market was just a catalyst, not the underlying cause of current global crisis" (Dušanić, 2012).

6. THE HELP FROM OUTSIDE

In 2008 the financial markets froze. While the financial crisis created problems for firms reducing their profits, it also attacked banking system. Banks stopped lending to each other in fear they would never be paid back. The help from outside was indispensable so the Government officials asked Congress for funds to fill in for to save credit markets. In response to this crisis **Troubled Asset Relief Program (TARP)** was founded, as facility created by the US Government to buy distressed assets from financial institutions. The main purpose of TARP was to create liquidity in the credit markets by buying (and freeing up) assets tied to mortgages from banks. That way banks with the help of TARP could continue lending. Of course, those institutions participating in this program were under Government monitoring (Dušanić, 2008).

European Central Bank (ECB) as one of the world's most important central banks and someone who implements monetary policy can provide liquidity via open-market operations. As crises was spreading ECB had to intervene, but even though ECB's gave its best effort, the market still kept high rates for interbank loans. Every time ECB tried to do something it was reflected in totally different way. Conducting an aggressive politics to provide liquidity made lenders pull back from the market even more, as they were more suspicious of borrowers. Bad situation on the market made a condition in which every ECB liquidity injection required a new one (Spiegel, 2011).

When housing prices began their slide they even fell to about a third of their initial value what to a wave of foreclosures. Banks were also on the loss as properties were worth far less than the underlying mortgages were seized. Having a wish to solve this issues the Government intervene by providing funding to Home Owners' Loan Corporation (HOLC) as its main purpose is to refinance home mortgages currently in default to prevent [foreclosure](#). With these funds HOLC could purchase delinquent loans, refinance them, and thus give homeowners a chance to remain in their dwellings.

7. CRISIS SPREADING

There is a spill over of the crisis from the U.S. to Europe and on to other developing countries. Governments of most developed countries had to intervene. Their main goal was to restore confidence in the financial system which was at an alarmingly low level, ensure the liquidity of many institutions and to stop the sale of property at low prices. All of this was a reason that they approved a large amount of money. This funding was much easier done with the investitures and countries that could borrow money from investitures than those who could not. The other short-term measure was recapitalization of banks.

Capital increase led to a reduction in leverage. Reducing supply and recovering demand, and also getting

prices of real estate to more realistic level was possible with state's purchase of mortgages at risk from banks.

In order to prevent the deepening of the crisis, all countries are obliged to do everything in their power to stop the significant decrease in demand. There are some projections of IMF experts to expansionary fiscal policy should be conducted by all countries with low indebtedness and where in the earlier period disciplined policies was conducted. IMF experts estimate that the fiscal expansion should provide about 2% of global GDP to avoid a significant reduction in global demand.

The Federal Reserve at the last minute halts global "domino effect". U.S. central bank has decided to make a radical at the domestic financial market. Due to the fact that Federal Reserve authorities have the responsibility of state regulators, it had an obligation to try to stop a possible domino effect. The Central Bank of the United States and its move to persuade rival investment bank, "Jay Morgan" to take part of the business of "Bear Stearns's" which was in great debt on the U.S. mortgage market, and to try to save it bankruptcy was a great surprise for those who strongly believed in free market. Such intervene of the Central Bank of the United States in the arena of U.S. financial markets has not been recorded since the thirties of last century (Vujić, 2008).

8. PROTECTING THE FINANCIAL SYSTEM

To date, no one really knows how much money is imported into a failed scheme of risk mortgage loans in the U.S. Experts are mentioning trillion of U.S. dollars. Also, no one knows for certain how many commercial banks and speculative funds around the world invested in maintaining the collapsed U.S. financial system.

It is certain that after the crisis, the redraw of financial system and the monitoring and supervision in the world has to come. Harmonization of the regulations and national policies is necessary, and to provide common rules in the recapitalization of banks as national approaches. The role of the IMF must be redrawn. It takes redraw in order to ensure timely multilateral temporary liquidity.

In order to protect the financial system a policy of fiscal expansion should be maintained but as a consequence a growth of a country's debt will occur. If the US mortgage market stabilize after the crises, what is firmly believed, an increase in the value of property taken over by the state in times of crisis can exceed the value of net debt in times of crisis. Being in the position of a recapitalization need, banks gave a significant share of the property to the state, so should gradually withdraw from ownership and return the banking sector to private hands (Petković, 2009).

Figure 1: Real House Prices for United States and European countries: 1997 to present
("The Mortgage Meltdown and House Prices", *The B.E. Journal of Economic Analysis and Policy*, 2009)

Figure 1 shows real mortgage rates over the same time period. As real mortgage rates dropped more quickly in 2002, house prices demonstrated a commensurate rise.

Ted Forstman renowned billionaire who runs one of the world's biggest private equity firms said (July, New York Times), "We are in a credit crisis the likes of which I've never seen in my lifetime. The credit problem is considerably worse than people have said or know. I didn't even know subprime mortgages existed." (Kjelleren, 2008)

CONCLUSION

Mortgage market crisis had first attack on real estate market in the U.S. and then spread into the financial system and economy, and all of this did not occur by chance. The causes of the crisis can be found in irresponsible business policy of relevant state institutions which were supposed to control the financial markets and lack of professionalism in the work of rating agencies. Furthermore, weaknesses that existed for years in the field of financial control and regulation in the United States also made a great contribution. New situation created few very bad movements. Foreign capital started to melt; stock market indexes had a dramatic drop and there was also a lack of fresh capital.

The idea of liberalization of finance markets, giving sub-prime mortgage loans to those who had questionable credit power and who did not fulfil all credit requests with almost no regulation, caused disastrous consequences. Initial optimistic forecasts proved wrong and unjustified, and what is worst, it reflected to the whole world as the crises started to spread beyond US borders what is pretty much logical due to the fact that all parts of the world are connected and inseparable. The spreading of the crisis even hurt the economy of countries that had no direct involvement in creating this crisis.

Although the Governments of all countries persistently struggle to develop a perfect program to neutralize or mitigate the effects of the global economic crisis, it seems that the right solution has still not been found. All programs already adopted or future once are concentrated on harmonization and synchronization actions of the competent institutions, wanting to achieve harmony between monetary and fiscal policy. It is necessary to provide the required level of liquidity, economic growth and protect the most vulnerable sections of population from the impact of the crisis.

BOT PROJECT FINANCING MODEL OF PPP: THE EXAMPLE OF THE ZAGREB PUBLIC UTILITY WASTEWATER COMPANY

Dragan Milošević¹

¹College for Business Economics and Entrepreneurship, info@vspep.edu.rs

Abstract: *Through creating a public-private partnership (PPP), the supplying of goods and services traditionally provided by the public sector should be provided in the most economical way. The aim of this article is to examine ways of the BOT financing of infrastructure investment projects and to present the example of a project financial construction of the Zagreb PUC Wastewater. Research methods are content analysis and case studies. Users of this research may be more interested in the infrastructure projects that consider the application of the BOT model for financing infrastructure projects. The BOT model of PPP is a model in which the private sector finances partially (or completely) the construction and equipping of a facility, which through the use of the goods carries out the return on investment with a reasonable profit. In this model the role of the public sector is very significant, although it does not necessarily entail financial investment. It consists of providing an environment for the implementation of the project and investment, as well as monitoring and controlling services which have traditionally been the responsibility of the public sector. The private sector interest in such partnership is a commercial nature of the equity capital and services intended to make a profit. The structure of financing the BOT model consists of three sources of capital: First, the initial capital invested by the concessionaire of the project at the beginning of the establishment of a concession company, which is collected by issuing ordinary shares or payment of equity. Second, long-term debt capital, which may consist of a senior (superior) and junior (subordinate) debt, depending on the risk taken. A senior debt is covered by some sort of collateral, and is similar to ordinary bank loans with long maturities. Although it does not necessarily occur, a junior debt – as it does not fully secure – is often contracted through the sale of convertible securities with a possibility of converting into equity securities, in order to attract investors. Third, a reserve loan used as needed in case of breaking the project budget. The BOT model of PPP gives the best results in projects which are totally new investment, in cases where there is high certainty of collection services from the BOT project. Shortcomings of this model could be complex and expensive tendering procedures, the cost of private capital and a problem concerning the replacement of the concessionaire in cases of contract termination.*

Keywords: *Public Private Partnership (PPP), project financing, BOT model*

1. INTRODUCTION

In Republic of Serbia, there is a large gap between the needs and possibilities for financing infrastructure projects. This is way one of the real option is the use of a model public-private partnership. BOT model of financing infrastructure projects is one of the frequently applied model of public-private partnership in the world, with different effects application. BOT models of financing of such partnership is in the group of project financing, which is a relatively new way of financing intensively developed in recent years. The aim of this paper is to explore the basic elements of the BOT method of financing investment projects and that the example PUC Zagreb Waste Water show his method of financing in practice. Research methods are the methods: content analysis, case study.

Application of public-private partnership brings both significant advantages as well as disadvantages, having a major impact on infrastructure development, because those projects are of great value and importance to the national economy.

Data on problems in the implementation and effects that carry the largest BOT projects are mostly outside of experts. The main sources of information are the data obtained from international development organizations that support the implementation of this partnership. Lack of public information and technical serious research can dramatically affect the errors in the application of public-private partnership. Users of this research could be all interested party in the infrastructure projects that consider the application of BOT model of management and financing of public-private partnership on its infrastructure projects.

Under the Law on Public-Private Partnership and concessions (2011): "Public-Private Partnership (hereinafter referred to as PPP), is a long-term cooperation between the public and private partners with the

aim to provide financing, construction, reconstruction, operation or maintenance infrastructure and buildings of public importance and services of public interest Cooperation may be contractual or institutional. "

Partnership between public and private sector-PPP (Public Private Partnership - PPP) is created in order to obtain a project or service that are traditionally provided by the public sector. The partnership allows each sector doing what usually working best, in order that public services and infrastructure are provided in the most economical way (European Commission, 2003).

Partnership of public and private sector based on the idea that the private sector meets the needs of services and goods for the public sector, with similar (or nearly similar) competitive conditions, guiding on commercial markets. The role of the public sector remains dominant, but is more focused on the development of public services, market control and monitoring tasks. PPP is implemented by selecting the model of cooperation and private partners, which will under the conditions of competition in the markets bidders, compete with each other through transparent public bidding.

The way of cooperation between public and private sectors should change the traditional way of creating, acquiring and distributing public goods from the point of service quality and efficiency of the use of social resources, which are located within the public sector management.

This is about a systematic approach to transform ways of meeting the primary needs of society and the common use of national resources with a view to optimal ratio of the obtained use and consumption of resources. The aim is to take full advantage of the private sector can offer in terms of efficiency and economy of resource use, with the opportunity to participate or even fully finance such projects

The partnership is based on the careful building of relationships that includes a win-win strategy where both of the parties must meet their own economic interests. If it is not respected, for any reason, the realization of cooperation will not be successful. So there must be a partnership, which reflects in the existence of the efforts of both sides to find for long term economic interests, even in situations that could not be previously predicted. Maximizing the interests of only one side, almost always leads to a deadlock, and then to the termination of cooperation.

One of the basic economic needs that must be met, is the formation of the economic cost of services, covering all costs. This precondition, allows smooth cycle of reproduction of public goods and services.

By forming the economic cost of services, raises the question of existence of the population that they cannot pay for (The World Bank & Inter-American Development Bank, 2000), (The International Bank for Reconstruction and Development and The World Bank, 2005). This leads to lack of use of their services or search for ways to make this part of the population involved in a range of users. Since it is a basic existential needs of the people, it is necessary to think about the way of subsidizing the costs for this population, taking care that it is not used for the continuation of inefficient operations, which is characteristic for the previous period.

The intention of the developed world is to increase the coverage and quality of public services, as a visible indicators of increased well-being of society (The International Bank for Reconstruction and Development and The World Bank, 2005). If, in addition to intention to increase the quality of existing services, there are plans to invest more in infrastructure and development phase of their expansion, the need to finance the implementation of such projects by the public sector are becoming financially unsustainable even for developed countries. At a time when almost all countries (for various reasons) have problems with balancing the budget of the country, it is difficult allocate funds for the dynamic development of infrastructure, certainly not to the extent that we want to achieve the planned level of development.

Due to the centralized structure of government, the public utilities in countries in transition are almost exclusively performed on the basis of obtaining goods and services from state-owned enterprises. Through the development of the private sector, performs the transformation of public sector services from centralized towards market direction. This can be seen as a new emerging market for private sector in countries in transition

2. INTERESTS OF THE PUBLIC AND THE PRIVATE SECTOR FROM THE PPP PARTNERSHIP

Under the Law on public-private partnership and concessions (2011), "a project of public-private-partnership is a project that is developed, proposed, approved and implemented by some of the public-private partnerships model, and makes a series of interrelated activities, take place in a specific order, in order to achieve defined objectives within a certain period of time and financial resources, and is in accordance with this law, is approved as a project of public-private partnership, with or without elements of the concession.

What is characteristic of all models is a combination of transfers of financial and nonfinancial assets in the models. While some time ago was the dominant consideration of financing, now are increasingly analyzed and entered into non-financial elements of the character. An illustrative example of non-financial elements is the question of transfer of intellectual property on PPP projects. This transfer from private to public sector should provide greater effects on investment, which will be mostly reflected in future efficiency of investments exploitation, than the public sector has traditionally provided.

According to Guy-and-a Crauser (Director General DG Regional Policy), "The European Commission has identified four principally role of the private sector in PPP schemes:

1. To provide additional capital funding.
 2. To provide an alternative to existing management and implementation skills.
 3. To provide significant added value for consumers and the public.
 4. To provide better identification of needs and optimal use of resources. "(European Commission, 2003).
- Private sector interests are primarily related to the profit and reduction of risk in capital intensive projects.

3. BENEFITS AND COSTS OF APPLICATIONS BOT MODEL

BOT system is an abbreviation of English term build-operate-transfer - BOT), including all sub-types of this system, based on the construction or reconstruction and financing of the entire building (equipment or facilities), its use and transfer of the title to the concession grantor within the agreed timeframe.

BOT allows the private sector: construction investment, manage the work (operations) and on the basis of that generate revenues from services they charge. From the private sector is expected to bring modernization and improvements of the concept, structure and way of satisfying needs, while funding and cost-effective usage of financial resources.

The key relationships in the PPP project are determined by defining the roles of the two key groups (the grantor and the concessionaire), according to who bears responsibility for the following activities:

- Ownership of property (land, buildings, equipment, installations, etc.).
- Financing of investments.
- Method of forming tariffs
- Commercial risk.
- Provision of services through operational work and maintenance of the investment made objects, plants, etc..
- The time in which a partnership agreement is concluded.

Evaluation of the sustainability of the PPP model (Milosevic, 2009) is based on the analysis and projection of cash flows that affect the following key elements:

- Size of consumer surplus.
- Method of forming tariffs for consumers (tariff system) and certainty of collection
- Projected capacity.
- The level of exclusivity of service (there is no alternative means of satisfying the demand for services).
- The level of financial support that is derived from government and other grants.
- possibility of applying the project (land acquisition, satisfaction, environmental conditions, etc..).
- Prices of capital engaged.

BOT project can offer a lot of economic benefits (Milosevic, 2009) such as:

- Sources of financing investments in infrastructure. Special benefits can be when it comes to external sources of funding, which guarantees the inflow of foreign currency into the country.
- The government of the host country maintains strategic control over the development of infrastructure.
- Increasing the efficiency of investment and reduction of operational expenses, due to well-conceived and executed design of the system.

- Transfer of new technologies and skills, especially for the local labour force.
- Development of relations between the private and public sectors, and certain sectors of the local economy, which appear as sub contractors on the project
- Development of local capital markets, by increasing the volume and financial instruments which may occur in the domestic market

Also there are costs related to the implementation of BOT model (Milosevic, 2009):

- Costs of the tender procedure.
- Consulting services costs for the host government, without sufficient knowledge and experience in negotiating and implementing the model.
- Cost of capital commitment, due to the risk premium, the issuing of collateral and the like.
- Approved an increase of costs of public service, becoming the costs of end-users.
- The increase in material prices due to rising demand initiated by the investment company.

4. FINANCIAL STRUCTURE OF BOT MODEL

BOT projects are mainly financed by foreign sources of funding accessed by the concessionaire, according to their solvency and the situation on international financial markets. At the time of concluding the contract on financing of the project, the concession company usually does not have sufficient assets that could be pledged. Everything is based on an assessment of yield capability of the project and the conditions of placement sources of capital that is partially or not at all covered by assets, which are only created through the investment cycle of the project. Also, PPP projects are not commercial, in the practical mining, and cannot easily find new customers for the concession company, if the existing funders plan to withdraw from the project.

This certainly implies a significant risk, which bears any capital which is involved in financing the project. Attitude to risk is essential for the initiation of investment and thus for development. United States, for example, various tax measures are taken in order to stimulate investments in capital investment projects.

For the determination of financial structure there are the three key elements that must be considered by financiers:

- Financial sustainability of the project. The level of (security) of profits generated by the project.
- The reallocation of profits between the stakeholders.
- Assessment and Allocation of risk among participants in the financing.

Structure of sources of capital used to finance BOT project (Milosevic, 2009), depending on the amount of risk taken, consists of three sources:

- **Equity.**
- **Debt capital (Long-term borrowed capital).**
- **Stand by capital (Capital reserve).**

Equity is usually provided by a sponsor or group of owners of the project, bearing all the risk on the project. It is engaged at the beginning of the project during the establishment of the concession company, which carries the concession. And upon expiration of the concession contract is drawn. Besides the sponsors who are dominant in this form of financing, the opportunity to invest in this type of capital is being given to other significant participants in the project (the main contractor, provider, supplier, etc.), in order to gain security that they will not lose business interest to be engaged in the project. Initial capital is being paid to the founders, with the realized gain or loss only after the payment of all obligations of the concession company at the end of the concession. If the project is well established residual value of the project is significantly larger than the funds invested in the capital. If the project realizes losses, then they have to be offset from the capital. So this kind of capital carries the greatest risk and so the losses or gains from investments in this type of capital, are the largest on the project. The interest of the sponsors of the project is that this part of the funding of the project is as little as possible represented in the funding structure. Initial capital may be well below the 20 to 30% depending largely on how creditors estimate that the project is defined, what the guarantees are given and what is quality management project.

Debt capital (Long-term borrowed capital) that may occur as:

- **Parent Debt (senior debt).** It represents medium-invested debt capital that is covered by some provision of the instrument collection. This type of capital requirements raises the largest net inflows from

future exploitation of the project. If the future net inflows of the project are not sufficient or have a significant risk, according to the Lender (creditor) estimation, then additional guarantees from the founders and sponsors of the project are required. Instalment loan payments must be made regardless of whether the project produces results or not. The deadline in which this type of debt is placed is (mostly) the medium, with (usually) agreed fixed interest rate. This is the kind of debt that is returned after the first operation. From the perspective of the founders of the concession company, this is the cheapest kind of capital, in terms of price, if it is contracted with a fixed interest rate and predefined instalments. The founders will tend to increase it to level that creditors accept. From the standpoint of lenders, rational relation with respect to the risk and ways to ensure payment will be required.

– *Subordinated debt (junior debt or Mezzanine capital).* Long-term invested capital, which has a significant collection risk, partly because there is no security or it, is partially secured from payment risk. Because it is located between debt and investment (basic) capital, it is called Mezzanine Capital. It is paid only if there are funds for payment. Here we paid the debt for a longer period than is superior long. Because of the significant risk taken, the interest is higher than the superior debt. The motive of the project sponsors to acquire equity in this way is the distribution of risk to a number of interested parties (stakeholders) on the project. This means that if the project generates sufficient amount of cash, a portion of profits will go to the payment of subordinated debt financiers. Failure to realize expected profits will cause that interest will not be paid, or in worse situations, even the main part of the subordinated debt. To attract investors, however, this type of capital is raised with an additional possibility for investors to convert subordinated to initial capital ("equity kicker"), whether the conversion is more favourable to investors, or because there is no possibility for payment, and are forced to awaiting completion of the project and the calculation of net value of the project. In some cases vendors are included in the project financing, through mezzanine finance, converting their claims into Mezzanine finances. This type of financing provides greater elasticity of the project company. The essence of the idea is sharing the risks of the project and giving up part of the profits, in order to cover risks through the price of the capital.

Capital Reserve (stand by capital). The role of this type of funding is to provide funds to start the project for possible funding overruns (perforation) of the budget or cash flow mismatches. At the time of contracting it is not known the moment or whether it will be in general use. It is reported separately in the balance of the project (depending on whether or not used). It is engaged as debt capital and is usually part of a contractual relationship with a superior debt. If is not provided at the time of contracting senior debt funding, it will be difficult later to find the source of funding when the project budget has already broken. In this case, the project sponsor must either finance the budget penetration or seek financing source under considerably worse conditions than they were at the beginning of the project.

In practice, financial structure has not necessarily have subordinated debt in their financing. Due to the significant amount of resources required and risk allocation agreements on joint funding of more investors are common. In making such a joint agreement among investors, consortium of financiers of the project is formed.

International development organizations such as the World Bank, EBRD, etc. can occur as co-investors, or initiate the formation of a consortium of large investment projects. Especially in projects which have significant effects on the development of the country and generate an adequate profit, which may cover the cost of financing.

The role of international development organizations is double. Besides participating in the financing of the project, they reduce the risk of lending through its rigorous control and thus motivate other investors to join the consortium and the project co-financing. Their role is not to appear as competitors to private capital, but rather create conditions, stimulating the private sector to be engaged in investment projects

5. FINANCIAL INSTRUMENTS USED IN BOT PROJECT

The most commonly way to obtain the initial *equity capital* is emission of ordinary shares or the equity provided by sponsors.

For superior debt, are used bonds or contract of superior credit with some kind of collateral, such as a mortgage or bank guarantee provided by the founders of the concession company.

For *subordinated debt*, it is used the equity that has no security. This is source of capital that carries a significant part of the risk, thus the profit carries risk as well. The instruments are:

- securities convertible into ordinary shares (common shares),
- preferences shares,
- bonds
- subordinated loans
- high-risk bonds (junk bonds)
- slightly less options and warrants (options, warrants).

Financial policy must take into account the circumstances in which the project takes place, the lack of property that is truly a commercially marketable thus reducing the possibility of market sales and the provision of investment.

Assessing the financial sustainability of the project is based on an assessment of the net discounted cash flows and risks of their realization. For this reason it is necessary in the financial policy to consider the following questions:

- Minimization of own funds in the form of capital.
- Maximize the long-term funding.
- Arranging fixed interest rate for the capital employed.
- Risk assessment and means of refinancing.
- Assessment of ways of motivating means of refinancing

In the BOT project financing not only additional guarantees (from the host government or sponsors) are required, but the solvency of the project sponsor (the founder of the concession company) is an essential element of the whole structure. Project sponsor should by its own creditworthiness and by transfer of the risk offer limited possibility of recourse, to the level of investment (its) assets. The very capital value of constructed facilities is secondary, because it actually has an extremely limited ability to be resold to third parties. For its part, limited recourse in the form of investment project sponsor provides some assurance and confidence to lenders that the project sponsor seriously approached the analysis of the project.

Government may finance the project from their independent sources. In cases where there is a shortage of financial resources to requirements, many projects have to wait for the time for implementation. In doing so, it can make a significant opportunity cost of not using additional sources of funding. BOT project does not require an implicit obligation of the host government to participate in co-financing the project. This may be important in certain cases when you need to improve the country's credit rating and sustain political stability in the country. Although it is not usual for the host country government to issue guarantees for equity, it may occur as a guarantor for certain aspects of risk. On the other hand, governments may seek performance counter guaranty. Return on equity, which lenders are expecting, is higher than the host governments are usually able to pay for funding. On the other hand, transfer of technology, the concept of cost-effective, efficient operations can add the benefits of private sector participation in financing, which in a way; create balance with the increased cost of capital commitment. As for creditors, they carry a significant risk to their investment, due to the length of implementation.

6. SOURCES OF FUNDING ON BOT PROJECT PUBLIC UTILITY WASTEWATER ZAGREB

Project wastewater treatment plant in Zagreb city is the first project for water utilities and waste water treatment plants in Croatia (Zagreb wastewater PUC, 2009) and one of the few in Balkan. The project allows the city of Zagreb wastewater treatment according to EU standards. The project envisages the construction of approximately 10 miles of main sewer, with approximately 5.5 km modification of the main drainage channel and construction of the pipeline bridge across the Sava River.

The value of the project is 288 million EUR which is invested in municipal water supply and sewerage services, for the population of the region Zagreb. The drive has a capacity of approximately 1.5 million users, it is estimated that this is projected needs of the city for the next 28 years.

The borrower (the first instance debtor) is a specialized Waste Water Public Utility Company Zagreb (PUC). PUC occur on the project in the role of main contractor and project manager during the construction phase. According to the contract, PUC took over the commercial (operational) and administrative tasks during the operational phase and the maintenance of buildings and equipment.

After completion of the entire tendering process, consortium of RWE, Aqua and SHW were selected as the best providers in 1999. The concession contract was signed with the consortium as the concessionaire in December of the year 2000. As Grantor appeared the city of Zagreb. Here we use the net retained profit realized on the project, as one of the key sources of funding.

Table 1: Sources of funding in the use of BOT Project Water Zagreb (Ruhe, 2007).

Use	million EUR	Sources	million EUR
Capital and other costs	209	Equity	38
Working capital	19	Internally generated cash	99
Financial costs	54	KfW main tranche	101
Taxes	6	EBRD main tranche	50
Total use of cash	288	Total sources of cash	288

Table 2: Structure of sources of funding in a PUC-BOT project (Ruhe, 2007).

Description	Conditions
The value of superior EBRD loan	55,2 million €
Grace period	Six year
Interest	The average six-month EURIBOR plus a margin.
Guarantees	Security: Includes security over ZOV's assets, bank accounts, insurance policies, receivables, pledge of the Sponsors' shares in the Company, Direct Agreement with City, Construction guarantee, Sponsor funds guarantee.
Co-financing: Kreditanstalt für Wiederaufbau (KfW)	110 million €

Contracted amounts of credit EBRD (55.2 million €, and KfW € 110 million) were higher than was predicted in the financial structure of the project (the main tranche of the EBRD and KfW E 50 and € 101 million) for the amount of capital reserve which was covering the potential amount of breaking the project budget. Reserve capital is financed under the terms of senior debt and at the moment when contracted the entire financial structure of the project. Subsequent contracting conditions of breaking the budget of the project, when project spend significant resources, is incomparably more difficult and demanding task, which is certainly reflected on the cost of capital engaged.

7. CONCLUSION

BOT as an investment project must be profitable in order to be acceptable to both parties. BOT model of PPP projects that private capital is fully or partially funded by, does not debit the public expenditure. The role of government is crucial in ensuring the necessary conditions for the project.

The costs of public procurement and the cost of private capital engaged, represent a significant position in the cost structure. Greater efficiency in use of private capital needs to compensate these costs. Its ability to finance infrastructure projects can have a multiplying effect on national development, provided that the state ensures conditions for competitive bidding.

This model shows the best results when it is completely new (green field) investment, and bad results in cases of applications in systems with low efficiency of collection of receivables from utilities, because the public sector has a better system of enforced collection than it can provide private sector.

FORMS OF FINANCING MERGERS AND ACQUISITIONS

Abstract: *This paper describes the problems of choosing proper form to finance mergers and acquisitions. Companies that consider integrations must perform serious analysis of the potential partner, but also examine their own performance, in order to find the best mode of financing. They should consider results achieved in the past, current value of the company or its shares, but they should also estimate potential future effects of integration and its synergy. A decision will be determined by these factors, and here are presented the main characteristics of these forms and their risks. The chosen form of financing can greatly influence the post-integration effects, both in the buyer company and in the target company and therefore this problem should be considered seriously before signing a contract.*

Keywords: *mergers, acquisitions, financing, cash, shares, bonds*

1. INTRODUCTION

An increasing number of mergers and acquisitions imply that integrations have become very popular form of restructuring. Integrations should enable participants to appear in new markets and thus lead to increased production and better competitive position. Merger represents a combination of two companies where the integrated company ceases to exist. In this case, the company that carried out the integration takes over the assets and liabilities of the acquired company. On the other hand, the acquisition means taking control of another company, its subsidiary or its specific assets. (Gaughan, 2004) It can be achieved by purchasing shares or assets of the target company, and the buyer becomes major shareholder, while integrated company that is merged may cease to exist. Important issue includes determining either the deal is a merger or an acquisition. If it is an acquisition, buyer must provide an acquisition premium because of control loss of target company's shareholders. On the other hand, if the deal is structured as a merger, these companies remain equal, so no premium is required since neither one loses control, or because both sides equally do. (Moeller & Brady, 2007) It should be pointed out that mergers or acquisition are not easy to accept as a solution, because they usually require a large sum of money that should be paid in a short period. The problem may arise in obtaining the money, and, unlike the internal development, in this case there is no possibility of sharing risk into several stages.

The main reasons for carrying out all forms of integration are diverse. The company can expand its area of operations by combining with a company that is engaged in another activity, and in the same way it can ensure its appearance on some new markets, where it had not operated earlier. It is often faster and more efficient way of growth but carries greater risk and uncertainty. However, many different forms of payment can be used in order to complete the acquisition process, and each of them brings a different view on integration process. (Krivokapić, Dulanović, & Jevtić, 2008)

2. FINANCING MODALITIES

The most commonly used forms of payment include exchange of shares or payment through money. The payment is often completed through the combination of these two forms, which means partial payment in shares, and the rest in cash. Also, the transaction can be paid by the bonds of the overtaking company, which brings benefits to the shareholders of the target company. In practice, large acquisitions and mergers are usually completed through the share exchange.

Financing through stock exchange

As noted, large integrations are usually financed by an exchange of shares between companies involved in the agreement. In that case, the buyer (The Company A) makes an additional issue of shares in the capital market, and transmits them to shareholders of the target (The Company B). (Ćirović, 2004) The target company has two alternatives – it can keep the acquired shares, and thus become shareholder of company

A, but it may also sell those shares on the financial market, and thus obtain the money which can be further invested.

A question of compensation can be very delicate. This analysis is based on the current stock price of company shares. It is logical that The Company A should pay for the shares of The Company B more than they really are worth on the market.

If we assume that the price of The Company A's share is 20 €, and The Company B's shares are worth 6 €, then, respecting the relations of market prices, shareholders of The Company B should receive 6 shares of A for its 20 shares. However, as already noted, the agreement is achieved as The Company B receives a fee for the transfer of its shares, so the relation between these shares can be defined as 2:1, for example. It means that the shareholders of The Company B should receive 10 shares of The Company A in exchange of its 20 shares. Thus the agreed course brings benefits to The Company B.

But defining this course is not a simple act. In fact, if it is estimated that acquisitions will not make (or will make very little) added value, then the relation will be the same as the relation of the current market prices. (Ćirović, 2004) However, companies usually enter such transaction in order to achieve significant added value, so the calculation is mainly based on that assumption. Redistribution of this added value depends on several factors, but it is mostly affected by the perception of future synergies achieved through the integration process, and negotiating power of those companies that should sign the agreement. It is not rare situation that The Company A insists on the implementation of such integration, even though it's aware that it overpays company B's value. This can lead to the situation that even more than the additional value is transferred to the shareholders of The Company B. Of course, this can cause large consequences for The Company A. However, if the share capital of The Company A is much larger than the share capital of The Company B, then the transaction will have no impact on the market price of its shares. On the other hand, a series of similar acquisitions will lead to the same effect as if one large is made. This can lead to the rate decrease of The Company A.

Financing through cash

The Company A may use cash in order to finance the acquisition. This money can be obtained in several ways: (Ćirović, 2004)

- Most often it comes from retained profits from previous periods. These funds can be used to finance ventures in the company, or to carry out acquisitions.
- Further, the inflows of money can be generated through the sale of the company's parts. The Company A provides money that can use to pay its obligations to the shareholders of The Company B. This is useful because The Company A thus divests segments it doesn't need any more, or those that have inadequate rate of return on capital.
- Finally, a company can come up with the cash by selling its bonds in the financial market, or by borrowing the money from banks. In this case the structure of liabilities should be concerned, because it increases the debt in comparison to equity.

Payment by bonds

Payment by bonds is quite rarely used, especially in comparison to the previous described types of financing. In this case the shareholders of The Company B do not receive any money or shares, but bonds of The Company A, in exchange for their shares. This is not the same as if The Company A broadcasts its bonds and sells them on the securities market, and then uses that money to pay for the acquisition of B. The Company B will accept payments through bonds only if The Company A has a high rating, and if the interest rate is appropriate.

It happens that The Company A issues convertible bonds and then passes them to the shareholders of The Company B. These bonds can be converted into ordinary shares at a predetermined conversion rate, but only if this option is used by a certain deadline. This conversion will occur if the market price of The Company A's shares is greater than the established rate. Otherwise, the conversion will not occur, but shareholders will retain the bonds, and earn from interest rates.

Earn-out model

This model is usually applied on medium-sized acquisitions, those that include companies which are not registered on the stock exchange. The evaluation of such companies is difficult, because they do not have formed stock price. According to this method, the financing is done with deferred payment, where the value of acquisitions depends on the performance of the acquired company. Income generation has specific and important role in this model. (Galpin & Herndon, 2007)

Let's assume that The Company A wants to make earn-out acquisition of The Company B. At the moment of reaching an agreement, this company will pay, for example, € 10 million. Also, it is estimated that during the next 4 years The Company B will gain profits before tax, respectively, € 2.5 million, € 3 million, € 3 million and € 3.5 million. The participating companies shall conclude an agreement that The Company A will pay to The Company B at the end of the fourth year, for example, triple the amount of profit surplus above € 2.5 million.

Therefore, the maximum earn-out payment for the period would be:

$$3 * (0 + 500,000 + 500,000 + 1,000,000) € = € 6,000,000$$

this means that the total payment was €16,000,000.

However, if The Company B does not achieve the projected profits, the residual part of the acquisition cost will be revised downward. This model is quite used in many developed countries, and it is reported that about 20% of medium-sized acquisitions in Germany include some earn-out elements.

3. THE CHOICE OF FINANCING MODE

The choice of financing method is determined primarily by economical motives and effects. In fact, if you look at the two major forms of payment, then you might conclude that the paying with shares brings the risk of value change at the moment of acquisition, in comparison to the moment of concluding the agreement, while the payment through money does not include that kind of risk. This interval is typically a few months, so the change of stock price is possible or even expected. If the payment in cash is agreed, there is no such a doubt. However, given the fact that nowadays the acquisitions are mainly carried out through exchange of shares, the problem becomes more and more complex.

Of course, there are different interpretations of the reasons why the company decides to choose one form of financing, instead of another one. Thus, if The Company A offers to pay in cash, then it bears all the risk, in case its shares drop on the market. This is interpreted as a sign that the company has a very great confidence on its business and acquisition, and expects the growth of shares. On the other hand, if the offer involves a payment in shares, the market accepts it as an indication that the leech does not have enough confidence in the sustainability of its shares price, and therefore wants to share the risk.

However, payments through shares may imply two completely different alternatives. Thus, the buyer can offer fixed amount of stocks for stocks of the target company, and in this case the target company takes the risk of share prices fall. The second option implies that the bidder offers a fixed value of stocks, so in case of prices fall, the target company cannot be harmed. This case looks like a cash payment, but differences occur after the arrangement is completed.

The risk of price change is related to the fact that The Company A almost always pays for The Company B more than what it is really worth. The premium is usually between 30 and 50%, and often higher. Its justification is in expectation that the acquisition will create a synergy that will affect the profitability of the participating companies. However, it could be doubtful whether the premium will be sufficiently covered by these synergetic effects. In fact, in all cases of overtaking The Company A must offer some benefit through a good price, so that the shareholders of The Company B are motivated to take part in the acquisition. This can result in attracting some other interested competitors, so The Company A might be forced to improve the offer. If it is really keen to make acquisitions, they it will pay even a price that is higher than the objective one, making a loss and hoping that the effects of integration will quickly make amends.

Besides, the market price of the company generally does not reflect only its current but also future business performance. (Weston, Siu, & Johnson, 2001) Since the premium includes improved operations, it is expected that the effects reflect also the current share price.

4. MAKING AND EVALUATING OFFERS

The company that wants to acquire the other must consider several criteria in order to choose the form of financing. First of all, it observes the price of own stocks and estimates whether they are undervalued, realistic or overvalued. (Ćirović, 2004) If they are undervalued, then it would be better to implement the acquisition through cash, which can be obtained in various ways (by selling parts, borrowing, selling bonds, etc.). In any case, it would not be a good decision to continue with the issue of shares, because they would be offered at a price that is lower than their actual value. Otherwise, if the shares are overvalued, then it's advised to perform a new issue, and conclude the transaction on the basis of newly issued shares.

The other aspect that should be considered is the evaluation of the expected synergies effects. If the company finds that the risk is significant, the integration should be completed through the acquisition of shares, as this reduces the risk. The market assesses this as a signal that the company is not sure of the effects, or that its shares are overrated. If the buyer, however, finds that the projected synergies will be achieved, then the transaction should be financed through the money.

Finally, the buyer should assess the market risk of its shares, for the period until the completion of the transaction. If it is low, then the acquisition should be completed by paying in cash or by exchange of shares with a fixed value. Otherwise, companies will seek to finance the acquisition with a fixed amount of shares, thereby shifting the risk to the target company. However, the question is whether the target company will agree on it, because it is aware that this kind of deal involves the transfer of risk to its side. Usually, it will agree only if the bidder is a company with a high credit rating and reputation, especially if the premium is high enough. Also, the target company can accept payment through a fixed amount of shares, but can also require establishing a lower limit price, which should prevent a large decline. In such situations the upper limit is often determined, because there is a possible increase of price, so the buyer wants to protect itself from potential losses that could be made in this case.

5. CONCLUSION

Depending on various factors, companies prefer a particular form of financing integration. Each of the described models provides some benefits, but also different levels of risk, and therefore every company involved in the agreement must provide very detailed analysis of the process. Many data from different periods of time are considered, in order to find some trend of these companies' value, and to predict effects of integration so that the appropriate funding can be arranged. (Dulanović & Jaško, 2007) Assessments are carried out both by the buyer and target companies, and these results could define the conditions of the contract. The target company should assess whether the offer is acceptable to potential acquires. Assessment begins with a consideration of the premium that the bidder provides, as well as through the evaluation of expected return on investment. Company management should assess whether such a return can be achieved if the integration is being refused.

Besides, it is necessary to consider the effects of partnerships in post-acquired company, given the fact that the target company's shareholders will become shareholders of the bidder in fact, if the payment is made through the stock. It is common interest to really achieve the projected synergies, because everyone loses otherwise. Therefore, the target company must also carry out the assessment of potential synergies, because it is normal that its shareholders share the effects of future business, both positive and negative.

MINORITY SHAREHOLDERS RIGHTS IN THE REPUBLIC OF SERBIA

Vladimir Djakovic¹, Goran Andjelic²

¹Faculty of Technical Sciences, University of Novi Sad, v_djakovic@uns.ac.rs

²Faculty of Business in Services, Educons University, andjelic1975@gmail.com

Abstract: *Minority shareholders have a significant role in the growth and development of the market, and represent the basis of marketability and market relations, especially in the countries in transition. The place, role and importance of minority shareholders are particularly evident if corporate governance is taken into consideration, and consequently, the efficiency of markets. A clear definition of the position and the rights of minority shareholders in the institutional regulation is a particular challenge in the process of analysing the mechanisms for protecting the shareholders. The subject matter of the research presented in this paper is the analysis of the position and degree of protection of minority shareholders in the Republic of Serbia. The research methodology involves the use of methods of analysis and synthesis with a special emphasis on comparative analysis, and methods of induction and deduction. The aim of the research is to gain specific knowledge about the position and possibilities of the protection of minority shareholders' rights in the Republic of Serbia with a special focus on corporate governance and institutional regulations. The research is important for both academic and professional audience, and even more for the policy makers in the Republic of Serbia in the field of minority shareholders protection. The results indicate that it is important to have an adequate regulatory protection of minority shareholders, and also point towards the necessity of employing specific measures and instruments in order to improve the position of the same.*

Keywords: *shareholders rights, minority shareholders protection, shareholders disputes, corporate governance, transitional countries*

1. INTRODUCTION

The issue of minority shareholder protection is an ever present question, both for the developed and for the transitional economies. A legitimate dilemma arises; namely, how to define and who to consider a minority shareholder? Is a minority shareholder any shareholder of a company who owns a package of shares by which majority control and decision making is not acquired, or the term refers to a group of shareholders who, when joining their shares, do not have the majority to manage a company? Therefore, it is obvious that, when defining the concept of minority shareholders, it is possible to talk about the concept in a broad and a narrow sense.

For developed economies it is typical that minority shareholders are better informed, as well as better organized; and consequently, the impact of minority shareholders on the company's business processes is felt more significantly. Transition economies, on the other hand, are characterised by a relatively low level of market awareness of the minority shareholders and their weak self organization, and consequently it is possible to manipulate with the minority shareholders rights. In that sense, it is always an issue of who should be concerned with the minority shareholders rights: the state in a systemic way, by acts and regulations; or is it necessary to enable a greater level of awareness and education of minority shareholders themselves, with the expectation that the consequences of their actions be a more efficient organization?

This issue is particularly important for the transitional economies and markets; these being institutionally incomplete and sub-capitalized markets in which ownership transformation processes have not yet been fully completed, and where there is a significant degree of market inefficiency. All this often results in a subordinate, inferior position of minority shareholders in the companies, which is mostly manifested through an insufficient level of awareness about their company's operations, insufficient involvement in the management of companies and in the decision making related to the number of shares held, and the like.

The subject matter of the research presented in this paper is to define, analyse and research the position and rights of minority shareholders on the market, with special emphasis on the Republic of Serbia, with an aim to reach concrete conclusions about the state of affairs in the studied area, and to propose a series of concrete measures and instruments in order to overcome these operational challenges.

If the current state of affairs is analysed in the transition markets, it can be seen that there is a considerable volume of information and news about the minority shareholders rights; also, the desire to enhance these

rights is continuously proclaimed. However, the facts and the real state of affairs point to a different situation. Namely, as changes on the transition markets become more intense, more manoeuvring space opens for endangering the status and rights of minority shareholders. This paper intends to draw attention of the professional and a much broader audience on the importance of minority shareholders protection in transition economies, because it is in this segment that the level of democratization of a society can be indirectly observed.

In this sense, one of the currently most endeavouring market challenges is the issue of minority shareholders protection, more precisely the issue of clearly defining the shareholders' rights and obligations in the system of market corporate governance. The Republic of Serbia, as a typical transition economy, does not significantly differ from other transition markets. That is the main reason why the following research emphasizes the status and rights of minority shareholders in the Republic of Serbia.

The paper is structured as follows. The introduction defines the basic elements of the study and reviews the studied problem. The second part focuses on theoretical assumptions and provides a review of previous relevant research in the area, as well as provides a review of the institutional regulatory arrangement position of minority shareholders, with a special focus on the Republic of Serbia. In the third part, the paper analyses the current situation, presents the concrete measures and instruments aimed at improving and promoting the position and rights of minority shareholders in the Republic of Serbia. In the summary, concrete conclusions and directions for further research are given.

2. THEORETICAL REVIEW

Defining, planning and a clear commitment to minority shareholder position in the market system of corporate governance are vital for the successful functioning of any economy. One cannot imagine an efficient market and an efficient economy, without a clearly arranged, well-defined position of minority shareholders. The essence of corporate governance, i.e. one of its main pillars, is exactly a clearly defined position of minority shareholders on the market. That is why in all market economies, the status, rights and responsibilities of minority shareholders are regulated systematically, with a relevant set of laws and regulations. A contemporary view of corporate governance cannot be implemented without considering the important phenomena and relationships that are suggested by the practice of developed countries. These are the rule of law, institutional development, and definition of corporative relationships by contracts, protection of property rights, managers' discretion, and the like (Vignjevic-Dordevic, 2010).

In this sense, one can notice certain differences in the approach of defining the position of minority shareholders on the markets of developed countries and the markets of countries in transition.

The term minority shareholders means the minority in equity and voting power; minority also implies that some shareholders – for various reasons, – did not vote for a particular decision accepted by the majority of the board, which triggers some specific rights provided by the law. Minority in capital, in the case of dispersed shareholders (as is often the case in the Republic of Serbia), is often majority in number (Paunovic, 2005). The status of minority shareholder is acquired by shareholders who own at least 10% of any shareholding company which was privatized in the last decade. In companies, where shareholders are not joined voluntarily, especially during the privatization process, an individual shareholder feels unprotected from the administration, the majority shareholders and institutions. To protect themselves, shareholders often join, hire consultants or rush to sell their shares on the first trading day on the stock exchange (Grubin, 2006).

In developed countries, the position of minority shareholders is clearly systematically arranged with a set of system laws, legal acts and regulations. The institutional framework governing the position of minority shareholders is all-inclusive and rather complex due to the fact that the issues of minority shareholders protection have an impact on all aspects of business activity. The legislation – regulating the position of minority shareholders – in developed economies has a long history, a natural evolution and a set legal way. This primarily includes a set of laws regulating the financial markets, financial instruments, the participants and technologies; it also includes the laws governing the economic and legal status of companies, corporate decision-making and responsibilities, as well as a set of legal acts governing the rights, obligations and responsibilities of both the minority and the majority shareholders.

The analysis and research of the issue of minority shareholders protection in transition economies is particularly interesting. These economies are characterized by highly dynamic, propulsive business

conditions, by less efficient (often in particular aspects even inefficient), and an emerging market, lack of market transparency, lack of corporate responsibility, unharmonised regulations and the like. All these facts have resulted in an often unequal, inferior position of minority shareholders on these markets. In this sense, many authors deal with issues of minority shareholders protection on these markets, attempting to suggest concrete measures in the form of different solutions in order to improve the position of minority shareholders on these markets.

Bearing in mind the investment processes under modern market conditions, it is necessary to consider how the degree of shareholder protection affects these processes. At the macro level, shareholder returns are higher in countries that, comparatively speaking, have less protection of minority shareholders, i.e. their rights and interests. At the micro level, companies with dispersed ownership (on average) have higher rates of return in accordance with organizational changes and by creating additional value in these companies (Christian, Betzer & Weir, 2007).

The role of shareholder activism is especially important when shareholders decide to retain ownership of the shares, and when they initiate changes within the company (without any changes in control). These investors can initiate reforms in the company by negotiating with the senior management (or board of directors) or by making proposals at the annual shareholders' meetings. Also, it can be concluded that the "shareholder democracy" is in correlation with the activities of minority shareholders, i.e. it represents the framework for the design and further development of regulations in the function of minority shareholders protection (Mallin & Melis, 2010).

The key obstacle to further growth and development of many emerging markets is the lack of regulatory protection of minority shareholders, especially in the case of company takeovers. Studies point to a lack of regulation in the given area, i.e. to a correlation between the lack of regulation and the high concentration of ownership, market illiquidity and the low level of the development of the capital market in transition economies (Parisi, Mathur & Nail, 2009). For the development of financial markets it is necessary to raise the level of corporate governance and minority shareholders protection (Pavlovic & Muminovic, 2010).

By providing protection to minority shareholders, the interest in founding capital societies increases, and so does the level of investments, i.e. the undisturbed acquisition of shares. Investors are attracted by providing adequate protection for minority shareholders, the abuse of majority rights is prevented and the principle of shareholder equality is established which is proclaimed and accepted in all legal systems (Knezevic, 2008).

The above-mentioned points to the actuality of the investigated area apply particularly in the case of transition economies and with a special emphasis on the Republic of Serbia.

3. MINORITY SHAREHOLDERS RIGHTS IN THE REPUBLIC OF SERBIA

The issue of minority shareholders protection on the territory of the Republic of Serbia and the enforcement of their rights is particularly interesting, considering the fact that the Republic of Serbia is in the so-called 'second phase' of transition, when the completion of the property-ownership transformation is expected, accompanied by the completion of the institutional frameworks; and thus the transformation of the Serbian market into an efficient market is expected. It seems that many challenges await the Republic of Serbia on this path, and this work is an actual attempt to provide quality information and propose concrete measures to accelerate the successful completion of transition reforms for market policy makers in the Republic of Serbia; and the effects will be largely felt in the field of improving the position and the rights of minority shareholders in the Republic of Serbia.

A characteristic of all transition economies is the relativization of the concept of the market and marketability in general, a presence of an insufficient level of ethics and morality on them; furthermore, a pronounced "thirst" for profit – no matter from which sources and regardless the costs, – an often incompatible and inharmonious regulations, low levels of market efficiency, etc. The results of all these circumstances are felt in significant market turbulences that contribute to an undefined position of minority shareholders on these markets.

A particular problem in the field of minority shareholders rights protection is the lack of knowledge about the area, the manipulation with market information and the ever-present desire of major capital holders for controlling minority shareholders. This situation has been a constant and significant source of conflicts on the

relation between major capital - minority shareholders - the state; and meanwhile little has been done to create real prerequisites for overcoming these conflicts.

The regulations in the Republic of Serbia which either directly or indirectly affects the minority shareholders rights are:

- Company Law,
- Law on the Capital Market,
- Law on Takeover of Joint-Stock Companies,
- Set of laws regulating privatization and the distribution of `free shares` to the citizens.

Analysing and researching the norms and standards contained in these regulations, it can be realized that they are often contradictory, insufficiently clear and reasoned, all of which having an effect of creating a large enough market space for possible abuses in the protection of the minority shareholders rights.

According to the norms governing the takeovers of shareholding companies and forced sales – the buying of shares in fact are not directed in the same direction. In the Law on Takeover of Joint-Stock Companies the emphasis is placed in particular on protecting the minority shareholders rights during the takeover; while according to the new Company Law, the scale of acquiring the possibility of forced buying/selling of shares has been reduced from 95% to the newly adopted 90% . This solution is quite uncommon and creates space for doubts, because there is a possibility that should an individual shareholder acquire 90% plus one share of a company, may buy the remaining approximately 10% of the shares of that company without further objections. This sends a very clear signal to the market about the glorification of the major capital in relation to minority shareholders, i.e. the small capital.

The question is still open how the activities considering the distribution of `free shares` to the citizens of the Republic of Serbia will be realized, and in what manner the citizens will be able to practice the rights given to them on these grounds.

All these circumstances directly contribute to an unstable corporate climate in the Republic of Serbia, and also strengthen the conflict between minor - major shareholders, with no clear commitment of the state to the how-to and the future directions considering the realization and protection of the minority shareholders rights in the Republic of Serbia.

Considering all the above mentioned, it is reasonable to propose measures, mechanisms and instruments whose implementation could improve the position of minority shareholders in the Serbian market and increase their rights. These mechanisms should be systematically targeted and coordinated towards several key directions.

The first group of measures should be related to the creation, modification and compliance of laws and regulations, particularly in the areas regulating the functioning of companies, the financial system and the market in general. By research it has also been found that the current institutional framework to some extent is adequate (but not significantly), and that in most cases, there is a need to further work on its change and modification. The greatest absurdity stems from the knowledge that often a good idea cannot be realized in practice because of inconsistencies between the regulations themselves. This is a job that can be performed relatively fast, and by the implementation of these modified measures, healthy conditions for the protection of the rights of all shareholders (especially the minority shareholders`) could be established.

The second group of measures should be aimed at strengthening the monitoring of market participants. In this regard the supervisory organs and institutions should be given a great importance, in order to prevent any possible abuse immediately.

The third group of measures should relate to a wide range of educational activities of the widest population, in order to let each individual become acquainted with all the existing opportunities one has as a shareholder. This is very important, especially due to the fact that all adult citizens of the Republic of Serbia are entitled to obtain the so-called `free shares` from the state, and it is important to let them know what is in their possession in fact.

The fourth group of measures should be aimed at harmonizing the system of market and media information, in order to avoid failures that might occur in the sphere of public information on important elements of

corporate governance, on the state of affairs in market opportunities, and therefore on the position of minority shareholders.

All of these measures must be implemented together, mutually be adjusted and synchronized, because that is the only way to accomplish the desired goal, which is achieving a considerable level of protection of minority shareholders' rights in the Republic of Serbia.

4. CONCLUSION

Bearing in mind all the above elaborated, a logical question arises of what to further do, in which directions to develop corporate governance and corporate responsibility in the Republic of Serbia, how to further guide the development of market relations and market trends through the prism of minority shareholders. The proposal is to do several activities simultaneously. Further development of laws and regulations strengthening the position of minority shareholders must be carried out, especially in the sphere of information and protection of the rights and obligations. It is necessary to strive towards the improvement of the investment climate in the Republic of Serbia and attracting foreign capital, because it is the only way to present the spirit of modern corporate governance in the Republic of Serbia. A continuous and systematic education of the population on shareholding, markets and corporate governance is also essential and must be significantly strengthened. The monopoly of certain state institutions is necessary to be reduced by systemic measures. Also, the question of the flow, exchange and protection of privileged information must be further regulated.

Taking everything into consideration, it can be openly concluded that the Republic of Serbia – considering the field of minority shareholders protection – is not high on the list of countries, and that this fact suppresses the inflow of capital from abroad. It is a common fact, that the so-called 'small investors' are the most attractive subjects of trading on financial markets of developed countries, and that it is them who really contribute to a healthy, mature and affirmative investment climate. In this regard, in front of the Republic of Serbia is a long way, where there are to arise many more challenges and ambushes.

Further research should be directed to reviewing and analysing the status, position and opportunities in the field of minority shareholders rights protection in the Republic Serbia, and to the study of the effects of implemented measures in this field.

ANALYSIS OF THE GLOBAL ECONOMIC CRISIS

Vojin Vučičević¹

¹ Ministry of Labour and Social Policy – IMG International Management Group, Belgrade, Serbia

Abstract: *Direct instigators of the crisis are regulatory bodies of the USA (FED, SEC) and rating agencies that have made conditions for the appearance and escalation of the crisis up to unimagined proportions by their unscrupulous work. Regulatory and structural shortcomings of the global financial crisis have provided the transformation of a crisis of one country into a global crisis that spread onto industrially most developed countries of the world in the first wave, whereas less developed countries were included in the second wave. Once an advantage of financial markets, their global character, now in conditions of the crisis represents the greatest disadvantage. In terms of globalization, space for finding solutions and exit strategies is narrowed down, as the level of market heterogeneity is drastically reduced [1].*

Keywords: *globalism, economic crisis, analysis, loans, seasoned and deseasoned price.*

1. INTRODUCTION

Current financial and economic crisis has affected all countries of the world with the same intensity, regardless of the development level and structure of economy, all economic sectors and all social layers and individuals. Crisis has caused the fall of all macroeconomic aggregates and indicators of all world countries. Key consequences are illiquidity, drop in production and exports, decline in employment and increase in unemployment, drop in living standard and growth of poverty.

Republic of Serbia in the period of economic crisis has, like other countries, recorded an increase of illiquidity of economy, drop in gross domestic product, industrial production, export and import, drop in employment and growth of unemployment, drop in earnings and purchasing power of population and growth in poverty. In Serbia as transitional country, delayed and piled transitional problems had primary impact on breaking of macroeconomic trends, and additionally the drop in aggregate demand, reduction of foreign capital inflow and increase of illiquidity in conditions of global economic crisis and recession [2].

2. ANALYSIS OF CRISIS IN USA, EU AND SERBIA

The reason for the appearance of sub-primary market lies in constant growth of real estate prices and desire for acquisition of an increasing profit. Constant growth of real estate prices is caused by overheated demand, which is financed precisely through mortgage loans. As the prices of real estate have constantly been growing, the number of granted mortgage loans by commercial banks and other smaller deposit-credit institutions such as nonbank banks and Thrifts has been growing. Nonbank banks have been dealing with jobs of granting loans or receiving deposits, but they have never joined two functions. Thrifts are financial institutions that are smaller than banks by size and primarily deal with granting loans to individual users and they do not deal with corporate jobs. One of the main actors that have contributed to the escalation of crisis in real estate market are precisely these smaller deposit-credit institutions.

Significant number of USA citizens due to unstable jobs they have dealt with and smaller earnings were not able to borrow in primary market from commercial banks, since they couldn't meet the required criteria for obtaining mortgage loan. Banks and other deposit institutions, wishing to use the trend of real estate prices growth and to acquire higher profit from its primary activity (loan placing) have initiated the establishment of a new submarket, sub-primary market of mortgage loans. In newly-formed market, clients with bad credit rating could obtain wanted mortgage loan [1].

Figure 1: Base monthly index of the movement of deseasoned and seasoned real estate prices in USA market in the period from 01.01.1991. – 01.11.2008. [1, 3]

As base month, we have taken January 1991, while prices growth in other months of the period observed is compared to the base month. Differences between seasoned and deseasoned prices are insignificant (figure 1). When we look at the graph, we can see constant growth of seasoned and deseasoned prices of real estate until June 2007 when growth trends was abruptly stopped. In period from 01.01.1991. to 01.06.2007., deseasoned prices of real estate have grown by 126% on average [3], while seasoned prices have grown by 124% [3].

Favourable loans that the banks granted to their clients have led to the creation of great demand for real estate, which was a pressure to the growth in real estate prices. Growth in real estate prices was also contributed by American Federal Reserve System (FED), which have led expansive monetary policy. Policy of low interest rates that was led in the period from 2001 to the half of 2005 has led to the situation in which cheap capital was placed in long-term and capially intensive projects such as real estate (figure 2) [4].

Figure 2: Review of the movements of reference interest rate of FED in the period from January 2000 to March 2009 [4]

From the second half of 2005 until the end of 2007, FED has led restrictive monetary policy which was reflected through raising the level of reference interest rate. Since the end of 2007, face with a growing crisis, FED was forced to relax monetary policy by lowering the reference interest rate in order to mitigate the effects of the crisis occurred. During 2007, defence interest rate of FED was lowered three times: on 18th

September from 5,25 % to 4,75 %, 31st October to 4,5 % and 11th December to 4,25 % [4]. Since the beginning of 2008, there was an abrupt trend of lowering basic interest rate, when FED lowered reference interest rate eight times. First lowering was performed on 22nd January 2008, when interest rate was reduced from 4,25 % to 3,5 % [4]. The second reduction happened on 30th January when reference interest rate was reduced to 3 % [4]. The next reductions of basic interest rate happened on 18th March (to 2,25 %), 30th April (to 2 %), 8th October (to 1,5%), 29th October (to 1 %) and 16th December 2008 (to 0,25 %). Measures of FED were aimed towards the reduction of costs of borrowing and improvement of the liquidity of USA economy.

Commercial and investment banks have suffered the greatest losses. Assets write-off in 2007 for Citigroup was 46,4 billion USD, Merrill Lynch 36,8 billion USD, and for Swiss UBS 36,7 billion USD. From mortgage market, crisis was transferred to the market of shares and bonds in the beginning of 2008. In September 2008, it comes to the escalation of financial crisis and real decline of American giants. The first to declare bankruptcy were Lehman

Brothers and Wachovia. State has nationalized Fannie Mae and Freddie Mac, which have controlled about 50 % of overall mortgage loans in USA. Merrill Lynch is saved by a takeover by Bank of America for approximately the half of real value and JPMorgan has taken over Washington Mutual. Morgan Stanley and Goldman Sachs were forced to change their status from investment banks into commercial banks. This decision resulted from the need of investment banks for financial aid of the state that only commercial banks could obtain. The biggest American insurance company American International Group (AIG) was saved from bankruptcy by debt redemption from the part of FED [5, 6].

The situation occurred has forced European countries on common measures in order to prevent crisis expansion. Leaders of fifteen European countries and Government of Great Britain have met on 12th October 2008, in order to agree on common strategy which they will undertake in order to exit the financial crisis. However, unlike the USA that is a single country, EU consists of 27 countries, which additionally complicated and makes finding of a common solution more difficult. EU has important financial institutions such as European Central Bank, but its great shortcoming is non-existence of European Government which would make rapid decisions and decisions that would be mandatory for all member countries. The existing legal solution provides each state to separately devise measures to overcome the crisis, without the need of the members to mutually harmonize the measures planned [7].

Figure 3: Movement of reference interest rate of ECB in the period from 01.01.2000. to 01.02.2009. [7, 8]

On October 13th, Germany has set aside 70 billion Euros in order to raise liquidity of banks and 400 billion Euros in order to provide interbank loans. France has set aside 40 billion Euros of financial injection for the banks and 300 billion Euros to provide interbank loans. Great Britain has given the aid of 20 billion pounds to Royal Bank of Scotland, and Lloyds and HBOS have obtained the aid of 17 billion pounds. British Government has assumed the control over mortgage bank Bradford and Bingley. Spain has prepared a package of measures of 30 billion Euros in order to pay for bad assets from banks and simultaneously increase their liquidity.

From Table 1 we can see that Slovakia, Czech Republic and Croatia are the most endangered, in case of which foreign capital has a share of more than 90% in ownership structure of financial institutions. In addition to Hungary and Macedonia, Serbia is among three least endangered countries with 60 and less percentage (table 1).

Direct effects of global economic crisis will leave deep consequences on countries that expect the most in international flows of capital and international trade. Unlike these countries, developing countries and countries that go through the process of transition will feel indirect effects of crisis for financial sector, which will be manifested through the drop in liquidity, lot of difficulties related to the construction and reform of financial institutions, as well as real sector through slowing down the economic activity. Serbia is a part of this group of countries, as a country in a transition well underway.

Table 1: Share of foreign capital in ownership structure of bank sectors of the countries mentioned [12]

Foreign ownership over financial institutions	
	Percentage in relation to the entire banking sector
Slovakia	97,4
Czech Republic	96,2
Croatia	90,4
Bosnia and Herzegovina	83,3
Bulgaria	80,0
Poland	79,6
Montenegro	78,1
Romania	70,0
Latvia	67,5
Serbia	60,0
Hungary	58,9
Macedonia	54,0

5. CONCLUSION

Crisis that initially appeared in real estate market of the USA, and then spread on financial system and economy of USA does not appear by accident. The crisis appeared as a consequence of leading irresponsible business policy of competent state institutions for the control of financial market (FED and SEC) and incompetence in work of rating agencies, as well as fundamental weaknesses that exist in the field of financial control and regulations in USA for years. Source of weaknesses mentioned comes from the idea of unlimited liberalization of financial markets, with minimal regulations and weak control of the business of investment banks and funds. Initial assumption is that big institutional investors who have enjoyed preferential treatment of regulatory bodies, will responsibly and in accordance with good practice of corporative management protect the interests of their owners, it basically appeared to be wrong and harmful. In addition to the fact that FED hasn't controlled banking system in a way in which it should have, by implementation of expansive monetary policy, through lowering the reference interest rate, FED has made loans even more cheaper and available to bigger number of users.

In August 2008, interest rate was increased to 4,25 % for a short period, then after the September of the same year there was an abrupt trend of drop which lasted until March 2009. From October 2008 until March 2009, ECB has lowered reference interest rate five times. During 2008, interest rate was lowered in October from 4,25 % to 3,75 %, in November to 3,25 % and in December to 2,5 %. In January 2009, reference interest rate was lowered to 2 % and then in March of the same year to 1,5 % [8-12].

Serbia has felt the first blows of crisis on its most sensitive part of financial market – stock exchange. Having in mind the characteristics and insufficient development of capital market in Serbia, it is believed that the impact of global economic crisis on that sector will be limited. Unstable political situation at the beginning of 2008 has additionally increased the uncertainty of investors and caused greater withdrawal of foreign capital, which has influenced the reduction of capital market liquidity and which had an unfavourable impact on future events on Belgrade Stock Exchange [13-15].

Decisions of the Governments of all countries to take more active and synchronized participation in solving the crisis were influenced by experiences from the period of great depression, in the 1930's. In that period, creators of economic policy have led laissez-faire policy, because they have considered that the market will independently establish the balance. It was attempted to lead the policy of a balanced budget and higher taxes in order to reduce budgetary deficit. [16-18] Central Banks have accepted the closure of banks and haven't taken any significant measures to neutralize the drop in monetary mass. In order to reduce the import and stimulate domestic production, protectionist external policy was carried out. Result of these measures was catastrophic, so the countries taught by events during the first global economic crisis have concluded that costs of not taking any measures was much greater than costs of interventionist policy. However, the question remains whether it is alright for the loss, generated by speculates' bad business decisions, to be socialized and for all burden of crisis to be taken by ordinary people.

Abstract: Accounting information features as the basis for business decision making in modern-day business environment. This information is produced by business entities' accounting information systems. To meet all the qualitative and quantitative characteristics of accounting information, the demand for the application of modern information technologies is set before the accounting information system. These modern information technologies significantly improve the operation of the entire accounting function. One of the modern information systems that have found significant extent of application in business practices is the Decision Support System (DSS). This article will attempt to shed light on the interdependence of business decision making quality and the appropriate accounting information system, laid on solid foundations. The effects of including decision support systems in raising the quality of accounting information systems will be examined, as well as the implications of including DSS in improving the quality of decisions made by corporate entity management. The aim of this study is to prove the indispensability of DSS in the implementation of strategic business decision making, as a decision making process typical of corporate top management.

Keywords: accounting information, accounting information system, decision support systems, business decisions, strategic business decision making

INTRODUCTION

The modern-day business setting is characterised by a high degree of turbulence, which is primarily reflected in incessant market change, accelerated technological advance and increased demands set before modern business entities, and appropriate response to such market trends necessitates their rapid response. This response, first of all, entails making appropriate business decisions providing the right response to such market trends. These business decisions should, first of all, enable eliminating growing market risk, and appropriate adaptation to modern-day market setting. Such response implies, first of all, availability of adequate information, which, first of all, stem from the accounting information system. Appropriately set up accounting information system is a good springboard for providing relevant information, necessary for making appropriate business decisions and eliminating threats entailed by increasingly intensive market change.

The expansion of modern information technologies has given rise to the development of numerous systems facilitating the process of making an increasing number of business decisions. The key role of these systems is to enable managers to see all the benefits or shortcomings of given business alternatives by means of strategic business decision making, and based on this information, select the one that will yield highest benefits. One of these systems include decision support systems (DSS), elaborated in this article.

- THE IMPORTANCE OF ACCOUNTING INFORMATION SYSTEMS

Functioning of any business entity will be successful only as much as its organisation structure is based in interdependence and mutual feedback between its segments and the whole. Thus set, the system will enable performing business activities with maximised achieved results, and minimised costs. This is achieved by implementing information systems in business entities.

Various information systems exist in each business entity. According to some authors, each business entity must contain the following information systems (www.crnarupa.singidunum.ac.rs, accessed March 10, 2012):

- production information system;
- marketing information system;
- accounting information system; and
- HR management information system.

Depending on each individual business entity's organisational structure, each of these information systems may exist either as an independent information system, or as a segment of the integral information system. As the pivotal point of this article is the accounting information system, our attention will be focussed on it. There are numerous definitions of accounting information system, depending on authors and criteria they took in their defining. For the purpose of this article, we have opted for the following definition of the accounting information system: "An accounting information system is a set of all techniques, technologies and methods for gathering, processing, distributing and archiving data" (www.ef.uns.ac.rs, accessed March 10, 2012). It is a constituent part of the business information system providing substantial support in all stages of system management. The very fact that it is an information system suggests the use of computers not only in its functioning but also all across the organisation. A given system can be broken down into the following constituent elements (www.ef.uns.ac.rs, accessed March 10, 2012.)

- Financial bookkeeping with pertaining analytic bookkeeping systems;
- Cost and performance accounting;
- Accounting supervision; and
- Accounting-based planning and analysis.

This division can be presented graphically as follows:

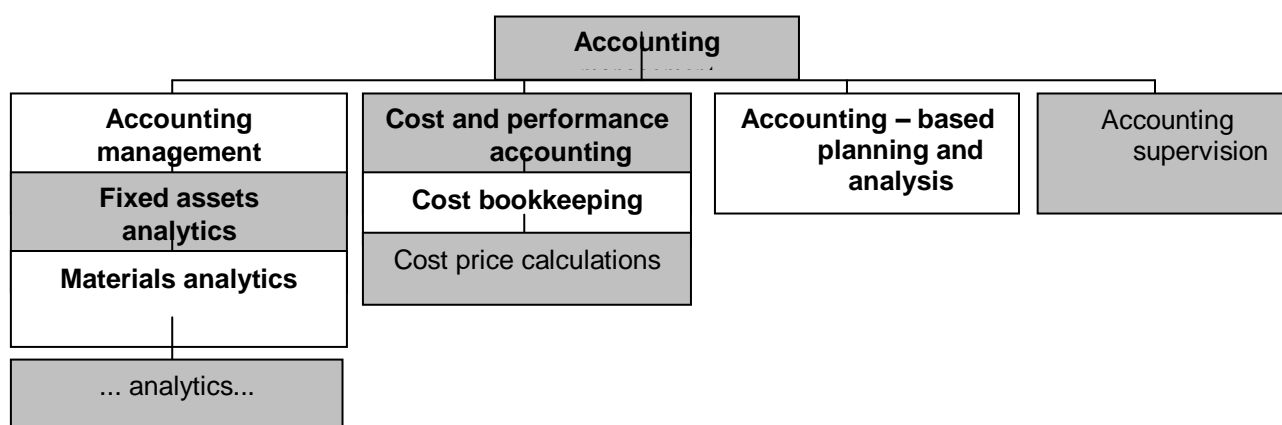

Figure 1. Constituent parts of accounting information systems (www.crnarupa.singidunum.ac.rs, accessed March 10, 2012)

Seamless functioning of accounting information systems implies prerequisite existence of the following constituent elements: human resources, equipment, procedures and data. This mean that employees use appropriate equipment and follow set procedures to produce accounting information based on given data.

The accounting information system is the oldest information system in an enterprise, containing and providing information required for conducting business transactions, decision-making, evaluating resources and performance, and reporting. To perform its role, it must cooperate with all other information systems in the enterprise. This cooperation must be a two-way-one; on the one hand, the accounting information system provides other information systems with relevant information, while on the other, these information systems provide relevant information to the accounting information system required for its seamless functioning. HR management information system provides the accounting information system with data required for payroll calculations; production subsystem provides data required for accounting coverage of production, etc.

The purpose of the accounting information system is to provide information of set quality and quantity tailored to the needs of various users. On the one hand, this system produces information of synthetic character, intended primarily for preparing and compiling annual financial reports, which is a part of financial accounting as a constituent element of the accounting information system. On the other hand, managerial accounting produces information tailored predominantly for manager to enable them to make business decisions, and it is always future-oriented.

Accounting information produced by the accounting information system are tailored for making appropriate business decisions, both by the management and all other users, both internal and external. The most important external users of accounting information include: capital owners, investors, creditors, national agencies, buyers and suppliers, whereas the dominant positions among internal users are taken up by

employees, trade unions, corporate auxiliary and expert services, etc. How the accounting information system meets the information needs of numerous users is illustrated by the following diagram:

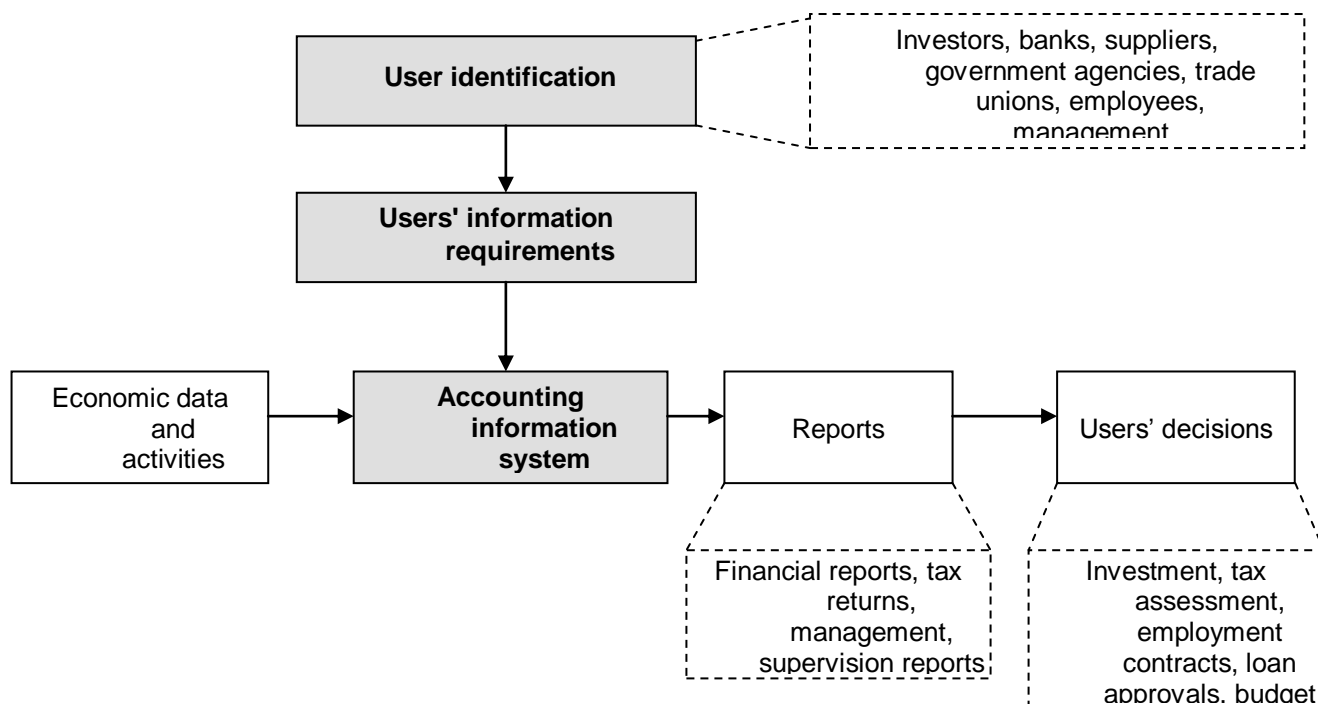

Diagram 1. Accounting information system for providing users with relevant information (Source: Teaching materials for the course in Financial Reporting and International Accounting Regulations from the 5th year of studies at the Faculty of Economics Subotica)

The diagram No. 1 shows that accounting information systems produce information tailored to the users' requirements. If the information is intended for top management, it must be synthesised, whereas if it is intended for lower management levels, it must be more analytical by nature. The figure above also shows that accounting information system produces numerous reports, such as financial reports, tax returns etc.

2. DECISION SUPPORT SYSTEMS

The increasingly intensive technological advances have resulted in numerous technological solutions whose action facilitates management processes in business entities. One group in the range of such systems are the Decision Support Systems (DSS).

Decision support systems are, in fact, model-based sets of procedures for processing and interpreting information supporting managers in their decision-making. They are, actually, an interactive computer information system intended for supporting structured, semi-structured and unstructured decision-making. They are a product of extensive theoretical research conducted in the 1960s aimed at facilitating an extremely complex process like decision-making and simplifying it as much as possible.

The above mentioned definition of decision support systems leads to the conclusion that their purpose is to resolve three groups of problems: structured, semi-structured and unstructured. Structured problems have all their resolving phases defined. This means that their resolving procedures, phases etc. are known. Structured problems do not have all their resolving phases defined and resolving them is based on intuition, whereas semi-structured problem have some of the phases or procedures defined. Resolving semi-structured and structured problems requires the use of individual decision support systems whereas resolving unstructured problems, encompassing a major number of alternatives, requires group decision support systems (GDDS).

Decision support systems have the following basic features (www.dss.com, accessed March 11, 2012): They:

- are intended for resolving unstructured and semi-structured problems;
- support to decision-making of various levels of managers;

- support group-based and individual decision-making;
- are easy to use and construct;
- are adaptable and flexible; and
- significantly improve the effectiveness and efficiency of decision-making.

To clarify and enable better understanding of decision support systems, we shall use the following scheme, showing the structure of decision support systems:

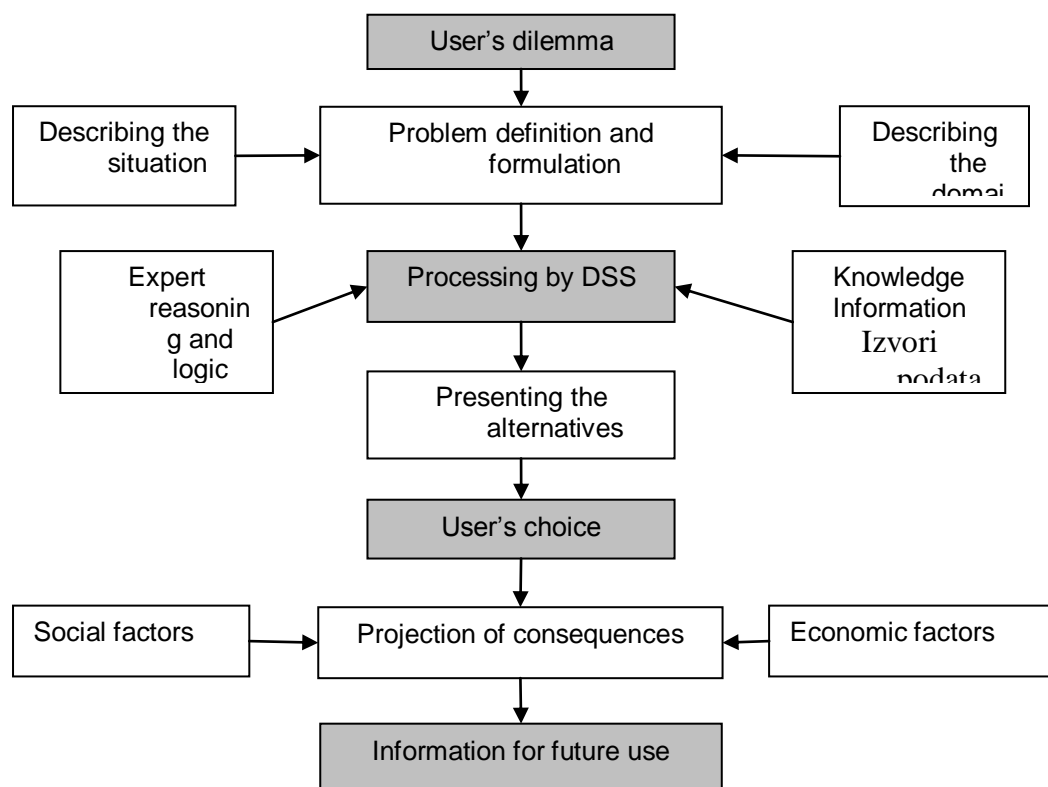

Diagram 2. Structure of decision support systems (www.dss.com, accessed March 11, 2012)

The diagram No 2 above shows that decision support systems require the user to provide precise definitions of problems or situation to be solved. After this, the system processes the presented data, and offers a certain number of alternatives to the user, with the consequences of each of the chosen alternatives. This enables users to make business decisions for which they can foresee the consequences (benefits or harms). This system cannot replace the decision-maker, i.e. the human; it can only facilitate the number between several alternatives and enable making the right business decision.

Depending on the level, there are several types of decision support systems: (www.ef.uns.ac.rs, accessed March 12, 2012):

- decision support systems for strategic decision making – intended for supporting decisions made by top managers, predominantly in semi-structured decision-making about problems related to setting goals, choosing business strategies, defining business corporate mission and vision, making plans etc.;
- decision support systems for management control – predominantly intended for middle managers, responsible for effective and efficient use of resources and managing individual functional areas;
- decision support systems for operative planning and supervision are predominantly intended for lowest-level management, responsible for executing decisions delegated by higher management levels.

The use of computer technologies provides insight into numerous advantages that they provide in corporate decision making (www.ef.uns.ac.rs, accessed March 12, 2012):

- speed, i.e. a large number of fast calculations at low prices;
- overcoming limitations in data processing and storage, as the latter may reduce the problem-solving ability (i.e. bad memory);

- cost-cutting in decision making
- technical support in storing, searching and transferring data, at higher speed and lower prices;
- high-quality decision making through better decisions, processing more alternatives, risk analysis,
- expert support; and
- agility of support.

As pointed out earlier, different management levels require information of different character. Higher-level managers are interested in information required for making decisions of strategic character, whereas this information, like market oscillations, price fluctuations, foreign currency exchange levels etc., is less interesting for managers of lower levels.

This is one of the shortcomings of decision support systems, which is resolved by introducing Executive Information Systems (EIS). These systems support differentiation in management's information needs. To facilitate insight into advantages and disadvantages of these two systems, i.e. make a comparison, we shall use the tabular presentation below:

Table 1. A comparative presentation of logistic DSS and EIS (Teaching materials for the course in Financial Reporting and International Accounting Regulations from the 5th year of studies at the Faculty of Economics Subotica)

Logistic DSS	Expectative Information Systems
- supplies data for decision making	- supplies data for performance management
- aimed at semi-structured and unstructured problems	- uses performance directions in relation to the plan
- secures instrument, not solutions	- secures information, rather than ad hoc analysis tools
- used by senior and middle management	- used by top management
- usable when developing alternatives and/or decision-making variants	- usable in reporting phase in decision making
- functions in interaction with the environment	- expressly usable when integrated in corporate culture & style

The table 1 above points to the fact that the executive information system is primarily tailored to support decision-making by top management, secures information, and is usable in the reporting phase of decision making. Unlike EIS, the logistic DSS is tailored for information requirements of both top and middle management, enables decision making in the case of multiple alternatives and provides decision-making tools, but the system itself makes no decision. Unlike EIS, which exists when integrated in the business entity's corporate structure, the logistic DSS functions in interaction with the environment.

3. MANAGERIAL DECISION MAKING AND QUALITY OF BUSINESS DECISIONS

Corporate decision-making process is a highly complex and demanding activity. The complexity of this process is notably manifest in the conditions of increasing uncertainty and a large number of alternatives that managers must take into account when making business decisions. This is primarily caused by the increasingly dynamic character of the business setting and the growing turbulence of business events.

Corporate decision making is primarily in the hands of administrators and managers of all levels. The administrative level determines the significance of business decisions made, and the importance of the made business decision also results in responsibility for future business and corporate survival. Thus, top management makes decisions of strategic character, whereas the lower management levels are mostly focussed on operative decisions.

There are numerous definitions of the decision making process, depending on the criteria and factors taken into consideration in classification. In this article, we opted for the definition of two prominent authors in the management area, Koontz and Weihrick, who view the decision-making process as choosing the direction, i.e. manner of action, where it features as choice between two alternatives. Decision making is the central activity of a corporate entity's management. The relationship between the corporate management and decision-making is best illustrated by the following diagram:

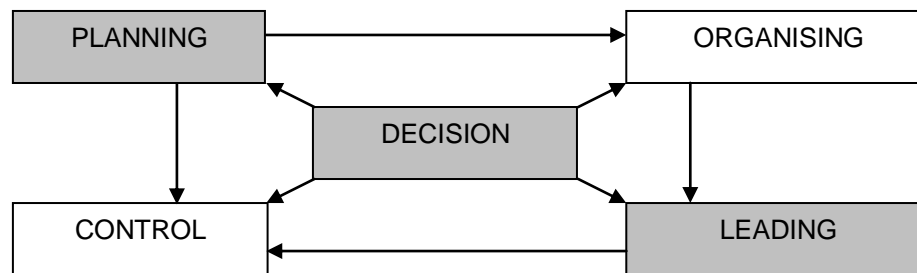

Figure 2. The relationship between management function and decision making (Bahtijarević – Šiber, Sikavica & Pološki Vokić, 2008)

The figure 2 above shows that decision making is not a separate management function, but, we can freely say, function used by management to fulfil their role in the corporate subjects. It is a superfunction, featuring as a constituent part of all classical management functions, i.e. planning organising leading and control. The outcome of the decision-making process is a decision. A decision is a choice between multiple different alternatives. For the decision to be relevant, one needs to have certain information serving as the foundation for the decision made. The decision-making process can best be represented by the following figure:

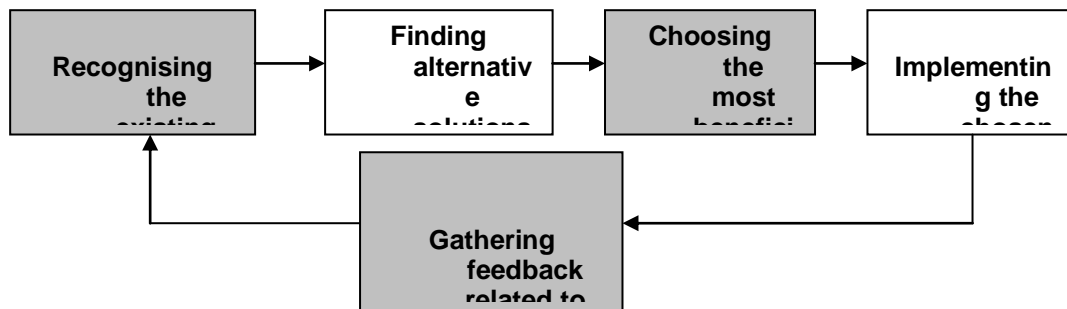

Figure 3. The decision making process model (Certo C.S. & Certo T. S, 2008)

The figure 3 above shows that decision making begins with appropriate diagnose of the problem, followed by considering all available alternatives for its resolution. After this, managers consider which of the activities are the most beneficial, choose one of them and implement the chosen alternative. This is not the end of the managers' activity, as they follow and gather all information related to implementing the given alternative, which is in the function of resolving the observed problem.

The managerial decision making process itself consists of several typical steps, as follows (Certo C.S. & Certo T. S, 2008):

1. recognising the existing problem
2. listing the possible alternatives for problem solving
3. choosing the most useful alternative;
4. implementing the selected alternative; and
5. gathering feedback to establish whether the chosen alternative contributes to resolving the problem.

Viewing the given decision-making phases, we come to a conclusion that they were made based on the diagram above. When managers view which alternatives can be taken into consideration when solving the problem, they must bear in mind that there are certain limitations acting outside the corporate entity itself, but also those. Actually, we can highlight that there are limitations existing not only within the corporate entity, but also limitations of external nature, such as social norms, legal provisions and other types of limitations. The given limitations are illustrated by the figure below:

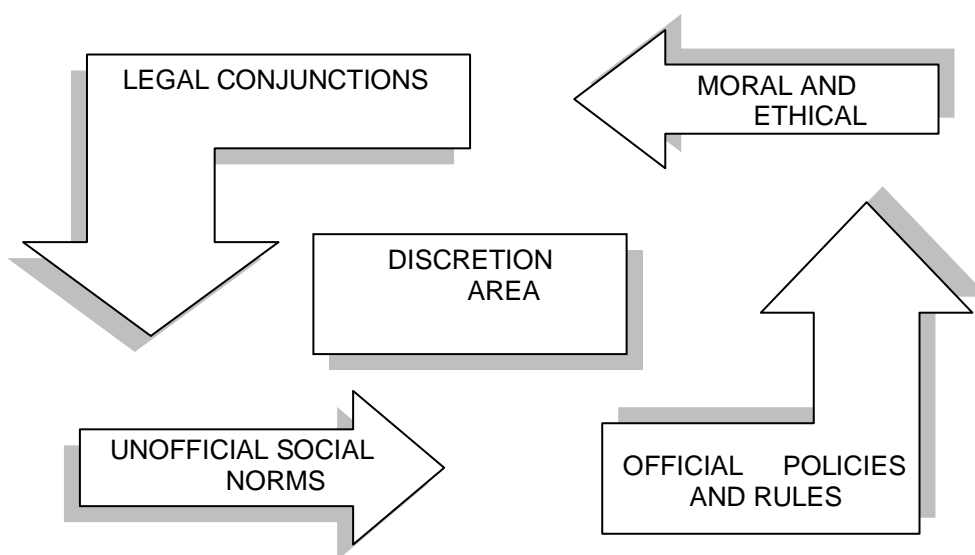

Figure 4. External factors limiting the management's number of alternatives for resolving problems (Certo C.S. & Certo T. S, 2008)

Given that each corporate entity is also a market player, in view of the fact that they conduct their business operations and earn their income, the decision making process is also influenced by the environment factors, best illustrated by the table below:

Table 2. Business environment factors exerting pressure on organisations (www.crnarupa.singidunm.ac.rs, accessed March 13, 2012)

Factor	Description
Market	<ul style="list-style-type: none"> • strong competition • growth of global market • development of e-market on the Web • new marketing methods • benefits of outsourcing with IT support • need for real-time online transactions
Customer demands	<ul style="list-style-type: none"> • demands for customisation • demands for quality, product range, assortment, and speed of delivery • increased role of customers and decreased loyalty
Technology	<ul style="list-style-type: none"> • more innovation, new products and services • faster outdated • greater information overload
Society	<ul style="list-style-type: none"> • more state regulation/deregulation • more staff turnover, increasing age, more women • concern about defence and terrorist attacks • compulsory reporting • more corporate social responsibility

As mentioned above, to function successfully management decision process requires all necessary information. This information is provided by accounting information system, so it can be freely regarded as a constituent element of the management information system, and its most vital element at the same time. The accounting information system encompasses four subsystems (Đogić, 2009):

1. subsystem dealing with the coverage of daily business events and making daily business decisions based on the former;
2. ledger and finance reporting subsystem, producing sets of financial reports, and other financial reports required by legal provisions;
3. fixed assets and capital investments subsystem; and
4. managerial reporting subsystem, providing information for corporate decision making.

The development of decision support systems has resulted in facilitated business decision making process. These systems are a symbiosis of a whole range of functional knowledge and information systems, whose fundamental function is to support corporate decision making processes. Actually, it can be concluded that decision support systems support all decision making process phases, starting from problem formulation through design, choice, down to implementing the chosen alternative.

Managerial decision support systems are best illustrated by the figure below:

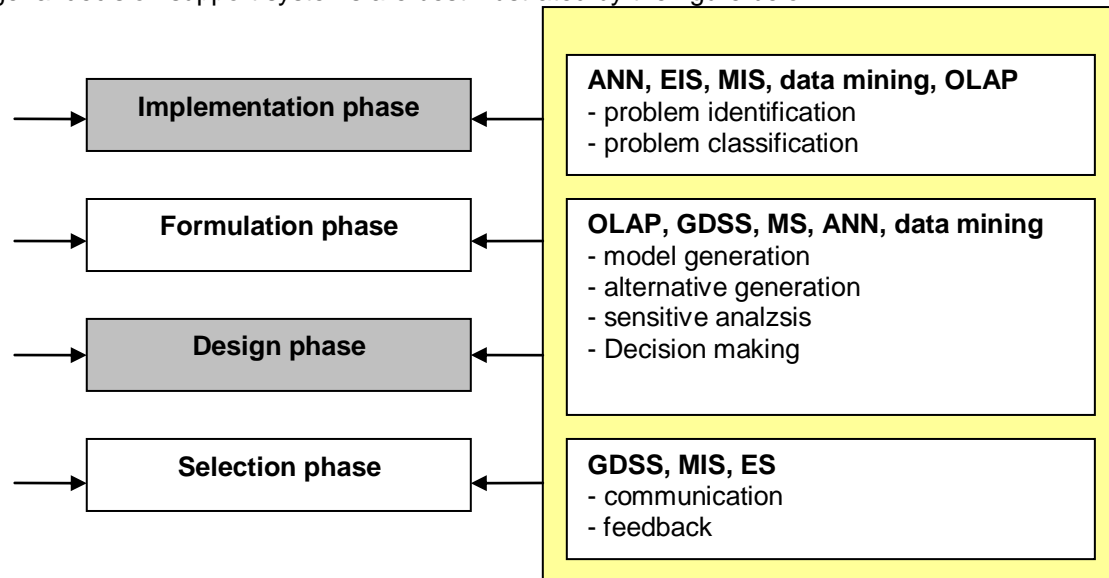

Figure 5. Computer support to decision making phases (Vasiljević, 2007)

The fundamental feature of decision support systems in corporate decision making is reflected in the following:

1. Decision support systems are used for loosely and inadequately specified decision.
2. The fundamental role of decision support systems is to assist the corporate decision maker.
3. Decision support systems contain trends in management science and traditional data processing function.

CONCLUSION

The decision making process in the modern-day market setting is gaining complexity, which is predominantly caused by powerful and constant change in the business setting. When making business decisions, managers face a large number of business alternatives, which must be taken into account so that the real business decision is made. This is where development and advancement of decision support systems gains prominence.

Decision support systems are to assist the corporate decision-making process in terms of encompassing a large number of available alternatives, analysing each of them, and point to the possible consequences of their implementation. Modern-day managerial decision-making is characterised by a large number of possible alternatives, but successful business operation forces corporate entities to choose the one that will yield maximum benefit against at minimum cost. This is what is enabled by decision support systems.

An oft-cited opinion is that high-quality business decisions only require IT support, and many people regard it as sufficient. Such a position is unacceptable, for decisions can only be made by humans, whereas the system's role is only to support business decision making. The decision cannot be made by the system itself; this is the prerogative of the manager. Responsibility for decisions made cannot be taken over by the system; it is the decision maker that is responsible.

COST ACCOUNTING AS A KEY INFORMATION SUPPORT FOR MODERN MECHANISMS OF COMPANY MANAGEMENT

Radmila Jablan Stefanović
University of Belgrade, Faculty of Economics, rasty@ekof.bg.ac.rs

Abstract: *In contemporary conditions of great external and internal complexity companies operate in an extremely dynamic world of interdependent and nonlinear events. The company's existence on the turbulent and uncertain market directly depends on the degree of fulfillment of customer expectations but also on the intensification and strengthening of cooperation with other organizations from the environment – customers, suppliers, and distributors. The modern company achieves its success as a result of the interaction with the environment, resources and management, i.e. its ability to employ the resources adequately, bearing in mind the company's position – its strengths and weaknesses. This requires, along with acceptable risk, a maximum exploitation of challenges brought by the environment, in order to realize the interests of various stakeholders. Managers face complex and numerous problems and challenges of successful company management. Achieving sustainable competitive advantages, as a condition sine qua non of modern business, in a dynamic and thoroughly uncertain environment necessarily requires sophisticated professional knowledge and skills, as well as designing an adequate information system as a quality support to larger and more complex information requirements of managers at all levels of management. This paper puts an emphasis on the importance of flexible designed cost accounting information system – a key information core of company's accounting information system – in generating quality information as a support to modern company management mechanisms. Only as flexibly designed it can qualitatively respond to numerous and various information requirements – it will be able to adapt to changes occurring in business environment as well as in the company itself. It also discusses some of the new and, in turn, enhanced existing tools, techniques, concepts and approaches to costing and cost management, which are fundamentally important in order to implement and support the competitive strategies of companies.*

Keywords: *management, strategy, competitive advantages, cost accounting, cost management*

1. INTRODUCTION

Last decades business environment has changed and will changing more than ever in the years that have to come. The trends of globalization inevitably result in sharp intensification of international competition and require systemic perception and coordination of business processes of all involved organizations. Quality decision-making requires having at one's disposal information relevant for solving a particular problem. Within business and financial decision-making cost accounting (CA), as the essential part of a company's accounting information system (AIS) as a whole, represents a reliable information support for the management. Therefore, it is necessary to continuously review its information offer, as well as to find new ways of generating quality information as a support for modern mechanisms of company management. Only flexibly designed CA information system can qualitatively respond to numerous and various information requirements – it will be able to adapt to changes occurring in business environment as well as in the company itself. Integrating the internal and external aspects it is possible to provide quality information for strategic management of a modern company. Strategic cost management (SCM) implies the use the cost data to develop and identify superior strategies that will produce sustainable competitive advantages. The purpose of the paper is to highlight the role CA has in offering support to managers at all managerial levels. Some of the new tools, techniques, approaches and concepts to costing and cost management (CM) have been emphasized (ABC/ABM, TQC/TQM, TC/TCM, LCPC/LCPCM, VCA, VSA/VSM).

2. KEY IMPORTANCE OF FLEXIBLY DESIGNED COST ACCOUNTING INFORMATION SYSTEM

Constant and dramatic changes in contemporary competitive environment, as well as the need of integrating into European and world market flows, require the knowledge of a wide focus cost and performance management. The management is expected to lead the company towards the achievement of set objectives, which in the contemporary settings of marked external and internal complexity requires sophisticated professional knowledge and skills, as well as quality information support. CA which measures and reports financial and non-financial information related to the organisation's acquisition or consumption of resources (Horngren, et al., 2005), has an exceptionally important position within the entire AIS of an organization because it provides information to both management accounting (MA) and financial accounting (FA) as subsystems of the AIS. When its information is intended for the FA it measures product costs in compliance with the strict legal and professional regulations; however, when its information is used for internal purposes it provides the basis for planning, control, and decision-making.

The importance of CA as information basis for external financial reporting (which is its traditional task) is particularly reflected in providing relevant data for the purpose of inventory balance and determining the cost of products sold. In compliance with the widely accepted regulations, it includes into the inventory value only the necessary costs of functional production fields – but not the costs of uneconomical spending, inefficient work and unused capacity, which represent period costs. Accounting data used for external reporting very often do not completely satisfy managers' needs for decision-making purposes. Attempts at slight modifications of financial accounting systems for managerial purposes rarely end happily – like eating soup with a fork: it is possible, but it is far from effective (Maher, 1997). Cost data for the purpose of internal reporting are meanwhile relatively free from the constraints of legal and professional regulations. When internal reporting is in question, analytical and short-term aspect – notably the success accomplished – is emphasized. Apart from presenting the overall business results of the company as a whole, it is possible to segment it from various aspects – it is an extremely important management instrument for planning and control. When activities of planning and control of the performance of the company and its narrower segments for various time intervals are in question, CA provides the management with relevant information, i.e. it represents the basis of the accounting planning and control. This is so because it assumes short-term and analytical aspect of costing, and compiling relevant reports as well, regarding the ever increasing need for planning and control of managers' performance. Therefore, internal reports created by CA are primarily used by MA for offering adequate information support to management for the purposes of planning and control of business activities, i.e. for the purposes of more qualitative and efficient operations and making various business decisions. Meeting various information needs of the management related to making individual business and financial decisions has been emphasized over the last few decades as the fundamental CA task – it assumes calculating costs and benefits of individual business alternatives. By using non routine cost-benefit analyses, CA creates reports based on the concept of relevant information. The concept of relevant costs (relevant revenues as well), in choosing among alternatives, assumes considering

the expected future costs which differ in alternative actions. Relevant cost analysis generally emphasizes quantitative financial information, but in decision-making, managers must pay due attention to quantitative non-financial and qualitative information and must, occasionally, give greater significance to qualitative or non-financial quantitative information. Non-financial information concerns legal and ethical considerations and long-term effects of decisions on the company image, employees' morale and the environment, and is relevant to particular business decisions.

While designing CA information systems one must not lose sight of the following (Maher, 1997): decision-makers' needs must be met; different cost information is used for different purposes – what works for one purpose will not necessarily work for other purposes; cost information must meet the cost-benefit test – namely, cost information can always be improved, but before establishing a new system, one basic question should be asked: will the benefits outweigh the costs? It is of vital importance that CA information systems should be flexibly designed. Due to the fact that they are relatively free from legal and professional constraints and are in function of the company management, they are, in accordance with the needs of internal users, able to generate a broad range of information. Organizational and methodological settings and functions are adapted to management requirements. Being flexible, it will be able to adapt to changes occurring in the business environment as well as in the company itself and, accordingly, respond in a qualitative manner to numerous and various information requirements of the company management. Today, there are new requirements for changes and continuous improvement so that the management could have adequate information support in managing the company – particularly key strategic variables.

The extent to which CA is capable of helping the management in serving the abovementioned purposes fundamentally determines its significance, i.e. the usefulness of its information. It is of great importance that the accountants should know their job well and seek the ways to add value to their organizations. In many successful companies in the world the accountant is a member of multifunctional teams as a reliable associate.

3. CONTEMPORARY CHALLENGES TO COST ACCOUNTING

In the last couple of decades numerous and dramatic changes in business environment have contributed to a high level of complexity, turbulence and uncertainty in the environment in which contemporary companies accomplish their economic mission. The trends of globalization followed by the removal of national barriers inevitably result in sharp intensification of international competition. What is more, the consumers' demands are changing more and more frequently and becoming more sophisticated, which, along with intense introduction of new information and communication technologies, drastically shorten product life cycle. As a response to numerous contemporary challenges, a broad range of new management approaches and philosophies is developing, such as: value chain analysis, setting up long-term relationships of close cooperation with key customers and suppliers, continuous improvement, broad empowerment of employees, new production management systems and many others. Despite the underlying notional differences, they all have the same universal motif – to master key factors for business success (cost, quality, time, innovations) and supply customers with superior value on the market. Powerful integration relations require systemic perception and coordination of business processes of all involved organizations. Therefore, managers in contemporary companies face complex and numerous challenges of successful company management. Achieving sustainable competitive advantage, as a condition sine qua non of modern business, in a dynamic and thoroughly uncertain environment necessarily requires sophisticated professional knowledge and skills, as well as designing an adequate information system – quality support to larger and more complex information requirements of managers at all levels of management.

In recent years, companies worldwide have considerably changed their strategies - from internally focused strategies to externally focused ones, whose top priority is customer satisfaction. There is a widely accepted saying that customers are company's most valuable assets. Profit is generated by customers, and products are only the ways of turning customer demands into profits. The quality of customer service is a sole criterion for distinguishing a successful company from unsuccessful one. The company's power is based on its superiority to create values for customers. The company manages to satisfy customer demands and enhance their loyalty if it succeeds to provide: a superior quality of their products to those of their competitors; products which are tailored to customer wishes and demands; reliable and timely delivery of

products; after-sales services; product quality guarantees; an effective communication system with customers, etc. Regardless of the concrete orientation regarding business strategy, the contemporary company inevitably faces the requirements of cost competition. Numerous and skilled competitors with new sophisticated approaches to CM and cutting edge technological achievements force it to manage costs carefully and skillfully. It is constantly being emphasized that CA should provide information useful for the decision-making process and particularly the information support for CM analyses and projects. Numerous studies point at the weaknesses of traditional formal CA systems, particularly emphasizing the problems of distortion, i.e. distorted information and limitations in presenting cost drivers, amounts and cost profiles in an extended business operations system. Thus, modern business environment inevitably requires CA restructuring and new approaches to costing and CM in order to improve cost information quality. It is necessary to provide adequate information support concerning the process of business strategy formulation and implementation, i.e. finding adequate directions leading to the strengthening of the competitive position on the increasingly turbulent market. In general, improved CA can reach more management objectives than traditional.

One of the new key themes in CA is turning our attention to the customer. *Customer in focus* is the key point of the organization's success. "To be customer-driven" lies at the heart of CM; among all aspects of business operations which the management must take care of, the customer is the most important because without him the organization loses its purpose. There is a permanent question in the way business operations are performed which puts the emphasis on customer satisfaction: how can value be added for the customer? The focus is on the most profitable customers and the ways to first attract them and then retain them. Today, companies first identify customer needs and demands, and then proceed with the product design and production. *Value chain and supply chain analysis* is also a key theme. Value chain (VC) facilitates consideration of the possibilities of achieving and retaining competitive advantage through strategically relevant activities. By using VC and activity cost information companies can identify strategic advantages on the market. Supply chain (SC) assumes the idea of an "extended company" - the focus expands from company *production* VC to *purchase* VC on the one hand to *distribution* VC as the final part of the whole industrial VC on the other. CM emphasizes integration and coordination of these activities through all links i.e. companies in the SC, as well as through each business function in the VC of individual companies. *Costs, quality, time and innovations* are key factors of business success. The management must continuously focus on these key strategic variables in relation to competition, which surpasses the frames of their company and draws their attention to changes in the external environment observed and assessed by their customers as well. It is of vital importance to manage them carefully and thus affect the level of customer satisfaction. Low costs are a significant business goal but cost improvement does not necessarily have to be sufficient. Customers want more than just lower prices and costs – they want quality, responsibility, punctuality. The combination of *benchmarking and continuous improvement* is an ever-present theme in the new approach to management. By comparing with the best examples, the management finds ways of continuously improving their proper practice. Benchmarking and continuous improvement are often described as a "the race with no finish" because management and employees displeased with a particular performance level seek continuous improvement. When they adopt this philosophy, the organizations perceive that they are able to achieve performance levels which they previously considered unattainable.

Thus, new environment brings new challenges and problems which inevitably impose the need for serious reconsideration of past business philosophy established in stable and predictable business settings. It is of great importance to adopt a wider external orientation with the constant focus on changeable and sophisticated customer demands. The company's existence on the market directly depends on the degree of fulfillment of customer expectations but also on the intensification and strengthening of cooperation with other organizations from the environment (customers, suppliers, distributors). Quality exchange of ideas and information, better inter-organizational coordination and integration of vital business activities are necessary assumptions for more successful competitive positioning of the company on the market.

4. IMPRUVED COST ACCOUNTING INFORMATION SYSTEM

There has been an increasing number of discussions about CM and extending various limits in the past decades. It is a dynamic process which assumes intensive efforts directed towards continuous improvement, i.e. improving the existing and inventing new tools and techniques, starting with early activity-based costing models and pursuing lately in the direction of *strategic cost management* (SCM) which implies the use of cost data to develop and identify superior strategies that will produce a sustainable competitive advantages. In that period, the most prominent trend has been *shift the focus* from determining product costs by using

standard traditional cost models, towards providing support for strategic and operational decisions by using certain forms of activity analysis. While considering the development of CM, it is very important to link it to modern challenges to organizations. Therefore, suggestions go in the direction of separating it from traditional accounting and abandoning the long-standing linearity of measuring historical costs and static standards. Managers should anticipate rather than simply react to changes in cost structure and financial performances.

The turning point in the development of CA was the advent of *Activity Based Costing (ABC)* which emerged primarily as an expression of the need to provide much more accurate data about the output cost price compared to traditional methods. It focuses on activities as parts of the entire process in a company and their cause and effect relations with the resources used as well as with cost objects (products and services, market segments, customers) i.e. activity drivers. However, management can use it not only for the purpose of calculation, i.e. more accurate product costing and, therefore, more successful price and product and service range management, but also for providing financial and non-financial information on activities, and effective CM – as assistance to activity based management. When considering the use of ABC for the strategic purposes, many experts think that it offers strategic opportunities to companies. Many companies have gained competitive advantage due to ABC information, i.e. cost reduction by lowering prices in order to increase their market share. *Activity Based Management (ABM)* focuses on managing activities with the aim of increasing the value which the customer receives and profit obtained by providing this value, which assumes driver analysis, activity analysis and performance evaluation. ABM assumes a set of decisions and actions based on ABC concept information. The goal is to increase the value delivered to customers and to boost company profitability to a higher level. Strategic and operational ABM are singled out. *Strategic ABM* assumes directing the organization towards the most profitable use of resources. Due to ABC information we can point out non-profit activities as well as the most profitable ones, and make decisions affecting product development and design, fixing sales prices, specifying the production and sales mix, and establishing and developing relations with key customers and suppliers. All this can be achieved due to skillful combining of the knowledge about cost behavior (i.e. their drivers) with the knowledge about customer behavior. *Operational ABM* assumes decisions and actions with the goal of continuous improvement of business processes; and for designing ABC systems, as its information support, several hundred activities may be necessary in order to obtain better insight into processes underlying production and customer service. Operational ABM is directed towards the improvement of efficiency and reduction of resources necessary for performing respective activities (Cooper&Kaplan, 1999). The advantages of activity analysis come primarily from the activity cost classification according to the possibilities of cost improvements. This classification enables managers to get an insight into how many current operating costs occur during inefficient processes or processes of low efficiency. ABC model determines where the greatest possibilities of cost reduction lie; but ABC information is not a current operating tool for the activities of improvement. This model offers the key direction for decision-making where to launch initiatives such as kaizen costing, pseudo-profit centers, TQM and reengineering. *Activity Based Budgeting (ABB)* extends the ABM idea to the planning cycle by using it to establish cost limits and control systems in organizations. Supported by activity analysis ABB uses benchmarking information to help the company to control costs and eliminate the increasing trend of exceeding the budget without improving the company's ability to create value for customers (McNair, 2007). ABB is directed towards future resources, activities and outputs and is a valuable information support to the process of strategic decision-making.

A philosophy of *Total Quality Management (TQM)*, in which managers strive to create an environment that will enable workers to manufacture perfect (zero-defects) products, is replacing the acceptable quality attitudes of the past. Reducing defects, in turn, reduces the total costs spent on quality activities. Four categories of *quality costs* are emphasized: *prevention* costs are incurred to prevent poor quality in the products/services being produced; *appraisal* costs are incurred to determine whether products/services are conforming to their requirements or customer needs; *internal failure* costs are incurred because products/services do not conform to specifications or customer needs; *external failure* costs are incurred because products/services fail to conform to requirements/satisfy customer needs after being delivered to customers. Quality costs can also be classified as *observable* (available from an organization's accounting records) or *hidden* (opportunity costs resulting from poor quality – not usually recognized in accounting records). A quality cost report is prepared to improve managerial planning, control and decision making (strategic pricing and cost-volume-profit analysis). Quality is one of the major competitive dimensions for world-class competitors (Hansen&Mowen, 1997). Organizations operating under the TQM philosophy have introduced a broad array of non-financial measures to monitor and improve the quality of their products/processes. For example, Motorola, a leading company in applying the TQM philosophy, adopted an

aggressive approach to quality, setting a quality target of a level representing fewer than 12 defects per 1 million parts (Cooper & Kaplan, 1999).

Target Costing (TC) is a tool (McNair, 2007) which emphasizes the relation between the price and market share as a basis for disciplining an organization's spending during product and process design, development and engineering. Basically, it assumes cost reduction per product unit. It is a completely new approach: how much a product *is allowed to cost* (Seidenschwarc, 2005). The implementation of new methods of identifying, measuring and providing information about critical factors of business success ensures the development of products to suit customer demands, regarding the features and quality, as well as the price. As a concept of a much more comprehensive and aggressive CM information support, TC is built in the decision-making (planning) process concerning introduction of new and making radical changes to the existing products and processes. *Target Cost Management (TCM)*, as a tool for a comprehensive cost and profit management and as a concept of long-term strategic CM, focuses on the design stage. It initiates CM in the earliest stages of product development and is aimed at intensifying the cooperation with the suppliers and other organizations on the market. TC operates after a general model: $\text{target costs} = \text{target sales price} - \text{target profit}$. If the target cost (as the difference between the sales price needed to ensure a previously determined market share and the desired profit per unit) is below the presently feasible cost, the management budgets cost reductions which direct real costs to target costs (Hansen&Mowen, 1997). Bearing in mind the organizational aspect, a successful implementation of TC concept assumes the creation of an organizational team structure that should include experts from different functional areas of the company as well as from the organizations it cooperates with on the market.

Life Cycle Product Costing (LCPC) is an extension (McNair, 2007) to TC tools, which links all costs driven by a new product, from the conception of the idea for the product through to its removal from the production program and withdrawal from the market, i.e. 'from the cradle to the grave'. The products are analyzed in order to determine whether they will bring profit during their entire life cycle. *Life Cycle Product Cost Management (LCPCM)*, according to the integrated approach, consists of activities leading to product design, development, manufacturing, marketing, distribution, use, maintenance, service and removal, with the aim of maximizing life cycle profits. As a result, product costs are tracked and analyzed through all stages of its life cycle, which is radically shortened due to changeable customer demands and the increasingly ambitious competition regarding the technological product innovations. In contemporary settings it is of vital importance to launch a new product on the market and replace the existing product with the innovated one as soon as possible (regarding quality and functionality). LCPCM stresses cost reduction, not cost control. Since 90% of the life cycle product costs are determined in its design process, i.e. in the stages of a new product development and construction, activity management during this stage of product existence is stressed. This should, by all means, affect the managerial decisions regarding investments and directing more resources towards activities in the early stages of product life cycle. However, the overall success depends on how well the managers in manufacturing companies understand the activities, cost drivers and interaction among activities. Although LCPCM is important for all manufacturing companies, it is particularly significant in short life cycle circumstances, when good planning is critical and the prices must be accurately determined in order to cover all life cycle costs and ensure a good profit (Hansen&Mowen, 1997).

Value Chain Analysis (VCA), i.e. costing and CM through the value chain, is a concept representing the broadest approach to management. It assumes monitoring the relations among activities that create value with the aim of cost reduction, where the problems of tracking, measuring, analyzing and managing costs are extended outside the borders of a company. Beside internal value chains (VC), it extends to the area of supply chain, i.e. suppliers, on the input side, and distribution chain, i.e. customers – distributors and end users, on the output side, because the internal VC of a company is built in the broader value system which includes both supply VC and customer VC. That is to say that the leadership strategy in low costs and/or the differentiation strategy can lead to sustainable competitive advantage, but successful application of these strategies requires the managers to understand all the activities that contribute to their achievement. It is necessary to understand the industrial value chain as a whole, not only the part in which the company participates. Without an external focus there is no effective strategic CM. With the aim of successful implementation of the relevant strategies it is necessary to break the VC into strategically relevant activities of a company. VC is a necessary approach to understand these activities; understanding both the complex links and interrelations between activities performed inside the internal VC of a company (internal linkages), and those describing the linking of activities of a company with the activities of suppliers' VC and customers' VC (external linkages). Therefore, in order to describe and exploit these relations, it is necessary to identify company activities and choose the ones that can be used for creating and sustaining competitive advantage.

The optimal choice assumes the knowledge of costs and value created by each of the activities, as well as relevant cost drivers.

Also, it is very important to point out that one of the critical factors of the success of pursuing competitive strategies on the market is to provide a rounded up performance measuring system. One of the solutions is the so-called *Balanced Scorecard (BSC)* which provides a comprehensive framework linking strategic objectives of the company with a coherent set of performance measures (Zimmerman, 2000). BSC attempts to unite and balance traditional financial perspective (concerning the measuring of current and designing future financial results) with three more perspectives of vital importance for a successful pursuit of competitive strategies on the market – the perspectives of customers, business processes and innovations and learning. In the BSC approach to performance improvement the most critical processes for the success of a strategy are identified. They are stressed not only for their potential for cost reduction, but also for their ability to fulfill end users' expectations. When using BSC, managers usually realize that for the implementation of a new strategy it may be much more important to stand out in completely new processes than to create gradual cost improvements in the existing processes (Cooper&Kaplan, 1999).

Value Stream Accounting (VSA) is characteristic of *lean manufacturing (LM)* which developed from Toyota production system based on the JIT model and is the complete opposite of traditional production. Many companies, aspiring to the "world class" position, follow LM whose objective is to improve efficiency and effectiveness in every area – including product design, interaction with the suppliers, factory operations, managing employees and customer relations. In order to keep this position, they must persist in "endless journey" which requires continuous innovations and improvement. "Lean" includes making the right product at the right place at the right time in the right quantity with minimum waste and sustaining flexibility. Thus, the key for successful LM lies in the achievement of production flexibility which includes physical organization of production plants and the application of automated technologies including CNC machines, CIM, *robotics*, CAD, CAM. Companies inclining to LM often use the tool *value stream map (VSM)* to present their business process graphically in order to identify the wasteful aspects which should be eliminated. VSM identifies all actions needed to complete product processing (batches or individual products) together with the key information about each individual action (it can include total labor hours, overtime, cycle time for the task completion, error rate). Some commercial VSM tools produce, beside the current state map, a future state map, describing the process which is lean – where waste is removed to the fullest extent. Since it is possible to identify, from the latter, the steps of the action of eliminating nonvalue-added activities within the process, it is also the basis for the lean implementations (Hall, 2008). Information needs of a lean company cannot be adequately supported by traditional information provided through conventional accounting techniques, because of inaccurate cost allocation, promotion of non-lean behavior, inaccessibility in real time, financial orientation. Therefore, many lean companies have adopted an alternative accounting model. Some of them see the solution in ABC method, but many replace it with a simpler accounting model, the so-called VSA. VSA tracks costs by the value stream instead of department or activity; the value streams cut across function lines and departments, i.e. horizontally, and thus links with traditional vertical reporting on structure and cost flows are broken (McNair, 2007). It is of fundamental importance for its implementation to define *product families* (Hall, 2008). As for the information support to lean manufacturing and world class companies, three information systems are being considered, from MRP (Materials Requirements Planning), and MRP II (Manufacturing Resource Planning), to ERP (Enterprise Resource Planning). In the past few years a range of software of the so-called ERP systems has been developed. ERP integrates departments and functions throughout the company into one system of integrated applications with a unique common database. A lean manufacturing company will thus have ERP system capable of external communication with customers and suppliers through electronic data interchange (EDI).

Considering that companies operate in an extremely dynamic world of interdependent and nonlinear events, we should finally emphasize that CM cannot stay focused on independent activities and simple linear cost models and their drivers. In order that CM could secure an important position in the 21st century and reject the label 'old wine in new bottles', it is said that it is necessary to withdraw completely from simple assumptions and traditional limitations and that the key of the CM future lies in understanding the dynamic relationships between various resources and the amount of value they can create for the company stakeholders. In that sense, key instructions are listed for the most recent research and practice regarding new techniques for the 21st century, such as: resource consumption accounting; the relative cost of intellectual capital and the value it creates; waste measurement and analysis; non-linear cost functions; dynamic cost modeling and prediction. Each of these techniques adopts a broader view of costs, focusing more on the way resources affect one another in creating or destroying the company value than on

measuring the status quo. CM follows the need to define measure and help the organization to maximize its potential to create value.

6. CONCLUSION

In the past decades there has been an increasing number of discussions about CM and extending various limits. It is a dynamic process which assumes intensive efforts directed towards continuous improvement, i.e. improving the existing and inventing new tools and techniques, starting with early activity-based costing models and pursuing lately in the direction of *strategic cost management* (SCM)- the use of cost data to develop and identify superior strategies that will produce a sustainable competitive advantage. In that period, the most prominent trend has been shift the focus from determining product costs by using standard traditional cost models, towards providing support for strategic and operational decisions by using certain forms of activity analysis.

New environment brings new challenges and problems which inevitably impose the need for serious reconsideration of past business philosophies of companies based on stable and foreseeable business conditions. Therefore, suggestions are heading towards the separation of cost accounting from traditional accounting, together with abandoning of the long sustained linearity of measuring historical costs and static standards. Only by integrating the internal and external aspects it is possible to provide quality information for strategic management of a modern company. The key point is flexibility - the cost accounting information system should be able to supply different data for different purposes. Practical application of some new solutions faces difficulties in developed countries as well, because of high investment and operational costs. It is particularly emphasized that, from the aspect of modern cost management, there is much left to be done in order to raise cost management to the highest level of the modern practices.

Our conditions are characterized, unfortunately, by underdevelopment and weak application in practice of the conventional as well as the new solutions for cost accounting. It is necessary to widen and deepen more intensively the existing theoretical and practical knowledge which will enable us to examine the wide focus of company cost and performance management and to recognize the right conditions for gradual development and implementation of new solutions along with the development of our economy. It also seems logical to ask the following question: How much do cultural features and mentality affect the implementation and efficient functioning of a particular solution? In any case, the new solution must be closely examined by the cost-benefit analysis which should clearly show whether the benefit of using particular information outweighs the costs of providing it.

EXPERTNESS IN BUSINESS PLAN DEFINING IN CRISIS CONDITIONS

Dragutin Dragojević¹ Snežana Lekić² Nada Vignjević-Đorđević³

Abstract: *The global financial crisis is caused by a structural disturbance, sudden lack of capital and a huge mass of liquid funds for the regular maintenance of economic trends in the world. Highly developed countries are threatened with the risk of long-term recession. In less developed countries, like ours, the global crisis has posed a much greater risk than a general financial collapse, due to limited resources to quickly overcome financial insolvency. For Serbia, the way out of financial crisis lies in a faster start-up of available unused national resources, where a relatively small investment project with new fresh capital can create new job positions in very short time, GDP growth and the fastest routing of new products and export services. The New Economic Development Strategy of Serbia depends on the skill and speed of running the huge resources available in the agricultural sector and industries that rely on the agricultural sector. The existence of more than 400,000 registered farms, along with several thousand small and medium-sized companies for the processing of primary agricultural products and logistical support, offers a real opportunity for a faster exit from the crisis. However, the available resources in the agricultural sector are still very limited with a range of products and services involving a higher degree of processing, which could be offered to our traditional foreign buyers. Even though there are conditions for the development of new export-oriented business ventures in Serbia, there is a lack of business ideas, knowledge and skills necessary to start such a business. In order to start new business ventures, hundreds of good business plans must be provided in a very short period. A business plan is an important document for providing necessary financial resources from the public funds or from commercial banks. In crisis conditions, it is difficult to choose an appropriate subject of a new business plan. Thus, the authors paid special attention to defining the optimal choice of subjects and a business plan in a crisis atmosphere. The expected effects of reducing unemployment and creating new jobs were not achieved with the activities of government institutions in underdeveloped areas in the agricultural sector with the financing from foreign grants. This is a limiting factor for a faster way out of the crisis and the promotion of rapid economic growth. It emphasizes the importance of the implementation of previous positive solutions to check market mobility of new programs, selection of the best technology and equipment with the lowest cost per unit, in order to achieve competitiveness in the market in a crisis situation. A good business plan is based on credible budgeting for the necessary financial resources, without which there will be no successful business. Proper analysis of the investment and business risk should provide security to entrepreneurs and owners of capital for investment given in the business plan. This research is primarily intended for current needs and implementation in practice, as a contribution to more rapid initiation of new economic activities in the agricultural sector meant to encourage the country's rapid exit from the current crisis.*

Keywords: *business plan, agricultural organizations, agricultural markets, financial incentives and new jobs.*

1. HOW TO GET GOOD BUSINESS IDEAS FOR CREATING AN EFFECTIVE BUSINESS PLAN

In the currently difficult economic conditions and tough competition in other businesses it is important, both for individual entrepreneur and a company, to possess the right knowledge and skills for organizing a successful business enterprise, if they want to survive in the market and make a profit. The main goal of any undertaken business is to gain profit.

Profit is realized when an entrepreneur or a company successfully operates, which means the best use of its available resources, contained both in mental and business acumen, their employees, all the material and financial resources engaged, in order to successfully place its products or services on the market at the lowest possible operating costs and by achievement of the highest possible income.

This includes well-designed and defined subject of a business plan as a starting point for achieving defined business objectives, particularly in the current crisis conditions. In the business plan, the limit point of return in a crisis atmosphere is best measured by establishing the relationship of fixed and variable costs in a

² Belgrade Business School - College of Professional Studies, Belgrade

³ Professor at State University of Novi Pazar.

planned and realized business. When defining the subject of a business plan, at the current difficult business conditions, this relationship is first to be checked. A company, whose total business organization is weaker, especially with inadequate market research, marketing and distribution, has higher fixed costs. Organization with higher fixed costs of its products and services per unit, will therefore increase its selling prices, become uncompetitive, lose its business arrangements, realize less revenue, operate with losses and quickly go into bankruptcy.

In crisis conditions, the definition of objects of a business plan is usually expressed as follows: Selection of an optimal subject of the business plan is correlated with the degree of successfully organized and achieved management of available resources, to become competitive on the market in order to achieve maximum sales impact and security of the long-term income and profit.

In practice this premise means that finding the product (s) or service (s) in the optimum extent based on previous market tests of demand volume and levels of sales price trends (sales) that could be placed under the best conditions, with the structure of the available resources (fixed and current assets), applied technology, expertise of employees and successful management.

2. THE KEY CHARACTERISTICS OF EFFECTIVE BUSINESS PLAN

Business plan is a key document for determining effective business and financial skills of legally organized company or its management in order to:

- start a new business undertaking or establish a new company,
- introduce the alternative business programme which is more competitive on the market and enables successful opposition to competition,
- enable business and financial consolidation of the existing company that sunk into financial difficulties due to the obsolescence of products or services, loss of markets, lack of funds and other weaknesses in the previous period, and
- Conduct planned expansion of existing operations, increase the capacities in order to meet increased demand of their products or services in the market and increase exports of goods and services.

An effective business plan, as an important starting business document of well-organized business enterprise is both a "tool" and a guide for the on-going management of successful entrepreneurial venture or business organization and is intended for:

- the entrepreneur who intends to initiate and conduct a new entrepreneurial venture,
- entrepreneur or legal entity that intends to develop new products and services, according to a prior assessment of market demand and the perceived intentions and actions by competitors,
- a legal entity that has decided to extend or change a registered business,
- Investors who intend to make investments in the purchase of new enterprises, plants, joint ventures, etc.).

An effective business plan is primarily intended for owners and management of the companies for reliable and secure planning of business activities and designing optimal business results. The aim of every business plan is to check the profitability of investment (financial) in business ventures, especially if they are subject to tough competition and difficult economic conditions.

3. THE STARTING POINT FOR EFFECTIVE BUSINESS PLAN IN CRISIS CONDITIONS

An effective business plan is usually prepared prior to the business and/or investment decisions. If this is done in critical conditions it is necessary to establish the main focus of activity of the crisis on the business entity (general illiquidity, an unfavourable investment climate, reduced purchasing power of population, significantly exceeding of the approved budget deficit, etc.). In such circumstances, an effective business plan seeks to use the best subject of future business activities, which will resolve the identified limiting factors for the successful continuation of business. Timely and proper selection of appropriate items of business plan provides the timely adoption of optimal business and/or investment decisions. This means that the business plan perceived correct directions of the projected business enterprise, and identified potential business and investment risks on time. Therefore it is possible to neutralize or minimize detected risks and set up adequate and safe business solutions.

In principle, an effective business plan is usually drawn in preparing loan applications submitted to banks or other lending institutions for timely provision of necessary short-term or long-term funding for the successful conduct of business. In the crisis situation other business purposes can be expressed, and primarily for

financial and business faster consolidation of the business entity, and define the appropriate exit strategy from the created of financial and economic crisis.

4. METHODOLOGICAL DIFFERENCES IN THE PREPARATION OF A BUSINESS PLAN

Tests conducted in 2011 and 2012 of actions on the training of unemployed people in undeveloped areas, which, with the help of foreign donations, should start own entrepreneurial ventures in agro-sector, based on the self-employment, showed that there had been many failures, why the goal - to reduce unemployment, has not been achieved. The main reason for not achieving the goal is that the official factors, foreign donors and consultants engaged to train unemployed people, do not perceive significant differences in the methodology for training persons in the development and use of effective business plans for new entrepreneurial ship and the establishment of new businesses, in relation to the methodology used to prepare business plans for existing businesses that have financial difficulties or need of expanding existing facilities.

In practice, there are important conceptual and methodological differences of preparation and drawing up effective business plans, for:

- a) New business ventures and the establishment of new companies,
- b) The purchase of the partial or complete facilities and enterprises,
- c) The change of the business venture orientation during downturns,
- d) For the business and financial consolidation of existing businesses, entrepreneurs or companies, which have come to financial difficulty, insolvency and continuing blockade of the current account of erroneous conduct of its work in the past?

4.1. Business plan for new business ventures,

Business plan for new business ventures, establishment of new entities and so, while preparing and drawing up an effective business plan focus the attention on the market research and finding the proper object of the intended venture. For the preparation of this type of business plan it is logical that a beginner first examines the market to which it intends to focus its attention, particularly in finding the right somersault of business and checks the market demand. This is the basis for determining its capabilities and ability for achieving planned sales and production of defined products or services. In doing so, it especially checks whether this increase in market demand represents current or permanent condition. It is also necessary to further determine the level of development of existing capacity and level of sales prices of other similar market players (competitors) in the local and global environment from the intended operation of the new program.

4.2. Business plan for the existing business ventures and existing companies

Business plan for the existing business ventures and existing companies is methodologically quite different from the initial entrepreneurial venture. The focus in this case is placed on analysis of current status, weaknesses and shortcomings of the existing organization. First, it is necessary to identify and analyse mistakes and perceived shortcomings in the use of available resources, then analyse the objective difficulties in placement of existing products or services, that occur due to technological obsolescence of products, tougher competition from other market players, adverse effects of economic measures that emphasize the import of products and restricting sales of national products, and the like. During preparation and assembly of this type of effective business plan attention is focused on research for alternative solutions to overcome arising difficulties, better use of existing resources, and quick improvement of the existing production technologies, improved business efficiency, in order to end the crisis and ensure profitable operations in the future. After examining the causes of such a situation and finding alternative solutions for the rehabilitation of future business, the following procedure is to conduction of detailed market research, assessment of market demand in order to redefine the business case, which will be then processed in the new business plan.

5. PARTICULAR ASPECTS OF DEFINING A BUSINESS PLAN IN CASE OF CRISIS CONDITIONS

An important feature for effective drafting of a business plan is to select the appropriate items of business enterprise, then determination of the appropriate scope of business activities and selection of the right methodological approach. Some banks and other financial institutions (Development Fund and similar institutions) determine for their loan claimants specific methodology for the preparation and presentation of effective business plans as a basis for reviewing and approving loans. Before preparation of the Business

plan, entrepreneur, business consultant, company management and others must first choose the institution to which they will address for securing the necessary funds.

In crisis conditions, providers of financial support require from the holder of an effective business plan to accurately describe the selected product or service, in order to test the comparative advantages of the offered items in relation to other market operators, subject to similar businesses. When describing the chosen item, the business plan should include, in particular:

- the main characteristics of products or services,
- the needs of customers for the selected product or service,
- the willingness of consumers to pay the projected cost of the product or service,
- Preparation technology on which the selected product is based and others.

In order to determine the possibility or chance of the selected product or service, there should be included the analysis of the situation in the industry or sector in which it operates, in order to resolve potential risks with appropriate modifications and other marketing measures.

6. THE IMPORTANCE OF TESTING MARKETING OPPORTUNITIES IN CRISIS CONDITIONS

Market research is very important and responsible task in preparing and drafting a business plan in a crisis conditions. Narrowed market demand due to reduced purchase options imposes more detailed examination and description of any significant market events that are related to the selected item of business plan. From the experience of good practice in critical operating conditions, careful market research should include:

- 1) Detailed assessment of characteristics of the selected product (service),
- 2) In particular, a detailed examination of the potential scale of market demand,
- 3) The verification of the formation of the selling prices of selected products or services,
- 4) Check the behaviour of competition:
 - Identify main competitors and their strength?
 - Identify their business strategy?
 - Consider the advantages and disadvantages relative to competitors in their own business?
 - Consider the production and sales capacity of competitors,
- 5) Check the selected sales methods and distribution channels that they intend to include in effective business plan,
- 6) Selecting the best advertising techniques to promote selected products or services provided in an effective business plan is one of the key elements for successful implementation of business ventures.

7. THE NECESSITY OF PRIOR ANALYSIS OF COMPETITION IN THE BUSINESS PLAN

Competition is a rivalry between alternative market entities that address the same group of customers, where each is trying in its own way to increase sales, marketing share and gaining higher profits. Competition is a latent (hidden) risk to a particular manufacturer and market subjects. Elements through which competition operates in the market are: volume, structure and size of bids, price and product quality, technology, capacity management, and financial and marketing power of the subject. The subject of research and proper analysis of competition in a crisis atmosphere directed primarily to offer their system (range, sale price, payment terms, the system of distribution and post sales service, display and use of marketing mix, market position). Based on the survey formed database includes: name of the entrepreneur or business entity, name of a competitor, location, program supply for market area in which it operates, technological capability and the like. The collected information relating to market share achieved in meeting the needs of customers needs to be fatherly analysed for the different market segments and key products, which are the subject of an effective business plan. It is also necessary to analyse the sales channels of competition, and how they cooperate with the customers, especially if they use discounts and the like.

8. SELECTION AND PRICE DEFINITION IN THE BUSINESS PLAN

The selection and definition of price is not a simple economic category. The economic entity, as the market participant trough defined by price can develop two types of strategies:

- a) A market strategy of price competition and
- b) A market strategy of non-price competition.

If the total costs of products or services (variable and fixed) represent a lower bound or "floor" price, then the level of market demand determines the upper limit or "ceiling" prices. Application of **pricing strategy** assumes that an entrepreneur or a company has mass production and low production costs. Sellers who implement this sales strategy are forced to have a policy of flexible sales price. Prices change due to changes in the structure of operating costs (increase of variable or fixed costs) or because of increased demand for particular products or services. Price changes are possible when the competition does so. The essence of pricing implies a good knowledge of market changes and the ways in which changes in market demand may influence the formation of different prices.

Strategy of **non-price** competition in the market applies to improving the quality of products or services over the competition, better and more attractive packaging, providing favourable conditions of sale, deferred payment or other services (free transport of goods or similar free installation and free services). In non-price marketing strategy vendors keep prices stable. Non-price market strategy is applied by entrepreneurs that previously positioned their products or services highly on market, using permanent maintenance of the high quality, better marketing promotions, additional services and other market activities...

9. THE FINANCIAL SEGMENT OF AN EFFECTIVE BUSINESS PLAN IN CRISIS CONDITIONS

The main objective of the establishment, commencement and conduction of any business ventures or the company is profit. Previously reviewed key financial parameters in the process of preparing an effective business plan (determined by structure of fixed and variable costs, marginal rate of income, the coefficient of possible sales charges, maintenance of the required coefficient of raw and finished products, materials, the coefficient of discharge of obligations to creditors, the expected rate of gross profit before taxation, financial liquidity and leverage, participation interest on the borrowed funds in the total income, etc..) determine the feasibility of a business venture, as to whether one could expect average earnings and return on total assets invested in a new businesses or financial consolidation of the existing business entity.

At the beginning of the preparation of the financial segment of an effective business plan it is necessary to make a realistic pre-estimation of the total funds required for the realization of the projected business enterprise. This amount usually includes: the amount of the excess, and the amount of missing funds (these funds are most often provided through banks loans, borrowed). Planning is done from the total amount of required financial resources - for which purpose it will be used. In this regard, it is necessary to:

- calculate the required fixed assets,
- calculate the necessary working capital,
- calculate the expected costs of all operations,
- estimate expected sales revenues,
- Make cash flow projections for the next 3 years.

To forecast the necessary financial resources it is very important to determine: the days for setting the time of sale, time of keeping the supplies and raw materials, reconciliation of accounts payable. In the following text we will present an example of model with integrated calculations of necessary financial resources, proven in practice for many years and accepted by many financial institutions that provide financial support to individually entrepreneurs and small companies.

10. THE EFFECTIVE PROCESSING MODEL OF FINANCIAL SEGMENT OF THE BUSINESS PLAN FOR THE PRODUCTION OF PACKAGING USED IN AGRICULTURAL PRODUCTS

It is assumed that the founders and co-owners of small company made the decision to prepare a business plan, to ensure the necessary resources for financing production of contemporary plastic packaging which will be used in the food industry. Previous market tests have shown that planned products are highly in demand due to the increased needs of industry for processing agricultural products intended for export.

After completing market research, major customers are defined, as well as their annual needs. Based on this, project of technology used for new plastic packaging is completed, and appropriate equipment was selected, and in connection with that, the technical, material and labour standards were established. An overview of the annual fixed cost for the company business is also determined. Based on the technical standards, the amount of material needed for productions are defined and preliminary contracts for the delivery concluded. According to the adopted technical, technological and labour standards, budget for necessary funds is being calculated (financial segment of the business plan), for the planned production volume. To calculate the necessary financial funds, for this example, we used defined parameters as follows:

- a) Projected annual sales volume of finished products is RSD 15.000.000.
- b) According to defined technical standards, direct costs are 40% of revenue from total planned sales
- c) Fixed costs amount to 20.40% against planned sales.

- d) Planned Amortization of permanent funds on average should be 10% per year
- e) Depreciation for the first year is covered by the planned fixed costs, and the rest is covered by the planned funds for the purchase of fixed assets.
- f) Sales financing are planned to be 30 days on average
- g) Funding of material, in accordance with the production technology and the on the dynamics from the contracts with suppliers, should be 85 days.
- h) Planed supplies of material for the beginning of the production are in amount of RSD 1.000.200.
- i) Planned purchases for the period in amount of RSD 6.300.000
- j) Provided supplies to the end of the period amounted to RSD 1.5 million, and are slightly increased due to the planned increase in production for the period
- k) The suppliers agreed to deferred payment terms for 20 days without interest
- l) The value of the acquisition of fixed assets in accordance to the business plan is RSD 2.5 million.
- m) The planned interest rate on the requested amount of the loan is 12% per annum.

Based on the previous parameters, the financial segment of an effective business plan includes:

- 1) Preparation of the projected income statement (check of business profitability),
- 2) The preparation of the budget for total funds required in business plan,
- 3) Checking the profitability and feasibility of an effective business plan
- 4) Preparation of the planned balance sheet in order to review the financial position and the certainty of return on invested funds
- 5) The preparation of the cash flow forecast to determine the ability of management to manage cash and generate invested money.

Here is the example for the preparation of financial segment of the effective business plan:

THE MODEL OF CALCULATION OF NECESSARY FINANCIAL RESOURCES

I) PLANNED INCOME STATEMENT

1. Projected sales revenue		15.000.000
Less direct costs:		
- materials (40% of No.1)	6.000.000	
- gross wages (20% of No.1)	3.000.000	
Total direct costs	9.000.000	9.000.000
2. Marginal profit		6.000.000
Less:		
- Fixed costs (20,40% of No. 1)		3.060.000
3. The planned operating profit (margin)		2.940.000
Less:		
- Borrowing costs (12% per annum, 60% of No. 9)		351.666
4. Net profit before taxation		2.588.344

II) PROJECTION OF NECESSARY ASSETS

5. Financing the purchase of fixed assets (2.500.000 – 250.000)	2.250.000	
6. Financing sales (15.000.000 x 30 days / 365)	1.232.877	
7. Funding maintenance of supplies (stocks)		
- initial stocks	1.200.000	
- supply in the period	6.300.000	
total	7.500.000	
- final stocks	1.500.000	
Net consumption of materials (7.500.000 x 85 days / 365)	6.000.000	1.746.575
		5.229.452
8. Use of the funds from suppliers (6.300.000 x 20 days / 365)	- (345.205)	
9. The total planned engagement of the funds	4.884.247	4.884.247
10. NET FUNDS NEEDED		2.295.913
Turnover ratio for engaged funds	3,07	Equity
The planned rate of net profit	17,26%	Loan
		918.365 40%
		1.377.548 60%

The rate of return on total funds invested 52,99%

III) PROJECTED BALANCE SHEET

A) ASSETS		
I. FIXED ASSETS		
- Purchase value	2.500.000	
- Depreciation	<u>250.000</u>	
- Current value	2.250.000	2.250.000 (1)
II CURRENT ASSETS		
1. Stocks	1.500.000 (2)	
2. Receivables from debtors	1.232.877 (3)	
3. Cash	<u>246.575 (9)</u>	
Total current assets	<u>2.975.452 (8)</u>	
Less:		
III CURRENT LIABILITIES		
4. SUPPLIES CREDITORS	<u>- (345.205) (4)</u>	
NET CURRENT ASSETS (NCA)	2.634.247 (7)	<u>2.634.247 (6)</u>
TOTAL FIXED ASSETS + NCA		4.884.247 (5)
Less:		
IV LONG-TERMS LOAN FOR BUSINESS PLAN		
		<u>1.377.548 (10)</u>
NET ASSETS OF THE OWNER		<u>3.506.699 (11)</u>
B) LIABILITIES + EQUITY		
1. Initial capital		1.280.731 (14)
2. Net profit after taxation (2.588.334 x 14/100)		<u>2.225.968 (12)</u>
TOTAL OWNERS EQUITY		<u>3.506.699 (13)</u>

IV) PLANNED BALANCE OF CASH FLOW

A) CASH FLOW FROM OPERATING ACTIVITIES		
1. Gross profit from the planned operation		2.588.334
2. Non-monetary activities included in gross income		
2.1. Receivables from debtors	- (1.232.877)	
2.2. Stocks	- (1.500.000)	
2.3. Liabilities to creditors	<u>+ 345.205</u>	
Total	- (2.387.672)	<u>- (2.387.672)</u>
3. Net cash flow operating activities		+ 200.662
B) CASH FLOW FROM INVESTING ACTIVITIES		
4. Investment in buildings	-	
5. Investment in equipment	<u>- (2.500.000)</u>	
Net cash flow of investing activities	- (2.500.000)	- (2.500.000)
C) CASH FLOW FROM FINANCING ACTIVITIES		
6. Loan for business plan	1.377.548	
7. Equity	+ 1.280.731	
8. withdrawal of funds	<u>- (112.366)</u>	
Net cash flow from financing activities	2.545.913	<u>+ 2.545.913</u>
		+ 246.575
D) INCREASE - DECREASE IN CASH		
9. Opening balance		<u>0</u>
10. Cash at the end of period		<u>246.575</u>

10.1. The rating for financial segment of the business plan

The presented methodological approach for processing the financial segment of the business plan makes it possible to establish the first anticipated profitability of the business enterprise. In this example, the planned income statement states that the marginal profit rate is 40%, which corresponds to a highly profitable business. The production of contemporary plastic packaging for food products is therefore profitable venture.

After determining the profitability of the planned business venture, the next step is to make the projection of the required financial resources, as a key segment of the business plan.

From the above stated parameters, a relatively small number of sales financing days is determined, which requires verification of the actual situation regarding the degree of collection of revenue from product sales. Preparation of the budget shows the existence of critical points of the items for required funds in the part relating to the financing of the volume of material production, due to the greater the number of days for keeping the stocks, prior to use in the manufacturing of the plastic packaging.

Number of inventory turnover days for the production of materials is determined by the structure of sources of supply of key materials. The total volume of stocks at highly automated production, such as the production of plastic packaging for the food industry, depends on the length of time for delivery of the last of components, especially those purchased abroad, with the prolonged delivery.

10.2. Reading and understanding of financial statements of the business plan

Checks and controls when developing and implementing an effective business plan include reading and mastering the skills of financial information. Introduction of accounting categories and logic, allows efficient evaluation of business projections made in the business plan, comparing the obtained results with those of other businesses, particularly in the following financial categories:

- a) Relation of fixed and current assets (to avoid excessive immobilization of funds)?
- b) Relation of long-term and short-term liabilities (to achieve greater financial liquidity)?
- c) The structure of equity (in order to strengthen the equity and financial position)?
- d) The structure of debt (principal and interest payments)?
- e) Relations of fixed and variable costs (for maintenance of rational organization of entities)?
- f) Relations of direct and indirect costs (for monitoring the efficiency of business)?
- g) Analysis of the calculated costs of products or services (in order to maintain competitiveness)?
- h) Analysis of the balance sheet for maintenance operations or financial position of the company,
- i) Analysis of the income statement - revenues, expenses, profit or loss (to maintain profitability)?
- j) The analysis of cash and cash management (to improve financial liquidity)?

11. WHAT IS NOT INCLUDED IN FIGURES IN THE BUSINESS PLAN

In financial calculations and financial information we cannot see, but, between the lines of a business plan, we can read following:

- the business skills of owners, entrepreneurs and management of a business entity,
- quality of organization and certainty of business success in the future,
- future demand for specific products and services company,
- The certainty or uncertainty of future operations (expected bankruptcy and bankruptcy).

As a rule, if the company's business - the business entity is simple or a smaller scale, the accounting data are less complicated, more efficient, more accurate and reliable for use. Financial accounts are usually prepared in a manner that would be adapted and prepared for a tax audit, which has been recently very present and represents a limiting factor for the proper and accurate preparation of financial budgets, business plans and preparation of new strategies that should ensure faster emerging from the crisis and boost future business development, increase revenue, net income and dividends.

Abstract: *This document presents a system of programming budgeting, that is a model management with a goal to establish relations between engaged and proposed resources, in fact achieved results. Special attention is dedicated to the needs as well as to the achieved results of the applied model in order to dispose rationally and finally to efficiently conduct determined tasks.*

Keywords: *programming budgeting, development, resources, management, defense system.*

1. INTRODUCTION

Changes in society and therefore in state, that occurred in the last decade of the 20th century and in the first decade of the 19th century, have influenced by the fact that the rooted attitudes and opinions have changed within the society which are a reptil of old times when it was thought that the education and defense are too important from a political, sociological and human aspect to be able to undergo some kind of economic calculations. On the contrary, in the today's situation, management structure of the system of defense must act immediately and make concrete decisions according that and, also, being faced with the problem of limited resources.

The additional problem for the defense system of the early 21st century, is that the previous system of financial resources, particularly budgeting, was not sufficiently effective and did not corespond to the complex requirements that were demanded of the management structure of the defense system of Serbia. The planning area of the defense system of Serbia was largely undeveloped and the need to regulate this in a qualitatively new basis was reported as an imperative. There were no mechanisms to provide sufficient information if the planned goals and objectives of the defense system would successfully implemented, and whether if an appropriate allocation of the resources for the realisation of the planned objectives would carried out.

Managing of financial resources was reduced to an allocation of available financial resources, without interconnections between the tasks of defense and financial plans. Also, there is problem of converting strategic objectives into financial plans that can be linked to budget resources. The fact is, of course, that many aspects of pre-defined objectives are implemented within the regular activities in the defense, but without feedback.

Financial planning, mechanisms for the preparation of financial plans and regulations for their enforcement haven't, until recently, provided sufficient information on whether the defined objectives have implemented successfully in practice. Because of this it was very important to improve the links between financial plans and strategies, to provide appropriate mechanisms for monitoring the effectiveness of their implementation and consideration of future needs. The introduction of functional programmatic dimension into the existing budget classification was one of those mechanisms.

The modern view and the view of overcoming problems of increasingly limited incomes also in the public sector of the Serbian government, found the solution in the 'budget directed to results' or program budget⁴. The role and place of the state in financing defense system is characterized by compromise in conflict resolution: to achieve the defined goal with minimal financial investment. The cause of this discrepancy is primarily the needs of the various growth opportunities that defense functions of the state require and its limited material and financial resources. However, the government of every state is obliged to, on the one hand, consider the economic situation of the country, and on the other hand, to give stable defense system, rationally using limited resources.

⁴ Program budgeting is based on the concept, methodology and practice of cycle management in project oriented organizations and recommendations of possible solutions of that model in the organizations of functional type in which belong the institutions of state administration.

Management structures of the defense system, as an integral part of society and its problems were faced, already in the 20th century and in the first half of 21th century, on the one hand, with the problem of transmission of liabilities from year to year, rising debts to suppliers, costs of court judgements for the delay in payments, penalty and interests for late payments of accrued liabilities, and on the other hand, with limited and insufficiently available financial resources. What necessarily required news and changes in management of financial and other resources of defense.

The significant changes have been implemented in the system of defense of The Republic of Serbia in recent years. The overall objective of the changes is the transformation of the system in line with modern security challenges and threats, that is needs and opportunities of The Republic of Serbia.

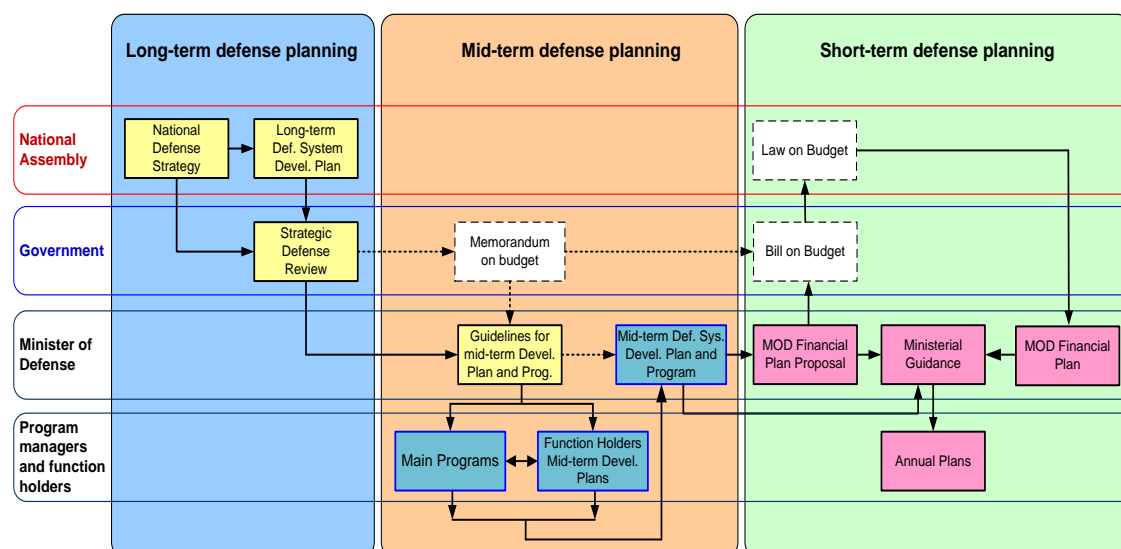

In order to ensure continuous growth in the quality of defense capabilities, increase efficiency of execution of the defense tasks, rational use of available resources, ensuring adaptability and flexibility of the process executing the defense tasks and coordination of development components of the defense system with the overall development of the State in the Ministry of Defense and the Army of Serbia in 2008. the system of planning, programming, budgeting and execution (PPBE) was introduced as a new management system of defense resources and in the final funding of developing programs and projects of defense system.

2. BUDGETING ANALYSIS OF DEFENSE SPENDING BEFORE AND NOW

Planning of the development of the defense system in the period before the introduction of program budgeting model was disintegrated and there was no continuity in the planning process. The development plans were made by the the office holders of the defense system each of them for themselves individually. Disintegration of planning functions, that existed before the introduction of a new defense resources management process, was a reflection of the existence of a large number of office hlders dealing with problems of planning. A particular problem was reflected in the lack of legislative and normative framework that would regulate this area.

Integration of the functions of development planning of the defense system, as it introduced a model known as program budgeting system PPBE, contributed to increase the overall performance of the Ministry of Defense and the Army of Serbia, because the defense system is viewed as a whole, fortified with all the tasks and resources required for their completion. Of course, the global financial crisis further complicates the problem, because the fundings for the tasks laid down by the Ministry of Defense and the Army of Serbia is getting more and more restrictive.

Decision makers in the defense system chose to introduce an integrated system of defense resource management, in order to bridge the created situation and to coordinate the requirements of the defense system and the possibilities of our society. Due to adoption and implementations of the PPBE system, integration of planning function as a first stage in the process of defense resource management comes into play.

Picture 1: Model of Serbian Defense Planning-now

Continuity in the programming phase is ensured with the development and adoption of long-term development plans of the defense system on which the medium term plans and development programs are made, which later serve for the development and implementation of short-term plans. Planning model which is represented in the defense system of the Republic of Serbia in 2011. is presented in picture 1.

Long-term planning is the process of setting objectives of the defense system for a longer period of time, as well as methods for their implementation. The long-term defense planning is an interdisciplinary process that involves many different activities. Activities are mutually dependent and precise coordination is needed. An interdisciplinary approach to planning requires close cooperation between the planners and military commanders, various specialists, political authority, etc.

The purpose of long-term defense planning is to consider the mission and tasks of the defense system and to establish realistic long-term objectives adjusted to the missions and tasks, as well as to determine the strategy of its realization. Long-term planning is oriented toward the relatively distant future and that represents a problem for planners as they face many difficulties that are the consequences of uncertainty in the future. Also, long-term defense planning should enable the appropriate development of defense system and avoidance of unwanted effects.

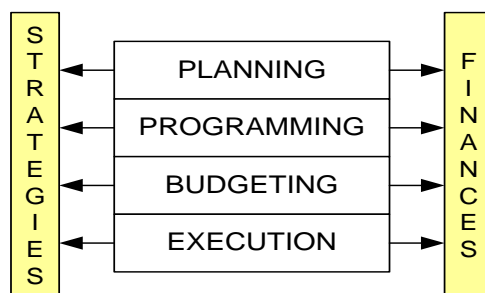

Medium-term planning is the process of determining the objectives of the defense system for medium-term planning period and the ways of their implementation. The objectives and priorities are determined by factors of development capabilities of the defense system that need to be realistic, purposive, implementable, measurable, time limited and classified according chronological and logical sequence.

Short-term planning is part of an integrated planning process that operationalized the medium term planning. In the defense system of the Republic of Serbia it includes a one-year planning period. Successful implementation requires the preparation of annual plans of a number of different plans that are different in content, level of detailing, the time interval covered etc.

3. PROGRAMME BUDGETING EXPENDITURE OF THE DEFENSE SYSTEM

In the public sector reform and within it performance-based budget or PPBE system, expenditures are classified according to programs and projects, operational objectives of each program are determined, and performance indicators are established for each program and activity. PPBE system is one of the important components of a wider process of reform of public finances. Specifically, it means the introduction of an effective mechanism for monitoring the achievement of defined objectives.

In the current environment of public finances, it is difficult to translate strategic objectives into operational plans and projects of development of the defense system, which can be linked to the budget means (picture. 2). The fact is, of course, that many aspects of already defined objectives are being implemented within the ordinary activities of direct budget funding.

Picture 2: Converting strategic objectives into financial plans

However, operational planning, mechanisms for the preparation of financial plans and rules for the enforcement of them, within the line budgeting, which was represented by 2008. in the defense system, did not provide enough information about whether the defined objectives are being successfully implemented in practice. It was therefore important to improve the links between financial plans and strategies in order to provide appropriate mechanisms for monitoring the success of their implementation and consideration of future needs.

Therefore, the program budget is a comprehensive system of defense resource management - a system of monitoring results (performance management system). Key feature of the program budget is in a change of

budget focus from budgetary commitments on short-and long-term results and reached objectives of the defense system.

However, limited resources imposes, in fact, wanted it or not, accepting different, basically an economic standpoint, which is characterized by:

1. the need for the best utilization of resources available for the specific purpose
2. the influence by the consequences of decisions in the present to a quality of development in the future
3. the necessity to be efficient, which correspond to a care that the set objectives achieve with adequate real available resources and
4. the obligation to legally dispose and permanently control the expenditure of resources for implementation of planned needs.

To increase the efficiency of the management structures of the defense system, changes in the sphere of budget expenditures were necessary, just because of limitation and scarcity of available funding. Otherwise the time and attention of management structures would be focused on securing funding for a reconciliation of the regular needs of defense and would be lost to the efficiency of doing the basic tasks.

4. SECTOR PROGRAMS AS AN INOVATIVE WAY TO BUDGETS EXPENDITURES OF DONATIONS OF DEFENSE

Defense expenses are financed by funds from the budget and donations from the European Union through Sector Approaches (also known as Sector Wide Approaches – SWAs). Sector Approaches are usually seen as programme-based approaches (PBA) operating at the level of a sector. PBA is defined as follows:⁵

A programme-based approach (PBA) is a way of engaging funds EU in development sectors programme, such as a National defence strategy, a sector programme, a thematic programme or a programme of a specific organisation (defence).PBAs have the following features:

- ✓ leadership by the host country;
- ✓ a single comprehensive programme and budget framework;
- ✓ a formalised process of donor coordination and harmonisation of donor procedures for reporting, budgeting, financial management and procurement end
- ✓ efforts to increase the use of this systems for programme design and implementation, financial management, monitoring and evaluation.

The European Commission (EC) is committed to delivering "more and better aid" for "legitimate strategies". One of the legitimate strategies is National defence strategy.

Sector approaches or sector-wide approaches (SWAs) are processes aimed at the development of coherent sector policies and strategies. They involve governments, donors and other sector stakeholders in a unified process and framework.

As mentioned above, EC decisions about whether and how to support a sector programme are based on assessments in seven key areas:⁶

⁵ European Commission, (July 2007).Guidelines for ec support to sector programmes – short version, p.23-30

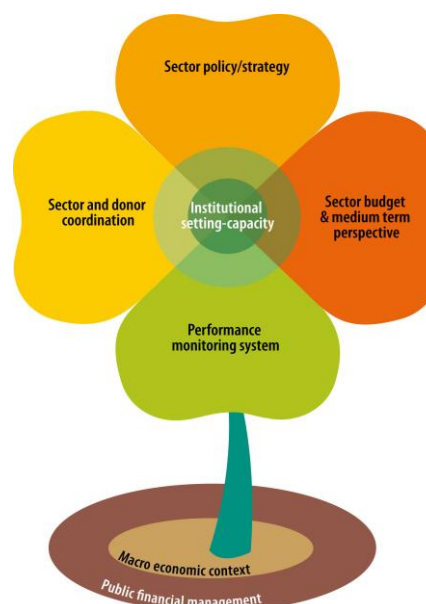

⁶ European Commission, (July 2007).Guidelines for ec support to sector programmes – short version, p.27-35

The five elements of a sector programme

1. The sector policy and overall strategic framework
2. The budget and its medium-term perspectives
3. Sector and donor coordination systems
4. The institutional setting and existing capacities
5. Performance monitoring

And the two additional elements influencing the sector programme's performance

6. The macroeconomic framework
7. Public financial management (PFM) systems

Limitations EC provide an insight into the basic concepts that are relevant to each assessment, identify key issues to be addressed and point to additional sources for more detailed guidance. The aim is to assist programme managers throughout the cycle of operations of EC support in reviewing the quality of sector programmes and deciding on appropriate support modalities.

Assessment of these areas would start during the programming and identification phases of the sector politics cycle, with the analysis then being completed during formulation. During implementation, these assessments would also need to be updated regularly in order to keep abreast of developments in the sector politics and each of the areas.

There are many overlaps between these assessments (for example, there are obvious connections between sector expenditure strategy, the macroeconomic assessment and the review of public finance management; all the other assessments may feed into the institutional and capacity assessment, and so forth).

Also, many of the assessments are also required for other aspects of EC work (e.g. a macroeconomic assessment will have been undertaken as part of limits preparation and to support any sector politics and so on. Those working on analyses should first of all draw on given limits, and if necessary update, existing assessments. Wherever there are relevant preexisting studies and materials, these should be drawn upon.

When it is possible, the EC works jointly with other donors, as well as with the partner government, on such assessments, and does so in ways that support the development of partner country capacity. The assessment required at the design stage of an politics sector is part of a continual process of monitoring and review of key issues. There are few, if any, absolute criteria involved in the assessments. Balanced judgements are required, which identify opportunities as well as risks, and which assess the direction of change as well as current levels of performance.

5. CONCLUSION

The introduction of the new model of program budgeting, situation in the field of management of defense resource is changing drastically. Namely, there is a process that takes place continuously. All plans and programs are integrated into one unit. The financial plan of the defense, as a function of plan holders, serve to establish a connection between the proposed appropriation of resources and results achieved. Mechanisms for monitoring the implementation of goals achieved are being introduced, which is advantage compared to the state so far.

The system of financial management of defense resources is becoming a complex, dynamic, interoperable, and integrated process. The main purpose of this process is management of maintenance and capacity building of the Ministry of Defense and the Serbian Army to achieve the defense objectives of Serbia. Finally, the purpose of defense resource management process is the provision of conditions for achieving the mission and tasks of the defense system.

However, the process of resource management is not just a technical procedure, but also an important political process. In the event that there is no political will and consistency in terms of sustainability of the planned and predicted values, there is a risk that the budgeting process could turn back into the allocation of available financial resources, as it has been the case until the year of 2010.

MEASURING FINANCIAL DISTRESS OF "VELEFARM" AD BELGRADE, USING ALTMAN Z-SCORE MODEL

Abstract: *The study of bankruptcy is becoming more relevant regarding the fact that even large companies are failing and therefore causing economic and social problems to the society. Using financial distress models to predict failure in advance is for most businesses absolutely essential in their decision making process. Hence, this study involves a critical investigation in the process of applying the Altman Z-score model in predicting financial distress in Serbia. The Altman model was developed in a different economic environment, time horizon, industry and country. Testing this model in the Serbia context is important for determining practical applicability and relevance of the model. The main objective of the study is to test the Altman model in determining practical predictive ability of failure in selected company - Velefarm AD, Belgrade, listed on the Belgrade Stock Exchange and to comment on the model applicability according to the empirical results. The data in the research consist of financial statements of Velefarm AD for the period of 2008-2010. The study is designed into three sections. The first section will discuss the theoretical aspects of the study. The second part will be the discussion of the research results, and finally the conclusion and recommendations of the study will be presented. Based on the conducted empirical research over financial statements of Velefarm AD, Z-Score model predicts bankruptcy for this company. The empirical results are interesting since they can be used by company management for making financial decisions, by regulatory authorities and by portfolio managers in stock selection.*

Keywords: *financial ratios, bankruptcy, Z-Score model, Altman, financial statements*

1. INTRODUCTION

Disclosure of the fact that the company is about to collapse represents fundamentally important knowledge which allows following the development of finance - threatening phenomena which might become a threat to the company's existence. It is important to have general financial outlook, methodology for monitoring the phenomenon and the people responsible for such monitoring and reporting the findings, along with the opinion about the implications and recommendations for dealing with the problem. Instruments for monitoring the emergence of financial distress represent the set of analytical tools that can be used alone or in combination. Financial distress is the situation when a company does not have capacity to fulfill its liabilities to the third parties (Andrade & Kaplan, 1998).

In making an investment, investors need to know how much risk they are taking. This paper attempts to answer how can we predict which businesses are likely to go bankrupt? About 40 years ago, Edward I. Altman set out to answer this question. Altman, then a financial economist at New York University's Graduate School of Business, developed a model for predicting the expectancy that a firm would go bankrupt. His model uses five financial ratios that combine in a specific way to produce a single number (Milojević, 2012). This number, called the Z-Score, is a general measure of corporate financial health. Later, Altman developed a modified version for private manufacturing firms and a second version for use by all businesses (Muller, 2008). This article describes the first original version, which is easy to use in Excel or similar application.

For this study, Altman Z-Score model is applied to Velefarm AD, Belgrade, one of the the biggest wholesaler of medications and medical products in Serbia, which is listed on Belgrade Stock Exchange since 2003. The data in the research consist of financial statements of Velefarm AD for the period of 2008-2010 (BELEX Belgrade, 2012). The study is focus on the potential bankruptcy of Velefarm AD.

2. ALTMAN Z-SCORE MODEL

The Z-score model of Edward I. Altman which was created at the end of the 60's of the last century. It attracted the attention of experts and was greeted with hope that it can be a very important tool for early detection of financial distress.

The intention of the model authors was to give investors an opportunity to evaluate (with one expression) status of financial distress, which might be better described as the probability that the company will enter into insolvency and threat to its existence (Gruszczynski, 2004). It is known that in evaluating the financial condition of a firm we can use many indicators based on the correlation between the two categories (ratios). Over time, these ratios drastically increased and those numbers alone have led to confusion. In a variety of ratios user does not have a clear idea on which to rely. In other words, an important issue emerged: Which ratio of gives reliable information on the status of the debtor? In response to this question Altman made the interesting structure which he called Z-score. Z-score model is based on a number of other terms, and all these expressions are in circulation in the financial professional community. Z-score model is an expression by which investors can make reliable investment decisions or judgments about whether their investment is safe or compromised.

Based on the above results, it is suggested that the Z-Score model is an accurate forecaster of failure up to two years prior to distress and that accuracy diminishes substantially as the lead time increases.

Z score bankruptcy model:

$$Z = 1,2X_1 + 1,4X_2 + 3,3X_3 + 0,6X_4 + X_5 \quad (1)$$

Original z-score component definitions variable definition weighting factor:

where X_1 = Working Capital / Total Assets

X_2 = Retained Earnings / Total Assets

X_3 = Earnings Before Interest and Taxes / Total Assets

X_4 = Market Value of Equity / Total Liabilities

X_5 = Sales / Total Assets

Z = overall index.

X_1 , Working Capital/Total Assets.

The working capital/total assets ratio, is a measure of the net liquid assets of the firm relative to the total capitalization. This ratio measures liquid assets in relation to the size of the firm. Working capital is defined as the difference between current assets and current liabilities. In general, a firm experiencing consistent operating losses will have shrinking current assets in relation to total assets. This ratio proved to be the most valuable liquidity ratio ever evaluated (Altman, 2000). Company which doesn't have sufficient working capital is handicapped and vulnerable to financial stress. Lack of working capital inevitably lead to insolvency.

X_2 , Retained Earnings/Total Assets

Retained earnings is the account which reports the total amount of reinvested earnings and/or losses of a firm over its entire life. It measures profitability that reflects the firm's age and earning power. The account is also referred to as earned surplus. It should be noted that the retained earnings account is subject to "manipulation" via corporate quasi-reorganizations and stock dividend declarations. The age of a firm is implicitly considered in this ratio. For example, a relatively young firm will probably show a low Retained Earnings/Total Assets ratio because it has not had time to build up its cumulative profits. Therefore, it may be argued that the young firm is somewhat discriminated against in this analysis, and its chance of being classified as bankrupt is relatively higher than that of another older firm, ceteris paribus. The incidence of failure is much higher in a firm's earlier years. In addition, this ratio measures the leverage of a firm. Those firms with high Retained Earnings, relative to Total Assets, have financed their assets through retention of profits and have not utilized as much debt.

If the balance sheet shows both retained earnings and a loss, we will take the difference between retained earnings and a loss. This difference can be negative, which will happen when the retained earnings are less

than the loss. In this case, the ratio between loss and total assets is negative as well. When the company shows only the loss in the balance sheet, then the Retained Earnings/Total Assets ratio is negative, too.

X_3 , Earnings Before Interest and Taxes (EBIT)/Total Assets.

This ratio is a measure of the true productivity of the firm's assets. It recognizes operating earnings as being important to long-term viability. Since a firm's ultimate existence is based on the earning power of its assets, this ratio appears to be particularly appropriate for studies dealing with corporate failure. Furthermore, insolvency in a bankrupt sense occurs when the total liabilities exceed a fair valuation of the firm's assets with value determined by the earning power of the assets. Altman (2000) point out that „this ratio continually outperforms other profitability measures, including cash flow“ (p. 11).

Although financial reports in Serbia are in compliance with IAS/IFRS, Earnings before interest and taxes need to be adjusted, with respect to the fact that distribution of positions within the income statement in Serbia differs from its equivalents in the USA. Earnings Before Interest and Taxes represents gross profit increased by interest expenses. However, if instead of a gross profit they achieved a loss, then the loss is subtracted from interest expenses, and that means that this result could be negative, which happens when the loss is greater than interest expenses. In that case, Earnings Before Interest and Taxes/Total Assets ratio is, also, negative.

X_4 , Market Value of Equity/Book Value of Total Liabilities

Equity is measured by the combined market value of all shares of stock, preferred and common, while liabilities include both current and long term. The measure shows how much the firm's assets can decline in value (measured by market value of equity plus debt) before the liabilities exceed the assets and the firm becomes insolvent. This ratio adds a market value dimension. It also appears to be a more effective predictor of bankruptcy than a similar, more commonly used ratio; net worth/total debt (book values). There is added Dimension of Market so, even if the market capitalization is higher and more sustained, confidence in the soundness of the financial position of the company is greater.

X_5 , Sales/Total Assets

The capital-turnover ratio is a standard financial ratio illustrating the sales generating ability of the firm's assets. This is a standard measure for total asset turnover which varies greatly from industry to industry. It is one measure of management's capacity in dealing with competitive conditions. This final ratio is quite important because it is the least significant ratio on an individual basis. However, because of its unique relationship to other variables in the model, the sales/total assets ratio ranks second in its contribution to the overall discriminating ability of the model.

Table 3: Relative contribution of the variables

Variable	Coefficients	Percent (%)
X_1	1,2	16,00
X_2	1,4	18,67
X_3	3,3	44,00
X_4	0,6	8,00
X_5	1,0	13,33
In total: X_1 to X_5	7,5	100,00

The above formula clearly shows that the author does not give equal importance to all factors. According to the above mentioned the top priority goes to X_3 - Earnings Before Interest and Taxes/Total Assets., followed by X_2 - Retained Earnings/Total Assets, then X_1 - Working Capital/Total Assets, then X_5 - Sales/Total Assets and finally X_4 - Market Value of Equity/Book Value of Total Liabilities with the lowest coefficient.

According to this model, zones of Discrimination are:

- $Z > 2.99$ -“Safe” Zones, this means bankruptcy risk is low. The higher the score, the better the company's chances of avoiding bankruptcy.
- $1.81 < Z < 2.99$ -“Grey” Zones, bankruptcy risk is possible, but not likely in the near-future
- $Z < 1.81$ -“Distress” Zones, bankruptcy risk is high.

In its initial test, the Altman Z-Score was found to be 72% accurate in predicting bankruptcy two years prior to the event, with a Type II error (false positives) of 6% (Altman, 1968). In a series of subsequent tests covering three different time periods over the next 31 years (up until 1999), the model was found to be approximately 80–90% accurate in predicting bankruptcy one year prior to the event, with a Type II error (classifying the firm as bankrupt when it does not go bankrupt) of approximately 15–20% (Altman, 2000). Over the time, the Z-scores gained wide acceptance by auditors, management accountants, courts, and database systems used for loan evaluation (Eidleman, 1995).

The Z-Score is not intended to predict when a firm will file a formal declaration of bankruptcy. It is instead a measure of how closely a firm resembles other firms that have filed for bankruptcy. It is a measure of corporate financial distress, a measure of economic bankruptcy.

Z-Score model weaknesses are:

- A prerequisite for any serious analysis of financial statements and therefore the prediction of bankruptcy, is that the financial statements are examined by an independent auditor. In the case of poor quality and unreliable financial information, Z-score test is useless and this model can't be compensated for deficiencies in the quality of financial information.
- Companies that have a low EBIT level have no chance of success when it comes to this test. Hence so much emphasis on state EBIT ratio by 3.3 (Kidane, 2004).
- This model does not take into account the issue of cash flow despite the fact that a cash flow represents a basis for payment and maintaining liquidity and safety. We should bear in mind the fact that cash flow is given significant attention only recently, and at the moment when the model was created, was not largely popular.
- Although this model is directed towards the future since it is designed as a tool for assessing companies bankruptcy, it takes into account only the historical data while any predictions of the future have no place in the model.

And yet, despite these concerns, the original Z-Score model is the best-known and most widely used measure of its kind (Pranovo, Achsani, Manurung, Nuryartono, & Nunung, 2010). This measure is not perfect, but it's easy to calculate in Excel and many practitioners continue to find it useful.

3. APPLYING THE ALTMAN Z-SCORE TO VELEFARM AD

Joint-stock Holding Company Velefarm Belgrade (hereinafter also referred to as Velefarm AD, the Company) is one of the the biggest wholesaler of medications and medical products in Serbia. Velefarm AD is the partner of biggest domestic and international producers of medications, medical equipment, medical devices, parapharmaceuticals, and specialized medical programs products. Velefarm AD has region-wide distribution network in Serbia, Bosnia and Herzegovina (Republika Srpska) and Montenegro. In the year 1999 Velefarm AD was the first Serbian company in the industry to implement a certified quality management system. The Company owns the largest, cutting edge storage facilities equipped with specialized chambers (VELEFARM AD, 2012). At the end of 2010., the Company had 142 employees.

Velefarm AD is listed on Belgrade Stock Exchange since 2003.

Velefarm AD seems like a good candidate for applying the Z-score given the size and reputation of the company, and the fact that there are evident signs of poor performance in the previous three years. Namely, the company has for years benefited and then in 2009 it began to suffer a great loss. The net loss for 2009. was RSD 2,108,178 thousand (approximately EUR 21,986 thousand), and net loss for 2010. was RSD 2,716,458 thousand (approximately EUR 25,749 thousand). At the time of writing this paper, data on financial results for 2011 were not yet known.

Auditor of the company is in Independent Auditor's Report on Financial Statements of Velefarm AD as of and for the year ended 31 December 2010, draw attention to the following matters: the Company operates with a shortage of permanent capital and working capital, The Company incurred a net loss of RSD 2,716,458

thousand during the year ended 31 December 2010, the Company's operations are burdened with the consequences of the global financial and economic crisis, which has a negative impact on the activities of a significant number of companies in Serbia and Europe. These conditions indicate the existence of a material uncertainty which may cast significant doubt about the Company's ability to continue as a going concern.

The company is in the process of negotiations over the restructuring of contractual obligations to creditors and suppliers and in the process of finding new sources of long-term finance.

Stock market price of the company also indicates a bad situation and which amounted to RSD 1,000 on December 31, 2010 and on the same date in 2009 same stock was worth RSD 2,444, and only a year earlier (in 2008, last year when the company had positive financial result) market price of shares was RSD 3,280. The latest data from the Stock Exchange from December 31, 2011, which amounts only RSD 300 per share, indicate a deepening distrust of the company and pessimistic forecasts about the recovery of the company in 2012.

In this situation, it is interesting to see the results of Z-Score model for the observed firm based on data from financial statements available for the last three years (2008-2010). The results are shown in Table 2.

Table 2: Z-score test of Velefarm AD

Variable	2008	2009	2010
X_1	$13,175,917/26,549,931 = 0.4963$	$3,555,457/16,614,687 = 0.2140$	$1,564,220/13,879,356 = 0.1127$
X_2	$160,724/26,549,931 = 0.0061$	$(4,656,102)/16,614,687 = (0.2802)$	$(7,013,266)/13,879,356 = (0.5053)$
X_3	$1,534,900/26,549,931 = 0.0578$	$(137,185)/16,614,687 = (0.0083)$	$(1,527,868)/13,879,356 = (0.1101)$
X_4	$5,113,831,600/20,401,092,000 = 0.2507$	$1,559,095,000/13,690,321,000 = 0.2783$	$1,559,095,000/13,684,357,000 = 0.1139$
X_5	$9,845,659/26,549,931 = 0.3708$	$5,402,261/16,614,687 = 0.3251$	$2,009,966/13,879,356 = 0.1448$
Z score:	1.316	0.3292	(0.7224)

Negative Z-Score shown in the obtained results can also be displayed graphically:

Figure 1: Z-score of Velefarm AD, Belgrade (2008.-2010.)

Based on the above results shown in Figure 1, all of the observed ratios show a deteriorating trend. In the observed period, calculated Z-score was in "Distress" Zones ($Z < 1.81$). The Z-Score model forecasts that Velefarm AD is approaching bankruptcy. Negative trend indicates this scenario of Z - overall index, which fell from 1.316 in 2008 to the negative 0.7224 in 2010. Time will tell if the forecast is correct.

4. CONCLUSION

This model, when it was created, caused a great deal of attention and was received with high credibility, and it appears that its actuality is not an issue even today. However, because of the limitations that are inherent to this model it should be used with other tools and financial indicators.

Although this test provides an excellent insight and synthetic view of the financial condition of companies observed, this model should not be only prediction tool. In the present test of Velefarm AD, model only indicates a problem, but for a reliable diagnosis it is necessary to perform a series of additional tests. This research points to the possible application of the Altman Z-Score test in Serbia, in which case minor adjustments are needed (Earnings Before Interest and Taxes adjustments).

In the past three years Velefarm AD has constantly been in "Distress" Zones, which means that bankruptcy risk is very high. The Z-score of the Company is constantly decreasing during this period, and in 2010 was even negative (-0.7224). The results indicate the imminent bankruptcy of Velefarm AD, Belgrade.

The empirical results are interesting since they can be used by company management for financing decisions, by regulatory authorities and by portfolio managers in stock selection.

² Erste bank, ad Novi sad, milosilic.ns@gmail.com

³Eurobank EFG, ana.bojovic@eurobankefg.rs

Abstract: *The aim of this paper is to present new trends and practices in cash flow management of an enterprise, and to show how the concept of financial supply chain management, as a modern solution of cash management but also as a new strategic approach, can help the company raise the efficiency of financial operations, reduce costs and increase profitability. In the analysis were used the achievements of financial theory and practical experience of large companies in cash flow management. Adoption of ideas, techniques and FSCM tools contribute to improving key performance indicators of financial flows, thus they increase the efficiency of operations along the supply chain and enable successful implementation of strategies of creating maximum value for consumers. Maintaining liquidity, faster circulation of funds and less engagement of working capital are particularly important goals in times of crisis when the financial and real sectors encounter lack of fresh money. Therefore the FSCM is a very relevant issue of concern to financial managers of companies of all sizes and industries, especially those who deal with a large number of invoices relating to customers and suppliers on a daily basis.*

Keywords: *financial supply chain management, cash flow, liquidity.*

INTRODUCTION

Modern business conditions, often characterized as dynamic and complex in front of companies and their managers put great challenges. The expansion of business across national borders, mass communication, a large number of suppliers and customers, the growing importance of accurate and timely information, have created conditions for the existence of global markets and global competition in all industries. In these conditions of "New economy" in order to operate successfully companies must optimize their operations in the way that will make maximum savings in all aspects of business, starting at procurement, production all the way to the distribution of products and services and collection of receivables. The dominant strategy becomes the strategy of activity management in all phases of supply chain, and as a primary goal the creation of the maximum value for customers with minimum costs for all participants in the chain.

In dynamic business conditions there is a growing corporate demand for financially efficient supply chains, with companies and their suppliers under conflicting pressures to improve payment terms, reduce prices and improve cash flow efficiencies. In order to achieve true efficiency within the financial supply chain, organizations must take a holistic approach and consider how to improve communication and integration between different parts of the business, as well as continuously improve the efficiencies of their working capital processes.

Within any corporate's organizational structure, there are numerous departments that all have an impact on the financial supply chain in some way. For example, procurement department manages procurement terms and sourcing, the treasury department manages working capital while the sales department generates revenues. There is also the finance department that manages all commercial payments, accounts receivable and payable. The problems that many organizations face, however, are the lack of coordination and integration between departments in handling the supply chain. Each department often has its own agenda and it's on set of key performance indicators (KPI's), so the efficiency of the supply chain may not be foremost in their mind when it comes to their everyday activities.

Financial supply chain management (FSCM) has the task to integrate all financial processes within the supply chain, to influence on growth of the financial KPI's, because only an efficient, on information technologies based FSC, can provide an adequate platform for the implementation of strategies of creating maximum value for the consumer with minimal costs for all participants in the chain.

1. RELATIONSHIP BETWEEN FINANCIAL SCM AND PHYSICAL SCM

Optimization of business processes from suppliers to the final customers with maximizing the total value generated for consumers is a basic principle on which to base strategies that recognize the SCM. Managing the physical supply chain is a long-standing practice of many companies, especially those who have chosen as a strategic option to create maximum value for consumers. According to Scott, Lundgren, Thompson (2011) physical or manufacturing SCM refers to the savings that are realized in relation to service areas:

- Transportation;
- Warehousing;
- Finance;
- Market research;
- New product design;
- Information, communication and technology (p.6).

The focus to date for many organizations has been the physical supply chain. Supply chain managers have worked hard to build cross-functional teams bringing together managers from sales and marketing, operations, procurement and logistics. Internal and external collaboration with suppliers and supply chain partners, particularly around logistics, has been the business priority.

In today's world of global trade, supply chain management is considered normal and often the necessary strategic approach, which requires a much greater capacity and expertise of professional managers who participate in the organization of the supply chain. Today, supply chain measure thousands of kilometers, tons and minutes and therefore anyone who works on the principles of activities management within the supply chain has the possibility to achieve large savings that he can bring a competitive advantage in the market and increase profitability in the long run.

Historically FSC is regarded as an independent process from manufacturing supply chain. Creating and transmitting value from vendor to the final customers is separately seen from the material aspect and the aspect of finance or cash flows. The functioning of a modern supply chain involves the necessity of closer links with all key business functions that are included to information, goods and money flows *within and between* different enterprises. Supply chain according to Braun (2008) encompasses three parallel flows:

- Physical supply chain: The flow of services or products, such as raw materials, that moves between the buyer and seller within the supply chain.
- Financial supply chain: The flow of financial transactions that pays for the physical goods or services.
- Information flows: Information associated with the payment for products and services also flows through the supply chain. This includes purchase orders, inventory documents, confirmations and invoices. The information initiates the physical flow of products and services as well as the financial transactions. It is a supportive flow and part of both the financial and physical supply chains (p.1).

Figure 1. Flows in the Supply Chains (Hausman, 2005. p.3)

The FSC can be defined simply as the flow of cash between businesses along the supply chain, which can be in the form of a payment between buyer, broker, carrier, third party logistics agent (3PL) and suppliers, or in the form of finance, either from a bank, financial institution or a supply chain partner willing to lend in the form of an early or extended payment. This definition needs to be extended to embrace the exchange of assets and liabilities within the working capital management cycle, again across the entire supply chain. Therefore, besides cash and bank debt, this also includes account payables, account receivables and the movement of inventory or stock.

According to the Robinson (2007) "at the heart of FSCM is the management of working capital and financial flows, but equally important is the management of information across the chain and the documents and data that support these flows, such as purchase orders, advanced shipping notices, invoices and payment approval processes. Much of the data contained in these documents is the same information that is used to efficiently manage ever more complicated physical flows" (p.1).

Managers agree that sharing critical information, in real time, has been shown to reduce costs dramatically and improves the performance at all SC levels. Collaboration by sharing information has joined the ranks of integration and automation as a hallmark of competitive advantage in the supply chains (Marquez, 2010). The convergence of physical and financial supply chains around increasingly electronic information flows has been a key feature of recent years.

Opportunities for greater savings related to the physical supply chain are mostly exhausted. Days required for processing the orders were reduced from 5-7 days to 1 day, the time required for delivery of goods to customers decreased from 2-3 weeks to 2 days. In recent decades there has been little progress in the areas of billing, receivables management and collection, assessment of client's credit ratings in general money management, so that today these areas are becoming the primary place for business improvement and generation of savings. FSCM as a set of knowledge, activities, tools for managing financial activities need to integrate, support and monitor physical activities of supply chain.

Figure 2. Connection between FSCM and production SCM (Philips, 2003. slide 9).

Global environmental challenges and the emergence of the global economic and financial crisis put modern financial management in even more difficult situation. Cash management and provision of liquidity represent a great challenge for financial managers today. Optimization of financial operations while maintaining the practice adopted, in relation to physical SCM, is becoming a trend for all companies who adopted a proactive approach and who are prepared to meet the emerging changes in the business. Proper management of financial flows and using modern tools, supported by information technology products, provide great opportunities to increase efficiency through automation and speeding up financial processes and eliminating the most significant vulnerabilities of financial operations, such as slow processing vendor invoices and reconciliation, a large amount captured working capital, the slow collection of receivables from customers, complicated and slow credit rating scoring, the more difficult possibilities of raising funds from banks.

2. CASH FLOW CHALLENGES

The financial crisis of 2008 showed that corporate finance volume depends not only on the market position nor structure of physical products, but also on the general health of the financial markets. Corporate's have felt the impact on trade credit, bank loans and cash flow in general, experiencing a shortage of liquidity. This is critical as sufficient liquidity is a fundamental condition when entering into a new business ventures or keeping existing alive. Without adequate liquidity support from banks or from business partners, some corporates could become insolvent because they would not have sufficient liquidity to pay their obligation.

The challenges facing companies today in the cash flows management come from the mass business activity, the more complicated financial relations and transactions between trading partners and between groups within large companies. Financial flow in the supply chain of a typical global enterprise includes thousands of invoices for which related payments and charges have to be addressed and processed. Problems such as slow processing of data, unreliable and unpredictable cash flows, expensive processes, high days sales outstanding (DSO) ratio, inappropriate decisions regarding the assessment of credit risk are caused partly by the effects of economic crisis and partly by using non holistic and non integrated method of money management, which is not based on the ideas of FSCM and the ideas of cooperation of all functions across the supply chain. Some of the internal causes of these miss functionalities and the reason for the emergence of a growing interest CFO's for better management of cash flows according to Hausman (2005) are:

- Manual and stand-alone processes. Manual processes tend to be slow, unreliable, unpredictable, and in the final analysis, often more costly than automated solutions.
- Lack of timely information. In many situations, financial flows do not contain sufficient detailed information for either manual or automated systems to accomplish their jobs. As a result, additional time and effort is required to obtain missing information (e.g., invoice-level detailed information such as item quantities and purchase order numbers).
- Lack of employee empowerment and compliance. If purchasing by individuals isn't carefully monitored and controlled, inappropriate spending may occur, undermining the company's initiatives to control expenses and improve strategic sourcing.
- Delays in invoice reconciliation. Delays in invoice reconciliation are a particular cause of additional working capital. They delay receipt of payments and increase day's sales outstanding. When there is a three-way mismatch of invoice, P.O., and shipping receipt, there is an inevitable delay while the mismatch is investigated. These investigations typically take time, as well as add cost.
- Manual processes for setting optimal credit limits. Companies often maintain their own departments to set customer credit limits. However, the ability to set optimal credit limits may require sophisticated algorithms that are often inaccessible to non financial companies (p.6).

Modern business conditions, followed by world economic crisis contributed to creating new streams in financial practice. Now the most significant source of short-term financing for companies becomes trade finance. Relationship with vendors and customers and adequate managing of receivables and liabilities today are the most important instrument for companies looking to optimize short-term bank loans and is a strong determinant of corporates financing costs. FSCM requires particular care to preserve the balance among established financing partners (Cavenaghi, 2012). Previously companies sought to extend their payments terms as long as possible, but now it is widely recognized that pushing cost and risk down the chain is no longer an effective proposition. Companies must work together to overcome raising challenges, so improving efficiencies across the whole chain, and therefore improving efficiencies for all parties, is now the ultimate goal.

3. FSCM-MODERN APPROACH

Adopting a strategic approach of creating maximum value for the consumers at minimal costs for all participants in the supply chain from companies requires cooperation and integration processes at all levels not only in relation to the physical-logistic aspect of business but also in the field of finance and information exchange. In practice, according to Cohen and Roussel (2005) this means achieving:

- Enterprise connectivity—business and transactional systems that are linked, allowing data to be seen and transported to different entities within the supply chain
- Distributed decision making—bidirectional information flow and defined business rules used to manage ongoing changes in demand and supply
- Real-time performance management—real-time, accurate information available to enable rapid and informed decision making (p.232).

Financial management in accordance with the principles FSCM can enable more efficient and effective way of managing cash flows which are every day more and more complex. In recent years much attention is paid to information technology, channels of mass communication and the opportunities they provide for improving the financial operations of the company. Current trends in the management of cash flows increases the efficiency of FSC through the application of new solutions in dealing with customers, suppliers, creditors, etc. Some of these solutions according to Hausman (2005) are:

- Purchasing cards and distribution cards. More and more companies are installing purchasing cards (P-Cards) as a way of making purchasing more efficient and cost-effective. P-Card systems also enable companies to aggregate spend data quickly and frequently, and to maintain compliance with company spend policies. They also increase financial transparency and help companies adhere to regulations. The distribution card is designed to re-engineer distributors and wholesalers accounts receivable (A/R) process through the replacement of cash, customer credit and promissory notes. By shifting the manual-driven process and burden of invoicing and collections from the distributor to the bank, the distribution card transforms the collection process into a quick paperless electronic payment, reducing accounts receivable (A/R) costs substantially. Sales proceeds can be immediately transferred into working capital for faster turnover.
- Electronic invoice presentment and payment (EIPP). Gradually, companies are moving toward electronic invoice presentment (EIP) and electronic invoice presentment and payment (EIPP). Today's new EIPP tools provide an excellent opportunity to perform financial flow and information flow tasks at the same time. The ability to send detailed invoice-level information (quantities, P.O. numbers, etc.) along with remittances enables the supply chain to transfer this information quickly and without errors often found in manual procedures.
- Invoice imaging. Some companies are creating soft copy images of paper invoices so that all payments can proceed along an electronic, paperless pathway. Others are creating data warehouses to maintain line item detail, with information from a P-Card solution or other sources.
- Supplier web portals for invoice inquiries. Another significant trend is to develop web-based automated inquiry systems for suppliers. Instead of accessing a call center to make a simple inquiry, suppliers can access a web portal for their company and perform self-service inquiry regarding the status of their invoices (received, in payables queue, in reconciliation queue, scheduled to be paid as of a certain date, etc.).
- Web-based financial reporting. To reduce costs, significantly improve spend management, and make more informed business decisions, many companies are finding that it's critical to electronically capture financial transaction and invoice-level data and then review it through a web-based reporting tool. This transaction and invoice-level data may be easily integrated with existing back office financial systems (p.7).

Best practice: Financial supply chain management with SAP ERP

SAP Financial Supply Chain Management (FSCM) supports companies optimizing their cash flows within the whole supply chain (from vendor to customer). That is, the financial process that accompanies the "real" business process from a financial point of view often offers potential for improvement in the areas of invoicing and reconciliation. The aim of the FSCM SAP component is to improve an organization's cash flow mainly in the Order to Cash business process. Components of FSCM are:

- SAP Credit Management- provides companies with the opportunity to monitor the total liability of their customers by using appropriate credit lines.
- Electronic Bill Presentment and Payment (SAP Biller Direct)- allows billers to send and customers to receive invoices electronically and making invoicing more efficient.
- SAP Dispute Management-offers the system support for processing payment deductions.
- SAP Collections Management- allows you to structure, classify and minimize the receivables owed to your organization.
- SAP Cash and Liquidity Management- supports the cash manager in efficiently managing liquidity and currency risk.
- SAP Treasury and Risk Management- offers a comprehensive set of functions for managing your financial transactions and risk.

All new trends in relation to cash flow management rely on achievements in the computers field, modern means of communication and data exchange. In order to realize successful implementation of strategies based on FSCM company and its business partners must have the appropriate IT infrastructure, knowledge and ability to adapt to new challenges. Education and training of employees and all other participants in the supply chain becomes continuous duty. A prerequisite for the successful management of financial supply chain is the existence of adequate communication channels based on the internet, allowing rapid exchange of large amounts of data, hardware devices and software solutions as well as qualified personnel. If such conditions are met a basic platform is created for the successful cash flow management, increasing the efficiency of financial operations and costs reduction.

4. FSCM MAKING CASH FLOW EFFICIENT

The adoption of new strategies and the introduction of new management practices of enterprises cash flows is caused by the growing need for raising the efficiency of overall operations. Improving the performance of financial operations, and therefore the overall results of the company means overcoming difficulties related primarily to the liquidity and eliminating the causes of their origin, through the implementation of latest achievements in financial management practice along the supply chain.

Firstly, FSCM practice contributes to improving the process of reconciliation of documents related to suppliers and customers. Matching shipping receipt, corresponding purchase order and invoice is now electronic, which reduces errors, speeds up the process of reconciliation accounts because the matching is done in the earlier stages of the process. Speeding up cash flow along the chain helps companies to save working capital, use it for covering other expenses or increasing profitability.

Secondly, modern solutions for managing electronic billing operations give the analytical possibilities to CFO's because they provide sufficient invoice detail so that many mismatches can be quickly diagnosed with the information provided electronically. This speeds up the reconciliation process significantly and accomplishes it at much lower cost. Cooperation between business partners in the supply chain is lifted to a higher level; all participants are now dedicated to creating maximum value for the end customer. The flow and exchange of information becomes significantly easier and quicker. Companies now have the ability to use common portals, for the information support to all participants in the supply chain.

Lastly, FSCM delivers company and its partners new capabilities in money management through a reduction days sales outstanding, reduce errors, transparency of business operations, better access to information, effective planning and control of cash flows, which ultimately results in less involvement of working capital, reduced operating costs. All this results in increased liquidity KPI's such as current liquidity ratio, future liquidity ratio, general liquidity ratio, supplier and customer turnover ratio (Vunjak, 2005).

The adoption of new strategies and the introduction of new practices in the management of cash flow of an enterprise imply a new way of organizing the financial function. The transition from manual processes to new fully or partly automated carries on certain risks related to system reliability, data protection from non authorized access, the time needed to learn new technology by staff and acceptance by the business partners etc. Regardless of the often high costs of implementation and the difficulties that the company and its business partners may have in the period of adjustment to new solutions, it is considered that potential benefits for the company are much greater in the medium and especially long run and that the impacts on liquidity, solvency and overall result of the company are primarily positive.

Modern business conditions require permanent adjustment of an enterprise, which despite some limitations, must lead towards automation and increasing efficiency of business processes. Adopting the idea of FSCM is not only a new way of performing daily activities, but also represents a new strategic approach aimed at creating maximum value for consumers and increase efficiency particularly of financial operations of an enterprise through the growth of cash flow KPI's.

CONCLUSION

Dynamic environment, a large number of suppliers and customers, their territorial distance, mass communication, free flow of goods, services, people and capital have led many companies to become a part of global market. Maintaining competitiveness in such harsh conditions of the company requires continuous improvement in efficiency of operations, increased cooperation with business partners, and proactive approach to problem solving. The emergence of global economic and financial crisis in 2008 pushed companies further into uncertainty and forced them to devote more attention to finding a source of savings in daily activities.

Common strategic direction that enterprises nowadays choose is management of activities at all stages of the supply chain, in order to create maximum value for consumers while minimizing the cost of business operations of all participants in the chain. So far, much attention enterprises dedicated to activities management in relation to the physical supply chain, thus the possibilities for savings in logistics, production, warehousing is almost exhausted. The problems that companies have nowadays are largely related to the question "How and where to find the cash". Difficulties in the area of liquidity are partly a result of the effects of the global economic crisis, and partly result of lack of adequate cash flows management. **Financial supply chain management can be defined as the flow of cash between businesses along the supply chain, including payment between buyers, brokers, carriers, third party logistics agents, suppliers, banks etc. Also FSCM deals with exchange of assets and liabilities within the working capital management cycle, again across the entire supply chain. Very important part of FSCM is information flow, as the way companies interact and exchange financial and other documents.**

Today corporates feel the impact on trade credit as DSO rates are high, on bank loans as conditions for external financing are more rigid and on cash flow in general, which has implications on more trapped working capital and higher expenses. Now the most significant source of short-term financing for companies becomes trade finance. Managing receivables and liabilities today are the most important instrument for companies looking to optimize short-term bank loans and is a strong determinant of corporates financing costs.

FSCM, based on the ideas of holistic approach and integrated money management of all functions across the supply chain, can help overcoming miss functionalities within cash flows and the cause's of their origin such as: manual and stand-alone processes, lack of timely information, delays in invoice reconciliation, slow processes for setting optimal credit limits etc.

Financial management in accordance with the principles FSCM can enable more efficient and effective way of managing cash flows through the application of new solutions in dealing with customers, suppliers, creditors such as: purchasing cards and distribution cards, electronic invoice presentment and payment

(EIPP), invoice imaging, supplier web portals for invoice inquiries, web-based financial reporting. Adoption of the previous solutions of FSCM practice contributes to improving the process of reconciliation of documents. give the analytical possibilities to CFO's, reduction days sales outstanding, reduce errors, transparency of business operations, better access to information, effective planning and control of cash flows, which ultimately results in less involvement of working capital, increased liquidity and reduced operating costs.

Abstract: *Debt payments of companies at maturity also imply regular payments received from customers. Therefore, time between debt payments and received payments from customers should be put to minimum. Using liquidity analysis we determine if the company is capable to contracted debt payments at maturity. In this paper authors present comparative analysis of liquidity ratio and cash conversion cycle between companies in manufacturing industry in Serbia. Financial reports of 100 joint-stock companies in manufacturing industry that have stocks quoted at Belgrade stock exchange were taken for this research. Companies were divided into 8 groups in regard to the branch of manufacturing industry and analysis includes three consecutive years. Based on conducted research it could be concluded that average liquidity of all analyzed companies in defined time was gradually increased in order to have the ratio of rigorous liquidity at satisfactory level in the last year. Nevertheless, it can be observed the deficit of cash funds at the analyzed companies as well as the long period of time between debt payments and received payments from customers. In conclusion authors present the measurements that companies should implement in order to increase their liquidity and ensure the smooth business activities.*

Keywords: *Liquidity, cash conversion cycle, analysis, manufacturing industry.*

1. PREFACE

Analysis of liquidity provides information about company's capability to meet their obligations at maturity. Liquidity analysis is necessary not only for companies management because of efficient business management but also for banks, suppliers, buyers, as well as insurance companies, that are interested in liquidity of firm with which they do business. Also, liquidity analysis is important to all employees and stockholders that expect regular dividend payment and constant growth of company.

Beginning liquidity analysis is based on determination of relation between working assets and short-term obligations. In case of equality between short-term assets and short-term obligations the company has short-term financial equilibrium. Equality between long-term assets and long-term financing sources brings to long-term financial equilibrium. On this way the conditions for keeping liquidity are ensured. Nevertheless, in practice the case of absolute short-term and long-term financial equilibrium is scarce.

If long-term financing sources are exceeding the company's long-term assets, there is certainty in keeping the liquidity, because the surplus of long-term sources can be used for financing the short-term assets. However, if long-term assets are not covered with long-term sources and they are financed with short-term sources, there is danger of illiquidity. Time period between generating the money and paying back matured short-term obligations isn't a match at expense of short-term obligations. Described structure of assets and financing sources isn't long-term sustainable and company must find way to increase their liquidity.

Also, it is necessary to accent that liquidity analysis isn't determined just with volume of short-term assets but also with its structure. Because of that for calculation of company's liquidity different indicators are used, that are presented in continuation of the paper.

2. LIQUIDITY ANALYSIS ON BASE OF RATIO INDICATORS

In short-term asset structure supplies are at the last place at the liquidity degree, because they have the slowest process of turning into cash. Next are short-term claims, short-term financial placements and cash and cash equivalents. There are different coefficients in regard to the relations between total short-term assets, liquidity assets and assets of large degree of liquidity with short-term obligations, such as:

Ratio of current (general) liquidity is calculated as relation between short-term assets and short-term obligations. Traditional thinking that this relation has to be 2:1 in favor of short-term assets should be taken extremely careful, as extenuate Krasulja, Ivanišević (2001) „with regard that on adequacy of general ratio have influence many general and specific factors, such as: category and size of company, business activity volume, time bondage of short-term assets in specific phase of business cycle, crediting conditions of suppliers in regards to the crediting conditions that are granted to buyers, efficiency of received claim payments, discipline of matured debt payment etc.“ (p.23). However, ratio value larger than 2 indicates the inefficient cash and short-term obligations management, while ratio value below 1 indicates the lack of liquidity assets for financing short-term obligations. Shortage of ratio is reflected in structure of short-term assets that includes supplies. Namely, company can have in their short-term asset structure large participation of supplies that have for consequence the indication of liquidity. However, because supplies have the slowest transformation process in cash, it is necessarily to reduce short-term assets in order to accurately calculate the liquidity (ratio of reduced liquidity).

Ratio of reduced liquidity is calculated with putting in relation the short-term assets with excluded supplies with short-term obligations. Given ratio indicates the number of dinars of liquidity short-term assets that covers the one dinar of short-term obligations. This ratio needs to be larger than 1. In numerator of this relation is cash, short-term placement in securities and receivables from customers. As receivables from customers presents category that doesn't have to be fully transformed into cash (if customer goes to bankruptcy and default in their obligations towards the given company), develops the need for even more rigorous valuation of liquidity.

Ratio of money liquidity, which is calculated with putting into relation the cash and liquidity securities with short-term obligations, shows if company possesses enough cash and highly liquidity securities to cover short-term obligations.

Company thrives to keep the optimal structure of short-term assets and improve their quality (problem of slow moving and obsolete inventories or uncollectible receivables from customers), that leads to the better liquidity of the company.

3. CASH CONVERSION CYCLE

During the liquidity analysis it is necessary to take in consideration the period between the debt payments and received payments from customers. Namely, company buys materials for product manufacturing that represents cash outflows, but from the other side they expects cash inflows from sale of manufactured products. It raises the question whether company receives payments from customers faster than debt payments or debt payments to creditors are faster than received payments for sold goods.

Cash conversion cycle takes in consideration the time bondage of inventories, time bondage of customers and time bondage of suppliers. As the time bondage of inventories implies time from first investment in supplies until the day of sale, and time bondage of customers implies time from sale until the received payments for sold products, combining the time bondage of inventories with time bondage of customers, result is period in which the company is without funds. From this sum it should be deduced time bondage of suppliers, in other words time that is necessary for debt payments of company. On this way time period between debt payments and received payments is calculated, that is called cash conversion cycle or (Brili, Majers, Markus, 2007):

$$\begin{aligned}
 & \text{Average supplies} / (\text{annual cost of sold products} / 365) \\
 + & \text{Average value of receivable claims} / (\text{annual revenue} / 365) \\
 - & \text{Average value of debt to suppliers} / (\text{annual cost of sold products} / 365) \\
 = & \text{Cash conversion cycle}
 \end{aligned}$$

Time discrepancy between cash inflows and outflows is reason for cash conversion cycle analysis that can be positive, neutral and negative. Positive cash conversion cycle indicates how much day's company must wait on received payments in order to payback its debts. Neutral cash conversion cycle (result is zero) implies time discrepancy between cash inflows from buyers and cash outflows for debt payments. Negative cash conversion cycle indicates number of days of money disposal before company must pay their obligations. Accordingly, company receives payments for sold products faster than payments of their obligations. Company tends to ensure low or negative cash conversion cycle.

4. RESEARCH OBJECTIVE

The paper's objective is to comparatively analyze liquidity ratio and cash conversion cycle between companies in manufacturing industry in Serbia. For purpose of these research financial statements of 100 joint-stock companies in manufacturing industry that have stocks quoted on Belgrade stock exchange are taken in consideration. At the same time random sample selection is used. Companies are divided into 8 categories in regards to branch of manufacturing industry they belong (tobacco, machine, chemical, metallurgy, wood, textile, food or construction industry). Analysis is following the consecutive three years. With this analysis authors determine trends of liquidity indicators of all analyzed companies, every branch of manufacturing industry, as well as their interrelationship.

5. RESEARCH RESULT

Average value of every individual liquidity ratio of all analyzed companies in manufacturing industry record slight but constant growth since 2008 until 2010. Ratio of current liquidity ranged from 1,69 in 2008, along 1,71 in 2009 to 1,73 in 2010, that indicates the gradual improvement of liquidity. However, with analysis of only current liquidity, wrong impression could be taken about apparent liquidity if the majority of short-term assets are the most illiquid assets. Rigorous liquidity ratio excludes supplies from short-term assets, and on the examined companies ranged from 0,85, along 0,92 to 1,04 in 2010. It means that on 1 dinar of short-term obligations company owns 0,85, 0,92 and 1,04 dinars of liquid asset. In first two observed years company can't settle occurred short-term obligations with liquid assets, while the liquidity of companies in manufacturing industry was improved in 2010 and has acceptable level. However, with analysis is determined that companies doesn't own enough funds - cash and liquid securities to settle short-term obligations. On every dinar of short-term obligations, companies owns only 0,07, 0,08 and 0,10 dinars of cash funds. Liquidity analysis by ratio indicators for 2008, 2009 and 2010 is presented on next picture.

Picture 1: Liquidity analysis for companies in manufacturing industry

Comparing the liquidity ratio in observed years at branches of manufacturing industry it can be spotted that liquidity ratio moved also in increasing and decreasing intensity that is conditioned with industry category, company's size and time bondage of short-term assets in specific phases of business cycle etc. The lowest value of current liquidity ratio was recorded in construction and wood industry, and the highest value in chemical industry. Ratio of reduced liquidity was also the highest in chemical industry, but the lowest was in metallurgy. However, ratio of money liquidity in all branches of manufacturing industry records low value. Average values of liquidity ratio indicators at branches of manufacturing industry are presented next in Table 1.

Table 4: Average values of liquidity ratio indicators at branches of manufacturing industry

Branch of manufacturing industry	Ratio of current liquidity (average values)			Ratio of reduced liquidity (average values)			Ratio of money liquidity (average values)		
	2008.	2009.	2010.	2008.	2009.	2010.	2008.	2009.	2010.
Tobacco industry	2.34	1.58	1.50	0.90	0.69	0.79	0.38	0.06	0.17
Machine industry	1.87	1.53	1.43	0.75	0.72	0.74	0.13	0.19	0.22
Chemical industry	1.94	2.67	2.32	1.03	1.50	1.48	0.06	0.14	0.08
Metallurgy	1.29	1.28	1.70	0.55	0.55	0.86	0.03	0.04	0.16
Wood industry	1.31	1.27	1.21	0.80	0.69	0.81	0.03	0.01	0.05
Textile industry	2.01	1.64	1.52	0.71	0.63	0.60	0.02	0.02	0.02
Food industry	1.73	1.74	1.81	0.96	1.03	1.19	0.06	0.07	0.07
Construction industry	1.22	1.47	1.10	0.83	1.01	0.70	0.00	0.00	0.02

Based on average values of inventory turnover ratio, claims and suppliers for every branch of manufacturing industry, average duration of cash conversion cycle for every individual branch was determined. The longest period from received payments to debt payments was recorded in wood and textile industry (from 200 to 400 days). Cash conversion cycle in food industry (in which there is the most companies that have stocks traded on exchange) is ranged from 88 to 102 days. Something lower time period was recorded in chemical, machine, construction industry and metallurgy. Since the 2008 companies in Serbia were stricken with global economic crisis that produced decreased business activities. In addition, there were problems with servicing matured obligations and increased borrowing that could only overpass problems of liquidity in short-term. Liquidity analysis in individual branches of manufacturing industry points out on conclusion that companies in chemical industry in relation to other observed companies managed to fight with consequences of crisis, achieves high ratio of current liquidity, acceptable ratio of rigorous liquidity and time between debt payments and received payments reduces on average 60 days.

6. CONCLUSION

Providing liquidity has great value for smooth functioning of business activities and company's survival. Liquidity analysis starts with checking whether the total short-term assets can cover all short-term obligations. Thereafter, is determination of how much dinars of liquid short-term assets comes on one dinar of short-term obligations, and last ratio indicator determines how much cash company owns for coverage of short-term obligations.

If liquidity is threatened, company has to conduct several measurements such as efficient inventory management. Namely, with providing the optimal inventory that don't disturb constant business activities, and don't bond unnecessarily, time desynchronized, money in material form, decreases the level of supplies on one side, and level of short-term obligations on the other side. Next, efficient received payments from customers can be reached with discounts for customers that regularly pay in short-term, while customers that are late with payments can be calculated interest. On this way the value of receivable claims is faster transforming into cash that company can use for settlement of occurred obligations and company's liquidity increases.

With increased liquidity comes the decreased time period between debt payments to creditors and received payments from customers. With efficient inventory management, received payments from customers and prolonging the time for debt payments, cash conversion cycle is decreasing.

Based on liquidity analysis of selected companies that have stocks coated on exchange, potential investors can make the difference between individual branches for investment activities. Next is analysis of individual companies from selected branch in order to make the best investment call.

Abstract: *In this paper we present a modelling approach to candlestick patterns based on interpolative Boolean algebra (IBA) which is applied to stock market BELEX. We have decided to use IBA instead of conventional fuzzy logic, since it simplifies the process of modelling and as a consistent fuzzy technique it further improves the existing efforts and resolves some known issues. Results show that a candlestick pattern modelling using IBA is indeed successful and should be adopted for further use. The proposed method gives a degree of fulfilment for observed patterns, thus giving traders easy interpretation of how much candlesticks fit into different patterns.*

Keywords: *candlestick, interpolative Boolean algebra, fuzzy, BELEX, stocks*

1. INTRODUCTION

Effectiveness of candlestick patterns interpretation analysed by some papers give opposite results. They prove to be useful on some markets and unprofitable on others. Some back-up negative results by the fact that candlestick patterns were invented for rise markets during the 1700s and are not suitable for today markets (Marshall, 2006). Still, vast number of traders uses this kind of technical analysis on an everyday basis. Emotional beliefs are an important factor that affects market prices and technical analysis is supposed to reveal these behaviours (Nison, 1991). Since this kind of behaviour is not completely rational, technical analysis transforms thought process of investors into charts in an effort to forecast the price change.

Since models are individual for each trader, we do not try to propose an optimal solution, but rather a methodology that can help traders to express their personal preferences. Emerging papers in scope of candlestick patterns show an uprising interest in their fuzzy modelling. Many of these papers show respectful results, but for traders who are not familiar with fuzzy logic, putting these concepts into action can really be difficult. Since conventional fuzzy logic lacks the ability to consistently treat all logical relations, for instance law of excluded middle does not hold in general case, using it for proposed models is not satisfactory. To address this problem we introduce interpolative Boolean algebra to candlestick modelling.

Method proposed in this paper uses interpolative Boolean algebra as a consistent fuzzy technique, introduced by Radojevic (2000), which should simplify steps in defining candlestick patterns. Conventional fuzzy approach is hindered by the fact that it cannot consistently describe elements of Boolean algebra, such as law of contradiction ($A \cap \bar{A}$), and stay in a Boolean frame (Radojevic 2008b). Therefore, proposed models cannot be implemented with traditional approach. Consistent fuzzy technique, as IBA is sometimes referred in literature, is applied in this paper to improve upon strongly set conventional one.

For testing purposes we used data from Belgrade Stock Exchange (BELEX) market. Our results reveal that transforming candlestick parameters into intensity of a candlestick pattern, using proposed methodology, truly depicts human perception.

A brief description of chapters 2 to 5 is given. In chapter 2 contemporary literature is analysed. Data and methodology are described in Chapter 3. Chapter 4 discusses results. The last section concludes the paper.

2. LITERATURE REVIEW

There are different opinions regarding the effectiveness of Japanese candlestick patterns on stock and similar markets. Some papers suggest that usage of such patterns for forecasting on stock markets is unjustified. For instance, studies conducted by Horton (2009) and Marshall et al. (2006) show that candlestick technical analysis does not produce profit. Marshall et al. used thirty-five individual stock indexes with carefully chosen sample period of ten years. Robustness of the system was tested using the bootstrap

methodology. One of the criticisms was addressed to the fact that candlestick patterns were originally devised for rice markets.

In contrast, recent study conducted by Lu et al. (2012) shows that some types of candlestick technical analysis patterns are indeed profitable when applied to Taiwan stock market. Data used for testing their method comprised of individual stocks found in Taiwan 50. To check the robustness of results, same as previously mentioned, bootstrap methodology was used. Although some of these results put shadow onto candlestick patterns effectiveness, never the less, many papers have been written regarding their usage in forecasting.

Lee & Jo (2009) created an expert system based on candlestick chart analysis. Their system looks up in a database for signals and interprets them as candlestick patterns. They get 72% accurate results on the Korean stock market. Model is rule-based and does not take gradation into consideration.

Tool which uses fuzzy candlestick patterns to describe investment knowledge on the Taiwan stock market was presented by Lee et al. (2005). By using fuzzy technique, they are addressing the problem of candlestick pattern definition vagueness which arises from different authors' comprehensions of the same pattern. In another paper, group of same authors compare their method with previously presented ones, acquiring better results (Lee et al., 2006). Finally Lee (2009) constructs personal ontology to describe candlestick patterns.

Approaches presented by Kamo and Dagli (2009) use candlestick method in gating network, by using rules for describing the market and also by fuzzy logic-based weight generator, as part of their hybrid system. As they have shown, fuzzy logic based systems deliver smoother and more accurate forecasting results. Another fuzzy-candlestick model for reversal point prediction was presented in (Lan et al., 2011). It tries to set a warning before a reversal of a stock price occurs. Reported results show precision far greater than 50%.

3. DATA AND METODOLOGY

Candlesticks are originating from mid-18th century, firstly introduced by a youngest child of Munehisa family – Homma (Nison, 1991). From his excellence in the field of trading, people started calling him “god of the markets”. Since Nison introduced Japanese candlestick trading methods to western markets, they rapidly gained popularity. Today, candlesticks chart analysis is one of the most widely used technical analysis technique. Candlestick patterns should reflect psychological state of the market and then traders should base their decisions on recognized patterns.

Candlesticks are formed out of open, high, low and close price for a predefined time period (figure 1). Body colour of a candlestick depends on whether a close price is higher or lower than an open price. If it is higher, body has a white, empty filling and oppositely, if it is lower, body is black. Lines called shadows above and under body represent highest and lowest price of the time interval, respectively. Body size indicates the market momentum and the shadows show extremes of the price movement. Body and shadows are usually described as long or short, when defining patterns.

Figure 2: Candlesticks example

Example on how a candlestick reflects a market state is for instance candle with white body without shadows, the so called White Marubozu pattern. Open price equals lowest price, and close price equals the highest (figure 2). That means buyers are very bullish, since market opened at one price and closed at another, never dropping below initial price, and closing well above it. The opposite rule applies for black bar, Black Marubozu.

Figure 3: Marubozu example

However, interpretation of candlestick patterns is individual. Investors can obtain different pieces of information from the same pattern and apply custom set of rules. This is one of the reasons why we use interpolative Boolean algebra, a consistent fuzzy technique, to model vagueness of candlestick patterns interpretation. This new approach simplifies pattern definition, making it easier for investors to use. Usage is straightforward and only basic mathematical skills are required. Need for gradation is also satisfied, for instance how intensive White Marubozu is. This gives information on certainty that the pattern rules will reflect the future market movement.

For test and example purposes, daily stock prices of NIIS (Naftna Industrija Srbije) from BELEX (Belgrade Stock Exchange) are used. Time period is one year, from January to December of 2011. Particular stock from BELEX was chosen because it can oscillate around an open price between 12% upwards and 8% downwards, as regulated by stock market rules.

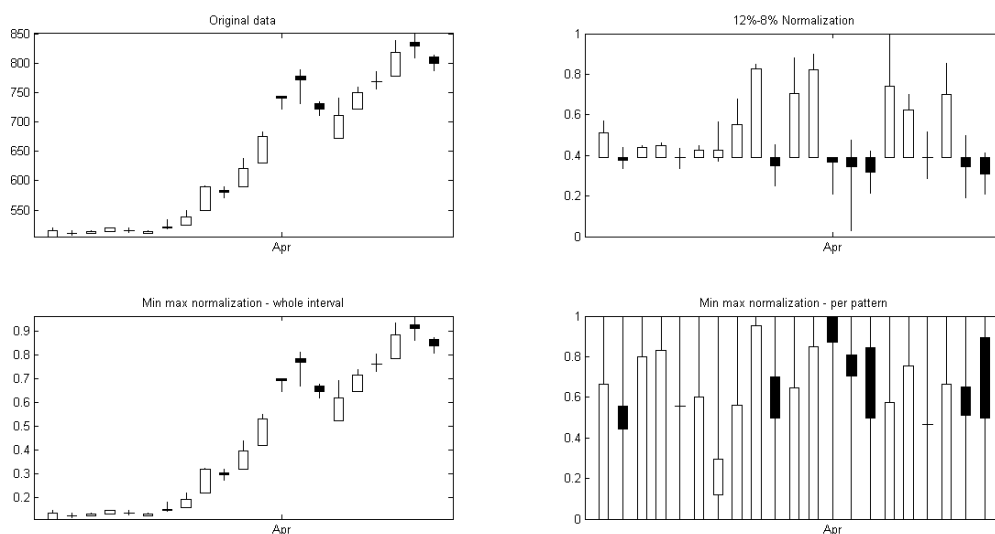

Figure 4: Real data compared to normalized data

IBA requirement is that all values must be on [0,1] interval. Candlesticks were normalized taking those rules into consideration (Figure 3). Since we know maximal possible price change, it is better to treat extreme movements with higher degree. The upward movement of 12% can be considered as 1 and downward movement of 8% as 0. One problem with this kind of normalization is that movements are sometimes too small, because movements near extreme borders are very scarce. Another problem is that when analyzing two or more bar patterns, one does not consider normalizing them in such a way, so that pairs maintain bar parameter relations. Easy solution to latter problem is Min Max normalization executed on the whole data set. However, this will not address the first problem. Another option is to normalize each group of elements that create a pattern. This way, relevant bars will maintain their relations. If bar size on the whole data set interval has any importance, one should consider aggregating results of two or more different normalization techniques. For simplicity sake, we used Min Max normalization on pattern groups.

Radojevic (2000) presented [0,1]-valued logic that is in the Boolean framework. With it we have the opportunity to use consistent fuzzy relations, also called interpolative relations (Radojevic, 2005), to measure logical similarity and dissimilarity between individuals. Interpolative Boolean algebra provides a frame for consistent realization of all possible elements of finite Boolean algebra. It is consistent in a sense that it preserves all the laws on which Boolean algebra relies.

We will use classical Boolean expressions to model candlestick patterns. As an example, a few expressions have been described. Equivalence is used when we want to state that parameters are equal. Relation of equivalence (\Leftrightarrow) is well-known expression of logical similarity between objects. Equivalence of two objects A and B is noted as:

$$A \Leftrightarrow B = (A \cap B) \cup (\bar{A} \cap \bar{B}) \quad (1)$$

For Doji pattern open equals close price so it can be defined with ease by stating $\text{open} \Leftrightarrow \text{close}$.

If we do not want attributes to be the same, logical choice of an operator is exclusive disjunction ($\underline{\vee}$). Relation of exclusive disjunction is complementary relation to the equivalence relation:

$$A \underline{\vee} B = 1 - A \Leftrightarrow B = (A \cap \bar{B}) \cup (\bar{A} \cap B) \quad (2)$$

Long day pattern can be modeled as an exclusive disjunction between open and close price. It can be expressed as close and open prices as far apart as possible. Candlesticks, whose open price is in relation of exclusive disjunction with close price, are best rated if open and close have values 1 and 0.

Very useful expression is implication (\rightarrow). It can be viewed as a not strict inequality relation - less or equals.

$$A \rightarrow B = \bar{A} \cup B \quad (3)$$

For instance, this expression can be used for defining Engulfing pattern which is described as a bar with a small body which is engulfed by a bigger body of a next bar.

These relations are based on interpolative Boolean algebra (IBA), which is real-valued [0,1]-valued realization of finite Boolean algebra (Radojevic, 2008a). Any element from the IBA has its corresponding generalized Boolean polynomial (GBP) (Radojevic, 2008b).

Transformation from Boolean expressions to GBP is described in (Radojevic, 2008b) and example explanation of the process for exclusive disjunction is given by (4).

$$\begin{aligned} (A \underline{\vee} B)^{\otimes} &= [(A \cap \bar{B}) \cup (\bar{A} \cap B)]^{\otimes} = \\ &= (A \cap \bar{B})^{\otimes} + (\bar{A} \cap B)^{\otimes} - (A \cap \bar{B})^{\otimes} \otimes (\bar{A} \cap B)^{\otimes} = \\ &= A \otimes (1 - B) + (1 - A) \otimes B - \\ &= A \otimes (1 - B) \otimes (1 - A) \otimes B = \\ &= A + B - 2(A \otimes B) \end{aligned} \quad (4)$$

The GBP is, as its name says, general form of polynomial. Generalized product (\otimes) is any function that satisfies conditions of commutativity, associativity, monotonicity and 1 as identity and non-negativity condition (Radojevic, 2008a).

$$\otimes: [0,1] \times [0,1] \rightarrow [0,1] \quad (5)$$

If both attributes are of the same type, we can use minimum t-norm as a generalized product. That would mean they are correlated. For instance, if we compare two persons by their height, intersection of their heights is height of a smaller person. If they are non-correlated attributes, product t-norm should be used instead. An example for this if compare two persons by their height and their wealth. At last, if they are negatively correlated Łukasiewicz t-norm-norm should be used.

Example above (4) can now be translated to:

$$(A \sqcup B)^{\otimes} = A + B - 2(A \otimes B) = A + B - 2\min(A, B) \quad (6)$$

Next, example models for candlestick patterns are given. This should illustrate how fuzziness can help in determining the intensity and avoid completely discarding candlestick patterns that only on small part do not satisfy conditions.

White marubozu:

$$open \Leftrightarrow low \wedge close \Leftrightarrow high \quad (7)$$

Black marubozu:

$$open \Leftrightarrow high \wedge close \Leftrightarrow low \quad (8)$$

Doji:

$$open \Leftrightarrow close \quad (9)$$

Hammer:

$$close \Leftrightarrow high \wedge close \sqcup low \quad (10)$$

Hanging man:

$$open \Leftrightarrow high \wedge open \sqcup low \quad (11)$$

Inverted hammer:

$$open \Leftrightarrow low \wedge open \sqcup high \quad (12)$$

Shooting star:

$$close \Leftrightarrow low \wedge close \sqcup high \quad (13)$$

Bullish engulfing:

$$open1 \rightarrow close2 \wedge open2 \rightarrow close1 \quad (12)$$

Bearish engulfing:

$$close2 \rightarrow open1 \wedge close1 \rightarrow open2 \quad (12)$$

Tweezer tops:

$$open1 \Leftrightarrow low1 \wedge open1 \sqcup low1$$

$$\wedge \quad (14)$$

$$close2 \Leftrightarrow low2 \wedge close2 \sqcup high2$$

Tweezer bottoms:

$$open1 \Leftrightarrow high1 \wedge open1 \leq low1$$

$$\wedge \quad (15)$$

$$close2 \Leftrightarrow high2 \wedge close2 \leq low2$$

4. RESULTS

Tests conducted on various models show that IBA approach to modelling candlesticks can indeed provide insight into pattern fitness. Traders can monitor provided indicators and decide when input attributes form candlestick patterns. Also, these pieces of information are easily used for creating automated decision support systems. By setting a border near value 1, traders can receive signals when a pattern occurs. IBA can be used for automation as a logical aggregation tool. This kind of automation can induce signals of pattern occurrences on which traders can base their decisions.

Results presented are a fragment of our research. Only one bar candlestick patterns are used in the example.

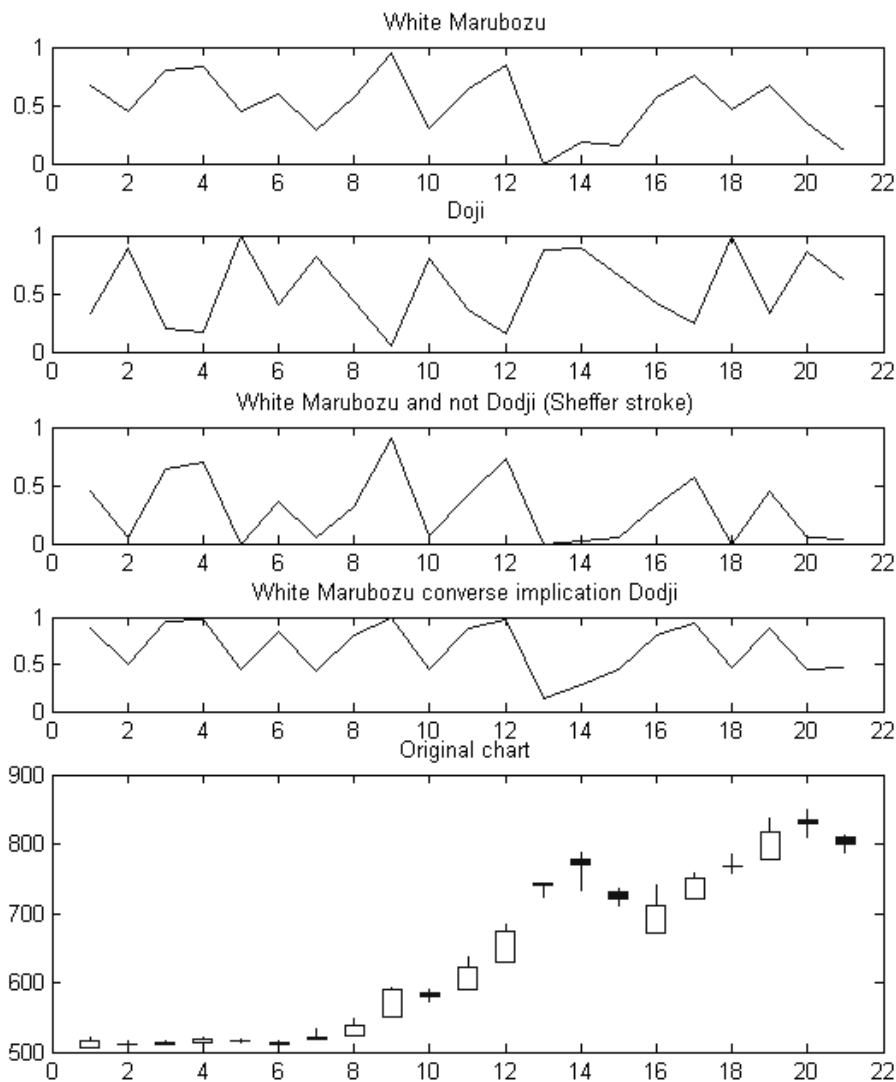

Figure 5: IBA candlesticks modelling results

Table 1 contains data on which previous charts are made (figure 4).

Table 5: Original data and results sample

Open	High	Low	Close	White Marubozu	Dodji	Marubozu ↗ ↘ Dodji	Marubozu ← Dodji
515	519	510	515	0,4444	1,0000	0,0000	0,4444

777	788	730	771	0,1897	0,8966	0,0196	0,2735
731	735	709	722	0,1538	0,6538	0,0533	0,4467
672	740	672	711	0,5735	0,4265	0,3289	0,8181
722	759	722	750	0,7568	0,2432	0,5727	0,9408
515	519	510	515	0,4444	1,0000	0,0000	0,4444

Some models described in chapter 3 are very rough and could use some improvement. Simplest way to improve Marubozu model is to compare it to Doji. Since there is no ambiguity in Doji pattern definition, we can use it to improve upon other models. For instance, Marubozu is a Marubozu, only when it is not a Doji. Marubozu models described in chapter 3 can have high intensity even when Doji appears. By definition, it is correct to treat them in such a way, but traders will dismiss them if they do not have larger body. That leaves us with at least two options. One is to look for Marubozu when Doji does not occur and the other is to look for Marubozu when Doji is described as less intensive.

The first scenario White Marubozu and not Dodji depicts traders who consider that Marubozu patterns cannot occur unless body has the opposite size of an ideal Doji body size. Second scenario (White Marubozu ← Dodji) is less harsh and the condition is met when Dojis intensity is smaller than the one of a Marubozu. It is interesting to note that both scenarios give very similar results, but the latter one, case with the converse implication between indicators, is more tolerant. It also appears shifted up compared to the first scenario.

Results depend on type of normalization chosen. For hammer, if data are for instance normalized using Min Max for each bar, we get redundant calculations left and right from ↗. But, if we choose some other type of normalization, results will change accordingly.

For data presented in Table 1 and Figure 4, we used Min Max normalization on each candlestick. If Min Max normalization on the whole interval was used, results would be different. Most notable difference is how logical relations influence changes. Sheffer stroke between White Marubozu and Doji will almost never produce maximal intensity. If converse implication was used, Doji will have very little influence on White Marubozu.

Another possible normalization presented on figure 3 is the one based on 12% and -8% price change boundaries. Since price changes are based on the above assumption, after normalization they are more intense. This affects results to be more volatile. Still, changes are small and there is a big chance of pattern getting recognized with high intensity as a Doji. Last normalization gives us the highest degree of change, so no difference between candlesticks regarding their relative size is made.

From presented results, one can conclude that by looking at intensities of individual or combined patterns, we can get more pieces of information than from two valued logic. Since there are other fuzzy approaches to this problem, strongest argument for using this one is that it is easier to model. From relations between one candlestick data, over relations between two or more candlestick patterns, to relations between complex patterns, everything is modelled using logical relations. Downside is that this approach works with relations, and as a consequence it can be less intuitive than the traditional fuzzy approach. But by using presented techniques, any type of candlestick patterns can be modelled.

As generalized product in GBP for Doji and Marubozu we use minimum t-norm, since all inputs have the same nature. But, for relations between them, we use product t-norm. If the proposed method needs more tuning, pseudo-logical polynomial can be used to introduce weights (Radojevic, 2008c).

5. CONCLUSION

In this paper we presented a way of modelling Japanese candlestick patterns which should be easy for traders to use. The base for creating more complex models is made. In our example we wanted to illustrate that the proposed methodology works satisfactory. To our best knowledge this paper is the first to address candlestick patterns modelling using IBA.

Earlier studies implemented fuzzy logic by defining candlestick elements sizes and then setting IF-THEN rules. Once applied, these methodologies show good results, but it can be hard for traders to get to that point without solid knowledge of fuzzy logic. Another arising issue is situation where multiple patterns should be combined into more complex ones or should be used in creation of trading strategies. Though possible, it is not a straightforward process. Our methodology uses basic logic expressions to model everything from candlestick patterns to strategies and then uses IBA to translate these expressions into values. This process is very simple for traders to comprehend.

Further studies should compare success rates of previous methods to the proposed one and test them for robustness. Also, they should create comparison of different normalization methods and show their influence on results. Finally, effects of using pseudo-logical polynomial on candlestick patterns modelling should be explored.

Abstract: *This paper presents possible usage of neural networks in forecasting stock returns within the Belgrade Stock Exchange. Forecasting is done on the example of the NIS (Serbian Oil Company) stock, which has been chosen as the most liquid equity with the biggest market capitalization. The neural network that has been used for this purpose is a classical multi-layer perceptron with one hidden layer. Technical indicators and stock valuation ratios have been used as inputs. Three combinations of input sets have been developed: the first consisting only of technical analysis indicators; the second consisting of financial ratios; and the third as a mix of the previous two input sets. Results are compared in order to investigate the potential of technical and fundamental analysis as a tool for predicting price changes. Stock valuation ratios have shown excellent characteristics in forecasting future price movements and outperform other approaches. Furthermore, the simpler model has made better results than the complex one, showing that more is not always better.*

Keywords: *neural networks, multi-layer perceptron, stock price forecasting, technical analysis indicators, stock valuation ratios.*

1. INTRODUCTION

Forecasting is certainly the most exotic field of science. Second half of the 20th century has brought exciting development to this field. With the emergence of computers, forecasting has become more and more interesting and many complex technologies rose. Forecasting is one of the main topics in finance. For centuries, men have sought to understand the underlying processes of financial markets in order to predict the future or at least one day ahead. It is the constant battle between man and the market forces. The efficient market hypothesis (EMH) asserts that in an efficient market stock prices movements are random and unpredictable. It means that predicting price movements is impossible. Therefore, analysing history data is useless given that no additional information can be extracted from historical data. But there is no consensus so far on EMH validity. There are numerous papers that give empirical evidence that it is possible to predict, to certain extent, future returns or at least direction of future price change. On the basis of those forecasts, many researches created trading systems that are profitable.

Since 1940's and the first mathematical model of single neuron introduced by McCulloch and Pitts, artificial neural networks (ANN) have gained their popularity in different scientific fields. Their ability to mimic structure and learning process of the human brain made them promising and interesting for lot of researchers around the world. But the main reason for their popularity lies in the fact that ANN requires few theoretical assumptions for modelling. After initial success of Rosenblatt's perceptron and the first criticism of Minsky and Papert, a dramatic resurgence of interest in artificial neural networks have begun in 1980's. Since then, ANN technology has been developing very fast with a wide variety of scientific applications and many types of business applications. Business application areas that require pattern recognition, classification and prediction were candidates for ANN technology. Therefore, it is not surprising that financial application of ANN were one of the most extensively studied, forecasting especially.

In this paper, we use feed-forward neural networks as one of the oldest and most commonly used ANN technology. We use technical and fundamental analysis tools, in order to extract additional information from the history data that we use as input variables in the ANN model. Using these input data we trained neural network to understand underlying process of the market in order to predict future price movements. Results indicated best performances of fundamental analysis approach based on stock valuation ratios. It outperformed other approaches and showed very good results in forecasting future stock movements with high hit rate which indicates what percent of predictions are on the right side of the market.

The remainder of this paper is organized into four sections. Section 2 will present theoretical background and literature review. In section 3 we describe methodology along with the data used for analysis. Section 4 will report results of the comparative analysis. In section 5 we present our conclusions.

2. BACKGROUND

There are a lot of financial areas that are suitable for artificial neural network applications. Credit rating evaluation, price/interest rate forecasting, bankruptcy prediction, corporate health estimation are just some of them. Wong and Selvi (1998) made a review and analysis of different ANN applications in finance.

Forecasting has been for decades one of the most interesting areas of finance. Many researchers studied different techniques in their efforts to discover the underlying model of the market in order to make accurate prediction of price changes. De Gooijer and Hyndman (2006) reviewed many different techniques that were used since 1982 and artificial neural networks have taken its important place among other forecasting methods. Atsalakis and Valavanis (2009) surveyed many scientific articles that focus on neural and neural-fuzzy techniques indicating that soft computing techniques are widely accepted for evaluating stock market behaviour.

Although very old, feed-forward neural networks (FFNN) are still one of the most used networks for financial forecasting. They are simple, fast and easy to implement. In (Atsalakis and Valavanis, 2009) we see that about one third of the surveyed articles use feed-forward neural networks as a forecasting tool. Multi-layer networks with one or two hidden layers are most commonly used. In principle, there is no need to consider other architectures, since the ANN with one hidden layer already has universal approximation capabilities (Bishop, 1994). Cao et al (2005) use simple FFNN with one and three input variables and compare the results with CAPM and 3-factor model. Their results indicate that ANNs do indeed offer an opportunity for more accurate forecasts.

In order to predict stock prices, authors use variety of different inputs. Technical analysis indicators and fundamental analysis ratios are very popular tools among traders and researches. For example, Armano *et al.* (2005) use historical prices along with five different indicators in order to predict prices for the next three days. Olson and Mossman (2003) used 61 accounting ratios for 2352 Canadian companies to forecast annual returns. In many cases, researches are not trying to predict actual prices of the stock or other financial instrument, but their daily returns. Cao et al. (2005) use univariate and multivariate FFNN to predict stock price movements (price returns). Predicting trading signals that can be used for trading strategies is also very popular among researchers. Tsang *et al.* (2007) use open, close, high and low price of the previous day, along with volume and momentum indicator in order to predict trading signals. Chang *et al.* (2011) use more than twenty technical indicators as input variables in order to predict buy and sell signals.

3. METHODOLOGY

Artificial neural network (ANN) is referred to computational model that is inspired by the structure of biological neurons. ANN consists of a certain number of artificial neurons that are interconnected and can be arranged in one or more layers and the information is processed through layers. The main characteristic of ANN is their ability to mimic the knowledge acquisition.

Artificial neurons are the constitutive units of ANN. It is a simple mathematical model of biological neuron. This model receives one or more inputs (representing the one or more dendrites) and sums them to produce an output (representing a biological neuron's axon). Usually the values of the input nodes are weighted and their sum is squashed or transformed by a function known as activation function. An activation function can be linear or non-linear, and most commonly used functions are: threshold, threshold linear, sigmoid and hyperbolic tangent function. There are no clear criteria regarding which activation function to use.

The feed-forward neural network (FFNN) is the oldest and the simplest type of ANNs. In this network, the information moves in only one direction, forward, from the input layer, through the hidden layers (if any) and to the output layer. There are no loops in the network. ANN that is used in this paper is simple feed-forward neural network (FFNN) with one hidden layer. Hidden layer is consisted of 15 neurons. Log-sigmoid functions were used as activation functions in the hidden layer neurons. There are several input variables and only one output variables. Activation function that is used in the single output node is threshold linear function. Figure 1 shows such FFNN with 8 input variables.

Figure 1: Architecture of the FFNN used in this paper

In order to train our feed-forward network we use recursive methodology. Instead of partitioning data “once and for all” into training and test set, we use the type of recursive methodology called expanding window. Within a given data set that is consisted of N daily values, we use the first $M < N$ observations for initial estimation to obtain initial forecast \hat{r}_{t+1} . Then we re-estimate the model based on $M+1$ observation, and obtain \hat{r}_{t+2} forecast. The process continues until the entire sample is covered. This methodology is called expanding window since the sample size becomes larger as we move forward in time.

3.1. INPUTS

In this paper we use three input sets for the same ANN architecture in order to make comparison of the resulting forecasts. In the first case we use technical analysis indicators as input variables, in the second case stock valuation ratios are used and in the third case both technical indicators and financial ratios are used as input variables for the purpose of forecasting. The idea of these three cases is to investigate the power of technical and fundamental analysis as tools for financial forecasting, first separately and then jointly. Table 1 and Table 2 present the selected technical indicators and stock valuation ratios, along with their formulas and verbal description.

Table 6: Technical analysis indicators as input variables

Indicator	Formula	Description
MACD line	$MACD(N, M) = EMA(N) - EMA(M)$	Moving Average Convergence/Divergence line tracks a difference between longer and shorter trend of the price.
ROC	$ROC(N) = \frac{Price_t - Price_{(t-N)}}{Price_{(t-N)}} \cdot 100$	Rate of Change is designed to show the relative difference between today's closing price and the close N days ago
RSI	$RSI(N) = 100 - \frac{100}{1 + \frac{EMA(upper\ mov, N)}{EMA(down\ mov, N)}}$	The Relative Strength Index is designed to measure the velocity and magnitude of directional price movements.
Chaikin volatility	$CHV(N) = \frac{EMA(H_t - L_t, N) - EMA(H_{t-N} - L_{t-N}, N)}{EMA(H_{t-N} - L_{t-N}, N)} \cdot 100$ $H_t - \text{High price}(t), L_t - \text{Low price}(t)$	Chaikin Volatility determines volatility of financial instrument using percent change in a moving average of subtraction of high and low prices over some period of time.
Volume-price trend	$VPT_t = VPT_{t-1} + volume \cdot \frac{close_t - close_{t-1}}{close_{t-1}}$	Generally, the idea of Volume-price trend is to show the trend of the volume and to investigate is it moving along with price trend.

Table 2: Stock valuation ratios used as input variables

Ratio	Formula	Description
P/E	$P/E = \frac{\text{Price per share}}{\text{Earnings per share}}$	Price-to-earnings ratio shows how much the investors are willing to pay per dollar/euro/dinar/etc of earnings.
P/S	$P/S = \frac{\text{Price per share}}{\text{Sales per share}}$	Price-to-sales ratio shows how much the investors are willing to pay per dollar/euro/dinar/etc of sales.
P/B	$P/B = \frac{\text{Price per share}}{\text{Book value of share}}$	Price-to-book ratio is used to compare a stock's market value to its book value.

3.2. OUTPUT

The selected input variables, presented in the previous section, are used for prediction of daily stock returns. Therefore, the stock return is the only output variable.

3.3. DATA

The proposed feed-forward neural network is used on the example of the Belgrade Stock Exchange (BSE) in forecasting daily returns for stock NIIS (Naftna industrija Srbije A.D.). This stock is selected as the most liquid equity on the BSE market. Naftna industrija Srbije A.D. is also the company with the largest market capitalization on the BSE.

This study covers the time period of May 4th, 2011 through April 30th, 2012. The data consists of 251 daily prices accompanied with daily values of the corresponding technical indicators and stock valuation ratios. Technical indicators were calculated on the basis of daily open, close, low and high prices and volume, collected from official site of BSE⁷. In order to calculate financial ratios, a manual review of the data from the annual financial report of the company⁸ was done. Table 3 presents the part of the data that are used in order to forecast.

Table 3: The data

Date	Return	Close price	P/E	P/S	P/B	MACD line (12,26)	ROC (12)	RSI (12)	Chaikin Volatility (12)	Volume-price trend

26.04.2012.	1,54	660	2,65	0,56	1,23	-9,67	0,00	42,55	38,39	81.549,47
27.04.2012.	-0,76	655	3,18	0,59	1,11	-9,27	-1,06	44,44	29,72	81.442,19

3.4. NORMALIZATION

Values of the input variables are normalized to [0,1] interval and afterwards put through neural network in order to forecast future stock returns. We use the following linear rescaling function:

$$X_{norm} = \frac{X_i - X_{min}}{X_{max} - X_{min}} \quad (1)$$

⁷ www.belex.rs

⁸ <http://www.belex.rs/trgovanje/informator/NIIS>

3.5. FORECASTING ACCURACY MEASURE

We compute the following three error metrics to measure forecast accuracy of the network:

- Mean absolute error (MAE)

$$MAE = \frac{1}{n} \sum_{i=1}^n |r - \hat{r}_i| \quad (2)$$

- Root mean square error (RMSE)

$$RMSE = \frac{1}{n} \sqrt{\sum_{i=1}^n (r - \hat{r}_i)^2} \quad (3)$$

- Hit rate (HR)

$$HR = \frac{\sum_{i=1}^n H_i}{n}, \quad H_i = \begin{cases} 1, & \text{if } \text{sign}(\hat{r}_i) = \text{sign}(r_i) \\ 0, & \text{if } \text{sign}(\hat{r}_i) \neq \text{sign}(r_i) \end{cases} \quad (4)$$

4. RESULTS

This paper is intended to analyze the power of technical and fundamental analysis as forecasting tools. For that purpose, the data were separated into three datasets. In the first dataset daily returns (1 output) and corresponding daily values of technical indicators were used (5 input variables). In the second dataset daily returns (1 output) were used along with the corresponding values of the selected stock valuation ratios (3 inputs). Third dataset was consisted of the data from both previously described datasets (1 output and 8 input variable). Therefore, in third dataset there are eight input variables. Forecasting results from these three datasets were compared with each other. The purpose of this analysis is to investigate usefulness of technical analysis indicators and stock valuation ratios as a forecasting tool, first separately and then jointly. Resulting forecasts are presented in Table 4.

Table 4: The results

HISTORICAL DATA		Approach 1	Approach 2	Approach 3
DATE	ACTUAL RETURNS	Technical indicators	Stock valuation ratios	Technical indicators + valuation ratios
		FORECASTS	FORECASTS	FORECASTS
07.03.2012.	-2,07	-1,10	-3,78	-0,34
08.03.2012.	0,42	-6,39	0,88	-1,62
09.03.2012.	-0,28	-0,68	-0,48	-0,75
12.03.2012.	-0,56	-0,37	0,55	-2,19
...
17.04.2012.	-0,15	-0,84	-0,15	-1,27
18.04.2012.	0,15	-0,53	0,31	-0,40
19.04.2012.	0,15	-3,01	-0,51	4,64
20.04.2012.	0,46	-0,59	-0,73	-0,44
23.04.2012.	-1,51	-4,75	-4,33	-1,05
24.04.2012.	-0,61	0,17	-0,73	-0,76
25.04.2012.	0,46	-0,75	2,17	-2,58
26.04.2012.	1,54	2,40	-0,61	-2,56
27.04.2012.	-0,76	-3,44	-0,25	-1,04

In order to compare these three approaches, we use mean absolute error (MAE), root mean square error (RMSE) and hit rate (HR). The following Table 5 gives the resulting errors for all three approaches.

Table 5: Accuracy measures

Accuracy measure	Technical analysis	Fundamental analysis	Universal approach
	approach	approach	
MAE	1,4902	1,1980	1,2497
RMSE	2,4114	1,7295	1,8751
HR	58,33%	61,11%	47,22

The most accurate is the second approach that uses stock valuation ratios in order to forecast future stock return. It has very a good hit rate of about 61%. It is very interesting that technical analysis approach had worst performances looking at MAE and RMSE, but it had good performances looking at the prediction rate. Surprisingly, universal approach that should use all the best characteristics of both approaches showed disappointing results. Perhaps, this finding proves that more does not always mean better. Cao *et al.* (2005) proved the same in their work when they unexpectedly got better forecasting results for univariate (with one input variable) multi-layer perceptron (MLP) than for multivariate MLP with three input variables. First two approaches have hit rates bigger than 50% which means they are most of the time on the right side of the market. However, this does not mean that they could bring profit to their owners.

Since it is the most successful approach, Figure 2 will show the graphical representation of the forecasting results achieved using stock valuation ratios. Forecasts are marked with circles in the upper graph and red bars in the lower graph, and actual prices are marked as crosses and blue bars. The upper graph represents normalized data while lower shows regular data.

Figure 2: Graphical representation of stock valuation ratio accuracy

2. CONCLUSION

In this paper, feed-forward neural networks (FFNN) are used in order to predict stock price movements on the example of NIIS (Naftna industrija Srbije A.D.) from Belgrade Stock Exchange (BSE). Even though FFNN are among the oldest and simplest neural network architectures the results shown that they indeed offer an opportunity for investors to improve their predictive power. Three different approaches are used in order to create accurate forecasting system. The first approach used stock valuation ratios to predict future stock movements, the second used technical indicators and the third was combination of the previous two.

Unexpectedly, it appears that simpler models are more successful in forecasting returns and price movement directions than the complex one. Results have shown that fundamental analysis approach gives excellent results. Stock valuation ratios outperformed both technical analysis and universal approach.

As for the future work, it will be interesting to investigate more carefully potential of fundamental analysis. Also, we are willing to assess the relationship between the number of input variables and the accuracy of the model. Furthermore, we will try to extract trading signals from the forecasting results in order to make profitable trading system.

THE CHAOTIC REAL EXCHANGE RATE GROWTH MODEL

Vesna Jablanović¹

¹University of Belgrade, Faculty of Agriculture, Serbia, vesnajab@ptt.rs

Abstract: Chaos theory is used to prove that erratic and chaotic fluctuations can indeed arise in completely deterministic models. Chaos theory reveals structure in periodic, dynamic systems. The number of nonlinear business cycle models use chaos theory to explain complex motion of the economy. Chaotic systems exhibit a sensitive dependence on initial conditions: seemingly insignificant changes in the initial conditions produce large differences in outcomes. The basic aim of this analysis is to provide a relatively simple chaotic real exchange rate growth model that is capable of generating stable equilibria, cycles, or chaos.

Key words: *real exchange rate, growth, depreciation, chaos*

1. INTRODUCTION

Chaos theory started with Lorenz's (1963) discovery of complex dynamics arising from three nonlinear differential equations leading to turbulence in the weather system. Li and Yorke (1975) discovered that the simple logistic curve can exhibit very complex behaviour. Further, May (1976) described chaos in population biology. Chaos theory has been applied in economics by Benhabib and Day (1981,1982), Day (1982, 1983,1997,), Grandmont (1985), Goodwin (1990), Medio (1993,1996), Medio, A. and Lines, M (2004), Lorenz (1993), Shone, R.(1999) , Jablanovic (2010, 2011a, 2011b, 2012). Deterministic chaos refers to irregular or chaotic motion that is generated by nonlinear systems evolving according to dynamical laws that uniquely determine the state of the system at all times from a knowledge of the system's previous history. Chaos embodies three important principles: (i) extreme sensitivity to initial conditions ; (ii) cause and effect are not proportional; and (iii) nonlinearity.

National saving is the source of the supply of loanable funds. Domestic investment and net capital outflow are the sources of the demand for loanable funds. At the equilibrium interest rate, the amount that people want to save exactly balances the amount that people want to borrow for the purpose of buying domestic capital and foreign capital. At the equilibrium interest rate , the amount that people want to save exactly balances the desired quantities of domestic investment and net capital outflow.

The real exchange rate is determined by the supply and demand for foreign – currency exchange. The supply of domestic currency to be exchanged into foreign currency comes from net capital outflow. The demand for domestic currency comes from net exports. Because a lower real exchange rate stimulates net export , the demand curve is downward sloping. At the equilibrium real exchange rate, the demand for domestic currency to buy net export exactly balances the supply of domestic currency to be exchanged into foreign currency to buy assets abroad.

The supply and demand for loanable funds determine the real interest rate. The interest rate determine net capital outflow, which provides the supply of dollars in the market for foreign –currency exchange. The supply and demand for domestic currency in the market for foreign-currency exchange determine the real exchange rate.

In an open economy, government budget deficit raises real interest rates, crowds out domestic investment, decreases net capital outflow, causes the domestic currency to appreciate. However this appreciation makes domestic goods and services more expensive compared to foreign goods and services. In this case, exports fall, and imports rise. Namely, net exports fall. An appreciation of the real exchange rate expresses that the foreign price of a bundle of goods has risen relative to the domestic price. If the real exchange rate appreciates it means that the real value of the domestic currency has depreciated

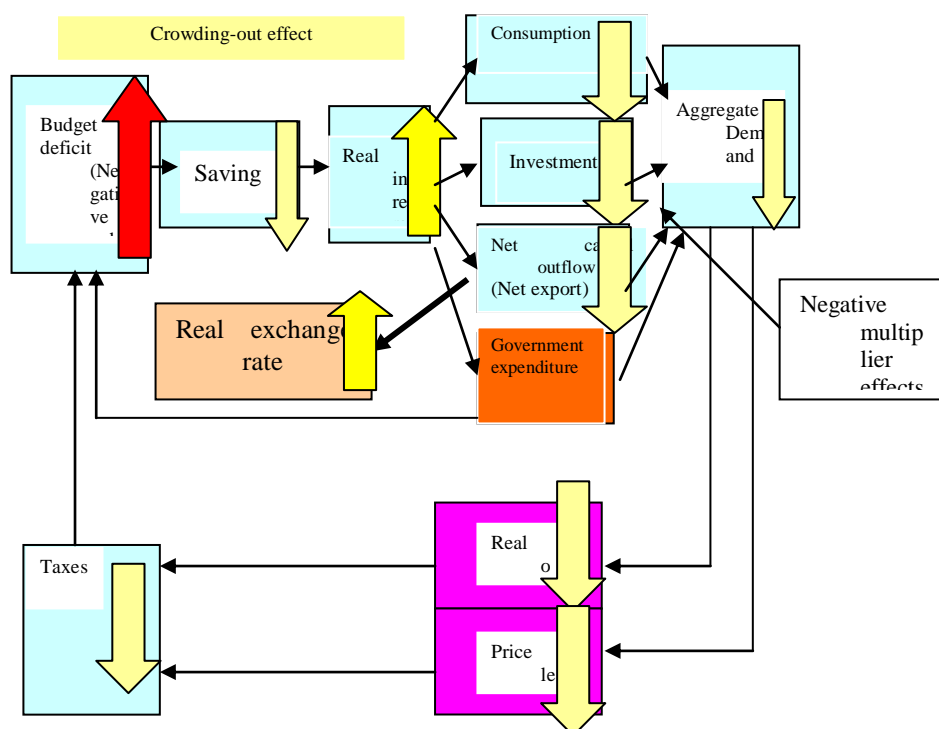

Figure 1. Relation between budget deficit, saving , investment, and real exchange rate

The basic aim of this analysis is to provide a relatively simple chaotic real exchange rate growth model that is capable of generating stable equilibria, cycles, or chaos.

2. A SIMPLE CHAOTIC REAL EXCHANGE RATE GROWTH MODEL

The chaotic real exchange rate growth model is presented by the following equation

$$k_m = \frac{\Delta K}{\Delta Y} \quad (1)$$

$$k = \frac{K}{Y} \quad (2)$$

$$Y_t = K_t^{1/2} \quad (3)$$

$$NCO_t = Nx_t \quad (4)$$

$$Nx_t = \gamma - \delta e_t \quad (5)$$

$$NCO_t = \alpha - \beta Bd_t \quad (6)$$

$$Bd_t = \pi Y_t \quad (7)$$

Where e – real exchange rate, NCO – net capital outflow, Nx - net export, Bd – budget deficit; Y – real output ; K – capital; k - average capital coefficient, k_m - marginal capital coefficient, $\alpha, \beta, \gamma, \delta, \pi$, -coefficients.

(1) defines marginal capital coefficient ; (2) defines average capital coefficient ; (3) determines production function; (4) the identity between net capital outflow and net export; (5) describes the demand for dollars which comes from net export; (6) describes net capital outflow as a function of budget deficit; and (7) describes the relation between budget deficit and the real output.

Firstly , it is supposed that $\alpha = 0$ and $\gamma = 0$. Further, by substitution one derives:

$$e_{t+1} = \frac{k_m}{k_m - k} e_t - \frac{1}{\beta \pi (k_m - k)} e_t^2 \quad (8)$$

Further, it is assumed that the current value of the real exchange rate is restricted by its maximal value in its time series. This premise requires a modification of the growth law. Now, the real exchange rate growth rate depends on the current size of the real exchange rate, e , relative to its maximal size in its time series e^m . We introduce ε as $\varepsilon = e/e^m$. Thus ε range between 0 and 1. Again we index ε by t , i.e., write ε_t to refer to the size at time steps $t = 0, 1, 2, 3, \dots$. Now growth rate of the real exchange rate is measured as

$$\varepsilon_{t+1} = \frac{k_m}{k_m - k} \varepsilon_t - \frac{1}{\beta \pi (k_m - k)} \varepsilon_t^2 \quad (9)$$

This model given by equation (9) is called the logistic model. For most choices of β , π , k and k_m there is no explicit solution for (9). This is at the heart of the presence of chaos in deterministic feedback processes. Lorenz (1963) discovered this effect - the lack of predictability in deterministic systems. Sensitive dependence on initial conditions is one of the central ingredients of what is called deterministic chaos.

3. LOGISTIC EQUATION

The logistic map is often cited as an example of how complex, chaotic behaviour can arise from very simple non-linear dynamical equations. The map was popularized in a seminal 1976 paper by the biologist Robert May. The logistic model was originally introduced as a demographic model by Pierre François Verhulst. Chaotic dynamics was made popular by the the logistic map. The most interesting characteristic of the logistic map is in the simplicity of its form (quadratic) and the complexity of its dynamics. It is the simplest model that shows chaos. It is possible to show that iteration process for the logistic equation

$$z_{t+1} = \pi z_t (1 - z_t), \quad \pi \in [0, 4], \quad z_t \in [0, 1] \quad (10)$$

is equivalent to the iteration of growth model (9) when we use the identification

$$z_t = \frac{1}{\beta \pi k_m} \varepsilon_t \quad \text{and} \quad \pi = \frac{k_m}{k_m - k}. \quad (11)$$

Using (9) and (11) we obtain:

$$z_{t+1} = \frac{1}{\beta \pi k_m} \varepsilon_{t+1} = \frac{1}{\beta \pi k_m} \left[\left(\frac{k_m}{k_m - k} \right) \varepsilon_t - \left(\frac{1}{\beta \pi (k_m - k)} \right) \varepsilon_t^2 \right] =$$

$$= \left[\frac{1}{\beta \pi (k_m - k)} \right] \varepsilon_t - \left[\frac{1}{\beta^2 \pi^2 k_m (k_m - k)} \right] \varepsilon_t^2$$

On the other hand, using (10) and (11) we obtain:

$$z_{t+1} = \pi z_t (1 - z_t) = \frac{k_m}{k_m - k} \frac{1}{\beta \pi k_m} \varepsilon_t \left(1 - \frac{1}{\beta \pi k_m} \varepsilon_t \right)$$

$$= \left[\frac{1}{\beta \pi (k_m - k)} \right] \varepsilon_t - \left[\frac{1}{\beta^2 \pi^2 k_m (k_m - k)} \right] \varepsilon_t^2$$

It is important because the dynamic properties of the logistic equation (10) have been widely analyzed (Li and Yorke (1975), May (1976)).

It is obtained that :

- (i) For parameter values $0 < \pi < 1$ all solutions will converge to $z = 0$;
- (ii) For $1 < \pi < 3,57$ there exist fixed points the number of which depends on π ;
- (iii) For $1 < \pi < 2$ all solutions monotonically increase to $z = (\pi - 1) / \pi$;
- (iv) For $2 < \pi < 3$ fluctuations will converge to $z = (\pi - 1) / \pi$;
- (v) For $3 < \pi < 4$ all solutions will continuously fluctuate;
- (vi) For $3,57 < \pi < 4$ the solution become "chaotic" which means that there exist totally aperiodic solution or periodic solutions with a very large, complicated period. This means that the path of z_t fluctuates in an apparently random fashion over time, not settling down into any regular pattern whatsoever.

3. CONCLUSION

The basic aim of this analysis is to provide a relatively simple chaotic real exchange rate growth model that is capable of generating stable equilibria, cycles, or chaos.

In an open economy, government budget deficit generates an appreciation of the real exchange rate. An appreciation of the real exchange rate expresses that the foreign price of a bundle of goods has risen relative to the domestic price. If the real exchange rate appreciates it means that the real value of the domestic currency has depreciated

A key hypothesis of this work is based on the idea that the coefficient

$$\pi = \frac{k_m}{k_m - k}$$

plays a crucial role in explaining local stability of the real exchange rate growth, where, k_m – the marginal capital coefficient, and k - the average capital coefficient.

THE INFLUENCE OF THE EMISSION OF GREENHOUSE GAS ON MANAGEMENT DECISIONS

Milena Antić¹

¹Institute "Mihajlo Pupin", milenaantic85@gmail.com

Abstract: *The emission of greenhouse gas and global warming are one of today's greatest climate problems. In order to reduce the emission of greenhouse gas and the slowdown of global warming, the international agreements, such as the Kyoto Protocol and the European Union Emission Trading Scheme (EU ETS), have been arranged. Both agreements are obligatory only for developed countries. These agreements have imposed obligations not only for the governments of developed countries, but also for the companies that operate in these countries. However, global warming is a problem that influences all countries, both developed and developing. Therefore, the inclusion of developing countries in the contracts mentioned above has been initiated. If this initiative comes to life, it will be necessary for companies operating in developing countries to introduce some changes in their decision-making process. These changes will entail the companies to calculate the price of the emission of greenhouse gas and include it in the costs-benefit analysis of new investments. Furthermore, the cost of emission might influence the profitability of products that are already produced within a company. Companies that operate in developed countries have already included the cost of emission in their decision-making process. Companies operating in developing countries must try to do the same, or at least include the cost of emission in their long-term plans in order to prepare their activities for future changes that will inevitably occur. The implementation of the Kyoto Protocol and the EU ETS, the inclusion of the price of emission in the decision making process and some problems related to it, as well as changes in the agreements that will probably happen and possible gains of companies have been described in this paper.*

Keywords: *the Kyoto Protocol, the EU ETS, cost of emission, developed countries, developing countries,*

1. PREFACE

The emission of greenhouse gas is one of the major climate problems in the world. In its Third Assessment Report (2001) the Intelligent Panel on Climate Change presented evidence showing that in the last 50 years global warming has, by and large, been the result of human activities. Therefore, human behavior must change in order to slow global warming down. The United Nations Framework Convention on Climate Change (UNFCCC) is the first internationally binding instrument that addresses the issue of response to climate change. UNFCCC has one ultimate objective – to achieve stabilization of greenhouse gas in the atmosphere at a level that would prevent dangerous anthropogenic (human induced) interference with the climate system. Other multinational agreements were also arranged in order to introduce the need for reduction of greenhouse gas emission in countries throughout the world. The Kyoto Protocol and the European Union Emission Trading Scheme are examples of these agreements. Those agreements are, for now, binding only for developed countries. Nevertheless, the global warming is a problem that affects all nations and all countries. Parallel with the industry growth of developing countries, the emission of greenhouse gas in these countries will rise too. The need for the inclusion of developing countries in the agreements mentioned above has already been discussed and it is probable that it will happen soon.

Agreements mentioned above have effect on the business activities of companies operating in developed countries. EC survey on corporate behavior indicated that 70% of companies were pricing the value of allowances into their daily operations and 87% into the future marginal pricing decisions. All industries stated that it was a factor in long-term decision-making. These companies had to include the question of reduction of emission and the valuing of emission in their decision making process. Entities that operate in developing countries, as Serbia, have not had to face this question yet, but they will probably have to do so soon.

2. THE IMPLEMENTATION OF THE KYOTO PROTOCOL

The Kyoto Protocol is an international agreement linked to the UNFCCC. Kyoto protocol set targets for 37 industrialized countries and the European community in order to reduce the greenhouse gas emission. Industrialized countries have agreed to achieve 20% of reduction of greenhouse gas emission by 2020, with 1990 as the base year. During the first commitment period, from 2008 to 2012, industrialized countries are

obliged to reduce their emissions, and minimum reduction should be equal to five per cent of the greenhouse gas emission in 1990. The difference between the UNFCCC and the Kyoto Protocol is that the former does not oblige countries to reduce emission of greenhouse gas and the latter does. The reason why only developed countries are obliged to reduce their emission of greenhouse gas is because developed countries are mainly responsible for the current level of greenhouse gas emissions, which is the result of more than 150 years of industrial activity.

The Kyoto Protocol is organized in the following manner: developed countries are given certain number of rights for emission of greenhouse gas annually. The quantity of rights every country has is called “cap”, and it is being reduced over time. Rights for emission are distributed to companies that operate in these countries. If a company does not have enough rights to cover its emission during a certain period, it can buy rights on the market. Also, if all emission rights are not used within a company, they can be sold on the market, or saved for future periods (when these rights will not be given free of charge). The possibility of selling rights on the market motivates companies to reduce their emission and earn profits.

Companies are given the opportunity to earn rights for additional emission of greenhouse gas through investing in the reduction of greenhouse gas emission in other Annex I countries (industrialized countries), or in developing countries. If a company decides to invest in reduction of greenhouse gas emission in Annex I country, it will earn certain number of “emission reduction unit” (ERU). If a company invests in reduction of greenhouse gas emission in developing country, it will earn “certified emission reduction” (CER). Both one ERU and one CER are equivalent to the emission of one tone of greenhouse gas. In both cases the result of investment must be controllable (the reduction of emission must be measurable).

3. THE IMPLEMENTATION OF THE EUROPEAN UNION EMISSION TRADING SCHEME

The organization of the European Union Emission Trading Scheme (EU ETS) is very similar to the organization of the Kyoto Protocol. The basic goal of 20% reduction of greenhouse gas emission by 2020, with 1990 as the base year, is the same as in the Kyoto Protocol. European countries are given rights for the emission of greenhouse gasses, which are distributed amongst companies. The difference between the Kyoto Protocol and the EU ETS is the existence of trading periods that last more than one year. The introduction of these periods was necessary in order to neutralize annual irregularities in emission of greenhouse gas that occur due to extreme weather events. The first trading period lasted from 2005 to 2008, while the second trading period still lasts and it will end on December 2012. Rights are also traded on the market, and their value is depended on the relation of demand and supply. It is not allowed to transfer rights that were not used from the first trading period to the second trading period (therefore, rights should be either used or sold on the market until the period ends). The third trading period will start in 2013. It is planned for more rights to be auctioned during the third trading period, which will probably have effect on entities' behavior.

4. THE POSSIBILITY OF INCLUSION OF DEVELOPING COUNTRIES

As it was previously said, the emission of greenhouse gas is a global problem. The reduction of emission in developed countries will lead to a partial solution of this problem. In order to address the problem adequately, developing countries must also reduce emission in their countries. Kyoto protocol encourages industrialized countries to invest in clean technology in developing countries, but the governments and companies operating in these countries must be motivated to do the same. The question is how to stimulate developing countries to invest in clean technology? The governments of developing countries have other things on their minds, and because industries in this countries are not big polluters (comparing to industrialized countries); the need for reduction of emission is often not being considered. More urgent problem developing countries must face with is the development of their industries. But, industrial development will inevitably lead to higher emission of greenhouse gas. If developing countries are not obliged to reduce emissions, all efforts from developed countries might prove to be pointless.

Some solutions to the problem have been suggested. One solution that is often being proposed is sectorial introduction of the Kyoto Protocol. This means that only sectors that are the biggest polluters (energy sector, for example) will be obliged to reduce the emission of greenhouse gas. Other possibility is that the Kyoto protocol will become obligatory for all countries. After the first commitment period of the Kyoto Protocol, some changes in the system will probably occur. One of the changes might be the introduction of greenhouse gas emission in developing countries.

5. THE INTRODUCTION OF COST OF EMISSION IN DECISION-MAKING PROCESS

The introduction of some of these systems for the reduction of emission in developing countries will influence business operations of companies that do not have to deal with this problem now. Same as with the governments of developing countries, top managements of these companies are struggling with the problem of managing day-to-day activities and developing the business.

If the Kyoto protocol or the EU ETS is adopted in developing countries, managers of companies that operate in these countries will have to face with the following question: Should we invest in clean technology, or should we buy additional rights for emission of greenhouse gas? Both options will influence future business results of the companies and their cash flows. The cost of emission of one tone of greenhouse gas will have to be integrated in their decision making process.

If, for example, management had to decide if the money should be invested in clean technology or not, total costs to total benefits related to this investment should be compared. If total benefits are greater than costs of investment in clean technology, the company will decide to invest. If, on the contrary, investment in clean technology is greater than benefits which can be earned by selling extra rights on the market, companies will opt for status quo.

The cost of investment in clean technology is relatively easy calculated. Price of filter that company wants to buy, for example, can be found on the market. Costs of maintenance and services will have to be included in total costs, too. Finally, costs of disposal of the filter will have to be calculated. All these costs are available on the market. In order to calculate present value of these costs, some of them will have to be discounted (one example of these costs is the cost of disposal).

The calculation of total benefits is far more complex. Total benefits include revenues earned from the selling extra rights on the market. Also, they might include some subsidies from government for the investment in clean technology. Finally, total benefits include auction price of rights that company will not have to buy in the following periods (comparing to the rights that would have to be bought if the investment was not made). In order to be able to calculate total benefits, company must forecast the reduction of emission (in tones) and price of one right for the emission of greenhouse gas. The biggest problem in this calculation is related to the prediction of the price of rights for emission.

To illustrate the difficulty of predicting the price of rights, we will use the example of the price of rights on EU ETS market. Variation of this price during the first trading period (from 2005 to 2008) will be depicted. As it can be seen from the Figure 1, the price of rights increased steadily until April 2006, when it peaked at 30 Euros per right. In the following month the price of right plummeted to only 10 Euros, because of news that some countries gave their industries such a generous emission cap that there was no need for them to reduce emissions. In March 2007 the price fell to 1, 2 Euros per right, and in September 2007 the price was only 0, 1 Euros per right. This big volatility and surge of price in the second half of the trading period made the managers recalculate their costs and change their decisions.

Figure 6: Spot price of European allowance

The biggest problem was the fact that until April 2006 no one could predict that price will fall. The change of price might have made the current investments in clean technology non-profitable. For example, a company has calculated that an investment in clean technology will reduce emission for 100 tons until the end of the first trading period. If a decision had to be made in February 2006, the price that would be used to calculate the value of saved rights would probably be equal to 30 Euros. Total value of rights that could be sold on the market would be estimated at 3.000 Euros. If the same company would calculate the values of extra rights one year later, the value of one right would be 10 times less (around 3 Euros, or even less than this). The value of extra rights would be estimated at only 300 Euros. If we assume that total costs of investment have been predicted at 1.000 Euros, the change of price of rights would have made the investment non-profitable.

The price of rights during the second trading period has also been volatile. The price of rights has also fallen, because of the economic recession in Europe and the whole world. According to research, the quantity of rights that countries distributed to companies during the second trading period was in line with their economic activity planned before the recession. However, after the recession the emission of greenhouse gases decreased drastically, leading to the increase in the supply of rights on the market and, consequently, to the fall of prices.

Managers must also be aware of the fact that most rights will be auctioned in the third (and all following) trading period. This means that companies will have to pay for the rights on the beginning of the trading period, and use them during the trading period. According to this, the market price of rights might not have to be used in the decision making process. It will be replaced with the auctioned price of rights. The quantity of rights will be calculated based on the predicted decrease of emission during the useful life of the investment. If we use the example mentioned above (the installation of filter), total value of emission cut during the second trading period will have to be increased with the total value of "saved" rights (rights that will not have to be bought in the future period due to the emission cut).

It is planned to use money earned from the auction of rights to subsidize new investments in clean technology. This fact will also have to be included in cost-benefit analysis, because it will affect the value of initial investment.

The price of carbon must not be used only for decision making for new investments. This information is very important for the calculation of profitability of both existing and new products. In order to include the cost of emission in the calculation of the profitability of every product, it will be necessary to distribute total company's emission to all its products. This is a complicated process and it cannot be done easily. There are usually more products made within a company or within one section at the same time, and the right key will have to be found in order to distribute total emission to all products. After the quantity of emission is calculated, it is necessary to determine the cost of emission of one tone, and difficulty of this decision is described above. In spite of the difficulties related to the distribution of total emission to a single product, this can be very useful information for managers, because they can see the quantity of emission that every product makes, and decide if that product is going to be produced in the future or not. Also, if emission related to some of the products is high, managers may try to find different method of production, or use different fuel in order to reduce emission.

6. THE POSSIBILITY OF WINDFALL PROFITS

Although the Kyoto Protocol and the EU ETS have imposed some obligations for the companies, some of them have used these systems to make gain. Those companies have been incorporating the price of carbon in the price of their products. This right has been reserved for companies that have monopoly on a certain market. If a company competes with firms that do not operate under the emission cap, it may not be able to pass on the full costs of rights to consumers. Also, if market is regulated by the government, the company will not be legally allowed to raise prices.

Under the EU ETS system, energy companies have had the opportunity to compute the price of rights for carbon emission in the price of electricity. The best evidence that can back up this behavior of companies can be found by monitoring the prices of electricity during the first commitment period. The fall of prices of rights in May 2006 was followed by the fall of the prices of electricity by 5 to 10 Euros. This price adjustment can be directly linked to the fall of prices of rights, because it was not connected to other energy market movements that could also affect electricity prices. These companies have treated rights that were given (free of charge) to them as a cost and increased the price of their products. To be precise, these companies have treated the price of rights as opportunity costs. The reason for this is the following: all allowances that

were given to a certain company could be either used to cover the emission of greenhouse gas, or sold on the market. The production (and emission of greenhouse gas) eliminates the latter option. Therefore, the companies have been giving up the profit they could earn on the market by selling those rights. Because of this, managers have been treated the price of rights that must be “saved” as opportunity cost, and increased the price of electricity.

As it was previously said, after the second trading period, most rights will probably be auctioned. Based on this, it will be legitimate for companies to include the costs of rights in the prices of their products.

7. CONCLUSION

The Kyoto Protocol and the EU ETS have imposed certain obligations to companies that operate in developed countries. These companies have been dealing with the problem of inclusion of the cost of the emission of greenhouse gas in their decision making process for some time. Along with their competitors from developed countries, the companies from developing countries will have to face with the problem of the reduction of greenhouse gas, now or in a couple of years. The managers of companies that think ahead will start to include the cost of emission in their long-term plans now and prepare their companies for future actions.

Abstract: *In this paper, we wanted to demonstrate how methods of mathematical modelling could be used for the improvement of vaccines procurement, for mandatory children immunization, with an objective to minimize the cost of administering vaccines. For the study purpose, we chose mandatory vaccines which are meant to be applied against the following diseases: Hepatitis B (HB), Diphtheria, Tetanus, Pertussis (DTP) and Haemophilus Influenza Type B (Hib), for children immunization in the first six years of life. We considered four vaccines producers and ten vaccines (six combined and four single), currently available on the market in Serbia. According to the presented results, there is a significant gap related to minimal costs, between an optimal vaccine schedule and the optimal vaccine schedule in which multiple vaccines are favoured. That gap is 10,080 RSD (approximately 90 EUR) per child. This fact should be borne in mind when considering the effective allocation of resources in the national immunization programme planning.*

Keywords: *mathematical modelling, vaccines procurement, children immunization schedule, resources allocation*

1. INTRODUCTION

Vaccination is one of the primary strategies used by public health authorities to control human infectious diseases (Tanner, Sattenspiel & Ntamo, 2008). After general hygiene improvements, as the clean water supply is, vaccines represent the most effective and cost-saving public health intervention. Immunization is the process in which a person is made immune to an infectious disease, typically by the administration of a vaccine (Gledović et al., 2009). Vaccines stimulate the body's own immune system to protect the person against subsequent infection or disease.

There are a great number of communicable diseases for which effective vaccines are available. Most of the existing vaccines have some specific requirements: multiple doses that must be administered in a specific minimum or maximum time window, some of them are forbidden to be administered in the same time with other vaccines, some diseases are uncertain about evolution of the epidemic strains, etc. Furthermore, there are challenges in the vaccine manufacturing process including uncertain yields, quality control, supply chain logistics, and optimal storage location of vaccine supplies (Zhang, Mason, Denton, Pierskalla, 2011). Finally, many new vaccines, which are present on the market today, are multivalent: they are including the combination of vaccines that can cover multiple diseases. Furthermore, it is a challenge to determine an economic package of vaccine types and brands that should be procured and that will ensure the immunization schedule requirements.

Childhood vaccination is the most common means of mass vaccination. Numerous models are developed to aid in the selection of a vaccine formulary, pricing of vaccines, and design of vaccination schedules (Zhang, Mason, Denton, Pierskalla, 2011). Jacobson et al. (1999) proposed integer programming models to determinate the price of combination vaccines, and later (2006) investigated a child vaccine supply shortage problem to assess the impact of child vaccine stockpile levels on vaccination coverage rates of the current guideline during supply interruption.

2. PROBLEM DESCRIPTION

A childhood immunization schedule in Serbia is a very complex and requires several visits to health centres for receiving mandatory vaccines. These visits are sequenced based on specifications of each vaccine. Official childhood immunization schedule in Serbia requires immunization against ten communicable disease which could be prevented by seven mandatory vaccines (Pravilnik o imunizaciji i načinu zaštite lekovima, Sl. Glasnik RS 11/06).

In this paper, we wanted to demonstrate how mathematical modelling could be used for procuring vaccines for a childhood mandatory immunization in Serbia, with an objective to minimize the cost of administering vaccines. The study is based on the proposed modernized immunization Programme, given by the medical experts (Radlović et al) and includes all vaccines and vaccines combinations available from different manufacturers, official recognized in Serbia. The major goal of this paper is to suggest the mathematical model, which could be used in selection of a most economical set of vaccines that should be procured to satisfy above-mentioned proposed immunization Programme schedule.

For the study purpose, we chose mandatory vaccines which are meant to be applied against following diseases: Hepatitis B (HB), Diphtheria, Tetanus, Pertussis (DTP) and Haemophilias Influenza Type B (Hib), for the children immunization, in the first six years of life. For combined vaccines, which contain the vaccine against Poliomyelitis, this single component will not be considered. There are four producers (labelled with P1, P2, P3, P4) and ten vaccines (six combined and four single, labelled with X1, X2, X3, X4, X5, X6, X7, X8, X9, X10) available on the market in Serbia. Total vaccination administering costs include: vaccine costs per dose and the cost of vaccine preparation by medical staff (table 1).

Table 1: Vaccines applications and vaccines delivery costs

Vaccine	Producer	Total costs per dose (RSD)	HB	DTP	Hib
X1	P1	300	0	1	0
X2	P2	1300	0	1	0
X3	P3	1450	0	1	0
X4	P2	980	0	0	1
X5	P3	880	0	0	1
X6	P3	750	1	0	0
X7	P4	650	1	0	0
X8	P2	3200	0	1	1
X9	P3	3150	0	1	1
X10	P3	4950	1	1	1

3. INTEGER PROGRAMMING MODEL

In this paper we presented an integer programming model for children vaccination procurement. This model was created in order to define the most economical set of existing vaccines, individual and combinations, by the brand (manufacturer), which should be procured in the certain age and in order to satisfy an immunization schedule proposed by health experts, as well as to satisfy all the vaccinations constrains.

All decision variables in the model are binary (0-1). Vaccines could be administered in the age of 0-1, 2, 3.5, 5, 15-18 and 48-72 months of life, and that is presented with six phases, respectively (table 2). For every phase in which certain vaccine should be administered, a set of binary decision variables is defined: a value one (zero) indicates that the vaccine should or should not be administered in that phase. Having said this, HB, DTP and Hib vaccination ought to be conducted in six phases, where in each phase against one or more diseases the application should be executed.

Table 2: Phases and schedule of vaccination

Phase	HB	DTP	Hib	Optimization possibilities
1	1	0	0	No
2	1	1	1	Yes
3	0	1	1	Yes
4	1	1	1	Yes
5	0	1	1	Yes
6	0	1	0	No

Each phase can be optimized separately, as a multi-phased optimization, since decisions made in current phase are not inflicted by the decision made in previous phase/phases.

From the tables above it is obvious to conclude that vaccination in Phase 1 and Phase 6 will be executed with vaccines X7 (650 RSD) and X1 (350 RSD) respectively.

The plan for the application of vaccines for the phases 2, 3, 4 and 5 can be optimized by using the following mathematical model:

$$\min F(x)^P: X_i C_i \quad (1)$$

s.t:

$$\sum_{i \in V_p} a_{ij} x_i = 1, j \in D_p \quad (2)$$

$$x_i \in \{1, 0\} \quad (3)$$

$$x_i, c_i \in V_p \quad (4)$$

P -current decision phase

V_p -set of vaccines which could be applied in the phase P

D_p -set of diseases for phase P of which vaccination is executed against

a_{ij} -binary parameter which denotes whether a vaccine i could (could not) be used against a specific j disease, $a_{ij} \in \{1, 0\}$

x_i -decision variable

$\min F(x)$ -the objective function for minimization of vaccines administration costs

Constrain in equation (2) will ensure that for each disease in phase P , the vaccine will be applied only once and the constrain (3) represents the nature of the decision variable-binary.

4. RESULTS

Presented integer programming model described in section 3 was used to develop economically sound packages of vaccines, by producer and combination, to meet the national immunization program. The integer model contains ten integer-binary variables. Constrains represented in section 3 (equations 2-4) are related with application of specific vaccines against the specific disease (2) and with the nature of variables (3). The integer programming model was solved using the GLPK v.4.47 software tool. Two cases were considered: first, with the optimal vaccination schedule and second, optimal vaccination schedule with multivalent vaccines. It have to be noted that, the presented mathematical model of integer (binary) programming could be used for the optimization of the full-scale Immunization schedule for children vaccination in Serbia (or any other territory), with as many vaccines as proposed by the national immunization schedule. The model could include all vaccines and vaccines combinations available from different manufacturers in Serbia and could be applicable on every new vaccination program which will be presented by the health authorities every year. However, the optimal schedule of vaccination, regarding to minimal costs of vaccination, for the chosen mandatory vaccines (HB, P, Hib) in the first six years of children immunization program in Serbia, is presented in table 3.

Table 3: The optimal vaccination schedule

Phase	Proposed vaccine(s)	Costs
1	X7	650,00 RSD
2	X1, X5, X7	1.830,00 RSD
3	X1, X5	1.180,00 RSD
4	X1, X5, X7	1.830,00 RSD
5	X1, X5	1.180,00 RSD
6	X1	350,00 RSD
-	Subtotal	7.020,00 RSD

The optimal schedule of vaccination, using the combined multiple vaccinations available at this moment in Serbia, regarding to minimal costs of vaccination, for the mandatory immunization in the first six years of children immunization program in Serbia is presented in table 4.

Table 4: The optimal vaccination schedule using combined multiple vaccines

Phase	Proposed vaccine(s)	Costs
1	X7	650,00 RSD
2	X10	4.950,00 RSD
3	X9	3.150,00 RSD
4	X10	4.950,00 RSD
5	X9	3.150,00 RSD
6	X1	350,00 RSD
-	Subtotal	17.200,00 RSD

5. DISCUSSION AND CONCLUSION

The issue of immunization financing in developing and transitional countries has become more critical in recent years. It is a challenge to meet all demands of national immunization programs and to try to increase coverage, to improve immunization safety and to add new, more expensive vaccines to national immunization programs (Economics of immunization: a guide to the literature and other resources, 2005).

Immunization policies compete with other public health interventions for limited budgets both at the national and global level. Within immunization budgets themselves, resource allocation decisions have to be made between different policies and options and one significant subject matter are safe, effective and efficient vaccines in national immunization programs.

Operations research has the potential to point out how full immunization against childhood diseases can be achieved with an economically sound package of vaccine types, brands and combinations. Operations research models can serve to optimize the way childhood immunization programs can be designed and implemented. Moreover, the models can also provide vaccine manufacturers with a tool to assess the impact of new vaccine combinations, as well as to determine whether an investment in such combinations is warranted. Therefore, these models can be embedded in expert systems that can guide vaccine procurement, vaccine administration schedules, identify vaccine combination opportunities, and encourage or discourage investment programs in new vaccines and/or vaccines combinations (Jacobson et al, 1999).

This paper reports how operations research and mathematical modeling could be used to address a national immunization program for children vaccination procurement and delivery problem. Integer programming model, described in this paper, was used to develop an economically sound packages of vaccines (by manufacturer and combination) to meet the requirements of national immunization program.

On the first place, vaccine has to be safe on human's health. An ideal vaccine is effective, covers a wide range of diseases, administered in a single or small number of doses, will provide lifelong immunity, is stable, can be transported easily and is affordable (Spier, 1997). Multivalent vaccines are usual in national immunization programs in most of developed countries. Primary advantage of these vaccines is a reduction of number of injections per a child and decrease of number of clinic visits as well.

National immunization services and their capacity for integrating new vaccines and other innovations differ across countries. According to presented results in this paper, there is a significant gap, related to minimal costs, between optimal vaccine schedule and optimal vaccine schedule in which multiple vaccines are favored. That gap is 10.080 RSD (approximately 90 EUR) per one child. One have to note, that the main reason for identified gap between costs of sets of single and multivalent vaccines is vaccine labeled X1 which production is supported as a national product.

Under the socioeconomic conditions, when the average salary in the country is approximately 360 EUR (based on available data of Statistical office of the Republic of Serbia), in the moment when the multiple vaccines are in considering for introduction in national immunization program for children immunization, bearing in mind all the advantages of these vaccines, planners should take into account the efficient allocation of the resources as well.

SUGGESTION OF A MODEL OF A CENTRALIZED SYSTEM FOR PROVIDING SERVICES IN THE FIELD OF CLINICAL TRIALS ON DRUG

Stamenovic¹, Suzana Pavlovic²

¹Pierrel Research, m.stamenovic@rocketmail.com

²Health Sanitary School of Professional Studies Visan, miskos@verat.net

Abstract: *This paper deals with the problems of current decision-making system in the field of clinical trials in Republic of Serbia and with a suggestion of implementation of proposal of innovative project management model of a centralized decision-making system in clinical trials. The current decision-making model in clinical trials in the Republic of Serbia has been observed as time consuming, expensive and non-transparent, what is burdening the sponsors of clinical trials, the institutions that conduct clinical trials as well as the participants of the trials. Contrary to this divided and localized system of the management process of clinical trials, in some EU countries appears that a centralized and more efficient system for providing services in decision-making processes in the area of clinical drug trials is possible, and it makes a contribution to the quality of the whole process. Research demonstrated in this paper has value for Ministry of Health of Republic of Serbia, Medicines and Medical Devices Agency of Serbia, Local Ethics Committees of Investigational Institutions within Serbia and international and domestic Pharmaceutical Companies and Contract research organizations involved in clinical trials processes in Serbia.*

Keywords: *health care management, clinical trials on drugs, innovation, new service development model, decision-making processes*

1. INTRODUCTION

A clinical trial is a study performed on humans with the aim to establish or confirm the clinical, pharmacological and pharmacodynamic effects of one or more drugs tested, to identify any adverse reactions to one or more tested drugs. It has for its aim to examine the absorption, distribution, metabolism and excretion of one or more drugs, as well as to determine safety and efficiency of the drug (*The Official Gazette of RS*, 2010).

A sponsor of a clinical trial can be a producer, a legal or a natural person (hereinafter referred to as the sponsor) and is responsible for the initiation, management, quality and financing of the clinical trial. The sponsor may transfer some or all obligations related to the conduct of clinical trial to a Contract Research Organization located in the Republic of Serbia (hereinafter referred to as RS), which is responsible for the activities that the sponsor had transferred onto them in the process of approval and conduct of clinical trials on the territory of RS.

The sponsor is responsible for the activities transferred to the Contract Research Organization (*The Official Gazette of RS*, 2010). Prior to the beginning of clinical trials, the Local Ethics Committee of the Research Institution makes a decision on the conduct of the clinical trial (*The Official Gazette of RS*, 2010).

The Ethics Committee considers the request for conducting the clinical trial with documentation submitted and brings a decision within 60 days from establishing that the application is complete (*The Official Gazette of RS*, 2010). The Ethics Committee is obliged to inform the sponsor of the clinical trial or authorized Contract Research Organization as well as the Medicines and Medical Devices Agency of Serbia (hereinafter ALIMS) about its decision within 15 days (*The Official Gazette of RS*, 2010). If the Ethics Committee does not make a positive decision on conducting the clinical trial, ALIMS will not issue the authorization of clinical trials.

The approval for the new clinical trials on drug/drugs implies that the sponsor of the clinical trial, who does not have an approval for the drug in RS, or the drug proposed to be used, must apply for the authorization of clinical trials and submit to ALIMS complete documentation in conformity with the law and regulations. The sponsor submits the documentation that includes: a summary of the nature and characteristics of the drug, conducted research in order to define its pharmacological and toxicological properties, clinical experience, the protocol of proposed trial, a list of all researchers and institutions involved in the study, as well as the

approval of all Local Ethics Committees of the Research Institutions (*The Official Gazette* of RS, 2010). The content of the request i.e. documents necessary for the authorization of the clinical trial, as well as the protocol of the clinical trial, is prescribed by the Minister in charge of health affairs (*The Official Gazette* of RS, 2010). If all the requirements stipulated in this law and regulations adopted in order to implement this law are met, ALIMIS will issue the authorization to conduct the clinical trial (*The Official Gazette* of RS, 2010).

In the RS the decision-making in the field of clinical trials is conducted in several phases, which are long, segmented, and with an uncertain outcome. The basic problem in the decision-making system - the department of service provided by state institutions in the field of clinical trials - appears to be in localization and segmentation of certain phases of the service in the decision-making system. Based on EU Directive 2001/20/EC, it is possible to implement various decision-making models in this field. Ministry of Health of the RS through ALIMIS implements a system in Serbia that includes the decision-making structure during the authorization of clinical trials or the authorization of variations of and amendments to clinical trials provided in the graphic (Figure 1). Funding for the entire decision-making process is provided by the sponsor of the clinical trials. The sponsor of the clinical trial on drug/drugs pays the appropriate sum of money for the services received from the Local Ethics Committee and the ALIMIS. The amount of money paid for the services completed is in accordance with the statutes of these institutions, and is paid as a compensation for the bringing of the appropriate decision according to the conclusion of the meeting of the expert committee and submitted documents of the clinical trials on drug/drugs.

The time component in terms of the length of the entire decision-making process is of great importance for to the sponsor of the clinical trial as well as for the researchers and patients (i.e. potential users of the drug being tested). In divided and localized decision-making system, the changes of the expected deadlines are frequent and endless. It should be noted that in this paper the decision-making process is being reviewed at its most important and most complex processes within the clinical trials related to institutional decision-making systems such as obtaining the authorization of clinical trials in the RS and obtaining the authorization of variations of and amendments to clinical trials.

The model from the graphic (Figure 2), of a centralized innovative decision-making system for provision of services in the field of clinical trials, provides the opportunity to avoid some shortcomings in terms of time, cost and efficiency of the existing models.

The main contribution of this system would be in optimization of the decision-making within the Ethics Committees centralized at the national level. Thus, the speed of decision-making would be greater, the chances to delay the process would be smaller and, ultimately the cost of the process would be reduced. The centralized innovative decision-making system enables the concentration of certain parts of decision - making. At the same time the proposed model would reduce the number of procedural and administrative processes in each institution and thereby it would reduce the cost and increase the efficiency.

2. THE EXISTING SYSTEM FOR PROVIDING SERVICES WITHIN THE DECISION-MAKING PROCESSES IN THE FIELD OF CLINICAL TRIALS

As part of this paper, the current system for providing services within the decision-making in the field of clinical trials, based on the existing legislation, is presented (*The Official Gazette* of RS, 2010). The process presented (Figure 1) considers a situation in which the sponsor of the clinical trial requests for the services in the form of an authorization for conducting clinical trials or requests the authorization of variations of and amendments to clinical trials. These two procedures are considered as the most complex requests in which we can see the most clearly the decision-making process in Serbia.

The system is managed by the highest authority, the Ministry of Health of the RS, through the ALIMS. The set system can be modified only in case of changes of relevant legislation relating to the existing procedures.

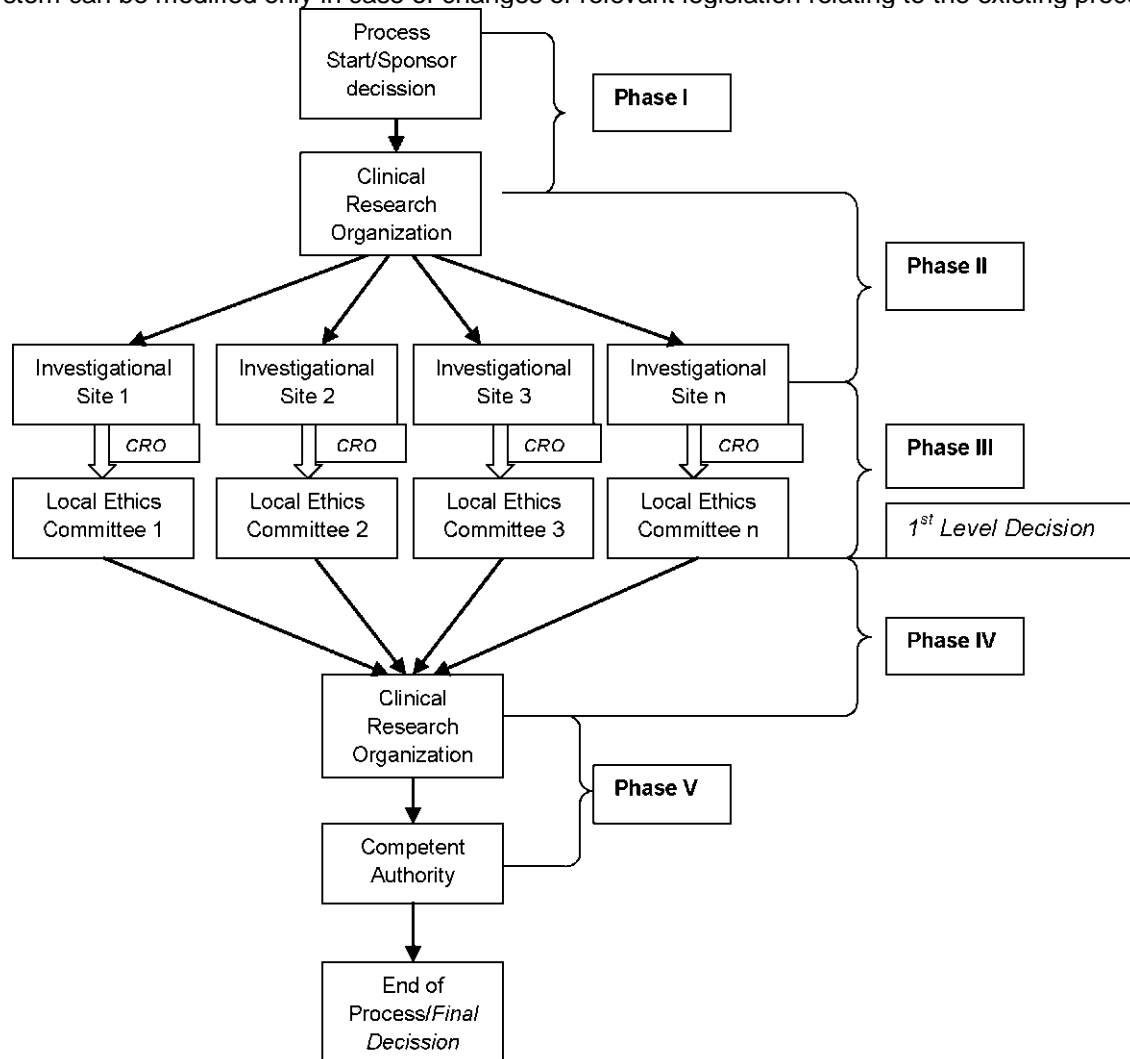

Figure 1: The current system of providing services in decision-making processes in the field of clinical trials, provided by the author

Phase I - According to the Law on medicines and medical devices of RS the sponsor of the clinical trial is required to submit all necessary documents to the decisions-making system within RS for assessment in order to obtain the authorization of clinical trials in RS or to obtain the authorization of variations of and amendments to the already authorized clinical trial on the territory of RS (*The Official Gazette* of RS, 2010). The sponsor of the clinical trial on drug/drugs e.g. a pharmaceutical company that wants to implement a certain stage of scientific trial on the territory of the RS, authorizes a Contract Research Organization (CRO) to apply for the conduct or variations within the clinical trial (*The Official Gazette* of RS, 2010). In the above mentioned graphic (Figure 1) the sponsor authorized the Contract Research Organization to submit the appropriate documents to the state institutions.

Phase II - The Contract Research Organization (CRO) is authorized by the sponsor of clinical trial (*The Official Gazette* of RS, 2010). Based on the contract between the Contract Research Organization and the sponsor, the Contract Research Organization has the authority to submit all legally stipulated documents to the authorities of the state responsible for the decision-making process related to clinical trials. In the case of the mentioned existing model in the RS, as shown in the graph (Figure 1), the institutions to which documents are being submitted to are Research Institutions, Local Ethics Committees of Research Institutions and the ALIMS, in the given order. In this step the necessary documents e.g. contracts, consents of the responsible persons, etc. should be submitted to Research Institutions and based on those documents the Contract Research Organization is able to move to the phase III. This phase includes the submitting of all documents related to the clinical trial of a medicinal product together with the documents

received from the Research Institutions of Local Ethics Committees. When the paid service is obtained in the form of approval of the Local Ethics Committees, that approval and all the documents are further submitted to ALIMIS whose services are paid additionally, depending on the type of service.

Phase III - The graphic (Figure 1) shows three Local Ethics Committees of Research Institutions and the fourth is shown as the n^{th} (there can be a maximum number within the number of existing clinical centers and medical centers in the RS, because each of them represents a potential research center for specific therapeutic indications (*The Official Gazette* of RS, 2010)). We can state that the number of 4-8 Research Institutions makes an average number of institutions participating in a clinical trial, and therefore the number of Local Ethics Committees that make decisions on clinical trials is 4-8 - each Research Institution has its own locally organized ethics committee that provides services in the decision-making process (*The Official Gazette* of RS, 2010). The Contract Research Organization (CRO) has the obligation to submit all the documents received from the sponsor (adjusted to the local laws of the RS) to the Local Ethics Committees under whose approval it may proceed with the process of submitting documents to higher instances (*The Official Gazette* of RS, 2010). In the case of RS the higher instance for decision-making is the ALIMIS. The Local Ethics Committees provide services related to appropriate decision-making according to specific demands of clinical trials on drug/drugs. They are being paid for their services by sponsors of clinical trials through the Contract Research Organization (*The Official Gazette* of RS, 2010).

Phase IV - shows the step in which the Contract Research Organization takes over the decisions made by Local Ethics Committees and with further adaptation processes submits the overall documentation received from the sponsor, together with the approvals obtained from the Local Ethic Committees to the ALIMIS (*The Official Gazette* of RS, 2010).

Phase V - shows the step in which the documents are being delivered to ALIMIS - (Competent Authority), and then within the legal deadline, depending on the service requested, final approval issued by the Ministry of Health of the RS is expected (*The Official Gazette* of RS, 2010).

Phases III and V, present the submission of documents by the authorized Contract Research Organization to the state authorities paid as a service provided by the state institutions in the name of provision of services in the area of decision making - making of appropriate decisions at the meetings of expert committees. Prices are determined by the statutes of the institutions to which the documents are submitted to. A number of institutions (committees for providing services in the decision-making process) lead to the multiplication of payments for basically the same service.

3. THE PROPOSAL OF AN INNOVATIVE CENTRALIZED SYSTEM FOR PROVIDING SERVICES IN DECISION-MAKING PROCESSES IN THE FIELD OF CLINICAL TRIALS ON DRUG / DRUGS

This section presents a proposal of a centralized system for providing services in the decision-making processes in clinical trials which is primarily based on the provision of such services on the territory of the Republic of Romania. Beside the Republic of Romania, many European countries have introduced a system for providing Centralized services in decision-making processes in the field of clinical trials (European commission, 2008.). Decision-making process itself is arranged differently from country to country and adapted to local laws. Among others, the Republic of Romania follows Directives of the European Commission 2011/20/EC, then Directive 2003/94/EC, 2005/28/EC and ICH E6, which make it one of the countries of the European Union that has fully harmonized its system with all the European and international regulations and standards (The European Forum for Good Clinical Practice, 2011). EU Clinical Trials Directive 2001/20/EC, allows the implementation of various models of the decision-making system - a department for providing clinical trials services. The system shown in the graphic (Figure 2), is primarily better due to centralized decision-making system. Within this centralization all Local Ethics Committees of Research Institutions (Figure 1, Phase III) that participate in clinical trials have created one, a National Ethics Committee, whose goal is to shorten the decision-making time and increase the quality of decision-making (Figure 2, Phase III). In the Republic of Romania (Figure 2), the National Ethics Committee for clinical trials is an independent body. National Ethics Committee is under the direct jurisdiction of the Ministry of Health of Romania (The European Forum for Good Clinical Practice, 2011).

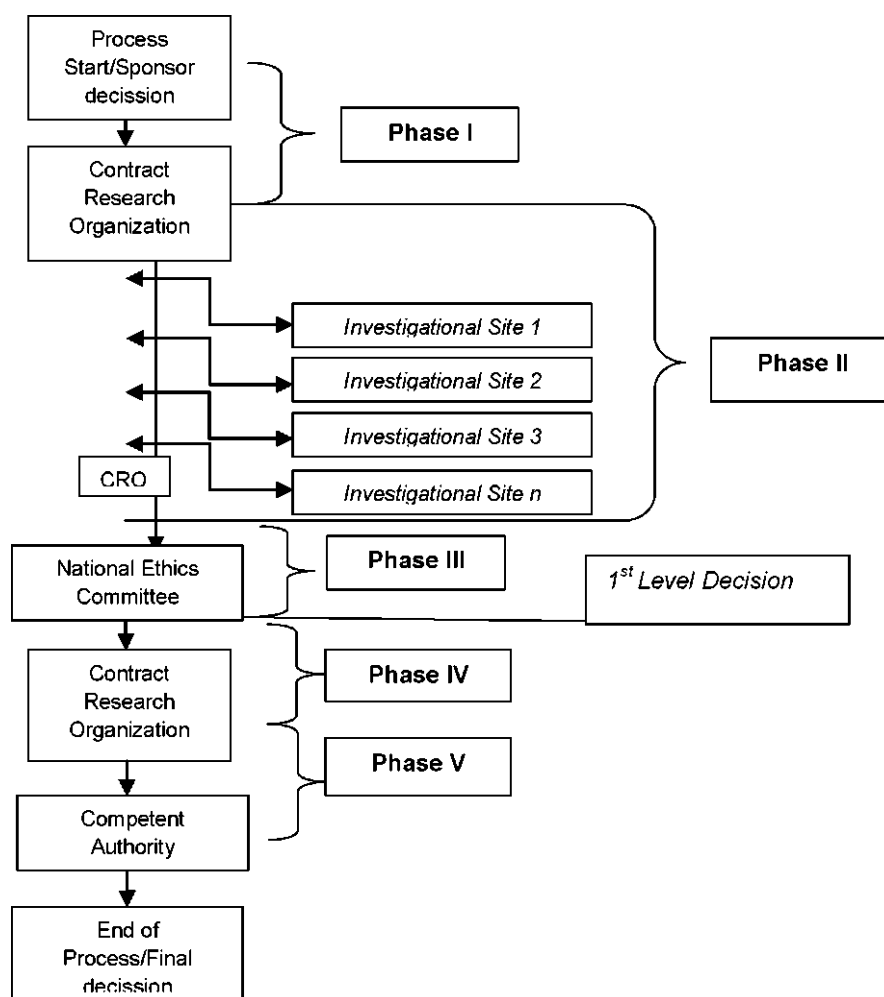

Figure 2: The proposal of an innovative centralized system for providing services in decision-making processes in the field of clinical trials, provided by the author

In the case of the innovative system based on the examples of service provision systems in the decision-making processes within clinical trials in the Republic of Romania, the sponsor of the clinical trial would be, as in the present system of the RS, legally required to submit the documents to the Contract Research Organization. This Organization would adapt the stipulated documentation to local laws, and submit it to the National Ethics Committee, instead of numerous Local Ethics Committees of Research Institutions. In that case the multiplication of the costs, prolongation of the decision-making process and non-transparency of the decision-making process in the form of paid services to local authorities, would be avoided. All other decision-making processes and procedural systems for providing services would remain the same as in the graphic (Figure 1).

4. A MODEL OF AN INNOVATIVE CENTRALIZED SYSTEM FOR PROVIDING SERVICES IN DECISION-MAKING PROCESSES IN FIELD OF CLINICAL TRIALS OBSERVED THROUGH A PHASE MODEL OF DEVELOPING INNOVATIVE SERVICES

The innovative system for providing services focuses primarily on the formation of a new National Ethics Committee and by that a new service provider in the decision-making process would be initiated. Activities of this innovative service would lead to cost reductions and greater certainty regarding time and finances within the decision-making process. In this paper, in the aim of further implementation of the model of centralized innovative system for decision-making in clinical trials, one of the well-known innovation project models in the services, the Sashimi model, can be used. Sashimi model is so called because it features overlapping phases, like the overlapping fish of Japanese sashimi (Ward, 1998). Initially it was referred to as the "waterfall model with overlapping phases" or "the waterfall model with feedback" according to Matkovic and Tumbas (2010). Since the phases in the Sashimi model overlap, it may point to existing

problems during the implementation of the project very well. The phase model of the development of the new service could be based on this model.

4.1 The phase model of the development of the new service

According to Milutinovic and Stosic (2011), the phase development of Sashimi model includes the following overlapping phases:

1. Possibility analysis
2. Feasibility and defining
3. Design and testing
4. Development
5. Implementation and a pilot test
6. Commercialization

4.1.1 Possibility Analysis

Within this analysis it is necessary to determine if the implemented service would be profitable and thus justify its implementation. If so, it is possible to move onto the next phase. Involved organizations estimate the prospects for implementation of such project in terms of capacity and support for further implementation of this project. The final decision on implementation in this case must be made by the state, i.e. the Ministry of Health of the RS. Within the Ministry of Health, organizational changes of the new service model would include institutions of the ALIMs as well as the Local Ethics Committees within research centers i.e. clinical centers and medical centers in the RS. Their network infrastructure would have to be eligible. The purpose of the implementation of this model of the decision-making process in terms of service, when making decisions about clinical trials, primarily is to provide transparent, more efficient and less expensive process that would bring relief to all participants in this process and mostly to the sponsor of the clinical trial e.g. cost reduction, the increase in speed of the decision-making process, then to researchers e.g. increase in speed of decision-making process, and finally to our patients e.g. enabling the use of the innovative drug in a timely manner. From the state's point of view, centralized innovative decision-making would contribute to a clearer and more transparent monitoring system of clinical trials that are underway, as well as to faster and more efficient decision-making and implementing decisions on existing or anticipated clinical trials. Also, with the increase of favorable business conditions and with the convergence of current conditions to efficient and applicable models in the world, the state would provide good business conditions and thus increase the number of sponsors to whom timely decisions and pricing could be crucial in the case of selection of the country where they would conduct their research and commercial activities. The increase in the number of sponsors enables the larger number of the above mentioned studies that can contribute to creation of new workplaces in the field of innovative technologies and services, as well as greater visibility and prestige of our Research Institutions in the world, which is partially reflected through a number of published and successful clinical trials in which our researchers were the participants. The innovative centralized service provision in the decision making process in the field of clinical trials cannot be initiated prior to the changes in the statutory legal framework that would enable its implementation. The ministry is also obligated to harmonize the internal affairs with subordinate legislations within 60 days from the date of enactment of the necessary legal regulations.

4.1.2 Feasibility and defining

Within the second phase the service provider/service should be defined. Getting out of this phase would be in the form of a draft of a final service. It should be defined in detail what the service implies. In the case of the proposed implementation of the model of the centralized innovative decision-making system in clinical trials main phases are listed in the graphic (Figure 1 and Figure 2). The graphic (Figure 1) represents the current service provision system within the decision-making process in clinical trials, and the graphic (Figure 2) represents an innovative model for centralized provision of services in the process of decision-making in the field of clinical trials. As stated in the introduction, this decision-making system is best to be observed through the most complex and the most important decisions related to the clinical trials in the RS. For providing the decision-making service and for revision of the submitted documents at the meeting of the expert board of a Local Ethics Committee of a Research Institution, as well as the ALIMs, certain compensation is provided in accordance with the statutes of these institutions. Such decisions include the authorization of clinical trials and the authorization of variations of and amendments to clinical trials.

The idea to implement the innovative model is based on the restructuring the existing decision-making process and the centralization of the existing decision-making system within which the service of the

decision-making would be transferred from the level of Local Ethics Committees of Research Institutions to the centralized innovative service of the decision-making system and thus avoid multiplication of submitting documents required for decision-making, reduce decision making costs i.e. one decision-making committee would be paid instead of all local committees for making individual decisions, and it would also reduce the possibility of prolonging the bringing of appropriate approvals - according to the centralized decision-making system (Figure 3).

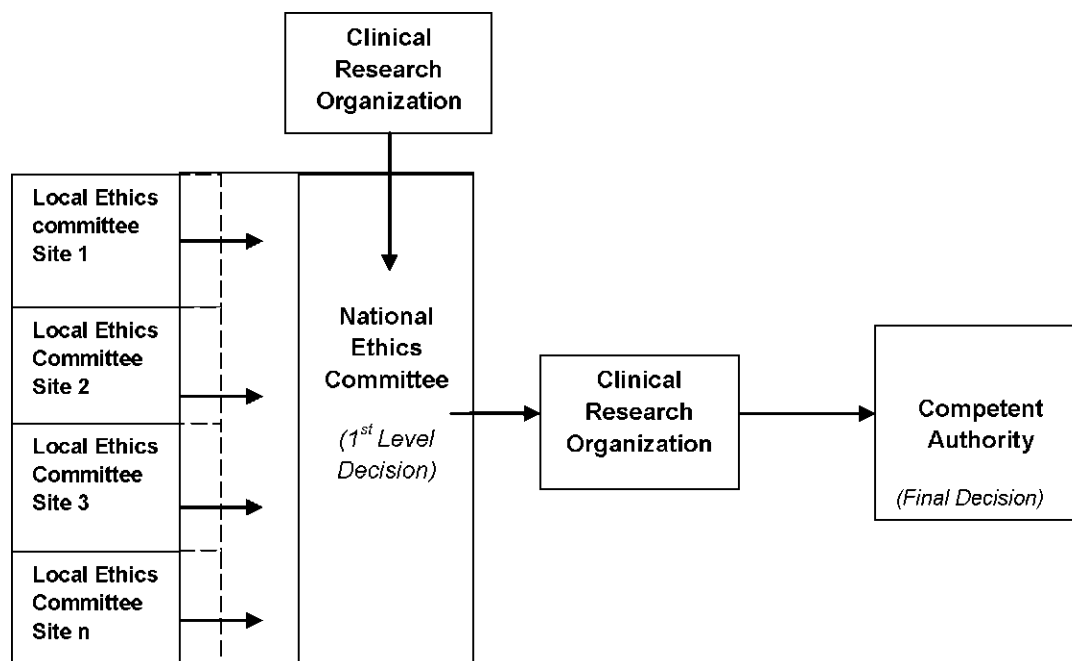

Figure 3: Proposal of substantial changes in the infrastructure network of the system for decision-making services from divided and localized systems into a centralized innovative system for providing decision making services in clinical trials, provided by the author

4.1.3 Design, development, implementation and pilot test

Within this phase, project should get a clear outline of the design in terms of further solving of the infrastructural problems. Declaration EU 2001/20/EC enables implementation of the innovative centralized service model for the providing services in the decision-making process in the field of clinical trials. Within this phase it is expected that all the components are included and the operational support systems are identified and defined precisely. The Ministry of Health should define a transition strategy to the innovative centralized service model for the provision of services in the decision-making process in the field of clinical trials. The design should be related to the Development of the project and it should be based on the action plan drawn up in accordance with the strategy. Given the specificity of the service that is being implemented, it is necessary to determine the position of the Central Ethics Committee i.e. National Ethics Committee, and official representative body for provision of service in the decision-making process. In order to reduce costs during the implementation, we suggest that the location of the Central Ethics Committee should be in the building of the ALIMS. In this way, the physical proximity of the two inevitable institutions in the service providing system of decision-making within clinical trials will contribute to the transparency of the service providing process. It is also necessary to establish a professional board of the Central Ethics Committee that would be responsible for providing services in decision-making in clinical trials on drug/drugs.

4.1.4 Development

The development is the phase of the model in which the infrastructure of an organization and the infrastructure of a service are combined and unified (Milutinovic&Stosic, 2011). After the planning process, the work on the infrastructural processes and the time component should be done. Ministry of Health of the RS is obliged to obtain all necessary documentation related to the implementation of the innovative centralized service for providing services in the decision-making process in the field of clinical trials.

4.1.5 Implementation and a pilot test

Serbian Ministry of Health should support all that is required within the implementation in order to carry out the listed services. The other segment is related specific testing of the innovative decision-making system in the field of the clinical trials. Within the implementation, it is necessary to analyze the very infrastructure and the needs for adapting the new services and to adjust them to enacted laws and regulations, in accordance with the desire for a more efficient service providing system in the decision making process in clinical trials.

4.1.6 Commercialization

Commercialization presents a phase of the Sashimi model which should sum all previous phases and thus ensure the readiness of the entire network for final functioning of the service in commercial purposes. The particularity of the project leads to further specificities of this phase. Namely, when a service system for decision-making in the field of clinical trials is changed once, it is not possible to proceed according to the previous decision-making system, i.e. the selection and the final implementation and commercialization of innovative system for delivering services in decision-making process in clinical trials would be a final and unique solution for all further processes of obtaining the authorization of clinical trials and obtaining the authorization of variations of and amendments to clinical trials. It follows that it is essential, before the project is finally commercialized, that all users of the innovative decision-making system in the field of clinical trials are clearly informed about the changes, as well as about the way of functioning of the new implemented system. Therefore, it is necessary to make a separate promotion system of a new innovative model of the centralized service within the decision-making process in the field of clinical trials that would provide all end users high quality information on time. These kinds of changes are made by the Serbian Ministry of Health in *the Official Gazette of RS*. According to the Public information law, new laws on which the future innovative system is based on will come into force eight days after its publication in *the Official Gazette of RS*.

5. CONCLUSION

Modern decision-making systems require optimization of resources and time. The present model is shown to be insufficiently flexible for various requirements of the pharmaceutical industry. In the RS, the decision-making system in the field of the authorization of clinical trials and the authorization of variations of and amendments to clinical trials is being conducted in several phases, which are long, segmented, and with an uncertain outcome. The main problem in the field of clinical trials, related to the decision making process, occurs precisely in the localization and division of certain phases of the service within the system of decision-making. Based on EU Directive 2001/20/EC the use of various decision-making models in this area is possible and the proposal of the model for implementation presented in this paper (Figure 2) would allow a significant improvement in the speed of decisions-making, or in terms of transparency and further cost reductions. Such services provided by the state and paid by foreign investors, in this case the sponsors of clinical trials, must be highly efficient and advanced to ensure the satisfaction of the end users of the mentioned services in order to fully optimize quality and time components. In a time of growing competition, we can say that every innovation in terms of service that enables optimization of resources represents a comparative advantage in relation to the countries that do not have such services. The investors who are satisfied with the clear and pragmatic solutions in the decision-making system in the field of clinical trials will be happy to re-engage in scientific research and commercial activity on the territory of RS. The benefits are multiple.

In this paper the proposed model of managing innovation projects in the area of new technical services is used. Based on the specifics of the innovative system, there are certain characteristics in the application of the Sashimi model. On the basis of adaptation according to the specifics of the innovative project for providing services in decision-making process in the field of clinical trials, Sashimi phase model of development of new service can be applied to this subject. Also, it should be noted that the phases of the Sashimi model may need further segmentation. Of great importance for the implementation of this innovative system is also legal - political framework, without which it is absolutely impossible to go into the process of changing the existing model. Experts need to initiate the process of changes on the basis of the evident shortcomings of the existing system, and the state should recognize further potential of the planned innovation projects. Also, the strategy and action plan should be done and in this way enable the implementation of the project. Considering the above mentioned, it can be concluded that during the development and implementation of new service the local environment must be taken into consideration, so that the phase model of the development of the new service could be applied in the right way.

Abstract: *The EU has started a process of integration of information and communication technologies in healthcare intended to provide better health services for patients, achieve mobility of people and create an opportunity for control and analysis of the entire healthcare system in economic and qualitative terms, which leads to the capacity of managing large health systems. This article shows that there is no common or unique approach in this area. Each country, depending on its socio-economic opportunities, finds the best way of solving problems related to the management and control of its health system. The electronic health care system comprises the implementation of information and communication technologies, especially the Internet, for the purpose of improving and ensuring health of individuals on the one hand, and the overall healthcare system on the other. The electronic health card is a basis of successful e-health system functioning. There are several types of health cards, but the following three types are the most important: Patient Data Card, Health Professional Card and Health Insurance Card. Introduction of electronic health cards in Europe has well advanced, with different models emerging in different countries. The article presents examples of the introduction of electronic health cards in each of the EU countries.*

Keywords: *healthcare, electronic healthcare system, electronic health card, Patient Data Card, Health Professional Card, Health Insurance Card.*

1. INTRODUCTION

Evaluating welfare of countries is mostly based on development level of health sector. The healthcare systems need improvement in quality, efficiency and attainability of primary healthcare, as well as acquiring new approaches and models for better health of population on a national and regional level. The notion that patients will use the Internet for medical information should come as no surprise (Gao G.G., McCullough J.S., Agarwal R. & Jha A.K., 2012). Accordingly, the implementation of information and communications technologies can lead to: improvement of population's state of health, cost reduction (by increase in efficiency in delivery of healthcare and increase in users' satisfaction in regards to health service delivery, as well as service provider's satisfaction).

This leads to the emergence electronic service delivery and the emergence electronic health care system - E health.

The electronic health care system comprises the implementation of information and communication technologies, especially the Internet, for the purpose of improving and ensuring health of individuals, on one hand, and the health-care system, on the other. It can be described as a system that is complementary to the traditional system of health services delivery; it eliminates paper as a medium and ensures that all the data on the patient and his/her health status are recorded in an electronic format and are accessed promptly and efficiently via a computer network – the Internet (Jovanovic Milenkovic, 2011).

The article presents bases of electronic healthcare that is setting the foundation for a new approach to organizing and performing business processes in the healthcare system, supported by information and communication technologies.

The main characteristics of the new approach are: orientation towards the patient, healthcare based on evidence, exchange of information about patient's health, in order to improve the healthcare and to reduce costs.

The electronic healthcare system covers a wide spectrum of activities regarding patients, service providers and healthcare systems. It contains comprehensive electronic health records of patients and

enables connections and exchange with regional and central structures for gathering and processing information within a healthcare system. It should support all processes in basic healthcare:

patients' records, rounds, treatments and events in clinics, as well as events within a ward: patient reception, treatment, and release.

In this regard, the world trend in the new area is moving towards developing medical and expert systems for improving diagnostic and treatment processes. It implies the existence of the following systems (Gibbons, 2010):

- the expert healthcare systems
- the systems of managing electronic healthcare documentation
- the systems for filing and handling images
- electronic health records (EHR)
- electronic medical records (EMR)
- electronic patient record and
- electronical health card.

Our attention will be focused on the development and introduction of electronic health card in EU.

2. ELECTRONIC HEALTH CARD

Healthcare organizations worldwide are implementing smart health cards supporting a wide variety of features and applications.

Electronic health card is a basis of successful e-health system functioning. Health cards can improve security and privacy of patient information, provide a secure carrier for portable medical records, reduce health care fraud, support new processes for portable medical records, allow secure access to emergency medical information, enable compliance with government initiatives and mandates, and provide a platform for implementing other applications as needed by healthcare organizations (Smart Card Alliance, 2010).

Electronic health card connects all participants in the health care system, as shown in the following figure.

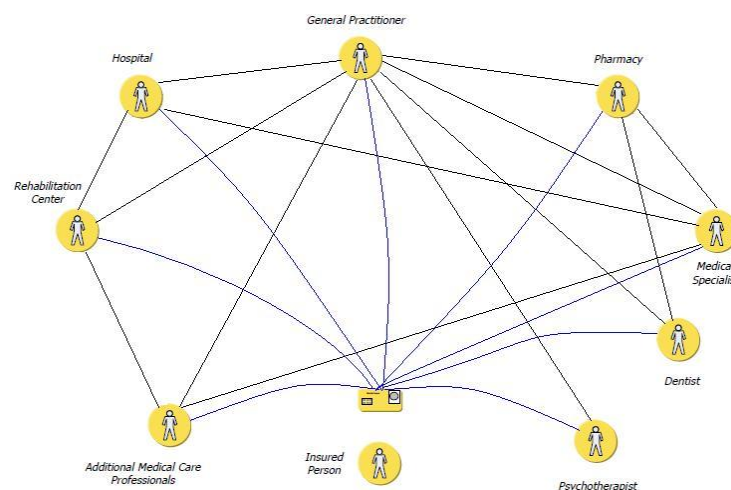

Figure 1. Electronic health card connects all participants in the health care system

There are several types of health cards, but the following three types are the most important (Istepanian, Laxminarayan & Pattichis, 2006):

- Patient Data Card
- Health Professional Card and
- Health Insurance Card.

Patient Data Card

Patient Data Card (PDC) is a mobile patient data carrier. It contains information about a patient that is essential for his/her treatment. Typical data on card chips are: the identity of a patient, information about insurance, emergency data, medical history and electronic prescriptions (Istepanian, Laxminarayan & Pattichis, 2006).

For patients, mobility means that they have complete and accurate health information at any time. Their essential patient data are always available when it comes to emergencies. Under normal circumstances, the usage of the card provides data finding and establishes an appropriate treatment for a patient. The card contains a record of all the prepared tests. This prevents excessive medical tests and examinations, and therefore results in urgency and efficiency in solving critical health problems of a patient (Partners HealthCare System, 2010). In this way, health professionals always have accurate medical information of patients. It is easier to find the best treatment and avoid risk of prescribing potentially dangerous drug combinations with these data.

Health Professional Card

Health professional has authorized access to health Professional Card (HPC). Health professional can read and write data to the card. Card carries a digital certificate and appropriate cryptographic keys for secure communication. Privacy and data security are guaranteed to patients in accordance with the rules of access, which prevent unauthorized access to their stored medical data (Istepanian, Laxminarayan & Pattichis, 2006).

For health professionals, HPC provides a quick and efficient information exchange between health professionals and other users in electronic health system.

Typical data on the card are: identification data of health professionals (name, address, phone number), a digital certificate, individual access rights for reading and/or writing patient's data, PIN to access the card. (Milenković, Jovanović Milenković, Vujin, Aleksić & Radojičić, in press).

Health Insurance Card

Health Insurance Card (HIC) is an ID card with an administrative function. It contains details of the insured, the insurance company ID and information about insurance model.

In some systems, PDC and HIC cards could be integrated into a single PDC card. In this way the administrative procedure for admission to the hospital, i.e. doctors' office is much easier for patients. HIC card increases patient satisfaction and reduces paperwork. Health information of the insured person are processed more quickly and accurately. A health professional gets fast, precise, easy and cost-effective data management. This means less paperwork, reduction of transaction costs and more effective payment. Insurance companies benefit because electronic data processing enables data on claims to be processed without error. Typical data on the insurance card are patient's insurance (insurance, social security number, expiry date), ID insurance, and insurance coverage (Milenkovic et al., in press).

The electronic health card is going to replace the now available electronic health insurance card. Its technology and functions will be extended and it shall be offered to the insured persons for use as a health card. For this purpose it is necessary to arrange the health card as a microprocessor card which is suitable for electronic identification, encryption and digital signature. In this way the best possible reliability and security of the data can be guaranteed.

3. INTRODUCTION AND IMPLEMENTATION ELECTRONIC HEALTH CARDS IN THE MEMBER COUNTRIES OF THE EUROPEAN UNION

Introduction for electronic health card in Europe are well advanced with different models emerging in different countries. The European Union (EU) is promoting their development through a range of projects and EU forums.

Electronic health cards in Germany

In Germany, electronic health card *The Gesundheitskarte* ('good health card') introduced in 2006. It contains basic patient data such as name, age, next of kin and insurance details, as well as electronic prescriptions (Figure 2.).

The Gesundheitskarte ('good health card') will contain information in a Chip-and-PIN style microchip on the side of the card, as well as a photograph and human-readable information. It replaces Germany's existing health insurance card. This card is only for patient. Healthcare professionals, including insurance companies, will need to use another electronic card to log in and read and change patients' card details (epSOS – the European eHealth Project, 2010).

Figure 2. Electronic health card *The Gesundheitskarte*

Electronic health cards and HPCs will become the electronic keys for the crossinstitutional cooperation of the stakeholders in healthcare, interlinking more than 80 million patients with about 123 000 physicians, 65 000 dentists, 2 200 hospitals, 21 000 pharmacies and more than 290 health insurance funds (Figure 3.) (epSOS – the European eHealth Project, 2010).

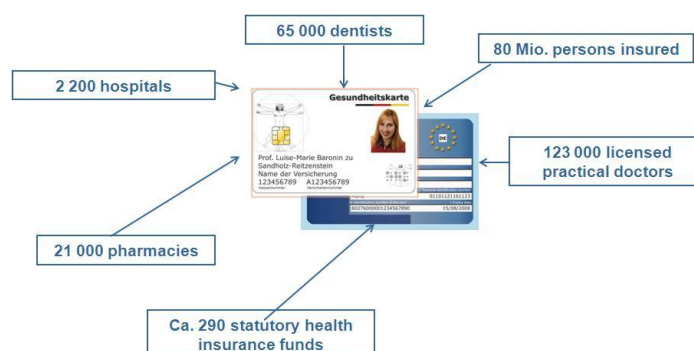

Figure 3. Connection between electronic health cards with other stakeholders in healthcare system

Electronic health cards in Italy

In Italy, electronic health card distributed in 2010. in region Tuscany is *Carta Sanitaria Elettronica* – CSE (Figure 4.). This card will replace the existing card. The card integrates all the information pertaining to hospital stays, examinations, vaccinations, medications, diseases, allergies and exemptions (ePractice, 2010).

In its new format the health card will allow accessing person's health data from home, from the doctor's practice, from the assistance points of the local health agencies. Although the cards belong to the citizens, general practitioners and pediatricians play a crucial role as they are the ones to collect most of the data that form the core of the citizen's health history building.

Figure 4. Electronic health card *Carta Sanitaria Elettronica*

Electronic health card in Slovenia

The Health Insurance Institute of Slovenia has announced that it will introduce a new electronic health insurance card system across the country. Initially will be used to obtain information on insurance. The electronic health card is the basis for access to electronic health records and getting e-prescription.

The national roll-out follows a pilot at the Dr Franc Deganc General hospital in the Nova Gorica region of Slovenia, which was completed in March 2009. After the pilot ended the system was extended to more than 100 organizations in the Gorenjska and Primorska regions. In 2010 electronic health card used more than 30,000 health professionals and two million patients. The system is the first in the country to cover both public and private insurance organizations (EHealth Insider, 2009).

Electronic health cards in Bulgaria

Bulgaria is issuing its first electronic health cards as part of the pilot project of the Ministry of Health and the National Health Insurance Fund (NHIF). Card was first distributed citizens in town of Slivnitsa and the village Aldomirovzi (both some 30 kilometers away from Sofia) in 2007 (The first European ehealth portal news, 2011).

With that card, the patient's insurance status and his/her assignment to a General Practitioner can automatically checked in the project. In addition, e-prescriptions for medications covered by the Bulgarian health insurance fund recorded on the chip (Figure 5.).

When visiting a physician, patients will identify themselves with the cards. The system automatically establishes a secure online connection to verify the patient's insurance coverage and his or her presence in the patient list of the physician. After the tests and trainings, the pilot project will go live and the first e-prescriptions will be issued and filled in Bulgaria.

Figure 5. Electronic health cards in Bulgaria

Electronic health cards in Republic of Serbia

In Republic of Serbia, we differ cards which issues Ministry of Defense of the Republic of Serbia and The Republic Fund Of Health Insurance.

The Republic Fund Of Health Insurance introduce electronic health cards during 2012. The cards will first be introduced in and after that pilot project, it will be in another town in Serbia. Valjevo is chosen because all health centers, hospitals and pharmacies are computer related with The Republic Fund Of Health Insurance (Figure 6.). It plans to change million cards in 2012, and another three years The Republic Fund Of Health Insurance will provide for all citizens (The Republic Fund Of Health Insurance, 2012).

This kind of medical identification will enable faster and easier with a doctor and raising drugs in pharmacies. On the card will be printed name, registration number and address of the insured. Medical records will be visible only by activating cards and entering the password. For verifying cards will be no need to collect receipts, but will perform automatic verification of the employer contributions paid to the insured.

Figure 6. Electronic health card which will be implemented of The Republic Fund Of Health Insurance

Currently the Ministry of Defense of the Republic of Serbia is aimed at the development of electronic health system which includes the introduction of military electronic health cards, as well as a rapid implementation of certain applications such as electronic drug prescription, durable medical summary, electronic records (Ministry of Defense of the Republic of Serbia, 2010). The usage of electronic ID cards reduces costs in the Ministry of Defense produced by an inadequate and uneconomical use of available resources - human, material, financial and information. It also increases productivity and data and information safety in information systems.

The card contains two chips – a contact and a contactless. There is an electronic record of data about a card holder in the visual part of the contact chip. The chip has such characteristics that it can accept all the other contents needed for record, by using security system to protect those contents from being accessible to unauthorized personnel.

On the body of the card there are the following data: name, identification number, capacity, serial number, personal number of the insured, issuing date and expiry date of the document, whereas the official data such as rank, military post, place of service, name of unit or institution (Figure 7).

Figure 7. Electronic health card applied at the Ministry of Defense and the Serbian Armed Forces

The introduction of electronic health cards in healthcare system of the military insurance is an integrating factor for the entire future military healthcare information system. Their introduction and application will ensure an organized and synchronized connection of military healthcare facilities. The usage of electronic cards and a gradual linking of all healthcare institutions in an internal computer network will enable the creation and safe use of a centralized electronic healthcare documentation. The main characteristics of access to the centralized EHD are patient orientation, the exchange of information about health of patients in order to improve health services and reduce treatment costs.

The centralized EHD establishment and electronic health cards implementation will enable the linking of medical data from different sources (electronic patient cards from the Military Medical Academy, military medical centers (MMC), pharmacies), forming a complete „health image“ of a patient and providing the data about a patient, such as allergies, reactions to certain drugs, contraindications, etc., currently available to a doctor in order to make the process of treatment efficient and effective (Commission of the European communities, 2004)

4. CONCLUSION

E-health system provides a foundation for a new approach to organizing and carrying out business processes in healthcare system supported by information and communication technologies. The main features of the new approach are orientation to a patient, exchange of information about the health of a patient in order to improve health services. The introduction and implementation of electronic health card will increase the capacity of collection, storage, copying, transmission, sharing and manipulation of information. Introduce an electronic health cards is of a strategic importance because it will mean a simpler procedure for users of healthcare services system, easier and more reliable operation of health professionals at primary, secondary and tertiary level of health care, more efficient control of the status of the insured and more efficient and effective process of treatment.

³tanjakov1987@yahoo.com

Abstract: *The importance of studying management in one of the most complex and most sensitive human activities such as health care is of great importance for the future provision of high quality and efficient health care available to all and is also making key strategic decisions for the continued development of a new, reformed health care system. The aim of this study was to define specific suggestions for improving the efficiency and effectiveness in Serbian health care system through the analysis of advantages and disadvantages of several systems of EU countries (Germany, Poland, France, Austria, Slovakia), and conducting comparative analysis of these systems with the current situation in the health sector in Serbia. The final section discusses the specific suggestions for improving the efficiency and effectiveness of the health system of Serbia, which will strengthen the functions of health care system.*

Key words: *efficiency, effectiveness, health system, health care management.*

1. INTRODUCTION

Health of the population of each country is conditioned by the influence of many factors, the most by distinguished lifestyle, environment and biological characteristics. Achieving a certain level of health of individuals and society as a unit is directly caused by the influence of the health system and its institutions at all levels of care, both public and private health institutions.

Public health policies which create change towards healthier lifestyles, can empirically demonstrate their effectiveness in various areas: from tobacco products control to the procedure of screening for cancer. However, if the health care system does not implement a public health policy in a way to respond by delivering services adequately, health interventions will not achieve anticipated results, and ineffective delivery of services is always inefficient.

Health care costs in the world continue to grow faster than national income. In recent years, initiatives to overcome this problem were based mainly on maintaining a certain level of costs. Instead of concentrating only on reducing the total cost of health care, internationally invested considerable efforts in order to adopt the view that increased spending on health services are an effective contribution to the productive economy and a way to improve health.

Decision-makers across the European region give priority to improving population health as a result of improved health care system. By combining the functions of the health system, population health can be improved by: providing quality and effective services in a way that ensures equality and meet the patients needs, financing of health care services, which separates provision payment, investment in improving the health of employees and innovative technology, and health system management in a way that all its functions take place towards the realization of the main strategic goal. To make these improvements sustainable, as with any other production functions, inputs (human resources, infrastructure, technology, procurement) must be restructured in a way that will enable the provision of the most effective procedures.

When it is possible to provide more funding for health, additional investment costs can be justified in terms of achieving better treatment outcomes and health outcomes, but should try to choose the most effective way of treatment or interventions whenever the different options are available.

In these circumstances, Serbian health institutions with inherited organizational structure and working methods of an earlier period, and with set rigid limits, can be very difficult to reorganize in order to ensure provision of adequate care. Inefficiency is always a risk, and it could be a source of irrationality in the use of resources. Serbia is currently facing this kind of challenges. Indicators of population health are relatively low compared to other countries, which requires fundamental changes in the organization of health services,

which includes a comprehensive transformation of the way that the founders, managers, professionals, and of course the patients refer to the health system.

The experience of other European countries shows that the strategic vision, good governance and political will, can substantially transform the system, even under less favorable economic situation. This involves designing the integration of health services at different levels of care, clearly defining the rights of health workers and patients in the newly established system, and ways of implementation of such changes.

The question of equality deserves special attention. Equity must be ensured in the provision of effective health care for people with similar needs, which is not only a moral obligation but also a requirement to ensure the efficiency of the entire health system. Finally, the health system must become more competitive at the same time, and in the process of European integration, maintenance and capacity development is important because of the challenges of free movement of patients within the European Union.

2. SERBIAN HEALTH CARE SYSTEM EFFECTIVENESS INDICATORS

Death rate, birth rate and life expectancy are used as effectiveness indicators of the health care systems in some countries (Garrin G, 2009). According to available data, the number of births in Serbia is increasing from year to year. This ratio is favorable compared to certain EU countries (Germany, Poland, France, Austria, and Slovakia). Life expectancy is another indicator used in determining population health in one country. In 2010 life expectancy for men in Serbia amounted to 71, while for women amounted 76 years. In comparison with the EU, this indicator is not satisfactory, and it can be concluded that among the lowest in the region. Adult mortality rate in Serbia is much higher than in selected member countries. In Serbia, 140 people of the 1000 inhabitants die between the age of 15 and 60, and in selected member states about 80 people of the 1,000 inhabitants die. (World Health Organization, 2010)

The main causes of death are different in Serbia and in the European Union. In Serbia, the largest cause of death is non-infectious diseases: cardiovascular diseases are in the first place, and they cause 55% death cases, and they also cause cancer with about 20%. The aging of population and high mortality rate which was caused by non-infectious diseases, have led to the constant growing of the death rate in Serbia, which reached 13.97% in 2010. Cancer is the second largest killer of the Serbian population, and it is responsible for more than 20,000 deaths annually. Cancer mortality is a big concern, especially cervical cancer (the incidence is three times the EU average), breast cancer (incidence is greater than twice the EU average) and all types of lung cancer, especially among women. A large number of patients with non-infectious diseases is closely linked with the existence of high levels of risk, i.e. unhealthy lifestyles, such as the high rate of smokers (about 30% of the adult population is smoking for more than 20 years) and increased number of obese children and adults. (World Health Organization, 2010)

The number of beds and the length of hospital stay are used as efficiency indicators. With 528 beds for 100,000 inhabitants, Serbia is below the EU average, and the average length of hospital stay in Serbia is 9.2 days, while in the EU average length of treatment is 8.8 days. In comparison to selected countries of the European Union, Serbia doesn't have necessary resources, and this is indicated by the following parameters: number of hospitals for 1,000 inhabitants, number of dentists for 1,000 inhabitants, the number of primary health units for 1,000 inhabitants, the number of doctors for 1,000 inhabitants and the number of nurses for 1,000 inhabitants. (World Health Organization, 2010)

Serbia lags behind most countries of the European Union by health indicator value. Poor health is the result of poor economic and social situation. Even though the general situation in the past few years has a positive trend, we cannot expect a rapid improvement in basic health indicators. Identified main problems of the health system, which have a stronger impact on health indicators and the population health, are arising from the fact that, at the secondary and tertiary levels, capacity and resources are the dominant ones, while the efficiency and quality of health care weren't a priority. Because of that, irregularities are starting to appear in the system, so it cannot function in a coordinated and integrated manner.

3. KEY ISSUES IN SERBIAN HEALTH CARE SYSTEM

The main problems, which are identified by comparison with key countries of the European Union, and which should be set as priorities for solving the problems are (S. Thomson, 2009):

1. There is a gap between established rights to health insurance and financial capabilities, large part of the private funds and the existence of informal payments indicate unsatisfactory access to health services in the public system - the basic package in the secondary and tertiary level is not defined.
2. The structure of health workers is inadequate and does not match the expectations and needs of the citizens, the number of non-medical staff in the structure is large.
3. Health care control and security system are not developed; there is no control over capture and the quality of registered data.
4. Inadequate health services payment method and ambiguous way of financing health institution - Health Service is funded by capacity, not by people's needs.
5. The lack of quality health care information systems and other mechanisms for better governance - without good data it is impossible to effectively lead a good health policy, to set priorities and allocate resources.
6. Private health care is not adequately regulated and it doesn't complement the public system network in a way that would lead to coordinated and integrated process of residents' health care needs.
7. Active two-way communication about the importance of taking care of your own health and about the need for the health care services has a large impact on population health indicators.

Although many of the health policy goals on the secondary and tertiary level are achieved to a considerable extent, for example development and efficiency of the health institutions network, with the available personnel and financial resources, it is still necessary to continue monitoring, reviewing and setting newer and higher goals, taking into account the emerging population needs. In addition, the quality improvement process needs to be continually accelerated, just like the improvement process of rationalization, optimization, resource management, transparency of funding and functional connection between the public and private health services for the better functioning of health care system and health care financial sustainability. The health policy main objective is to preserve and improve population health with sustainable health care system by upgrading through a continuous process of diagnosis and analysis of the problem causes, setting priorities and timelines for appropriate activities, evaluating redefinition of certain objectives. Natural health system status and evolution is a constant upgrading and improvement.

4. SUGGESTIONS FOR IMPROVING THE EFFICIENCY AND EFFECTIVENESS IN SERBIAN HEALTH SYSTEM

Improving the health care system to improve efficiency and effectiveness, based on previously done analysis done, involves intervention (reform) to reinforce the basic functions of the health system: resources (staff, IT), the provision of services (network / integration, package, quality, technology assessment), funding of the health care system (basic principle: payment services or payment capacity), management.

Defining the priority areas of reform provides the basis for the selection of optimal programs and activities to improve public health and ensuring a stable and financially sustainable health care financing system. The main objective of the company, including health facilities, which are its strategic goal is further specified through two main strategic objectives, ensuring continuity of operation and ensuring the continuation of efficient operation (planned development of the company) (Jovanović 2007).

Based on the analysis, one of the basic features of Serbian health system is the idleness of the existing personnel, due to inadequate geographic distribution, and consequently the dispersion of specialty and sub specialty, ways of organizing work dominantly directed towards the supine patient and the work of the department and ways of conceiving of job descriptions that causes overwork of specialist staff with jobs that require lower levels of expertise.

For the efficient performance of health services and effective management of the health care system, beside the personnel, premises and equipment, information's are also needed. Information is the key resource of health services. E-Health solution would improve progress in health services, provide better management, dissemination of medical knowledge and would help development of health services (medicine) based on evidence.

Montenegro Ministry of information society point out that: "The strategic priorities for the development of e-Health include:

1. Establishing basic information of infrastructure in healthcare and the creation of organizational, human and technological preconditions for the development of information system, defining basic collection of medical and social data for establishing and maintaining electronic patient records, which will form the basis for the definition of electronic health records.
2. Defining of security and technology standards for secure communication, management and data storage in the health system (medical records).
3. Building an integral information system in health.
4. The merge of all health and social information systems into a single information system through the construction of an electronic portal." (p.39)

Available data indicate that the Serbian hospital's health care system is faced with a paradox. Starting from the vital health indicators, health needs of the population of Serbia are approximate health needs of residents of EU countries, while the hospital capacity in Serbia is not only smaller than the hospital capacity in the EU, but also their utilization rates are significantly below the EU average also. Montenegro Ministry of Health point out that: " In order to increase capacity utilization it is necessary to:

1. Review and revise the organizational model of providing hospital care to ensure adequately overwork of doctors in order to rationalize the use of available.
2. Review and revise the model of work organization to the special attention devoted to providing health care in day hospitals and ambulatory care health priority programs.
3. Channel underutilized capacity as support the realization of public resources and improving the quality of health care." (p.44)

New model of health care organizations should facilitate the introduction of private service providers in cases where this is necessary only to ensure the availability of high quality and efficient health care, which also excludes the possibility of the parallel existence of the public health department that the low quality and inefficient way of providing services. The application of this approach should be carefully considered in each case. Montenegro Ministry of Health point out that: "The decision to include the private sector should be made:

- After conducting the analysis of health needs to determine whether there is a misbalance between the "bid - providing health care services and" demand-health needs.
- When it is evident that all feasible options and options for improving the effective and efficient access to quality services as a result of reorganization measures and rationalization of the existing service delivery models.
- After a detailed analysis of costs and benefits of introducing private sector. When assessing the benefits of providing services by the private or public sector, the risk may be important to measure and therefore has to establish a framework for assessing issues related to risk. " (p.48)

It is recommended to identify areas in which it is desirable to consider the possibility of the introduction and use of private sector initiatives (cancer, emergency medical services, respiratory diseases, diabetes, CVDs, mental health, palliative care, hip replacement, maternal health...).

Analysis of the health care system in Serbia shows that this system is based on the principle of universal access to free health care. However a major lack is that Serbia has defined the standard package of services and it is one of the first things to do in carrying out reforms.

Conceptually speaking, the basic package of health services should include three aspects (Corrigan, et al., 2002):

1. Breath (co): refers to the proportion of the population covered by the basic package,
2. Scope (what): refers to services that are the subject / content of the package,
3. Debt (as) refers to the existence of arrangements aimed at reducing the financial pressure on health budgets in terms of being able to introduce cost sharing arrangements and the cost of the patient for each service provided.

These three aspects of the basic package are key determinants of the extent of the protection of the population / insured from financial risk. It should be noted that the scope and cost-sharing is strongly affected by the exercise of the principle of equality in terms of burden of financing the system and accessing to health services. The basic package has a very important role in improving transparency, particularly in circumstances where informal payments registered a considerable extent, which represent a serious barrier to achieving effective access to the health care quality care.

5. CONCLUSION

Protect the Serbian health system requires urgent reform. Improving the health care system to improve efficiency and effectiveness, based on an analysis that was the subject of this work involves interventions to reinforce the basic functions of health care systems: resources (staff, IT), the provision of services (network / integration, packaging, quality, technology assessment), the financing of health care system (basic principle: payment services or payment capacity) and management. It is necessary to define priority areas for reform, because it provides a basis for selection of optimal programs and activities to improve public health and ensuring a stable and financially sustainable health care financing system.

The goal of any health system is in a qualitative manner and accurate respond to citizens' needs for health services to solve health problems that can be cured, and ensure the provision of care and treatment, in cases where the disease is not curable. The challenge set before the current health system is to be as efficient as possible, which means that you need to achieve the best possible results and achieve improved health outcomes for a similar amount.

Abstract: *Work results have become the primary measure of employees' values and therefore the implementation of a model for assessing the quality of their performance becomes imperative for any organization that seeks growth and development. If used well, the assessment of work quality can be the most powerful tool that an organization can use in order to achieve its strategic objectives, direct the organization members' energy towards the achievement of their mission and corroborate the importance of living in accordance with the organization's vision and values. However, the realization of these principles is only possible through the application of valid and reliable assessment systems, i.e. systems that focus on objective assessment of performance results.*

Given that the assessment of the employee's work quality is usually a result of the assessor's subjective judgments on the quality of his work, one must take into account possible errors that can occur in such judgment. There are several types of errors that can be committed by the evaluators when assessing the employees' work quality. This paper offers an approach to the identification and reduction of distributional errors made by assessors (most widely used in organizations with large numbers of employees) in assessing the military drivers' work quality.

Keywords: *assessor distributional errors, evaluation, work quality*

1. INTRODUCTION

Given that the process of evaluating the employees' work quality- requires the assessors to make subjective judgments about others, it is necessary to take account of possible errors that are always related to a subjective judgment which can occur accidentally or not.

The assessment errors are the judgment errors that can occur systematically when observing and evaluating another individual. These can be defined as a difference between the results of human judgment and an objective, accurate assessment that is not colored by prejudice or other subjective effects (*Bogicevic Milikic 2008*).

The errors can seriously affect the quality of assessment system, i.e. the objective and reality assessment results. It is extremely difficult to eliminate them from the evaluation process; given that the evaluators are often unaware they make them. Even if they were aware, they are often unable to correct them.

There are several types of errors that can be committed by the evaluators in assessing the employee's work quality ("halo" and "mermaid" effect, the effect of similarity with the evaluator, contrast error, context error, timing error, the attribution error, first impression error, the effect of physical attractiveness, high potential error, previous results error, stereotypes). However, the errors that often distort the evaluation results within the organizations with more employees are "assessor distributional errors" (*Noe, Hollenbeck, Gerhart & Wright, 2006*).

2. ASSESSOR DISTRIBUTIONAL ERRORS

Distributional errors are assessors' tendency to use only one part of the rating scale. This means that almost all employees receive the same assessment marks-high, low or average. Accordingly, there are two basic types of distributional errors (*Bogicevic Milikic, 2008*):

- mild and/or strict evaluation error;

- central tendency error;

“Mild” and/or “strict” evaluation errors indicate a tendency of giving higher or lower ratings than according to actual results. In such cases, there is a moving up of the mean value of the scores in regard to the mean value of the assessment scale (mild evaluation) or down (strict evaluation).

As previously stated, the existence of distributional errors is connected to the evaluation of a large number of employees. In every organization with many employees it is expected that the score distribution performance approximates to the bell-shaped curve, which represents a normal distribution- Gaussian curve. In the case of rigorous evaluation errors, a score distribution approximates to a curve which is shifted to the left from the standard distribution curve, Figure 1.

Figure 1: Assessor Distributional errors

Central tendency error occurs when the assessor evaluates all employees so that their ratings are close to middle value on the assessment scale, Figure 1. Only a few employees or none receive very high or very low scores.

The existence of any type of distributional errors indicates a situation in which no distinction is made between good and poor quality of work. Also, these errors can create problems when comparing the quality of the individuals evaluated by different evaluators. If one of the evaluators is mild and other severe, the employee judged by a stricter grader will get less reward than the one rated by more lenient grader.

3. AN APPROACH TO THE IDENTIFICATION OF ASSESSOR DISTRIBUTIONAL ERRORS

An establishing of the existence of these distributional errors is possible in several ways. One of the most popular approaches is the calculation of standard deviation. A small standard deviation indicates the existence of distributional errors but for proving the presence of mild or rigorous assessment errors or central tendency errors it is necessary to compare the mean value and the mean value of the scores on the assessment scale.

If the mean value of the scores is less than the mean value of the assessment scale, then there is an error of rigorous evaluation. If the mean value of the scores is higher than the mean value of assessment scale, then there is a mild assessment error. Finally, if the mean value of the scores approximates the mean value of the assessment scale, there is an error of central tendency (*Bogicevic Milikic, 2008*).

In this paper, we present the approach to investigate the presence of any of the above types of distributional errors when evaluating military drivers' work quality in Serbian Army. Checking is done within the transport troop which consists of 56 drivers, civilians, and was conducted after the regular assessment of this category of drivers at the end of the calendar year (Lukovac, 2010). The distribution of performance ratings on a 5-point grading scale (unsatisfactory, satisfactory, good, stands out, particularly stands out) is shown in Figure 2.

Figure 2. The distribution of military drivers' ratings on an assessment scale (Lukovac, 2010)

According to the described approach for determining the presence of distributional errors within the evaluation process in order to calculate the standard deviation (Std. Deviation) and the mean value of the scores (Mean), all scores were statistically handled by SPSS 11.5 for Windows. The distribution of all grades at the troop level after their processing in SPSS 11.5 is shown in Figure 3.

Figure 3. The distribution of military drivers' ratings after their processing in SPSS 11.5 (Lukovac, 2010)

The third Figure shows the small standard deviation score (0.41), indicating the existence of a distributional errors within evaluation process. Given that the mean value of the scores (4.31) is significantly higher than the mean value of a grading scale (3.00), it is evident that there is a mild assessment error.

Based on analysis results, it can be concluded that in the appraisal drivers' work quality within the transport troop which was subject to a review, the assessor had committed a slight assessment error.

4. AN APPROACH TO DECREASE ASSESSOR DISTRIBUTIONAL ERRORS

Despite many errors made by the assessors in the process of work quality evaluation, there are ways to significantly reduce them to an acceptable level. In order to accomplish this, it is necessary to have appropriate measures and activities the organization must take into account, and the following suggestions may help significantly to the objective and equitable evaluation process:

- **Conduct related to the quality of work document in the log.** Evidence suggests that the ratings are usually more accurate and more resistant to assessor errors, if the log is kept of specific critical events for each employee. Diaries, in which the critical events are recorded for each employee, should encourage evaluators to focus on behavior related to the task performance rather than the employee's characteristics, and thus reduce the number of assessment errors.
- **You should involve multiple evaluators.** As the number of assessors rises, thus the likelihood of obtaining reliable information is increasing. If the assessor error follows the normal curve, increasing of the number of evaluators will result in a gathering of most of them somewhere around the middle. This approach can be seen in sports competitions such as figure skating and gymnastics. A group of evaluators (judges) judges the performance, the highest and the lowest score are omitted, and the final score is compiled from the cumulative points of those that remained. The logic of multiple assessments applies to the organizations. If the employee's work was monitored by ten people and was assessed excellent by nine of them, one can neglect the value of a bad grade. Accordingly, the likelihood will increase to obtain accurate and reliable score if more appraisers are involved (like with the 360-degree assessment).
- **The assessors should be trained.** Training of assessors is one of the most important and popular mode of operation in order to improve and raise the quality of their estimates. Introducing the usual

assessor errors, their actions and so, can positively affect the assessors and their relation to the evaluation process. Assessor training generally includes (Jones, 2001):

- Introduction to the most common assessor errors;
- Introduction to individual differences and the fact that they regularly show Gaussian curve, which suggests that it is quite logical that a big difference in performance between employees occur (identify);
- Training to identify and define the appropriate criteria and standards for the identification and evaluation of behavior and the differences in performance;
- Training to conduct effective conversations about performance, in order to improve and develop associates.

Many surveys indicated that the training had a positive effect on reducing errors in the evaluation process. Ideally, each organization should conduct a formal and comprehensive training program that must be attended by all of the evaluators as a prerequisite for the implementation of the assessment. This training usually lasts one to three days but it may not always be necessary to take you so much time. The organizations also need to repeat training for all appraisers, immediately before the assessment and discussion of results.

The lack of such an ideal situation, every organization can afford to conduct a one-hour briefing, which will help the assessors to implement their authority with minimal level of security. Cited a case in which the halo and distributional errors are reduced immediately after evaluators passed an instructive session that lasted only five minutes. The allowance of such minimum level of training, in addition to the actual benefits training provides by providing a more accurate assessment is also useful for organizations if accused of discrimination as a result of the work quality appraisal.

- **Evaluate horizontally.** A Horizontal evaluation is technique to reduce assessment errors. The evaluator first assesses one work performance dimension (one evaluation criterion) of all people to be assessed,

then the other dimension, then the third and so on. The Horizontal evaluation goes beyond the usual vertical assessment in which all dimensions of a person's success are simultaneously evaluated.

According to these suggestions for reducing assessor errors, the person who previously played the role of assessor in the transport troop which was subject to verification, had been trained. Upon completion of the training, he was now tasked to re-evaluate all 56 drivers, using the horizontal evaluation technique. The time difference between these two assessments was only seven days, and the distribution of scores on the drivers' grading scale after this assessment, that is, the assessment after the training (horizontal evaluation technique) is shown Figure 4.

Figure 4. Distribution of drivers' ratings on assessment scale after the assessor training

These ratings (evaluation after the assessor training), were also statistically analyzed in SPSS 11.5 for Windows and are shown in Figure 5.

Figure 5. Ratings distribution in SPSS 11.5 after the assessor training

The Figure 5 shows that the standard deviation score (1.11) is almost three times higher than the assessment prior to the assessor training (0.41). The mean value of the scores (3.64) is also much closer to the mean value of the grading scale (3.00) in relation to the assessment before the assessor training (4.31).

According to these results, it can be concluded that the training of assessors and horizontal evaluation techniques contributed to a measurable reduction of mild assessment errors committed by the assessor before. Also, one can conclude that the involving of more assessors in the assessment process and keeping a diary to document the behavior of employees, have further contributed to a fairer and more objective work quality evaluation.

5. CONCLUSION

An analysis to identify the possible errors that evaluators might make when assessing the work quality of an employee to the transparency of appraisal system and thus a greater employee acceptance of the system. Only such an approach to the evaluation can motivate employees to a maximum engagement, commitment and influence them to do better and more efficient.

The most common errors in assessing within the organizations with large numbers of employees are "assessor distributional errors". Knowing that the standard deviation score indicates the presence or absence of assessor distributional errors, and the relationship between the mean value of the scores and the mean score on evaluation scale defines the type of distributional error, is the basis for conducting the analysis in order to recognize these assessors errors in the work quality evaluation.

Using the appropriate software for statistical data processing, namely SPSS 11.5, only contributes to the effectiveness of this procedure.

It is important to emphasize that although there are no protection measures that can guarantee an objective assessment, there are ways to significantly reduce assessor errors to acceptable levels. Training of appraisers, horizontal evaluation, the inclusion of more appraisers in the assessment process and logs in which critical events are recorded for each employee, are the measures to help reduce errors and contribute to a more objective work quality appraisal.

Abstract: *Modern business requires continuous training and education of employees. The manner in which employees evaluate various programs of education and development, and the degree of importance which they give to it can significantly affect their motivation, commitment, and satisfaction with their participation and their acceptance. The aim of this study was to find out how employees evaluate various educational programs offered to them within the organization. The study included 275 respondents from 23 organizations. The study included a total of 12 different training programs that often occur in practice. Respondents evaluated the importance of each particular program. Employees of different genders and age, coming from organizations of different sizes, evaluated different individual education programs. Classical training was evaluated by respondents as the most important education program, whereas the one based on role-playing was estimated by them as the least important. In this study we made an initial review of the situation in the area that will allow further development and adaptation of the programs concerned. These findings may have broad application in designing future training programs for employees, paying particular attention to the efforts of these programs to be better adapted to the participants, and as specific. The results emphasize the need for tailor-made programs, specially designed for each individual organization. Such educational programs will have a positive effect on the organization itself, provide better adapted employees, reduce costs, and save time.*

Keywords: *human resources management; employees perception, employees training, training and development programs, management and business.*

1. INTRODUCTION

Technology, accounting, financial practices and the like can be copied and transferred to other companies. Employees are the only element of the success of companies that can not be replicated and which gives a certain tone to all other activities of the company.

Simply, the total intellectual, professional and other skills are not a simple sum of individual abilities, but a new quality, which depends on other factors whose influence may be lower or higher. This is the reason that employees are now the most important competitive advantage of each company, and their successful innovative management is the most important way of achieving and maintaining this highly desired goal. One segment of that innovative human resource management is related to education of the employed (Ackermann, 1989; Barjaktarović & Ječmenica, 2011, Šiber, 1999).

The high quality standard for all other functions of the organization and the overall success of the organization depends on the quality of staff, which makes the human resource management so specific. No other business function has such a comprehensive and immediate impact on what happens in the organization and each of its segments as this one has. Human resource management is a key for achieving competitiveness and effectiveness of each organization (Zerbe, Dobni & Harel, 1998).

The perception of the overall state of education and development in the organization. As Drucker (1999) says the most valuable asset of any organization in the 20th century was a manufacturing technology, but in the 21st century the most valuable guidelines do not apply to technology but to people. People are now becoming the most valuable asset of any organization. The most successful organizations are those whose workers are the most educated, skilled, creative and most able to adapt to constantly changeable business environment.

Contemporary studies concerning "best practices", of high commitment, high involvement of human resource management imply that organizations are required to provide for their employees the resources and opportunities that will enhance their motivation, skills, attitudes and behavior (Kuvaas, 2008). These opportunities are provided by a large number of organizations through the training of the employees. The continued need for individual and organizational development can be traced to numerous demands, including maintaining superiority in the marketplace, enhancing employee skills and knowledge, and increasing productivity. Training is one of the most pervasive methods for enhancing the productivity of individuals and communicating organizational goals to new personnel. Given the importance and potential impact of training on organizations and the costs associated with the development and implementation of training, it is important that both researchers and practitioners have a better understanding of the relationship between design and evaluation features and the effectiveness of training and development efforts (Arthur, Bennett, Edens & Bell, 2003).

Organizations in the present business environment have an urgent need, if they want to remain competitive, to set up the education of their employees as the key organizational activity (Ivancevich, 1974; Stewart, 2001). They are necessarily focused on education and development of their employees, so that their knowledge and skills can be used to improve the organization's operations in return. More specifically, investment in education and development of employees increases the value in the value chain through the larger production, better quality of products / services, increase of the customer/consumer satisfaction, altogether leading to higher efficiency and competitiveness of the company (Vokić & Grizelj, 2007). This means that organizations have to continuously invest in knowledge, skills, motivation and behavior of each employee to ensure competitive advantage (Boxall, 1998; Lado & Wilson, 1994; Pfeffer, 1995; Schuler & Jackson, 1987; Wright, McMahan & McWilliams, 1994).

Numerous studies have confirmed the above-mentioned reflections on the connection between the competitiveness of the organization and its investment in the education of employees (Appleyard & Brown, 2001; Delaney & Huselid, 1996; Fey, Björkman & Pavlovskaya, 2000). In these empirical studies, no matter how different they were and that different organizations were involved in them, almost always there was the result that showed the positive correlation between the amount of education that was offered to employees and the success of such organizations.

It is interesting that when we talk about competitive advantage, education and staff development, business improvement, the whole issue is seen only or mostly from the perspective of the organization as a whole. Very little or almost none of the surveys have addressed these problems by looking from the perspective of employees (Ansari, 2011; Gellatly, Hunter, Currie & Irving, 2009). The employees are ultimately those who determine the competitiveness of the organization, they are the ones in which the organization invests and which are expected to give feedback in terms of business improvement (Kuvaas, 2008). Although the evidence clearly showed that education and staff development are needed and desirable factor in the improvement of business organizations, still, the process is bidirectional, and it seems that we are in a constant lack of information concerning the other side, the employees. We know that different methods of education and staff development are being used, but it is hard to know how employees react, how they assess their importance. Some studies show that employees of different ages differently perceive the practice of human resources, and it includes the training of employees (Stassen & Lee, 2009). The older employees who estimate that their organization is "relatively old" significantly better evaluate the practice of human resources, than those older employees who estimate that their organization is "relatively young". These employees also impart a greater sense of importance that the organization shows for them, greater trust and respect are given to them.

This kind of information can be crucial for when and what methods should be used, the benefits or disadvantages of one over other can be discovered. In order to have a full potential of the employees' education and development, to make that activity come to an end with a practical use and with the performance and profitability maximization, information about the perception of these methods, these organization efforts done by the employees is needed. To make education and development successful practice, the employees themselves have to agree on that, because it is intended for them. In our opinion, obtaining the consent of employees, designing customized training and development is a key to obtaining high-quality and long-lasting results. By providing the consent of employees their readiness for training, development is increased, their commitment to change, which is inevitable in the present modern business environment is also increased, as well as their willingness to apply new knowledge and skills in the improvement of business organization (Kegan, 1971; Kuvaas, 2008; Zerbe, age & Harel, 1998). It is already proven many times that the way employees perceive different practices in the organization significantly

influences many outcomes such as satisfaction, intention to leave the job, affective commitment and the success and acceptance of different training programs for employees can increase if we find out of what importance it is for the employees (Chang, Rosen & Levy, 2009).

Therefore the specific aim of this study was to obtain a description of the perception of employees about the different methods, different training and development programs that are aimed at employees. The aim was to find out how employees perceive various education and development programs, how much importance they assign to each other and how much to others. The answer to this question provides insight into the problem from another perspective and takes into account the view of employees, who are the ultimate beneficiaries of such programs, therefore it provides the ability to adequately adapt these programs, thereby increasing the willingness and commitment to employees for them.

2. METHOD

Sample. In this study, the sample consisted of 275 subjects (Table 1), employees in organizations of different sizes, different education, different age and gender. The study involved employees from 23 organizations based in 13 towns in Serbia.

	Total	Gender		Age			Degree					No. of employees		
		Male	Female	To 29	30-39	Over 40	Secondary school	Two-year college	University	Postgraduate studies	Doctorate studies	To 200	201-500	Over 501
N	275	143	132	95	95	85	99	42	93	35	6	85	101	89

Table 1: The survey sample

The variables and the instrument. Independent variables in this study were gender, age of the respondents (to 29, from 30 to 39, over 40), education (secondary school, two-year college, university, postgraduate and doctorate studies) and the size of the organization (up to 200, from 201 to 500, over 501). Dependent variables were the importance that employees attach to special education programs. Assessment of the importance of different training programs was conducted by the direct question : " How important is role-playing as a type of training programs and employee development". The instrument designed specifically for this study consisted of 12 direct questions pertaining to various programs, methods of training and staff development (theoretical lectures, individual instruction, simulation games, role playing, case studies, classic training, staff development, multimedia , movies, interactive video, education, computer-assisted learning). This instrument follows the Likert procedure with five answers: not at all important-1, unimportant - 2, Neither important nor unimportant - 3, Important - 4, Very important -5.

The process of research. Researchers have personally visited 23 organizations that participated in the study gave to the employees an instrument of paper-pencil type. Before completing the instrument respondents were informed about the research, the mode of anonymity protection of the respondents data, after which they started the test.

3. RESULTS

Statistical analysis was performed in SPSS program 15. For the easier presentation of results we will often use the tables in the further text, in which the cells that we want to emphasize will be in bold.

We started the results display with the table that informs us about how the respondents' answers were arranged by percentage on every item in the instrument (Table 2). From the results shown it can be seen that the employees as the most important programs designed for their education and development, estimated classical training, which is associated with about 77.5% positive responses. The program, which was assessed as the least important in their education and development program was the role-playing, which was assessed by 71, 3% of employees as absolutely irrelevant.

Table 2: Percentage response display

Education programs	1 Not at all important	2 Unimportant	3 Neither important nor unimportant	4 Important	5 Very important	Total
Theoretical lectures	17.1	13.5	14.5	34.9	20.0	100%
Individual instructions	12.7	7.3	17.8	27.3	34.9	
Simulation games	29.5	20.7	25.5	20.4	4.0	
Role playing	47.6	23.6	09.1	15.3	4.4	
Case studies	24.4	20.4	24.7	13.5	17.1	
Classical training	3.6	0.7	18.2	13.8	63.6	
Employees development	8.4	4.0	32.4	24.4	30.9	
Multimedia	58.5	10.9	9.1	8.0	13.5	
Films	24.4	22.5	27.6	12.0	13.5	
Interactive video	46.2	10.5	21.5	8.7	13.1	
Education	15.3	10.5	27.3	5.8	41.1	
Computer assisted learning	29.5	14.2	27.3	10.9	18.2	

This research enables us to see if there are any significant differences in the perception that employees have of the various programs of education and development in connection with their gender, size of organization, their education, and their age. The results (Table 3) reveal whether and how men and women differ in valuing the various training programs

Table 3: Correlation between the respondents' gender and the perception of various programs

Education programs	Hi-square	sig.
Theoretical lectures	83.833	.000
Individual instructions	41.799	.000
Simulation games	40.495	.000
Role playing	30.496	.000
Case studies	38.217	.000
Classical training	74.801	.000
Employees development	72.613	.000
Multimedia	19.604	.001
Films	112.304	.000
Interactive video	70.533	.000
Education	40.953	.000
Computer assisted learning	40.885	.000

As it can be seen, all the differences for each program of training and development are statistically significant. In the column "educational program" in bold are those programs that women significantly value more than men do. It can be said that men and women give importance to completely opposite programs. When you see only positive responses, i.e. responses that are highly value the program, those are the answers 4 and 5, it is showed that women generally evaluate most programs lesser, therefore in absolute values, although some programs were assessed as more important than men did, the importance is not of not at a much higher level.

The employed in this study, regardless of age, have the same estimation of most programs' importance (Table 4).

Table 4: Correlation between the age of the respondents and assessment of the significance of some programs

Education programs	Hi-square	sig.
Theoretical lectures	83.833	.000
Individual instructions	41.799	.000
Simulation games	40.495	.000
Role playing	30.496	.000
Case studies	38.217	.000
Classical training	74.801	.000
Employees development	72.613	.000
Multimedia	19.604	.001
Films	112.304	.000
Interactive video	70.533	.000
Education	40.953	.000
Computer assisted learning	40.885	.000

The exception is the simulation game and theoretical lectures. Theoretical lectures are more significant to middle aged respondents, from 30 to 39 years of age, then a little less importance is given by the youngest, and the smallest importance is given by the oldest employees. This is somewhat surprising finding which will be discussed. When talking about the simulation game greatest importance is given first by the oldest, then by the youngest and finally by the middle aged employees.

The correlation between the staff education and their perception of the relevance of education and development programs designed for employees reveals that regardless of the level of education, the employees give importance to different programs in equal measure. By this criterion the employed do not differ significantly and there is no need to show these results in the text.

The correlation between the size of the organization in which employees work and their assessment of the relevance of education and development programs is presented in Table 5.

Table 5: Correlation between the size of the organization and assessment of the significance of some programs

Education programs	Hi-square	sig.
Theoretical lectures	83.833	.000
Individual instructions	41.799	.000
Simulation games	40.495	.000
Role playing	30.496	.000
Case studies	38.217	.000
Classical training	74.801	.000
Employees development	72.613	.000
Multimedia	19.604	.001
Films	112.304	.000
Interactive video	70.533	.000
Education	40.953	.000
Computer assisted learning	40.885	.000

In the front line there are the results of a program that imply classical training, where employees, regardless to the organization they work for, give the same, high degree of importance to the education and staff development. When you take a closer look you can see that the program "theoretical lectures" is significantly higher estimated by the employees who work in the larger organizations of over 500 employees. Also the program "computer assisted learning" is estimated as more significant by the employed in the smaller organizations, in contrast the employed in the larger ones. These findings can show the experience that the workers had in the course of their work in these organizations. For a great number of workers it is very difficult, time-consuming and expensive to organize some kind of computer-assisted learning, and it is assumed that employees in large organizations had little experience with these type of programs, while,

because of the size of the organization, some theoretical programs were more available to them, they encountered them more often, and that is the reason they assess them as very important.

4. DISCUSSION AND CONCLUSION

As can be seen so far there is an ample evidence to justify and emphasize the quality of human resources as a decisive preponderance in achieving greater competitiveness of any organization. Constant improvement of employees, systematical occupation with them, the investment proved to be profitable in many ways, better productivity, greater satisfaction, less absenteeism and resignation are all the results obtained by changing the focus from just technological progress and improvement, to the improvement of human capital. Between the competitiveness and improvement of human capital there is a positive feedback connection (Chang, Rosen & Levy, 2009).

Although with all this knowledge and experience accumulated over the years, there are frequent lapses in planning, organizing and implementing educational and development programs. These are solutions that often can not simply be copied from one organization to another, because each is specific in its own way. Regardless of how the organization is confident in its program, its development strategy and education, we need information from the other side, from the employees themselves, because these programs were made for them.

The manner in which employees evaluate various programs of education and development, the degree of importance which they give, can significantly affect their motivation, commitment, and satisfaction with their participation and their acceptance. In this study we made an initial review of the situation in the area that will allow further development and adaptation of the programs concerned. It can be assumed that programs such as "role-playing, simulation games, case studies" that are rated as the least important will be to the extent be accepted and adopted as the preferred forms of training and staff development. In contrast to these "classical training and individual instructions," employees assess as highly significant and their intensive use and improvement can help organizations in their efforts to provide employees the best conditions for progress.

The results show that men and women have significantly different assessments of the importance of some programs. When planning and implementing programs certain attention has to be given to this, and where necessary, adjust the programs to the actual users. The importance of the more specific solutions is revealed. Furthermore it is noticeable that women give much less importance to education programs, which can significantly impact their engagement and activism necessary for successful implementation. A possible explanation is that most of programs are designed in that way that they are fit for the men and are not adequately designed for all the participants. This knowledge can be practically be applied in such organizations operating in the typical economic activities and where there is great disparity in gender representation.

The findings somewhat are not consistent with the previous concerning the perceptions of the human resources practice by older employees (Stassen & Lee, 2009). The results reveal that assessing the training program disappears the difference between employees of different ages, and that they are equally evaluate different programs as important. The only difference is expressed in terms of "theoretical lectures". One explanation might go in the direction that the oldest employees have already mastered the theory and have no more need for it and failed to distance themselves from the present moment, when they do not need that kind of program any more. Middle aged employees evaluated this program significantly more important than other respondents, perhaps because after the initial entry into the job and work for a certain number of years, they realized that no matter how practice was important, it must develop parallelly with the theoretical part, which allows the transfer of knowledge to other contexts, and provides a good basis for further progress.

Also the results show that the significance of some programs has a different estimation in the organizations of different sizes. This again emphasizes the fact that it is almost impossible to copy and transfer solutions from one organization to another. Again there is need for more specific solutions.

It is up to the organizations to adopt these findings and begin dealing with their own employees in a manner that will enable them to better prepare and empower in the modern world of business which requires continuous changes. Continuous changes require timely intervention, education of employees in accordance with the preservation and enhancement of competitiveness, which means that organizations can not allow

any errors in the process. Waste of time, resources and staff often questions the survival in the market. Therefore the organizations long for specific, tailor-made programs with which they will achieve the best results. These findings may help them in this way and open to them the new possibilities in improving human resource practices. This study can serve as a good basis and a springboard for further, more specific studies, such as e.g. when talking about different industries, different regions in which they do business, the different ownership structure... These are all suggestions for further research which will enrich our knowledge in this area, and which has great practical significance.

There are many questions related to human resource management, and in providing the answers all the interested parties should participate, from the researchers, over the employees and the employer, to even the state.

Emphasizing the importance of the employees for the company success and scientifically dealing with the human side of the company and management is not new. What is relatively new is the real, practical interest of companies and their management for employees' potential and their development as an objective assessment of the vital interest not only of the business development and success but also of a clear determination and definition of what makes this company different from the others. This difference is reflected in some elements which represent a key competitive advantage, and are considered an important element of the appearance on the market. The goal of every corporate subject is to develop such a competitiveness or gain it, and in global processes it is the only formula for survival and for realizing the mission and vision of each company.

STAFFING FOR INTERNATIONAL ASSIGNMENTS IN MULTINATIONAL COMPANIES: EXPATRIATES VERSUS LOCALS

Tatjana Ivanovic

Faculty of Organizational Sciences, University of Belgrade, Serbia; tatjana.ivanovic@fon.bg.ac.rs

Abstract: *More and more organizations tend to extend their operations to international markets. Globalization and growth of international business have led to more extensive internationalization of human resource management (HRM). Nowadays it has been widely recognized that effective human resource management is a key to success of multinational companies (MNCs). This paper seeks to address the issues that multinational companies are faced with in managing diverse human resources in an international context. The paper explores the key role which global staffing plays in international human resource management, particularly focusing on one of the most critical decisions a multinational company has to make, which is the one concerning decision on an appropriate mix of parent and host country nationals in foreign subsidiaries. The aim of the paper is to reveal advantages and disadvantages of employing each type of staff in terms of their nationality and summarize the common reasons for transferring expatriates abroad or employing locals in foreign subsidiaries. Conclusion of the paper is that both options – employment of parent and host nationals in a MNC's foreign subsidiary may create advantages and disadvantages opposing to each other, so that in the course of the staffing of a foreign subsidiary MNC needs to elaborate all relevant aspects of the decision, from legal, technical and cultural to financial. This paper may present value to multinational companies intending to enter new markets when deciding whether to employ parent or host country nationals in the managing positions in the foreign subsidiaries and what aspects to consider in order to create a mix of the human resources which will ensure successful operation of the subsidiaries.*

Keywords: *human resource management, international human resource management, multinational company, global staffing, expatriate, parent country national, host country national*

1. INTRODUCTION

Global competition encourages companies to invest in foreign countries with an aim to create or to maintain competitive advantage. Whilst postulates of human resource management can successfully be implemented in companies operating in one single country, human resource management in international environment is much more complex in view of differences between countries in which the company operates and the diversity of employees. Growing number of companies which tend to spread their operations beyond the borders of parent country led to emerging need for definition of different approaches to human resource management.

According to Schuler et al. (2002) the purpose of international human resource management is to enable multinational companies to be globally successful, i.e. to be: competitive all over the world, efficient, sensitive to local environment conditions in foreign country, flexible (adaptable in a shortest possible term) and capable of transferring knowledge throughout globally dispersed subsidiaries. Many authors agree that international human resource management refers to human resource management all around the world (Schuler & Tarique, 2007) aiming to help organizations effectively use their human resources in international environment (Shen, 2005). International human resource management may be considered as a set of activities intended for managing human resources in organizations in order to accomplish organizational goals and gain competitive advantage at the national and international level.

2. SIGNIFICANCE OF STAFFING IN INTERNATIONAL HUMAN RESOURCE MANAGEMENT

Multinational companies operate in many different countries through their subsidiaries – “semi-autonomous entities with entrepreneurial potential, within a complex competitive arena, consisting of an internal environment of other subsidiaries, internal customers and suppliers, and an external environment consisting of customers, suppliers and competitors” (Birkinshaw et al. 2005, p. 227). In the process of establishing subsidiaries in foreign countries MNCs may face different problems. Even though all aspects of international human resource management are important, staffing is often considered the most significant international HRM activity, crucial for efficiency and success of foreign subsidiaries (Widmier et al., 2008). Making staffing decisions in MNCs is usually based on applicant's nationality. This approach to staffing helps reaching numerous strategic goals, such as achievement and maintenance of global integration and control, response to business conditions in a foreign country and transfer of knowledge beyond national borders (Colakoglu et al., 2009). Scullion and Collings (2006) define staffing in international context as “the critical issues facing multinational corporations with regard to the employment of home, host and third country nationals to fill key positions in their headquarter and subsidiary operations” (p. 3). This means that a company has an option to fill its key management positions in foreign subsidiaries by mixing three categories of employees: parent country nationals, host country nationals and third country nationals. Parent country nationals (PCNs) are employees of MNC who are citizens of the country where MNC's headquarters is located (home/ parent country); host country nationals (HCNs) refer to citizens of the host country where the foreign subsidiary is located, while third country nationals (TCNs) represent employees of MNC who are neither citizens of a parent country nor citizens of a host country (Tarique et al., 2006).

Employees moved across national borders in order to take different roles and perform various tasks have traditionally been called expatriates (Dowling & Welch, 2006). An expatriate is a term used to define a foreign service employee, or an individual working and temporarily residing in a foreign country, but planning to return to his/her home country or transfer to another country (Cascio, 2003). It may be concluded that an expatriate represents a global manager, regardless of his/her parent country. Parent country nationals and third country nationals are always considered expatriates, because they are sent to foreign subsidiaries to perform particular assignments. Even host country nationals may become expatriates in case a MNC decides to transfer them from the subsidiary in their home country to the MNC's headquarters. In such cases those employees are called inpatriates (Reiche, 2007).

Expatriation may include the transfer of all types of employees working in a MNC (De Cieri et al., 2007). Choosing a mix of host, parent and third country nationals that will achieve organizational goals in the best possible manner seems to be a serious challenge for MNCs. However, even though all three categories of employees may be seen as expatriates, the vast majority of the literature examining expatriates is focused only on parent country nationals. In this paper the term expatriate will also be used to indicate only the employees of the same nationality as the MNC.

3. APPROACHES TO GLOBAL STAFFING

The approach a MNC will use for filling vacancies in foreign subsidiaries depends on: general staffing policy for key management positions in the MNC's headquarters and subsidiaries, limitations regarding employment policies defined by host governments, and availability of human resources (Dowling & Welch, 2006). As far as subsidiary staffing policy is concerned, this paper will refer to widely accepted categorization of global staffing approaches given by Perlmutter (1969), indicating that the global staffing policy chosen by a MNC depends on attitudes of top managers in the headquarters towards building company's worldwide operations. Three general approaches to staffing foreign subsidiaries were identified: ethnocentric (home country oriented), polycentric (host country oriented) and geocentric (focusing on the whole world). This means that a MNC may choose to fill its subsidiaries only with parent country nationals, may recruit individuals both from parent and host country, or may adopt an international perspective focusing on unlimited employment of different nationalities.

In an ethnocentric staffing strategy all key decisions are made in the headquarters. Key management positions in both home and host country are filled by PCNs. As knowledge from the home country is seen as the most useful, home country policies and practices are usually established in MNC's parent country

and then transferred to all foreign subsidiaries. Polycentric approach focuses on cultural and other differences between countries. According to this approach MNC treats each foreign subsidiary as a distinct entity with a certain level of autonomy in decision making. Subsidiaries are managed by HCNs who are rarely transferred to headquarters, while PCNs hold key positions in the headquarters and are rarely sent to foreign subsidiaries. HRM policies and procedures are developed in the host country. Geocentric policy means that MNC has a global approach to its worldwide operations and understands that each part of organization provides its unique contribution to company's performance (Dowling & Welch, 2006). PCNs, HCNs and TCNs may be promoted to top positions both in the headquarters and the subsidiaries solely based on their capabilities, regardless of their nationality or location (Shen, 2005). Later, one more approach to staffing was added – regiocentric (Heenan & Perlmutter, 1979), which allows MNC's employees to be transferred to foreign subsidiaries, but only within their geographic region.

The key strategic issue regarding the MNC's international orientation refers to the level of control of the headquarters over subsidiaries and to the practices of managing human resources in the subsidiaries (Briscoe et al., 2009). Monks et al. (2001) suggest that in early phases of internationalization process companies usually tend to use ethnocentric approach, meaning that they send expatriates to the foreign subsidiaries in order to transfer corporate culture and ensure implementation of the company's procedures in the foreign subsidiary. After a while, companies usually move to polycentric policy. As confidence of parent company in local managers in foreign subsidiaries is growing, they are promoted to the top positions in the subsidiary. With the increasing level of internationalization, companies are getting closer to adopt a geocentric or regiocentric approach to staffing.

4. REASONS FOR TRANSFERRING STAFF FROM MNC'S HEADQUARTERS TO FOREIGN SUBSIDIARIES

An apparent difference between domestic and international human resource management is that in international HRM employees are moved outside of the borders of one country to undertake various roles in international operations of a company. Employees in MNCs may be transferred in different directions – between the headquarters and subsidiaries, or between subsidiaries. A key characteristic of MNCs as employers is their ability to transfer HRM practice across the borders (Edwards et al., 2007). There are numerous reasons for sending expatriates to foreign subsidiaries instead of using host nationals.

The main reasons for transferring MNC employees from one country to another include filling of vacant position, management development and organization development (Edström & Galbraith, 1977). Companies usually send employees abroad when it is necessary to fill the positions in foreign subsidiaries where host nationals with required qualifications (specific knowledge) are lacking or when it is too demanding to train them for a certain job. Lack of qualified local staff is the most common reason for sending employees abroad. Companies encounter this problem most often when investing in the developing countries. In such cases function of expatriates is to bring expertise in the company's foreign subsidiaries, i.e. to transfer technical and managerial knowledge and train local managers in the subsidiaries (Harzing, 2001a).

International assignments are often considered as a mandatory step in career development of top managers (Dessler, 2011) which means that even when qualified individuals are available among local staff, companies will send employees abroad to enable them to acquire experience needed for their own career development. Such transfers provide international experience to the managers and prepare them for undertaking important tasks in foreign subsidiaries or in the headquarters in the future (Harzing, 2001a).

As per Reiche (2007) the development of an organization involves the establishment of control and coordination over its geographically remote entities. Expatriates are an important tool in control and coordination mechanism of a MNC. They are familiar with the strategic goals, policies, procedures and practices of MNC, and will ensure that they are adopted in the subsidiaries with an aim to enable the company to maintain control over its subsidiaries (Tarique et al., 2006) and provide efficient connection between the subsidiaries and the parent company. Key positions in foreign subsidiaries are filled with employees from the parent country with an aim to provide consistency in operations of different subsidiaries around the world with the organizational goals and ensure that the subsidiaries comply with

company's general objectives and policies. Those employees manage subsidiaries in compliance with behavior models established and approved by the headquarters, which enables MNC to apply a unique management technique in all countries where it operates. Also, the use of parent country nationals enables effective liaison and communication with parent country staff.

Moreover, employees from the parent country are familiar with the corporate culture of MNC (Tarique et al., 2006). They transfer knowledge related to the strategy and organizational culture from the parent company to the local staff in a foreign subsidiary (Selmer, 2004), with an aim to facilitate knowledge sharing among employees in different parts of the organization, creating international corporate culture and developing common corporate values. In addition, they encourage the local staff to develop their international perspective.

According to Brewster et al. (2007) the main reasons for transferring employees abroad include professional development of employees sent to foreign subsidiaries, transfer of knowledge, provision of scarce skills, control and coordination. The authors explain that all of these factors bring certain direct values to a company (financial value, value to relationship with stakeholders, human resources, international business processes or virtual infrastructure).

Harzing (2001) uses certain metaphors to explain the roles of expatriates in MNCs. It has already been mentioned that expatriates are seen as agents of direct control over a subsidiary, ensuring that the subsidiary complies with the MNC's rules and procedures (Dowling & Welch, 2006). Harzing (2001) labels these expatriates as "bears", underlining their domination and control in the subsidiary. Expatriates may also carry out indirect control over subsidiary through socialization. In this case they are viewed as "bumble-bees" moving from one organizational unit to another. While being transferred from one unit to another, expatriates build informal communication networks in the MNC, performing the role of "spider". Dowling and Welch (2006) add a few more advantages that expatriates may bring to a MNC. They serve as boundary spanners, or a link between MNC's home and host country, collecting necessary information about the host country to which they are transferred and act as representatives of their MNC in the foreign country. Also, parent country nationals act as language nodes in the host country.

5. REASONS FOR RECRUITMENT OF LOCAL STAFF IN FOREIGN SUBSIDIARIES

The staffing decision is often considered as an appropriate choice between PCNs and HCNs. Traditionally MNCs are sending their employees abroad to ensure that the policies and procedures of the parent company are implemented in foreign subsidiaries in the same manner as in the headquarters (Schuler et al., 2002). However, many employees are not willing to move abroad for work-related purpose (Dessler, 2011). In addition, transfer of employees abroad is associated with significant costs (Harzing, 2001a). Having in mind that expatriates are paid better than local staff (Selmer, 2004), their movement to foreign subsidiaries may be much more expensive than employment of local workers. With increasing costs of sending PCNs, while career development issues made international assignments less attractive, MNCs started to turn to local human resources to meet their international recruitment needs (Black et al., 1999).

In addition to lower costs of hiring local staff in comparison to PCNs, as a primary goal, there are other reasons for using local human resources instead of sending expatriates to foreign subsidiaries.

One of the most important reasons for employment of the host country nationals in top management positions in foreign subsidiaries is their familiarity with local market and business practices, as well as with cultural specificity of the host country (Harzing, 2001a). Locals have the ability to respond effectively to the local requirements (Tarique & Schuler, 2008). These employees know well cultural, economic, political and legal environment of their country (Tarique et al., 2006), as well as business practices in the host country, while, on the contrary, employees from the parent country need a lot of time and effort to get familiar with characteristics of local environment to reach the level of familiarity of local staff (Harzing, 2001a). Local staff knows business customs in their country much better than any foreigner.

By assigning local staff to top management positions in foreign subsidiaries MNCs may successfully avoid problems of getting expatriates (and their families) adjusted to a foreign country, which may be very serious – particularly in cases of big cultural differences between parent and host country (Harzing, 2001a). In this way a need for expensive trainings aiming to prepare expatriates for living and working in a

foreign country and facilitate their adaptation to another culture will be eliminated (Dowling & Welch, 2006). Employment of locals also overcomes language and cultural barriers (Selmer, 2004), which otherwise may cause numerous problems in communication and doing business.

Employment of local staff in top positions in foreign subsidiaries may have a positive impact on the moral of local staff (Selmer, 2004). It provides opportunities for advancement and promotion to HCNs and increases their commitment and motivation. Having in mind that local employees work in their country of residence, it is more likely that company will keep them for a much longer period than expatriates, who usually work in a foreign country for a limited period of time and then return back to their home country or transfer to another country. Another advantage for organization is that there is not a need for transferring these employees to other countries.

Additionally, HCNs are usually preferred by host country governments, as employing locals brings advantages to the host country. That is one of the reasons why sometimes host governments may encourage hiring HCNs and limit opportunities for employing foreigners.

6. CONCLUSION

Effective human resource management is perceived as a competitive advantage of multinational companies.

MNCs recognize that human resources have a crucial role in achieving a competitive advantage in a highly competitive global market. Even though all aspects of human resources management are very important, staffing continues to be an essential international HRM activity. Staffing key management positions in foreign subsidiaries is a strategic challenge for a MNC. That is why a successful international assignment is often seen as an integral part of establishing a host country subsidiary (Olsen & Martins, 2009).

There are different goals companies tend to accomplish through the use of international assignments. Some of them wish to improve business performance, solve technical problems, develop and share best practices, develop international leadership or control financial results (Brewster et al. 2007). Some of these objectives may be achieved by sending expatriates to foreign subsidiaries. However, primarily due to high costs of transferring parent country nationals to foreign subsidiaries, companies often need to turn to host country nationals to satisfy their recruitment needs.

It may be concluded that both options - using expatriates and locals to staff a foreign subsidiary - may bring a MNC some disadvantages. Usually disadvantages of employing one category of employees are at the same time the advantages of using another, and vice versa. When deciding on which of the options to use MNCs have to take into account all aspects of this issue which include consideration of associated costs, availability of appropriate staff, cultural differences and language barriers, specific requirements of host country government, level of control over subsidiaries. Choosing an appropriate mix of expatriates and locals still remains a crucial issue in international staffing, often having a significant impact on foreign subsidiary performance.

ROLE AND IMPORTANCE OF THE LEADERSHIP IN MUSEOLOGY - EXAMPLE OF THE MUSEUM IN PRIJEPOLJE -

Jelena J.Rvović
Faculty of Dramatic Arts, Belgrade, jelena.rvovic@gmail.com

Abstract: *How could one of the smallest and youngest museums in Serbia, Museum in Prijepolje, which does not meet even the most basic working conditions achieve such success, become the first candidate and get nominated for the museum's most prestigious European award in the field of museology? This question has initiated the project and represents the main objective of this research. Specific objective of the research is to analyze the character of the Director of the Museum in Prijepolje who has been working at the museum since its founding, and is at the position of the director for 18 years. This research investigates the relationship between personality traits of the director of the Museum in Prijepolje and the success of the museum.*

Keywords: *Museum in Prijepolje, director, manager, leader, European Museum of the Year Award 2012*

INTRODUCTION

Analyzing the beginning of this institution, it can be assumed that the Museum in Prijepolje either stops working or becomes part of the National Museum in Užice. But the fact that record its history since 1994 until today, says the exact opposite, telling the story of a surprising twist. Instead, under the Act, the Ministry of Culture Museum in Prijepolje close or submit them to the jurisdiction of another museum, the Museum of Prijepolje on the basis of several national projects that have been realized, financed by the Ministry of Culture of Serbia, given the status of a regional museum and recognition for its highly successful operation. Following the implementation of important national projects, which are still funded by the Ministry of Culture, along with receiving prestigious awards, the museum acquired conditions that, according to strict criteria of the European Museum Forum in Liverpool, for the first time in history of Serbian museology, applied for the largest museum prize in Europe "European Museum of the Year 2012" and become the nominee.

Hypothesis: The role of leadership characteristics, which owns the director of the Museum in Prijepolje, has a decisive importance in achieving the success of the museum.

The research methodology included qualitative method of interview with the director of the museum, observation/ monitoring (extensive biography of the director, analysis of documents from the archives of museums, as well as articles about the museum in the media), a qualitative analysis of collected content, analytic and synthetic use of the information. In order to bring relevant conclusions, the methodology also includes an interview with the employee ethnologists and museum audience's survey, using random sampling method.

THEORETICAL FRAME OF THE RESEARCH

Bass(1981) points out that "the most useful studies, from the stand point of understanding of leadership, are those in which the leader's behavior is described and analyzed on the basis of direct observation and analysis of biographical data and historical data in case" (p.66). Proper analysis of leadership includes not only the study of the leader, but also situations in where the leader is present.

Presenting the problems of the unsuccessful organizations, Bennis and Nanus (1985) are in study of leadership concluded that they are seen in a great number of managers, and a small number of leaders. They show on a significant difference between managing and leadership." Leadership is based on ability

to create a good vision which attracts followers to concrete number of ideas or values. Managers, on the other hand, are capable to do things right, while leaders are interested only to do the right thing. Leaders are very engaged persons and they must be in order to keep their role which dismisses all doubts and uncertainties, giving a clear picture that represents base for action" (p.4).

Although studies about leadership characteristic have a long and controvert history, research shows that possessing of the certain values doesn't guaranty successful leadership, although it is obvious that efficient leaders are different from other people with certain key aspects. (Kirkpatrick, Locke, 1991).

What characteristics make a manger-a leader? There are three types of characteristics which are most frequently in studies of leadership, Brayman points out (1986). "First, there are physical factors like height, weight, look and age. Second, researchers have investigated values such as intelligence, language fluency, education and knowledge. The third thing is broad personality, conservatism, introversive-extroversive person, domination, adjustability, confidence, interpersonal sensibility, and emotional control" (p.19). Despite a great amount of negative proof, results points on week connection between leadership and age, height, weight, physical appearance, energy, domination and mood control. Proofs are equally divided with characteristics as introversive- extroversive person, self confidence and emotional control. (Bass, 1981)

According to study done by Kirkpatrick and Locke (1991), key leadership characteristics are urge (broad specter includes desire for accomplishment, ambition, energy, durability, and initiative), desire to be a leader (not a desire for power itself), truthfulness and integrity, confidence (which is in direct connection with emotional stability), cognitive abilities, and knowledge of business. These are six characteristics that make difference between leaders and non-leaders¹ (p.48).

Managers can have some of these characteristics, but only if they have each one of them, they can be leaders. , Kirkpatrick and Locke believe that key leader characteristics help leaders get necessary skills, form organization vision and efficient plan, and necessary steps that implement vision and reality.

CONTEXT

After he graduated at the Faculty of Philosophy in Belgrade (at the department for general and national history), director of the Museum in Prijepolje started working in 1981 as a curator-historian in just opened museum of Yugoslav pioneers and youth, which was located in the Memorial Center Bosko Buha in Jabuka near Prijepolje. As a historian at this museum he worked as a curator-educator, related to the presentation of cultural monuments. He also organized educational excursions in a way that was many years known, and very popular in primary schools, which keep visiting this Memorial Complex. Thus designed and unusual program of participation and communication between museums and specific target groups of the school population sparked the attention of not only participants but also the Ministry of Education and Culture Ministry, which were positively evaluated this way of organizing the museum and educational work.

The desire for accomplishment in this, museum director could be seen at the beginning of his career, according the days spent in the museum. That need is an important motive among effective leaders, and even more important among successful entrepreneurs. Leaders, who achieve their goals, get satisfaction for successfully performed tasks; achieve standards of excellence and finding better ways to do the job. To build their way up to the top of the organization, leaders must possess the desire to complete challenging tasks and projects (Kirkpatrick, Locke, 1991:49). It also provides the acquisition of technical expertise (expert opinion), through education (Faculty of Philosophy in Belgrade) and work experience, as well as initiating and passing through organizational change.

As the permanent exhibition at the Museum in Jabuka was exclusively related to the participation and crimes against children in the NOB (concentration camps at Jasenovac, Jastrebarskom, Gradiski), the director of the museum dealt with the study of historical materials related to this problem, as he prepared to change a part of permanent exhibition and fill it with new data. The 90-ies events have led to the

¹ Proofs for characteristics such as charisma, creativity and flexibility are less clear.

change the museum exhibits concept of the Museum in Jabuka. Director of the Museum in Prijepolje, at this point, still working as a historian, formed an expert team that prepared a synopsis of the new museum exhibit, which was submitted to the Ministry of Culture of the Republic of Serbia, to finance it. Because of the changes in the system in 1991, and changes in entire former Yugoslavia the memorial complex Bosko Buha was closed.

How is the director of the Museum in Prijepolje overcome this obstacle? Kirkpatrick and Locke (1991) point out that "leaders have the ability to objectively look at the problem and have a degree of strength and endurance. They must be relentless and persistent in their actions and must follow the changes. The course of action is not the only thing that counts; there is also the selected direction that they have to stick for. Effective leaders must continue to primarily "push" themselves to the goal, so that they could "push" others as well. Persistence, of course, must be used intelligently" (p.51).

In the final stage (1991) the director was involved in the work of this working group, where he became a curator of a recently opened museum.² At the recently opened museum he takes a historical collection and as a curator-historian he starts studying The River Lim and Lim valley medieval period. Another feature identified in this part of the biography of the director of the Museum in Prijepolje is activity. "Effective leaders do not sit with their arms crossed and wait for something to happen, but make decisions and take actions that lead to changes, i.e. showing high degree of initiative. Instead of sitting around waiting to be "fate smiled", the leaders themselves initiate this process" said Kirkpatrick and Locke (1991, p.50).

Since its foundation until 1993, the Museum in Prijepolje hasn't been organizing any significant project or exhibition. Employed professionals were working on the museum collection, worked in the facility that wasn't suitable for museum operations and trying to make a plan on how to work. The Museum in Prijepolje had the status of local homeland museum. In the period between 1991 and 1993, the museum staff was director, and three expert workers: curator - historian, archaeologist and ethnologist, librarian and hygienist. Archaeologist and ethnologist have just started their first working day in the newly opened institution, with no experience and vision of what should be done. In the first years they have just acquired a basic museum knowledge, while museum director, on the other hand, had 10 years experience in the museum at the time of establishment.

Law on Protection of Cultural Property ("Official Gazette of RS", no. 71/94) identified conditions that a museum institution must meet in order to start working, and that also applied to the Museum in Prijepolje. The building had to be determined by standards relating to the gallery space, office space for employees and what is most important for the museum-existence of the depot. When the Museum in Prijepolje registered, it had no depot, but a small ancillary building on the south side facility (kitchen at the time the facility was in elementary school). The museum collection was placed in the space of 20 m². The museum exhibits are not permitted to be stored in such a space (which was not adequate and did not have the basic conditions of care), but the small number of artifacts was found in it, because the rest of the few collection was on permanent display. Number of professional employees is another condition of the said Act. In addition to all the conditions when it comes to building and museum collection, the institution must have employed three professional workers. Since the beginning of the Museum until 1993 that requirement was met.

However, when a museum director left his office and went into retirement, a new director was elected in December 1993, curator- historian, and Museum in Prijepolje automatically was no longer fulfilled the necessary condition to begin working as a museum institute. The situation became dramatic in 1997 when the curator-archaeologist left the museum. Museum then left without any options, not only for the realization of national and major projects, but in general the existence of a functioning museum. Jokic (2010) point out that "the fact is that human resources play a special role in unfavorable material and socio-economic conditions, especially when it comes to professions and employees who represent a stable core of the organization in unstable conditions" (p.7).

Museum in Prijepolje, despite attempts, since 1994 has not been able to hire a qualified person. So at the Museum in Prijepolje work only two professional staff and one of them is still performing the function of director.

² Then the Museum in Jabuka became a part of the Museum in Prijepolje.

After three years of work at the Museum in Prijepolje, curator-historian takes over position of the museum director. Kirkpatrick and Locke (1991) point out that “effective leaders are very ambitious in their jobs and careers and have a desire for continuous improvement” (p.50). Although working as curator-historian, he also accepted the post of director of the museum. In addition to initiatives, this data reflects the ambition and desire for leadership, which implies a desire to lead and influence others. “People with high managerial motivation often affect other people, by the conquest of arguments or greater authority possessions. They prefer to direct rather than having subordinate role. Jon Bentz describes successful managers as those who have “a strong desire to compete for the position ... power ... and they need to be known as people of authority.” (p.52)

The recommendations of the municipal authorities were the same as for the establishment of the museum that the museum should remain an institution that will deal with all efforts of preservation locally, as part of the Cultural Centre, together making a whole. This time director who takes over has his own, different vision of the Museum in Prijepolje as a significant cultural institution. Formulating plan to implement a bold goal, as it then seemed³, steps towards realizing the vision he saw in big projects, in cooperation with relevant institutions and prominent scientific individuals, by which museum could fight for his place among the institutions for the protection of Serbia. Dragicević Šešić and Dragojević (2005) point out that: “the vision of its future, given in the form of development scenarios, should be realistic but ambitious representing a step forward from the daily, ongoing routine, and to be mobilizing and inspiring factor for selection of brand new, sometimes radical and risky strategies” (p.120). The director of the museum in Prijepolje knew the answer to the question “how”, in 1994, he saw the museum in his vision almost twenty years later, he also knew the answer to questions “what, where, where to”. Is this enough to conclude that this manager is a leader?

Therefore, this vision that the director hasn't given up, tells about self-esteem. A person imbued with self-doubt will never be able to take necessary action and gain the respect of others. Self-confidence plays an important role in making decisions and gaining someone's trust. Obviously, if a leader is not sure what decisions to make or express a high degree of suspicion, it is less likely that his followers will believe him and follow his vision (Kirkpatrick, Locke, 1991).

On the other hand, self-confidence helps effective leaders to remain calm. The leader, who loses self-control quickly, will not encourage trust and team work as one that has emotional control (Kirkpatrick, Locke, 1991). Describing the supervisor, an ethnologist at the Museum in Prijepolje said: “Director speaks to me in the same way, even in a crisis situation is not angry and does not react impulsively”.

Various defined vision necessary brings the different strategies and methods of operation (Dragicevic Šešić, Dragojević, 2005). Leaders should be intelligent enough to formulate suitable strategies, solve problems and make the right decision. If someone wants to lead, followers want that person to be more skilled in these things from them. “The collection, integration and interpretation of vast amounts of information reflect the cognitive ability of a leader”, point out Kirkpatrick and Locke (1991) and also say: “These requirements are now higher more than ever because of the rapid technological progress” (p.55).

There is no document, from the period of creation of his vision, which defines and closer explains the planned concrete steps, except the oral narratives of director. Creatively chaotic state (Ichak Adizes) which is incorporated in an imaginary vision was difficult to observe in its entirety only by in-depth interview with the director of the museum. On the other hand, vision without concrete actions to materialize and embody, is just an idea. Is this vision converted in concrete projects that have contributed to its realization? To answer this question, director of the museum has placed at the disposal extensive documentation which enables getting more complete picture.

Projects of the Museum in Prijepolje are than being systematized (science meetings, seminars, exhibitions, science- examinations and art projects, lecturers and other things that can be considered as models of culture projects) in the aim of forming the sequence of their initiation and realization⁴. Thanks to

³ Especially considering the inadequate facility, depot, and only one expert employee, as well as lack of support of the municipal government.

⁴ Analyzing of the gathered information, and by retrospective view of the newest till the oldest projects, we come to the identical year-1994.

the projects, in few years Museum in Prijepolje was given a status of the regional Museum on territories of Prijepolje, Priboj, with inherency for organizing important projects of research on this important historic territory. Museum in Prijepolje is also one of the rare museum institutions that exhibited out of the country and organized several international meetings, as well as exhibitions of National Museums of other countries.

Beside initiating and realization all of the projects, the director of the museum himself personally leads all of the organization, actively involves in their realization and successfully fulfills the aims of every project started. Leaders must possess a lot of energy. Kirkpatrick and Locke (1991) said: "long work hours, intensive work during many weeks (and many weekends) during years; they must be physically active, mentally and emotionally ready. Leaders possess high level of energy, durability and are generally active, full of life and be able to keep stable productive tempo of work" (p.50). The need to have energy is today even bigger, because more and more institutions expect that all employees, including directors spend time traveling and visiting parts of organizations which are on other locations.

If the leader wants to be efficient, he must possess a high level of knowledge about institution, work and technical issues. Technical expertise makes a leader able to understand worry considering technical questions. Harvard professor John Crotter claims that the expertness is more important than formal education. Although cognitive abilities are needed for understanding of business, formal education is not necessary. Only 40% of business leaders according to studies of Bennis and Nanus had degrees from business. Kirkpatrick and Locke point out that: "knowledge of organization and industry allows efficient leaders to make decisions based on exact information and understand implications of those decisions" (p. 56).

Integrity is a connection between words (vision of the director of the Museum in Prijepolje) and works (the list of realized projects), and honesty implicates the truth. *Morgan McCall* and *Michael Lombardo* from the Centre for creative leadership conclude that managers, who have reached the top, used the following formula: "I will do exactly what I have said I will do, and if I change my mind, I will inform you in advance so I wouldn't imperil you with my actions." Successful leaders are open with their coworkers, and they are also direct, but without hurting the confidence. (Kirkpatrick, Locke, 1991). One of the employees of the Museum in Prijepolje- ethnologist says: "The director was consistent in his work". Sincerity is absolutely necessary for efficient managing. "If we are ready to follow someone, to the battle or to the meeting room, we must believe that that person is trustful. We want to know if he or she is truthful, ethically correct and principled. We want to be completely sure that integrity of that person is correct", point out Kirkpatrick and Locke (1991, p.54).

While working on projects, the director of the museum, makes a lot of contacts and cooperation with the most important and most eminent science institutions of Serbia and in the region (which was also one of defined aims of the vision), but it also upgrades communications of museums with public. At the same time, without open dialog with state, society and media, about different political possibilities, where people included are aware of their responsibility for society in whole, museums will stay some kind of necessary aim, that won't be clear. (Gavrilović, 2008).

Vujičić, Stankov and Besermenji (2010) point out that: "Definition of the museum as elitist, academic, educational institution that works according to strict rules is a long time history. Now the museums are in race with competitors, where they fight for the free time of the potential visitors. This fight overcomes inter institutional levels, turning into competition with new cultural attractions. (Industry of fun, culture, subculture) that becomes more frequent day by day." (p.324). It seems that the director of the museum was lead with the same conclusions, which were said many years later and which are still not recognized in many museums in Serbia.

Šola's presentation on conference „Best on heritage 2009“ in Dubrovnik, gives definition of the museum success using a formula (Vujičić, Stankov, Besermenji, 2010) : $E=m \cdot c^2$. Perfection (excellence) is accomplished with formula: museum times communication square, amplifying the importance of communication in work of modern museums. With amplifying the importance of communication and its constant upgrading, we come to improvement on the field of interpretation, which comes from two way communication between museums and visitors.

Gavrilovic (2008) points out that: "Unfortunately, museums (and museum employees) in Serbia are still far away from those new ideas." (p.48). Is the museum in Prijepolje exception? We must say because innovation in museum work is said to be the main reason for nomination for the reward from the European Museum Forum, and brought Museum in Prijepolje a specific approval that kind of innovation?

The director of the museum, in 2009 in Paris, on the meeting of ICOM, for the first time read the text of the competition and conditions for reward "European Museum of the Year 2012". After careful analyses with colleagues from the region, he gave out his idea that projects realized in Museum in Prijepolje can be nominated for this greatest European Museum reward. His colleagues believed that the projects of the museum deserve such reward. In the year 2011, in May, director collects documentation, without much financial support, shoots amateur film and sends data to the jury in Liverpool. In a very short time, he gets the answer that the Museum is a candidate for the reward. In October, a president of the Jury comes to Prijepolje, museum expert Hartmut Praš⁵. Conversation with director was lead in the museum, and more documentation was checked. Two months after this visit, the director of the museum was informed by the jury panel of the European Museum Forum in Paris, that the Museum in Prijepolje was nominated for the reward.

RESULTS OF RESEARCH

The director of the Museum in Prijepolje planed, organized, lead, coordinated, controlled and was also involved in realization of every project of the museum. He is a manger, but is he a leader? Starting from this study as a theoretical frame, director of the Museum in Prijepolje possesses all key characteristics of the leader. Activity, movement, and finishing all the assignments (project realized by the museum) according to Bass (1981) are leadership. "Leader is a person that takes responsibility (plans and realizes the vision he believes in) and coordinates activities of the people in their eager to reach the aim" (p.66).

If we suppose that leader is not only manger that possesses certain combination of characteristic, which is claimed by many researches, than it is only work relationship between members of the group, where leader gains status trough his active work and demonstration of ability to cope with assignments until reaching a goal (Bass, 1981). According to this presumption, director of the Museum in Prijepolje is a leader, considering that every project was successfully finished with his active involvement, and realized at end.

As we wanted to see public opinion, and see these positions from their perspective, we have done questionnaire amongst 100 people. Most of the people involved had university degrees 55%, high school degree 27%, 2% finished only secondary school, while 16% were students. More than half of the people involved go to Museum very often (51%), 43% sometimes, and never 6 %. As an occasion of visit, 34% choose special programs (all of them said they attended basketball farewell of Vlade Divac, one of museum's projects), and other things (exhibitions, promotions and lectures..), 21% people said they came to the museum for work and school obligation, while the smallest number of 5%, answered the occasion of their coming to museum is permanent exhibition of the museum. (People, who said they don't go to museum, didn't answer these questions). On the question: "What was your greatest impression from Museum visit?" most of the people 89%, said interior and atmosphere in museum, as well as kindness and commitment of the director to answer all the questions. Only 5% circled exhibits. 97% of the people know that the Museum was nominated for some European reward (45% knows which one). From 97 which knew about the reward, on the question "What do you think who should take credit for the success of the museum?" 85% answered – the director, while 15% said that they don't know. This question had no offered answers.

Results of the questionnaire weren't surprising, although a small number of people involved, is a bit restricting. It is not unusual a high number of people who are informed about the work of the museum and reward nomination, because Prijepolje is a very small town where only a few number of institutions, especially cultural, work with success. Low percentage of people who come for permanent exhibits is

⁵ Director of the Museum of National culture *Spittal*; earlier, EMF national correspondent 1999; member of the Board of Austrian Museum association since 1994; vice-president of the Museum association *Carinthian* since 2005; member of the board ICOM, since 2007; member of the executive council of ICOM-Austria, in the period from 1998 to 2004

expected because of the fact that there are not many permanent exponents in the museum. But being informed about projects of the museum (farewell of Vlade Divac, promotions, lectures) shows the good communication of the museum with audience, audience who maybe never would visit the museum if they weren't animated in an adequate way. The picture, that public has, about personal director's credit for the museum's success⁶, is another kind of data that matches the quality analyses.

CONCLUSION

Leadership characteristics of Directors' of the Museum in Prijepolje, and personal commitment and his contribution to the success of the museum, testify about the importance of leadership in a museology. With newly founded institution, director has managed to achieve an enviable status that is registered and validated in scientific institutions, museum and other preservation institutions. Museum in Prijepolje by the implemented projects and programs is one of the major museums, and undoubtedly the leader in the region and southwestern Serbia.

It is very important to note that during the civil war in former Yugoslavia, and later, director of the Museum in Prijepolje organized projects related to history, culture and traditions of national minorities that live for centuries in the area and Polimlje and Lim valley. For the first time, monuments of Islamic provenance were listed, exhibitions and lectures of Bosniak-Muslims were organized, which contributed to the respect and appreciation of the Museum in Prijepolje and beyond. The Islamic community Prijepolje, Society for Science, Culture and the Arts of Bosniaks "Ikre" Prijepolje through public statements in the media evaluated the work of the Museum in Prijepolje with great respect with sincere gratitude.

Thanks to the projects, huge personal engagement in the field of protection of cultural heritage and museology, He is one of the few managers whose re-election, six times, followed the unanimous support, although not a member of any political party.

Dragicevic Šešić and Stojkovic point out that: "awakening the entrepreneurial spirit, especially in small towns and communities, can do much in the cultural field" (p.116). The success of the smallest and youngest museums in Serbia, Museum in Prijepolje and its director, was crowned with the candidacy and the nomination for the prestigious award "European Museum of the Year 2012". The jury of the European Museum Forum will bring decision on the winner on 19 May 2012-International Museum Day in Penafiel in Portugal.

DATA BASED SYSTEMS EVALUATION FRAMEWORK

Vladan Jovanovic¹, Zoran Marjanovic²

¹Georgia Southern University, vladan@georgiasouthern.edu

²University of Belgrade, Faculty of Organizational Sciences, zoran.marjanovic@fon.rs

Abstract: *This paper presents an outline for a comprehensive data based systems evaluation framework and characterizes some novel approaches to validation as illustrations of the framework's use. Furthermore, the framework effectiveness as a tool for directing research is indicated by exposing gaps in or insufficient coverage of the existing evaluation approaches. Our primary motivation was to elaborate the evaluation process by defining user's involvement, to select important general characteristics of evaluation methods and to recognize model elements to be covered by the evaluations. Main contribution of the paper is a simple framework for systematic characterization of evaluations for data based systems. The approach used in the research follows the modelling tradition of systems design combined with the analysis of small case studies. The cases are also used as a mechanism to illustrate both the proposed evaluation framework and effectiveness of recognizing problems in empirical designs. Key contribution is an independent framework enabling the definition of evaluation processes over the entire scope of a data based systems evaluation lifecycle.*

Keywords: *data systems evaluation framework, validation by domain experts, Sharp's method, database application testing, SQL testing, data warehouse testing*

1. INTRODUCTION

The complexity as well as rate of change is increasing rapidly in all areas of organizational life and data based systems development is not an exception. While new agile paradigm evolved to match the expectation in terms of speed (see for example Scott and Sadalge 2006, Scott 2007, Jovanovic 2008) and novel methods are introduced (Sharp 2002, and Ratklif et al 2011) it appears that database evaluation practice lacks some systematization as well as vigorous empirical research compared with a strong research stream available in software engineering field (compare extensive survey in Juristo et. al 2004, with Eppler and Witting 2000). This situation motivated our on-going research involving specific methods for database design evaluation as well as an extensive exploration in evaluating and testing of SQL code. One observation became apparent, namely that database evaluation scope is broad but that approaches used are narrow in focus and methods and techniques are not easily comparable with alternative approaches. This led us to recognize that something may be missing, and to postulate possible value of an overarching broad database (that scope later evolved to cover broadly all types of data based systems, data warehouses, mater data management, heterogeneous and distributed data systems, multimedia record preservation systems, data stream based systems, archives, backup systems etc.) evaluation framework that will include testing and verification, as well as validation activities. That thought provided motivation for the research whose preliminary results are presented in this paper. The scope of the framework as given here should cover both the database and the data warehouse systems, but it is worth noting that most of the testing and evaluation literature so far dealt with data bases.

The existing body of literature dealing with evaluation and testing frameworks of interest to database/data warehouse area of study is diverse and includes prominent focus on data quality, see Wang et. al 1994, Hoxmeier 1997, Hoxmeier 2000, Peralta 2004, Bouzeghoub 2004, Gasdoue et. al 2007, an industry standard GS1 2010, and Borek 2011. There is also a well-grounded stream of research focused on queries (Graefe 1993, Brass and Goldberg 2008, Tuya et. al 2010), and on testing entire data driven applications (see Chays 2000, Kappfhamer and Soffa 2003, Cabal and Tuya 2004, Willmor and Emubry 2005, Zhenyu and Chen 2007 dealing with automatic test generation for database driven applications, Smith et. al 2008 addressing security, Alalfi et. al 2009 addressing dynamic web applications with databases, Gollfareli and Rizzi 2009 assessing data warehouse system testing, and Blanco et al 2012 addressing specification based testing of DB applications. In the requirements for white-box testing for database-driven applications, Haller 2009, provided broad perspective approaching what we may call a framework for white box testing. Structural testing of SQL is covered in cabnal and Tuya 2009, and Tuya et. al 2010.

The extensive literature deals with SQL testing and database application testing, but considerably less with data model or database design validation. As Celco 2005 pointed out, the best SQL programmers can not compensate for bad schema, so more needs to be done in the area of validation (beyond Sharp 2002, Jovanovic 2008, Ratklif et. all 2011, and Jovanovic 2012). One of the first observation, uses of our framework, was to recognize a very limited role of users in existing evaluation approaches. In addition to presenting a simple framework it is quite appropriate to illustrate database evaluation approaches with some less known but fairly simple approaches namely the Fitness test and the Independent model validation (by domain experts). This paper illustrates evaluation with two novel methods of interest specifically by providing for more domain expert involvement and thus supporting a more balanced validation.

2. PROPOSED EVALUATION FRAMEWORK

The term evaluation is used here to encompass verification and validation activities, execution based testing, human and automated assessment and specific quality assurance activities dealing with evaluation of the evaluation artefacts such as tests and checklists.

Primary goal of a framework is to organize comparison and help identify relevant evaluation approaches, methods, and techniques, in a manner that may possibly help in organizing and comparing research in the data based systems evaluation. Furthermore, simplicity and effectiveness are what we may refer to as meta requirements or salient expectations from a framework.

The essential (mandatory) aspects and its corresponding requirements for a comprehensive evaluation framework (for data intensive systems) are:

- Subject of evaluations; to recognize major categories and typical artefacts as subjects of evaluation in a broad scope of entire data system (database and/or data warehouse) lifecycle,
- Mode of evaluations; to systematize general classes of evaluations
- Classes of participants; to identify roles for humans (developers, users, professional testers, etc.).

In order to maintain simple representation any more detail characterization of specific evaluation methods (approaches and techniques) may be standardized in a pattern like format, and is subject of our on-going research. Among the generic but optional features of evaluation methods to be elaborated upon are: a) grounding theory and/or principles it is based upon (that is a model of the artefact the evaluation is based upon), b) specific coverage achievable by the method, c) possible tools and documentation involved, d) exemplar or guidance for use, e) supporting competency source, or major reference etc..

To indicate what major evaluations are to be expected to be under the umbrella of one such framework, we started our first approximation of the scope by broadening a defined scope of agile database testing according, to Scott 2007. Our first visualization, shown as Figure 1, expanded the scope to include model validation and human based usability evaluations, see artefact Design Model and related activities of expert validation, design review and fitness test as well as usability testing among evaluation types. The intended meaning of the symbols are: a) thick arrows depicts data flows, b) thin arrowed lines indicate evaluation methods, pointing to the subject of evaluations, and c) other symbols name major artefacts to be evaluated.

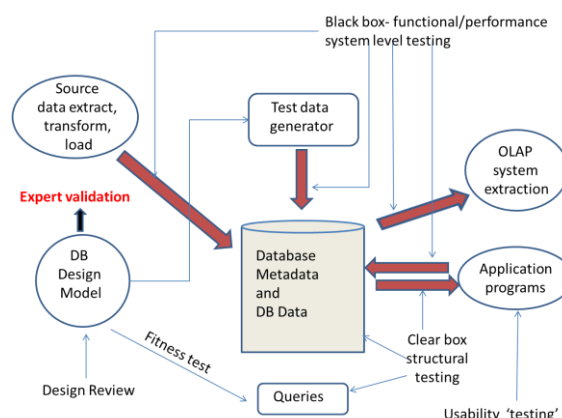

Figure 1: Broadening the Scope of Database Testing to Data Systems Evaluation

Note the usage of the word testing both for fitness test and usability test, is an example of common use as opposed to formal or reserved use of the word testing, for execution based evaluations with the intent to discover existence of defects.

The coverage of artefacts by evaluation methods, from Figure 1 as a straw-man of a framework is informally checked against a generalized database application development work breakdown, such as the one maintained by authors (shown as Figure 2). This served as a form of preliminary validation of the scope in terms of artefacts before an abstracted, stone-man schema is proposed. The framework version 0.2 is shown as Table 1, note abstracted categories of artefacts and modes of evaluation, as well as broadening of the scope to explicitly cover evaluation of systems performance and security, as well as to cover evaluation artefacts themselves. A future, ironman, version for the data systems evaluation framework (as version 1.0) will be formulated after a detail analysis of feedback data expected from the on-going research involving comprehensive characterization of existing method. The way to populate the framework is to enter name of the method and defined roles of human participants, for example Shapr's method for independent data logical (relational DB model) evaluation and Data Model Fitness Test are positioned within the framework version 0.2. It is worth noting that even a cursory review of possible entries into the framework (matrix that is Table 1) reveals one of the problems with current evaluation methods namely imbalance favouring developers over domain experts and focus on verification (testing), notable exception are the two novel methods indicated.

Table 1: Evaluation Framework for Data Based Systems

The Figure 2 addresses database environments but can also be used as a baseline for similar work breakdown chart for data warehouses and business intelligence systems as well as any other data based systems (at least in outline).

3. EVALUATION METHODS CHARACTERIZATION PATTERN

Here we will illustrate expected characterization pattern using as example an approach applicable to evaluation of conceptual data models, which is an early and inexpensive internal (for use by developers) validation method based on input from users as domain experts. The Data Model Fitness Test approach (pointed to, among others, by Jovanovic 2008) consists of the two related activities separated in time, one performed by users and one by developers. In addition to whatever requirements developers may collect prior or during the modelling and design of databases, the Fitness test requires a sample (usually of about ten questions per subject area model) of valuable questions, expectations from the future database under development.

Proposed (preliminary) pattern for characterizing evaluation method includes following elements:

1. **Name:** Data Model Fitness Test
2. **Subject:** Conceptual Data Model
3. **Mode:** Static
4. **Roles:**
 - a) Users (as domain experts) post a sample of validation questions in natural language,
 - b) Developers evaluate feasibility of queries over the data model
5. **Principle:** Reachability of attributes by queries targeting original questions
6. **Coverage:** Most of the Entities and Relationships
7. **Tool:** (recommended) Visio Stencil for Relational Algebra Query Trees (see Figure 3.) for query visualization;
8. **Guidance:** the procedure involve light and fast mental exercise in conceptualizing potential queries and depends on developers proficiency in SQL/relational algebra as well as in assessing suitability

of a data model; if developer can make a SQL (or relational algebra with a benefit of visualization) query for every validation question.

9. **Source:** Jovanovic 2008.

10. **Effectiveness and efficiency claims** in the context of suggested timing and applicability of the method. Effective in uncovering missing relationships, takes under one hour per 10 questions.

To explain or to use the Fitness testing by experienced developers it is not necessary to use query visualization as the queries can be 'parsed' as a mental experiment of evaluating reachability per each question. We not only recommend but support use of visualization of queries in teaching Fitness testing especially to students. In order to standardize relational algebra visualization we developed the following Visio stencil (see Figure 3). One example of the stencil use is shown in Figure 4, for a question: show all guests names, if any, that have booked all the hotels in London.

Figure 3. Visio Stencil for standardized representation of Relational Algebra Query Trees

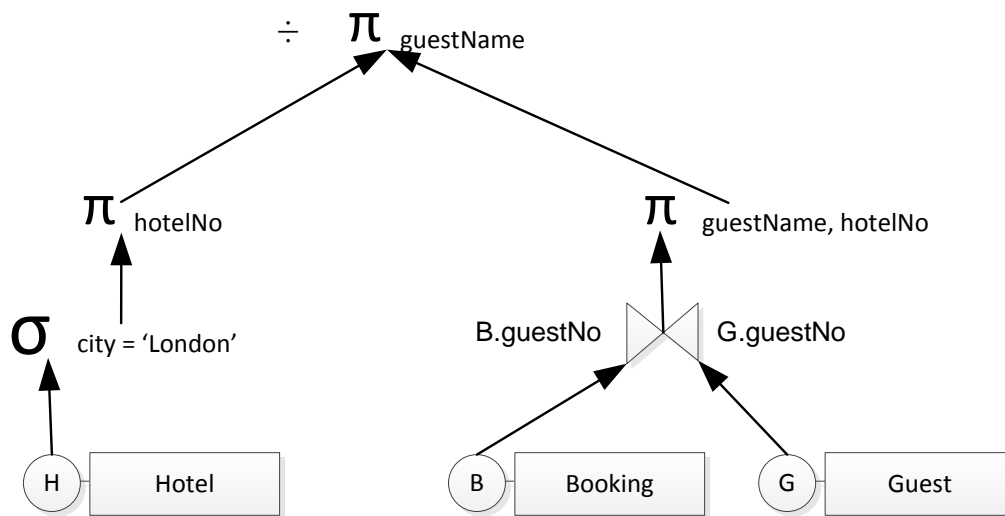

Figure 4. A Relational Algebra Tree

4. CONCLUSION

Among the contributions presented in the paper are: a preliminary version for a comprehensive framework for data based systems evaluations, and a characterization pattern as shown for the Data Model Fitness Testing, demonstrating use of the framework in defining novel/improved methods and supporting planning and other efforts on organizing research in the evaluation field. The characterization pattern is a set comprised of a method's name and nine describing elements (facets), three of which are explicit part of the Evaluation Framework (and obviously necessary). Among remaining elements only 'Tool' is optional while the last element 'efficiency and effectiveness claim' is clearly important (it may not be readily available) and defines very clearly open research problems, for those methods that do not have them yet explicitly.

This paper can be used by database and/or data warehouse practitioners in assessing scope of coverage and potential risks/deficiencies in intended evaluation methods (due to lack of certain aspects of database evaluation coverage for example) as well as by researchers, of data based systems, in setting up research

directions and for comparison and analysis of research results in the area of data based systems evaluation techniques, methods and approaches.

We intend to 'test' and standardize characterization facets and support formation of a catalogue of evaluation approaches, methods, techniques and eventually tools.

IMPACT OF METHODOLOGY IN THE SUCCESS OF ENTERPRISE RESOURCE PLANNING (ERP) IMPLEMENTATION

Dragan Manojlov¹; Miroslav Lutovac²

¹AICON, Management and Information Systems, dmanojlov@aicon.rs

²Singidunum University, Belgrade, mlutovac@singidunum.ac.rs

Abstract: Organizations need to use a proven methodology to reduce implementation risks and enable the ERP solution to be put into operation as quickly as possible. The right implementation methodology will also help ensure that the ERP implementation fully addresses the organization's business goals and objectives. Modern ERP methodology in implementation encourages and supports a progressive approach to management for users of ERP systems. The company is constantly seeking better methods and models for decision support in all kinds of decisions, developing / copying new products / markets that generate the growth of the company. On the other hand, the company creates efficient and effective operations that improve return on investment (ROI), because ERP is always considered as an asset. This paper focuses on the interaction of the company culture, business strategy and organizational skills, and balances the relationship among ERP methodology, ERP implementation and performance of the company. Considering the fact that different ERP systems use different methodologies, at the beginning of this paper short descriptions of each brand name ERP should be analysed (OracleFinancials, PeopleSoft and SAP implementation methodology). Although all the methodologies may look similar, the selection of proper methodology is the most critical part in ERP investment. The focus of this paper is on SAP methodology. Accelerated SAP methodology, known as ASAP methodology, is most frequently used on the worldwide market of ERP systems. In particular, the paper will provide an analysis of the impact of ASAP methodology on business processes in companies.

Keywords: ERP system, SAP, OracleFinancials, ASAP methodology, AIM methodology, implementation

1. INTRODUCTION

Enterprise Resource Planning (ERP) system is based on an information technology (IT) infrastructure that facilitates the flow of information within the organization. ERP systems integrate all information and processes of an organization into a unique system with unified database that concerns how organizations gather, collect, store, access, summarize, interpret, and use business information. An ERP system integrates different components through the technical integration of software, hardware and business processes. In a typical organizations structure an implementation cost of the ERP system consists of 15% software, 30% hardware, 40% systems integration, and 15% personnel (Malhotra&Temponi, 2010).

Unfortunately, ERP systems are not successfully implemented in many companies. For example, in Indonesia, more than 80% of companies implementing the ERP systems did not succeed in their implementations, more than 50% of the companies implementing ERP in the world failed to gain optimal return value, while in China, only 10% of the companies gained success. Some researchers show that 50% of the companies implementing ERP failed to gain success (Dantes&Hasibuan, 2011).

An ERP solution will provide no return if users are unable to use it effectively. It is interesting that more than 40% of mid-size companies had two or more ERP software packages, where more than 15% companies had three or more ERP packages. Based on Aberdeen Group surveyed it follows that 10% companies plan to replace strategies supporting by appropriate ERP system for the next year, while 15% companies plan to replace existing solution in next two years. Almost 25% companies are looking for a new ERP solution that will replace existing one in next three years. The main reason for replacement of existing ERP solution in 50% cases is a need for more functionality, 40% are unhappy with clumsy user interface, and 35% need a standardized solution with international capabilities.

There is a long list of companies that have problems in implementing ERP systems, such as the most known and successful Dell computers, Apple computers, or Whirlpool (Shahin, Sadri,&Gazor, 2010). An inappropriate application and implementation of Enterprise Resource Planning system can harm

performance of organization. Some authors report that the success rate of ERP implementation is very low, and in some countries the failure rate is up to 90%. Therefore, it is very important to find out a framework for the evaluation of ERP as managerial and organizational aspects rather than technical aspects. Even more, aspects such as managerial and organizational can decrease the risk of failure in the implementation of the system in an organization.

ERP implementation methodology involves various processes and procedures, which constitute the conditions or means for formulating the actual implementation of ERP projects. The most famous ERP methodologies are developed by the biggest worldwide ERP systems such as SAP and OracleFinancials.

ERP methodology is essential in each ERP project; if company insists on deviation of standard ERP methodology, it could have the great impact on the whole implementation. Normally, ERP methodology is stipulated in pre-sales phase of the ERP project. Progressive management in the company must to push the best solution for them and to choose the right methodology considering with specifics in the project.

SAP ERP system is an ERP system that covers most of the world market of information systems. SAP has developed ASAP methodology and it will be analysed in details in second part of this paper. There are many positive and negative factors in each ERP implementation. Identification of brake factors to successful implementation on the time is the key to a good implementation. The best methodology must to provide the tool for it.

2. IMPLEMENTATION METHODOLOGIES – SAP, ORACLEFINANCIAL AND PEOPLESFT

2.1. ASAP - Accelerated SAP Implementation Methodology

Generally there are two organized ways of implementation: Conventional method and organized method of implementation. The conventional method is known as “SAP Procedure model” methodology and lately has been replaced by ASAP methodology (AcceleratedSAP). However, an old SAP methodology is also in use today, primarily because of the flexibility in applying the huge company, with revenues overcoming trillion dollars.

SAP procedure model consists of the following stages:

- Organization and Conceptual Design.
- Detailed design and customization of the system.
- Preparation of production.
- Support to production.

Such a methodology requires a detailed design of the existing system, implemented existing functionality and business processes. Considerable time is required to spend on AS IS and TO BE analysis. Decision making is very slow and is based on by consensus, which requires time to achieve.

The negative side of this approach are the following:

- Given that this is the analysis of existing functionality, SAP implementation using SAP procedure model often become a mirror of the existing implementation. In other words, do not get the significant added value of such an ERP system implementation.
- Another negative consequence is that the the company implementation is used as the basis of existing business processes or does not use SAP best practice.
- The long implementation period, as the phases of analysis and conceptual design often prolonged.

In order to keep costs under control is introduced ASAP methodology that significantly accelerates the deployment and ends at the time ordered by the project plan. While the conventional method requires a number of years, ASAP implementation methodology is usually one year.

ASAP methodology or Accelerated-SAP provides proven, comprehensive, rich and operationally feasible method for managing an implementation of the project. ASAP cover the implementation, upgrade-e, strategic studies and more. Some of the key tools that support the methodology include: SAP Solution Composer, SAP Roadmap Composer and SAP Solution Manager. Testing software from SAP during 2011

implementation showed that over 30% of projects considered to have failed because they lacked an effective project planning, while, on the other hand, less than 10% rated as failures due to technological reasons.

The main features of this methodology are:

- Using predefined templates (Solution Map).
- Q & A db - database of questionnaires.
- Diagram Explorer - model of the process.
- The use of auxiliary, prepared draft documents, spreadsheets and presentation of the implementation.
- Intensive user involvement in the implementation process.

Roadmap defines the phase of implementation of SAP ERP systems that are supported by a comprehensive plan.

The speed of implementation is supported by numerous tools, models, examples, reference facilities that provide a complete structural development of all the jobs that followed the accession of resources respectively. Each ASAP process is supported with a comprehensive set of tools, the tools contained within the ASAP products provide continuous education and addressing current issues, problems and requests. Using ASAP methodology, supporting tools and features in mySAP ERP implementation phase, significantly reducing total cost of the project reaching the deadline indicated. The quality of work performed at a high level, while the risk of failure is minimized.

ASAP as methodology was launched in 1996 in order to accelerate the implementation and meet the world market ERP systems in the domain of middle-sized company with more than a year 2.5 billion US dollars. ASAP has brought a change in the domain of SAP ERP systems, focusing on the implementation of the methodology rather than on software. ASAP is a methodology that supports project management, team members, business process consultants, external consultants and technical people.

2.1.1.What ASAP can do?

ASAP is designed to standardize the implementation of SAP. Anyhow, it initiates a straight implementation of SAP ERP system. ASAP methodology characterized by the following:

- Optimizes time, quality and resources.
- Forces the best business practices.
- Delivers process-oriented project folder (ASAP Roadmap), which describes the incremental phase.
- Defines the terms and costs of implementation.
- Provides the processes, tools, training and services.
- Detailed help through the various stages of implementing.
- Answers questions of implementation costs and time to ensure quality, have chosen appropriate tools and optimize resources.
- Check-List, technical questionnaires and manuals.
- Supports continuous improvement in implementation.

2.1.2How ASAP is implemented?

The client that implements the ERP system has no usually internal expertise that is necessary for the implementation of complex software. Thus, the client engages an external consulting company to actively lead and participate in the implementation of the ERP project.

SAP recommends that you usually choose ASAP certified partner in the SAP implementation project. The consulting company becomes a partner of ASAP if at least 70% of its staff of consultants have completed training ASAP and therefore are completely familiar with ASAP methodology.

2.2. ORACLE Implementation Methodology

Oracle Financials uses AIM methodology as management model for implementation of Oracle Financials. AIM incorporates two things. First, it is a methodology showing what tasks are required, what order they should be completed in, and what resources are required. Secondly, it provides deliverable templates for all

the tasks that require them. Hence the hybrid of methodology with a deliverable template tool makes AIM a powerful product.

One biggest disadvantage of AIM methodology is that it is very complicated. Complicated in the sense it has a large number of deliverables which are more than 225 in number. In other words, the project time frame can have a direct impact on this methodology. AIM is supposed to be used by experienced project managers that pick and choose the tasks they require for each project. Most consulting companies have fine-tuned and taken a tailored approach for AIM's methodology, based on their standard implementation practice.

AIM defines business needs at the beginning of the project and maintains their visibility throughout the implementation. It defines internal, external, and time sensitive business events and maps each event to the responding business and system processes. Using this method, the client gains an accurate understanding of the business requirements that need to be focused on during the course of the implementation.

The processes in AIM represent a related set of objectives, resource skill requirements, inputs, and deliverable outputs. A task can belong to only one process. Project team members are usually assigned to a process according to their specialization and background. A brief description of the AIM processes is given below:

1. **Business Requirements Definition:** Business Requirements Definition defines the business needs that must be met by the implementation project. You document business processes by identifying business events and describing the steps that respond to these events.
2. **Business Requirements Mapping:** Business Requirements Mapping compares the business requirements to standard application software functionality and identifies gaps that must be addressed to fully meet business needs. As gaps between requirements and functionality emerge, they are resolved by documenting workarounds, alternative solutions, application extensions, or by changing the underlying business process.
3. **Application and Technical Architecture:** During the Application and Technical Architecture you design an information systems architecture that reflects your business vision. Using the business and information systems requirements, this process facilitates development of a plan for deploying and configuring the hardware required for a successful implementation.
4. **Module Design and Build:** Module Design and Build produces custom software solutions to gaps in functionality identified during Business Requirements Mapping. Custom software solutions include program modules that must be designed, built, and tested before they can be incorporated into the system.
5. **Data Conversion:** Data Conversion defines the tasks and deliverables required to convert legacy data to the Oracle Applications tables. The first step of this process explicitly defines the business objects that are required for conversion and the legacy source systems that store these objects. The converted data may be needed for system testing, training, and acceptance testing as well as for production.
6. **Documentation:** Documentation begins with materials created early in the project. Using detailed documents from the project, the writing staff develops user and technical material that are tailored to the implementation.
7. **Business System Testing:** Business System Testing focuses on linking test requirements back to business requirements and securing project resources needed for testing. It supports utilizing common test information including data profiles to promote testing co-ordination and to minimize duplication of test preparation and execution effort.
8. **Performance Testing:** Performance Testing enables you to define, build, and execute a performance test. Use the results to make decisions on whether the performance is acceptable for the business and to help propose tactical or strategic changes to address the performance quality shortfall. Performance Testing is closely related to Application and Technical Architecture; they are interdependent.
9. **User Training:** Training prepares both users and administrators to assume the tasks of running the new application system. It includes development of materials and methods as well as administration. Instructors and courseware developers orient their material toward roles and jobs, and not toward application modules.

10. **Production Migration:** Production Migration moves the company, system, and people to the new enterprise system. Following production cutover, it monitors and refines the production system and plans for the future. The Production Migration process encompasses transition to production readiness, production cutover, and post-production support.

2.3. PEOPLE SOFT Implementation Methodology

PeopleSoft uses PeopleSoft methodology consisting of the followed phases: project planning, analysis and design, configuration and programming testing transition and post production, that is

1. **Project planning:** Plan the engagement to the task level based upon the current information.
2. **Analysis and Design:** Gather additional data in order to prepare preliminary designs to meet the desired results.
3. **Configuration and Programming:** Configure the application to process in such a manner to meet expectations using best practices.
4. **Testing:** Test the functionality of the configured system and the operational readiness.
5. **Transition:** Coordinate and inform all organizations of the solution.
6. **Post Production:** Make appropriate adjustments and fine tune the solution.

PeopleSoft methodology is practically fits in AIM methodology since the Oracle acquisition of PeopleSoft completed in 2005. Until 2005, PeopleSoft was the dominant ERP in South and North America.

3. HOW THE METHODOLOGY AFFECT THE SUCCESS OF IMPLEMENTATION?

There are several factors to consider when selecting the methodology used for implementation. Some of the factors that are external to impose some strict procedures, and some are internal.

External factors might include the following:

1. **Invitation to tender a public sector procurement information system.** As part of the tender, there is a functional specification of the future information system. Functional specification defines a list of all the functionalities needed to implement the ERP system in the future. During an initial preparation of functional specifications, the potential consulting firm does not know the functionalities (basic and advanced) that are built into the logic of a particular ERP system. Functional specification in most cases is an analysis of existing processes and does not take into consideration specifics of an ERP system. Therefore, there is a large discrepancy, if during the implementation strictly adhere to the functional specification that represents a major obstacle to successful implementation. In this case the recommendation is to use SAP procedure model implementation as the only solution for the successful implementation of the the company.
2. **Legislative requirements.** Each brand name ERP system (SAP or Oracle Financials) has embedded localization part. Localization is the set of processes / reports that the state has prescribed. If it is not financially approved due to the same reasons (a few of the clients, the industry line, etc.), the central management of an ERP system does not decide to make a localization set for a given business process / report that is required of a state of the company. In this case, the consulting company can do extensive editing code (programming), and therefore the deviation from the ASAP methodology that offers the best solutions and shorten implementation time.
3. **The turbulent market environment.** Continuous changes in business processes caused by market factors consequently impose a change in the information system. For example, the company X was the case that the sale of product A, which generated 65% of income stopped, but there is a niche market to sell the product B, which is obtained by re-processing of the product A. In this specific case, it was necessary to implement new business processes for the transfer of goods under an operating system and a new business process in the production module. However, changes imposed by the market are often unpredictable. If the company wants to be competitive, it is imperative that they must follow and incorporate business processes in the information system.

Internal factors might include the following:

1. **Regressive company`s policies** defined by the non-active, sluggish top management of the company. If top management does not want changes in business processes due to various factors (profit is still a big risk if something changes, there is no interest to participate), the risk of failure of implementation is very large.
2. **The project team has no motivation to participate in the project.** Often, employees in company are unhappy with the current working conditions and have no motivation to spend even more time by participating in implementation of ERP solutions. In this case, consulting company recommends two solutions:
 - The company to hire new graduates, fresh people who are exempt from the burden of outdated business processes and are ready to prove the new environment.
 - Management of the company to create the rewarding model that motivates employees participating in the ERP project.

Some of the mentioned factors as turbulent market conditions are unavoidable and the client and consulting company has no effect on them. Practically, the recommendation is that the company and especially management in the company must to pay attention on braking factors and eliminate them or at least minimize them. That would be led to successfully implementation of an ERP system. Anyhow, the progressive management of the company has to bring a huge influence in implementation in order to maximize implementation and consequently improve business processes.

ASAP methodology has also implementation costs. There are no two SAP implementations identical, because there are many variables included such as company size, no. of divisions, project scope, approach, company culture etc. Therefore, it is very difficult to measure implementation costs. However, Aberdeen group made case study in 2010 based on their SAP implementation using ASAP methodology. This study determined that implementation costs at these sites could be broken down as follows

- Consulting fees 36%.
- In-house labour 21%.
- Licence costs 20%.
- Training fees 6%.
- Hardware costs 17%.

The main difference is that consulting fees decreased portion in overall cost of the project comparing with congenial methodology whereas consulting company spends about 50% project money. ASAP is now established as standard SAP methodology. A very large pool of expert comprising more than 140 000 consultants worldwide has been trained in this methodology (ASAP, 2012).

3. CONVENTIONAL VS. PROGRESSIVE IMPLEMENTATION METHODOLOGY OF SAP ERP SOLUTIONS

As all methodologies, there are reasons for and against using a certain methodology. The table below compare to compare certain characteristics of ASAP and SAP Procedure Model's implementation methodology. It is clear that the ASAP methodology complete winner.

Table 2: Characteristics of ASAP and conventional methodology

	Characteristic	ASAP	Conventional method
1	Time	Fast	Slow
2	Reingenering of the business processes	Time consuming due to new processes	Very fast because existing processes are implemented
3	Approach	Fast, without deeper analysis	Based on detailed analysis and consensus
4	Implementation	Focus and narrow	Comprehensive
5	„Upgrade“	Less testing required a minimal code changes are implemented	More testing required due to extensive code modification
6	Cost	Minimal	Very expensive
7	ABAP development	Minimal	Extensive due to excessive

			custom requirements
8	Number of consultants	Relatively few are required	Large team of experts
9	Employee turnover	Low, due to less knowledge during implementation	High, as extensive knowledge gained can be leveraged for a better job
10	Knowledge transfer for employees	Low, since project is rushed and consultant allocate insufficient time	High since feature are configured gradually with employee participation

Also, progressive company management always prefer to accept new business processes based on SAP best practice. In this manner, they can avoid costly arguments for ERP implementation and consequently vastly reduce business blueprint phase. When best practice are adopted configuration is also reduced since the best practice processes are already configured. The following Table 2. is displaying standard cost via SAP procedure model and accelerated costs.

Table 3: Characteristics of ASAP and conventional methodology

Phase	Standard cost	Accelerated cost	Savings
Project Preparation	\$50,000	\$100,000	-\$50,000
Blueprinting	\$125,000	\$50,000	\$75,000
Realization	\$175,000	\$80,000	\$95,000
Final Preparation	\$125,000	\$125,000	\$0
Go live	\$25,000	\$25,000	\$0
Total	\$500,000	\$380,000	\$120,000

AIM methodology of Oracle Financials and Peoplesoft's methodology are considered as conventional methodologies due to fact of their standardization and long existence.

6. CONCLUSION

Top management of the company must to be progressive in choosing of the right methodology. Additionally, they must to participate as control factor in each phase of an implementation. Also, top management must to provide appropriate conditions for ERP implementation. Balanced interaction between consulting company and top management of the company lead to optimizing of ERP implementation.

Anyhow, top management of the company is responsible for creation of the company culture and their influences in each ERP implementation is the biggest. Progressive top management initiates new business processes according to best practice embedded in newest ERP methodologies. New business processes is needed in order to response on market environment and continuous challenges from competitors.

A future work will be on analysis of methodology influence on ERP solutions in such a way that the future ERP solutions will be simplified, more accessible and easier to use, based on cloud computing, and agile methodology.

Abstract: *This paper presents key notes for framework development, based on practical experience. Framework is a very important aspect of software development. Nowadays there are already lots of frameworks which facilitate software development, and every programmer has a goal to build a framework which will speed up software development. During the years of practical experience in the development of business desktop applications based on relational databases, we have noticed some basic rules which are proposed as key notes for the framework development of this kind. After some theoretical discussion we will give key notes of framework development through an insight into the Oz framework development. The Oz framework generates a three-tier application with incorporated CRUD database operations for the defined problem domain.*

Keywords: *software, software development, framework, software patterns, code generator*

1. INTRODUCTION

Constant growing needs for software products force software development companies to shorten software development process. Most common way to achieve this goal is to use already existing solutions or to build a new framework which will be used in later software development. The main idea is to build reusable software components which can be combined easily.

There are lots of definitions of framework. One of the main reasons for that is a fact that term framework is very wide. The most accepted definition for an object oriented framework is: „a framework is a set of classes that embodies an abstract design for solutions to a family of problems” (**Johnson, 1988**). Another good definition is “a framework is a reusable design of all or part of a system that is represented by a set of abstract classes and the way their instances interact” (M. Mattsson, 1995).

First object oriented framework was developed during 80's. Ever since this is the most common approach used to shorten software development lifecycle.

This paper will present key notes for framework development, using an example of **Oz framework** development. **Oz framework** is made to speed up development of business desktop applications based on **relational model**. In general Oz framework should be used to generate three tier application with incorporated CRUD (create, read, update, delete) operations on underlying relational database for defined domain model. Both, framework and generated applications are implemented using C# programming language.

Paper is organized as follows. Firstly we will give overview of definitions for framework development process. After that we will show development of Oz framework in brief. We will present domain analysis, and framework design phase of framework development. We will give a very short definition of **Framework use**. At the end of the paper we will give final conclusion.

2. FRAMEWORK DEVELOPMENT PROCESS

Lots of authors tried to give an overview of framework development process. For instance Markiewicz and Lucena propose classic framework development which is consisted of domain analysis, design, and framework use (**Markiewicz and Lucena, 2001**). Johnson considers this approach ideal in theory but in practice very inefficient and not payable. Therefore he suggests iterative way of framework development according to which one group of programmers develops framework while other group tries to use it to develop application for specific domain (**Johnson**). We found that Bosch gave proposition of framework development process which is most suitable for development of **Oz framework**. Bosch dismember two

different activities in framework development: development of **framework core** and development of **internal add-ins**. Core exists, unchanged, in every framework instance (every single use of framework) (Bosch et al , 1999). Core is consisted of **frozen spots**, in other words it is consisted of interfaces and classes which are already implemented in framework and as such are used in every framework instance. On the other hand, parts of code that are generated for every concrete application (specific domain model) are **internal add-ins**. In case of Oz framework these classes are generated from relational model. Parts of code which makes code flexible are called **hot spots**. These hot spots in most cases are some abstract classes or methods that must be overridden (Bosch et al , 1999). In order to generate executive code, e.g. concrete desktop application, one must implement application specific code for every **hot spot**. Final application, generated using framework, is consisted of **framework core**, **internal add-ins** and application specific code(implemented hot spots).

All authors have same opinion that use of design patterns is inevitable in framework development. Patterns that are identified as significant in framework development are: (Johnson),(Amatriain)

- Pattern of three examples
- white box
- component library
- Hot spots pattern
- Pluggable objects
- grained objects
- black box
- Visual builder
- Programming language tool

From **Oz framework** definition it is obvious that framework domain is very wide. Therefore, one of main tasks in development of Oz framework is to determine architecture of applications which the framework should generate. The architecture must be reusable and very flexible. Designing object-oriented software is hard, and designing *reusable* object-oriented software is even harder. Design should be specific to the problem at hand but also general enough to address future problems and requirements. You also want to avoid redesign, or at least minimize it “ (Gama, R. Johnson et al, 1995).

3. OZ FRAMEWORK DEVELOPMENT PROCESS

As said before, **Oz framework** should generate **three tier application** which will implement CRUD operations for specific domain. As we said we think that the Bosch's proposition of framework development is most suitable for developing this kind of a framework.

Modified Bosch's method will be used for development of Oz framework. It will have these phases (Bosch et al , 1999):

- **Framework development** which has following sub-phases:
 - **Domain analysis** – in domain analysis, as described in **pattern of three examples**, three applications will be analyzed to determine general architecture of applications that will be generated by Oz framework. Result, at the end of this phase of framework development, will be classes which will consist **framework core** and classes that will consist **internal add-ins**.
 - **Framework design** – Besides framework architecture design, one of most important things during this phase will be to determine all necessary transformations for generating components that are part of **internal add-ins**.
 - **Implementation** – framework will be implemented using C# programming language.
 - **Framework testing** – this phase of software won't be considered in this paper.
 - **Framework documenting** - this is the phase that Bosch didn't isolate, but lot of other researchers point out that this is also very important phase .
- **Framework use**– it will be conducted as case study in chapter 2.5
- **Evolution and maintenance of framework** – further evolution exceeds limits of this paper

Primary objective is to determine architecture of desktop application which will be generated using the framework. It is necessary to reveal which components do not depend on relational model, and as such will

be part of **framework core**. Besides that, it will be necessary to determine components that depend on relational model and to determine transformations which will be done in order to generate them (classes). These generated components will form an **internal add-ins of framework**. In this paper we will present only **domain analysis** and **framework design** phase.

3.1 Domain analysis

In most cases domain is presented by domain model, in particular via relation model, which is most common way for storing data for business applications. In case of **Oz framework** it will be input for code generation. First question relevant in this phase of framework development is **what is the best way to start domain analysis**? Solution that is presented in pattern of three examples, recommends that domain analysis should be based on three specific desktop applications. Because we want to develop framework which will generate business desktop applications based on relation database meta-information, following the pattern of three examples, three specific applications are analyzed to insight similarities and differences in order to do some abstractions.

Software systems that will be analyzed are:

- Application “**Shoe store**” for storehouse management, developed for Mastaco company
- Application “**Admission test**” for organizing admission test, developed as seminar paper for subject “Information system Design”
- Application “**Restaurant**”, for ordering

Objective of this phase is, as said earlier, to define general architecture of business applications which the framework should generate. As main tool for determining which components will be part of the architecture, we have used patterns in their general sense.

3.1.1 Architecture components analysis

In this phase all parts of three tier architecture are analyzed (figure 1). These components were built using generalization of classes from the three specific applications. Perceived concrete classes which were exactly same in every application, were added to **component library**.

Figure 1. Three tier architecture – components

In case of Oz framework, we have firstly analzed **graphical user interface** (GUI), then **GUI controller**, **business logic** and **database broker** classes for three mentioned applications.

Goal of component analysis is to get interfaces, abstract or general concrete classes for all components in question.

Following the goal we have identified classes that will be part of **framework core** and ones that will be **internal add-ins**.

```

public partial class FGeneral : Form, InterfaceForm
{
    Fields

    Constructors

    #region Events
    public virtual void FGeneral_Load(object sender, EventArgs e) {...}
    public virtual void btnNew_Click(object sender, EventArgs e) {...}
    public virtual void btnSave_Click(object sender, EventArgs e) {...}
    public virtual void btnCancel_Click(object sender, EventArgs e) {...}
    #endregion

    #region Data grid view metode
    public virtual void gridOdo_DoubleClick(object sender, EventArgs e) {...}
    public virtual void gridOdo_KeyUp(object sender, KeyEventArgs e) {...}
    public virtual bool DeleteItem() {...}
    public virtual void ChooseItem(object sender, EventArgs e) {...}
    #endregion

    #region Fields Manipulation
    public virtual void EnableFields() {...}
    public virtual void DisableFields() {...}
    public virtual void text_EnterTab(object sender, System.Windows.Forms.KeyEventArgs e) {...}
    public virtual void SetFokusOnFirstField() {...}
    #endregion
}

```

Figure 2. Code for FGeneral class (method signature)

For instance After conducted analyses of GUI components these are conclusions. A graphic form will be created for every relation (table) from database. In case of dependant objects that form will be available only from parent form (form for “parent” table).

At the end of conducted analysis of GUI particular graphical components and methods that are often called are isolated. On this bases interface, which all forms must implement, and one general class **FGeneral** are created (figure2.).

In order to create concrete form which override abstract methods of **FGeneral**, relational meta data are required. On this findings we can conclude that concrete generated forms will be part of **internal add-ins** while general class **FGeneral** and interface are part of **framework core**. In design phase all necessary transformations should be determined.

Figure 3. Look of FGeneral form

At the end of analysis one should have general architecture of framework and its instances. We can divide this architecture in two parts

- **framework core** – consisted of classes that will be built unchanged in every generated application
- **internal add-ins** – classes that depend on metadata of relations and as such will be generated by Oz framework

In case of the Oz framework, framework core is consisted of:

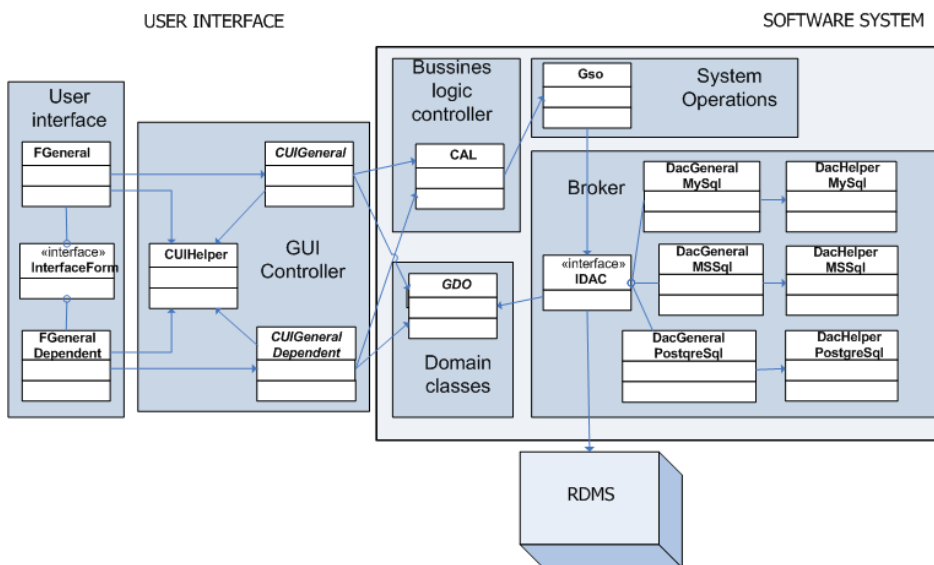

Figure 4. Framework core architecture

According to this, an instance of Oz framework (generated application) will have this architecture. Classes that are painted in orange are part of **framework core**, and those that are painted with green color are part of **internal add-ins**.

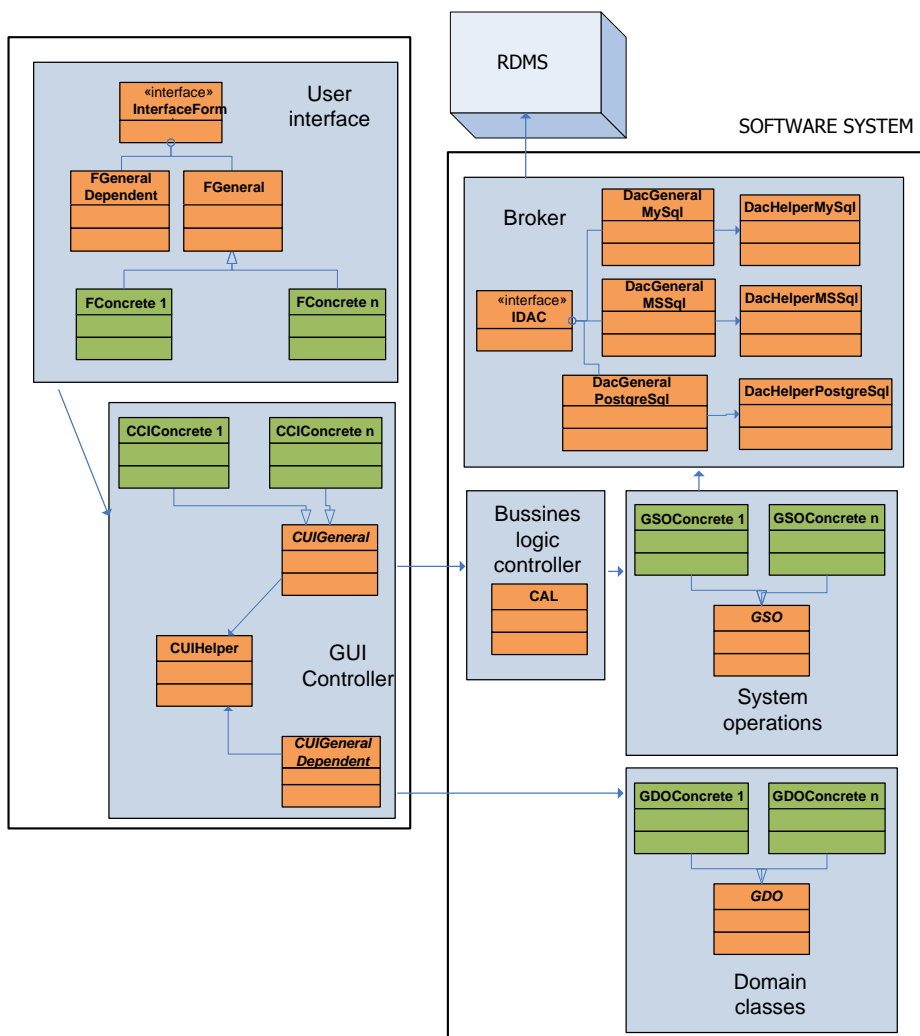

Figure 5. Relation between framework core and internal add-ins classes.

3.1.2 Framework design

The objective with this activity is to end up with a flexible framework. The activity is effort consuming since it is difficult to find the right abstractions and identify the stable and variable parts of the framework, which often results in a number of design iterations. To improve the extensibility and flexibility of the framework to meet the future instantiation needs, design patterns may be used. The resulting framework can be a white-box, black-box or visual builder framework depending on the domain, effort available and intended users of the framework.

One should base framework design on grounds of previous phase. The key contributions of previous phase is separation of classes that are part of **framework core** from those that make framework **internal add-ins**. Abstract classes and interfaces that makes framework core are usually organized as **component library**.

Next step in this stage of framework development is to determine whether there is a way to define a **code generator** for classes which will be part of **internal add-ins** in every framework instance, although this can be done manually in every framework instantiation. Thought this is in a way already done in previous stage of framework development here one should determine and design all necessary transformations which will be used during code generation. There are lots of tools, like FreeMarker, Apache Jakarta Velocity etc., which can be helpful for code generator development. Code generator can be observed as a kind of application, therefore it can be created using any of existing software development methods. One of key differences from classic software development is inputs e.g. domain. As mentioned before **database meta-data** will be inputs for this application. In a raw framework there will be just a few additional data that user of a framework have to provide. One can call this as framework fine tuning.

One of conclusion that can be made in this point is that there is no strict line between domain analysis and framework design phase. This is reason why some authors do not point out domain analysis as a phase of framework development.

One can use various techniques and method for framework design. For instance some of agile methods can be suitable for framework design.

3.2 Framework use

Framework development process is iterative and incremental. In every framework use user will see all good and bad sides of framework and this will be starting point for next increment. In most cases user will have to provide additional information during or after framework instantiation.

During the use e.g. test of generated application user should determine potential **hot spots** which can be made in next increment of framework development.

4. CONCLUSION

Objective of this paper was to show guidelines for development of framework which is used for generation of three tier desktop applications based on relational metadata. After brief introduction and presentation of various framework definitions, **patterns** that are widely used in framework development were identified. Most widely used patterns are **pattern of three examples, white box, component library, hot spots, pluggable objects**.

Proposed framework development process is based on Bosch's method for framework development, which is consisted of **Domain analysis, Framework design, Implementation, Framework testing** phases.

In **domain analysis** authors suggest that one should use **pattern of three examples**, especially for type of framework in question. Objective of this phase is to do abstractions in order to get classes that will be unchanged in every generated application and those which will differ depending on specific domain model. This should be done using **software patterns**. On the example Oz framework authors has given guidelines how the component of three tier application should be analyzed and all necessary abstractions are done. As a result of analysis components that are part of **framework core (application frame)** (they are same in every generated application) and those that depends on relational metadata and as such are part of **internal add-ins** should be identified.

Framework design, should be conducted on grounds of previous phase and there is not a clear line that divides this two phases of framework development. In this phase one should determine how to organise the framework and to design code generator transformations, if needed.

As we said Framework development is iterative. Therefore **framework use** is just an input for a new increment.

Abstract: *This paper presents our approach to the identity and access management system with respect to authentication method. After defining basic concepts of such system, like identity, digital identity, service provider, identity provider, paradigms of identity providers, multilateral security, the paper offers an analysis of identity and access management systems usage. Furthermore, an overview of different technologies and standards is given. We have also done a survey on brand name identity management solutions. Downsides of proprietary brand-name solutions are described, and an alternative, open-source based architectural approach is presented. Small to medium size organizations can especially benefit from this alternative approach.*

Keywords: *identity management, system architecture, open-source, privacy, authentication*

1. INTRODUCTION

The rise of network-based, automated services has brought some fundamental changes in every organization's activities. One of the most important changes that have occurred was the change in the way the business companies offered their products to customers. The business processes have become increasingly automated. As a result, the way in which customers create trust relationships with service providers has changed, because business transactions are conducted online. Traditional ways of establishing trust relationships between negotiating parties are no more applicable, when customers purchase or use services delivered to them electronically on their computer. Windley (2005) points out that the usual trust marks that customers have relied on in the past are either missing or easily forged. Moreover, in addition to changes in relationship between business companies and their customers, the whole business processes have become automated. The relationships with partners, suppliers, and employees have moved to electronic world. This leads to increased risk of attacks such as identity theft and identity disclosure. Therefore, digital identity management needs to be properly implemented in order to elevate overall business process security.

Digital identity as concept has application in many areas, not only in business. Al Khouri (2012) states that "the last few years have witnessed the evolution of the digital identities or so called e-Identities by various Governments across the world." According to United Nations E-Government Survey (2012), South Korea holds the first place in implementing digital IDs and national ID based commercial transactions. Second place is shared by Nederland, United Kingdom and Denmark, while the United States, Canada, France, Norway, Singapore and Sweden follow closely behind. Moreover, smart cards and biometrics are frequently used for border control and national IDs. For example, visitors to US have to pass through US-VISIT programme, have their fingerprints scanned, and photos taken. South Korea national IDs use smart card technology, and it is possible to conduct digital ID-based transactions, with identity validated and verified by the government. Identity management system with iris recognition as authentication method is used in UAE for border control.

Identity management is an asset of essential value for all of real-world activities and systems described above. There are many different requirements that described systems have to fulfil, such as single sign on capability, or strict confidentiality for personal data. Only one thing here is sure, it is very hard to find a business area or government activity, where identity management is not at least of some importance.

2. IDENTITY

One of the main concepts and terms in identity and access management systems is identity. Question is what is actually identity in the aspect of digital technology. Identification actually establishes unique digital identities. There is a lot of definitions, but we can say that identity is something what describes individual

person with set of attributes. Identity is the representation of user entity which should be provided to applications and services. There is the distinct character or personality of an individual. Identity can be used by applications and services to differ users from each other and provide different privileges to different users (V.Bertocci et al. ,2008).

The identity of a person include a lot of personal data with respect to individuals. The person includes all subsets of an identity. Some of these “partial identities” solely identify the person, who may be represented by different partial identities. An identity management system provides the tools for managing these partial identities in the digital world.

Authentication associates an individual with a unique identity. Providing evidence for the association is essential to this. Authorisation is enforcing what services the subject is entitled to access. Identity Provider is responsible for the processes associated with giving subject some role, establishing and maintaining the electronic identity (Senk, C. &Dotzler, F. ,2011).

3. IDENTITY MANAGEMENT

The only way to control identity is by identity management. That is the system and framework used in computer or communication systems and it is an integrated system of business processes, policies and technologies. That kind of system enables organizations to facilitate and control user access to online applications and resources while protecting confidential personal and business information from some types of attacks. These systems can be very vulnerable, so it is important to protect them with all level of security. Identity authentication, authorization management, access control, and operation audit are based on digital identity and there is set of policies, methods and rules for that (Elliot,J., Ford,M. &Birch,D. ,2011).

Basic concepts of identity management are user, service provider and identity provider. User must have a legal identity if he wants to use services. Service provider has to make available services to the user. Identity provider offers different trust level to different type of user. He has two functions. One of them is to implement services for users like user registration, verification reality of user identity and user identity storage. Service provider and user send requests for authentication to identity provider who must process those requests. User is the client of service provider and also identity provider.

According to all of this explanation identity provider types are:

- Credential Identity Service,
- Identifier Identity Service,
- Attribute Identity Service and
- Pattern Identity Service.

Paradigms of IdM (identity management)are:

- Network Centric,
- Service Centric and
- User Centric.

Network centric paradigm happens at the first stage of growth of IdM technology. Here is single entity for all community and user, and it is not user-related or service-related paradigm. Creation of identity and some other operations doesn't have connections with access. (McCusker,J.P., Lebo,T., Chang,C., Silva,P.P. & McGuinness,D. 2012). At service centric paradigm, there are different access control level of trust and security. It is made of services from different service provider, which are located across multiple domains. User is the center of everything at user centric paradigm. Actually, user is find his place between identity provider and service provider, as he can make decision whether or not to share identities with some trusted thirds parties. OpenID, Windows CardSpace, and Lightweight Identity (LID), Simple Extensible Identity Protocol (SXIP), Higgins are examples for this kind of paradigm.

Three models of IdM (comparision shown on Table 1.) which are most important and we must pay attention on them are:

- Isolated Model,
- Centralized Model and
- Federated Model.

At isolated model, there is single server at one level, which is at the same time service provider and identity provider. That single server play role of identity storage and user operations by himself. Service provider can do identity allocation, deletion, modification, authentication and authorization.

Functions of service provider and identity provider are divide at centralized model. User identity storage and user authentication here are implemented in the same servers-identity provider. PKI, Kerberos, and CAS are examples for this model.

Federated model make a global inimitable domain virtually. He actually connects different domains together. When a user is authenticated to one service provider, he is also identified and authenticated with all the other service providers (García,S.S., Gómez,O.A. & Pérez E.B. 2012). Federated Identity Management lets computer systems distribute identity information and tasks across security domains. Here is realized single sign on (SSO). It means that they can authenticate once and then get access to protected resources in many places, without need to re-authenticate.

Table 4. Comparison of these three models (Yuan Cao, 2010)

Model	SP Type	IdP Type	Service Composition	Cross Domain Access	Identity Storage	User Control over Identity	Privacy Protection
Isolated	Single SP and IdP, SP is IdP	Single IdP and SP, IdP is SP	Sole service	No support	On SP	No control	Few and very weak protection
Centralized	Multi SPs	Single IdP	Multi services but in the same domain	Limited support	On IdP	Few control	Much but weak protection
Federated	Multi SPs	Multi IdPs	Multi services form multi domains	Nearly fully support	On both SPs and IdPs	Much control	Much and strong protection

Also, an important concept connected to identity management is multilateral security. That means that is necessary to supply security mechanisms to all parties who are involved in communication, first of all, we mean on the basic concept of identity management. Pfitzman introduces a classification of technologies for multilateral security according to the number of cooperating parties at runtime. He make difference between unilateral (encryption of local storage media), bilateral (cryptography to achieve confidentiality-one of the main concept of security trial CIA, of communication content), trilateral (PKI-Public key infrastructure) and multilateral technologies (mechanisms which provide anonymity with regard to communication), (Pfitzman, A., 2001).

4. ANALYSIS OF IDENTITY AND ACCESS MANAGEMENT (IAM) SYSTEMS USAGE

Improving agreement, reducing risk and increasing business value are the main holders for identity and access management projects. The greatest use of this drivers are in the sector of Financial Services and the Information, Communication & Entertainment sector. The Infrastructure, Government and Healthcare sector is least concerned with improving compliance and reducing risk. This is the result of survey conducted by KPMG IT advisory with Everett Supported.

The best way to authenticate someone is using two factors authentications. Actually, authentication mechanisms can be classified in three way: someone knows something, someone has something and someone is something. According to that, survey of different authentication methods usage frequency is shown on Figure 1. Username and password is an authentication mechanism that was reported by all researches who were involved in this survey. Tokens are also popular with more than 50% of the researchers. Smartcards or other certificate-based mechanisms scored 35%. RFID and biometrics were both reported at around 12%, Hermans,J. & Valkenburg,P. (2009).

Figure 6. Authentication methods (Hermans,J. & Valkenburg,P., 2009)

Very important aspect in modeling system of identity management is their architecture and technology (Barisch,M. ,2011). On Figure 2, it is possible to see popularity of different architectural approaches. According to the respondents which were involved in this survey, central authorizations management is the most important principle for defining their organization's IAM need (39%). When organizations are selecting their required IAM solution, a large amount acquire the solution of their preferred supplier and only 18% perform a vendor selection in order to select a 'best of breed' solution.

Figure 7. Architectural principles for IAM (Hermans,J. & Valkenburg,P., 2009)

5. BRAND NAME IDENTITY MANAGEMENT SOLUTIONS

Many brand name solutions are available in the market. Potential customers can choose between various vendors and solutions, such as Novell Identity Manager, IBM Tivoli Identity Manager, Microsoft Forefront Identify Manager, etc. At first glance, each of these solutions seems to satisfy every need an organization might have. All of them claim to provide automation of all organization's identity management tasks, such as enterprise-wide identity integration, user provisioning and deprovisioning, auditing and reporting capabilities, seamless integration, and many more.

However, brand name solutions seem to have some downsides. As first, they have many different features included. Although this could be seen as their advantage, in a lot of cases it is not. The reason is simple, the more complex the solution is, the higher is its price. Sometimes the functionality gap to the simplest system that meets requirements is quite bridgeable, and it is better for potential customers to role out their own implementation, using open source components and in-house development. Moreover, there is the issue of interoperability. Sometimes, there are proprietary hooks implemented into software, instead of using open protocols. Also, complex proprietary solutions can be hard to understand and maintain.

Still, many organizations prefer using off-the-shelf products. When organisations apply this typically “corporate” approach to sourcing an IAM solution, they usually overlook six 'C's, problems that are common to all brand name identity management solutions alternatives (Prasad&Rajbhandari 2011):

- **Conceptual Subtlety** - A suggestion that effective system integration can be achieved through appropriate data and protocol design is often unconvincing, and people are generally more impressed by solutions that take care of everything.
- **Centralised Model of Design** - A prestigious (and expensive) IAM product is expected to comprehensively manage user data by itself, because its purchase cannot otherwise be justified. This leads to numerous problems.
- **Commoditised Functionality** – Many open source solutions deliver same functionalities as the proprietary solution, and are equally robust and reliable.
- **Complexity of Features** - Some functions and data structures seem common to most organisations, but the generic implementations provided by major IAM products tend to be more complex than an average organizations requirements.
- **Custom Requirements** - Not all specialised requirements can be met by simple configuration settings on a generic product. Because of this, some customization is required, and this leads to additional expenses and difficulties.
- **Closed Interfaces** - The components of many brand-name products are often described as “tightly integrated”. Practically it means that they are designed to be used with components from the same vendor.

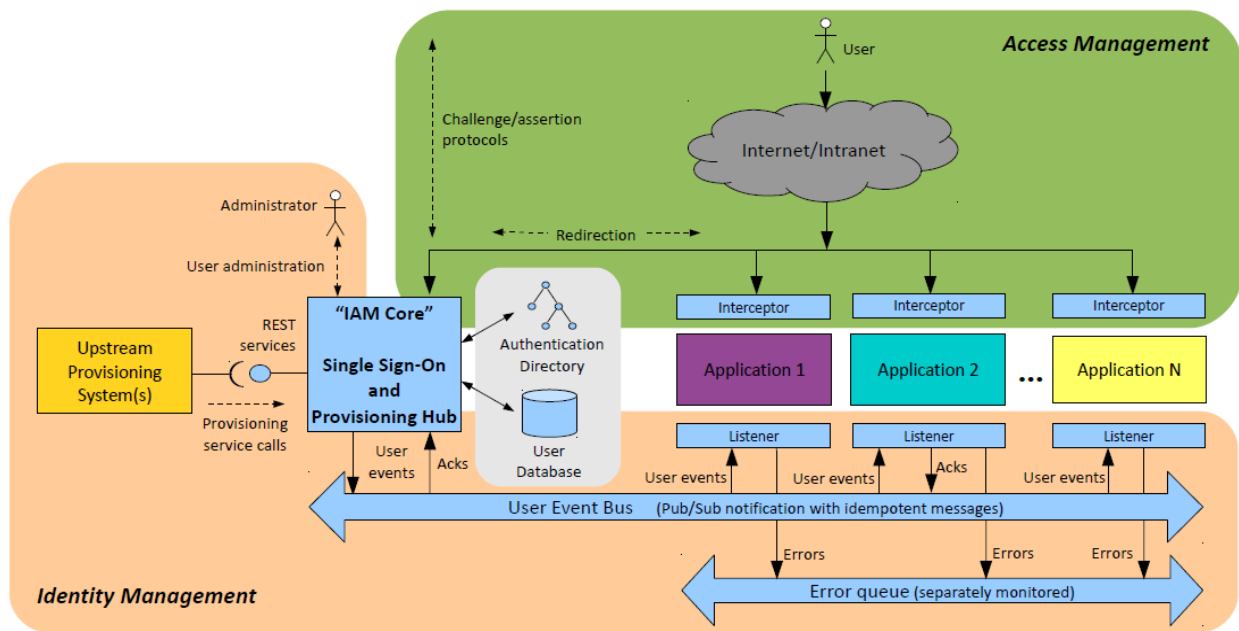

In order to implement a truly service oriented architecture, “loose coupling”, not “tight integration” should be the desired goal. It is possible to overcome these six 'C's by implementing a system based on “Loosely-coupled Identity Management Architecture” (Prasad&Rajbhandari 2011). This approach is different from brand-name vendor products because it imposes loose coupling instead of tight integration. Functions are decoupled, and only bare minimum of functional dependencies are retained. In other words, it is easy bind components together, and there are no limitations imposed. Also, appropriate data design also plays important part in such “loose coupling” scheme. Sometimes, if data is properly managed, there is no need for physical component to act as decoupling intermediary. Therefore, the system architecture is simpler, and it is easier to avoid unnecessary centralization. As a result, it is possible to develop a highly customized identity management system based on open-source components using this architectural approach.

6. IDENTITY MANAGEMENT SYSTEM ARCHITECTURE

Figure 3. illustrates logical components of “Loosely-Coupled Identity Management Architecture”. In order to preserve clarity, only a brief overview of various architecture components and principles is given.

The interceptor is a component that is placed in front of an application. It is used for redirecting access to the Single Sign On server. It may also perform the access control (authorisation) function based on the user identity and any other user attributes sent back by the SSO server. Such interceptor implementation allows application to be completely unaware of IAM authentication and authorization functions.. Prasad&Rajbhandari (2011) point out that “A specialised interceptor component not only relieves the application from having to implement these aspects of security, it can be treated as part of the enterprise security framework and is also a more easily auditable control point”. There are many possible choices for the interceptor implementation, for example a Java servlet, or an authenticating reverse proxy that is common to a group of applications.

This system architecture allows system to implement either centralized or federated identity management. There are several possible choices for Single Sign-On Access Management solution. Shibboleth is a good choice for a federated identity solution. JASIG's Central Authentication Service can be used for centralized systems. It is a ticket-based Single Sign-On system based on the Kerberos architecture but specially tuned for web applications. Both of these are Open Source, which means there are no licence fees, but more importantly, that there are no hidden hooks or dependencies.

All IAM components are in light blue:

Figure 8. Logical Components of an Identity Management System (Prasad&Rajbhandari, 2011)

IAM communication with upstream systems is based on standard synchronous request/response paradigm. However, the interaction between IAM and downstream systems needs to be asynchronous and loosely-coupled for maximum flexibility. These aspects are described below.

An observer pattern is used to propagate user events to systems “downstream” of IAM. Multiple systems that maintain local copies of user data need to be notified when there are changes to user data (adds, updates and deletes). To receive such notifications, they have to subscribe to IAM. Such a publish/subscribe model is easily implemented through a “bus” mechanism. IAM publishes user events on the “User Event Bus” and systems subscribing to these events receive such messages and make updates to their local data accordingly. After notification, downstream systems process the event. If the processing is successful, there should be no response, just like in Unix environment. Where notification is unavoidable, a simple acknowledgement event on the same bus is used. Error handling is logically separated from the user administration function. All errors are logged to a separately monitored “Error queue”.

User administration functions are exposed as simple REST services. There are two types of “upstream” applications that will invoke the REST services exposed by IAM, in addition to any business applications that may need direct access to user data. The first is a Human Resources type system, which is the authoritative source for adding new employees, and removing those who don’t work for company anymore. The second is a resource management system that is used to grant and revoke user access to various business applications. IAM’s own Access Management capability can be used to restrict control to these HTTP-based services

IAM performs only coarse-grained role-based access control. Fine-grained access control is applied by the business applications, while IAM supplies them only with necessary user attributes. Such delegation of duties enables IAM not to take care about requirements of every application in the system. In their work, Prasad&Rajbhandari (2011) have concluded that “Fine-grained access control by IAM is a largely infeasible task, and allowing it to be part of IAM is not a very wise solution”.

Both authentication directory (LDAP) and a relational database should be used. Authentication credentials are stored in LDAP directory using simplest possible tree structure. All other user attributes are stored in the relational database. The database design will be unique and specific for every organisation. User UUID (Universally Unique ID) is used for mapping between user record in the directory and corresponding record in the relational database. Universally Unique IDs (UUIDs) are extremely large numbers that are randomly generated, and virtually guaranteed never to collide, because their range of values is extremely large. A globally unique User UUID is used to associate multiple system accounts (application-specific user

IDs) across different systems, including the IAM directory and database. A single Person UUID is used to associate multiple user UUIDs.

7. CONCLUSION

In this paper, we have presented an overview of different basic concepts related to identity management. The definitions of identity and identity management were given and different existing models and paradigms of identity management have been explained. We have provided data from surveys that show identity management systems usage trends. In general, from different surveys, articles and commercial products it is possible to conclude that identity management is a very important issue for any type of organization.

Also, we have shown that an alternative to proprietary brand-name products exists. Using open source components, it is possible to develop a fully functional identity and access management system. It is very important to emphasize here that using “Loosely-Coupled Identity Management Architecture” does not implicate any security compromises. Although brand name companies solutions comply with various security principles and standards that need to be followed in such obviously risk-sensitive area, after deployment they also require auditing, in order to be sure that there are no security shortcomings. Therefore, there is no exemption from this procedure for organizations that implement an off-the-shelf product, as opposed to an in-house build.

Identity and access management solution based on open source can save organization a substantial amount of funds. This is especially significant for small to medium size organizations, because in most cases their needs are relatively simple but specific. It is difficult for big vendors to precisely predict needs of such companies, so their systems usually require additional customization. This paper can help different organizations to evaluate their needs for identity and access management, and consider opposing alternatives.

² University of Belgrade, Faculty of Organizational Sciences, marinaj@fon.bg.ac.rs

Abstract: *This paper briefly presents resources that need to be allocated in the establishment of the document management system in business organization. The resources needed are planned based on real business environment parameters in which a document management system is to be established. The paper describes the way of planning software and hardware resources for establishing an enterprise document management system with the calculation of necessary communication resources for content replication between two repositories. Calculations are performed for two cases in which objects replication times are different. Based on well-defined parameters of a real business environment and projections on document management system usage it is possible to predict optimal software, hardware and communication resources required to establish the projected system.*

Keywords: *document management system, distributed repositories, replication, content replication, resources, resources calculating*

1. INTRODUCTION

Document management system provides a systematic solution for entering, organizing, managing and storing content within the business environment. Using such a system, unstructured information can be managed in accordance with predefined business rules, policies and procedures; connections between content areas are established giving possibility to use the same information in different contexts. (Milenkovic, 2006)

Content generated from document management system is stored in repositories¹. Repositories are connected in distributed systems within a computer network, while maintaining consistency of data between them is achieved by data replication.

During the design of business document management system necessary resources must be kept in mind. Resources are defined and calculated based on requirements that describe projected system. Basic requirements for document management system design are: the number of system users, the number of repositories, repository organization model, spatial repository distribution and number of repository objects that system will operate with.

Based on identified demands, use of appropriate software, hardware and communication resources is planned in order to establish a document management system, including data repositories and data replication.

2. MODELS OF DISTRIBUTED DOCUMENT MANAGEMENT SYSTEM REPOSITORIES WITH CONTENT REPLICATION

Usual content repositories organization model in large business systems is a system of two or more distributed repositories with replication (Figure 1). This model is based on objects replication between starting and destination repository. Document management system repository object includes documents stored in their original format and documents metadata (those data describe the documents such as keywords, owner, version, links, creation date, etc.) (Hodge, 2001). Additional document management system configuration defines which objects will be replicated and how often, furthermore, all replicated objects are clearly marked in order to identify them as replicas. Distribution is done by pre-defined business rules or in response to user requests.

¹Repository is a central place in which an aggregation of data is kept and maintained in an organized way, usually in computer storage. (ORACLE, 1998)

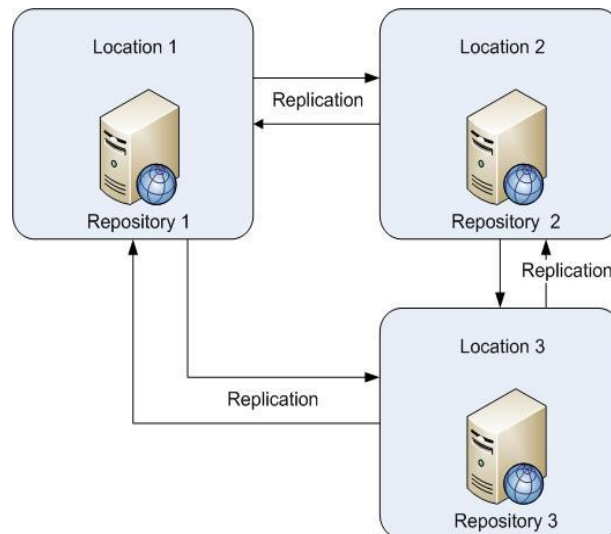

Figure 9: Conceptual model of distributed repositories with content replication (Milenkovic, Jovanovic Milenkovic & Pejanovic, 2012)

Another frequently used content repositories organization model is a system of distributed repositories with the content replication organized into a federation (Figure 2). This model is also based on objects replication, but it provides a higher level of automation in the content replication management.

This type of system declares one repository as the federation leader. Other repositories are considered members of the federation. After such a model configuration, every change on document management system users, access rights, or any other administrative changes may automatically reflect all member states of the federation, according to the system parameter settings.

Figure 2: Conceptual model of distributed repositories with content replication – federation organization (Milenkovic, Jovanovic Milenkovic & Pejanovic, 2012)

3. REQUIRED RESOURCES FOR DOCUMENT MANAGEMENT SYSTEM

Resources needed for document management system establishment can be categorized into three groups:

- software resources,
- hardware resources and
- communication resources.

Software resources

Common document management system software resources are software licenses for:

- Content management server. Content management server is a software solution that provides a central repository storage, management and retrieval of all types of content (EMC, 2012) (text, graphics, hyperlinks, multimedia files).
- Database server. Database server provides a standard infrastructure for content management and all transactional operations in relational databases.
- Applications server. Applications server provides mechanisms for content organizing, controlling and delivering to and from repository.
- Client. Client licenses are kind of software that is installed on the client. Client may be thick or thin, depending on functional, system and infrastructure requirements.
- Input management services allow the incoming data translation into business-ready content and optimize the information flow across business organization, thus enabling faster access to the mission-critical information needed. (EMC, 2012)
- Other additional services. Licenses for other services providing advanced functionality of document management system solution (electronic signatures, security mechanisms, etc.).

Table 1 presents listing of measure units with specifications which determine the way of licensing for document management system (DMS).

Table 5: DMS licensing measure units specification (EMC, 2012)

Measure units	Sign	Explanation
Central Processing Unit (CPU)	Per CPU	Maximum number of CPUs that software can be installed on.
Concurrent connections/seats	CNC	Maximum number of users able to simultaneously use software.
Pages Per Year	PPY	Maximum number of pages that can be processed by a server within a year. This kind of licensing is used for sizing Input Management servers.
Seat/User	ST/USR	Maximum number of users who are authorized to use the software, regardless of whether those users are actively using the software at any point of time. This kind of licensing is most often used for client applications.
Server	SVR	Maximum number of physical servers on which user can install and use DMS.

Hardware resources

Hardware resources for document management system functioning are expressed by following elements: number of CPUs, RAM and HDD size for each server and storage² resources. Table 2 presents usual hardware resources for document management system server.

²Place where data are held in an electromagnetic form for access by a computer processor. (ORACLE, 2010)

Table 6: Display DMS servers hardware resources (EMC, 2012)

	Server	CPU	RAM	HDD
				System partition
1.	Content management server	1 x Core2Duo Intel Xeon	8GB	50GB
2.	Database server	1 x Core2Duo Intel Xeon	6GB	50GB
3.	Application server	1 x Core2Duo Intel Xeon	4GB	50GB
4.	Imaging server and Scan server	2 x Core2Duo Intel Xeon	4GB	100GB
5.	Index server	1 x Core2Duo Intel Xeon	4GB	50GB
6.	Content cash server	-	2GB	10GB

Reported values in Table 2 may vary depending on size of designed document management system. For items 1, 2 and 5 it is necessary to provide space on storage system to store content, database, and index data, respectively.

To determine required document management system storage space (S_s) following expressions are used (EMC, 2012):

For database server (DBs), for each document and each version saved 10 KB of additional memory space is required:

$$S_s(DBs) = 10KB \times verNum \times docNum \quad (1)$$

For content management server (CMs), for each document we need to plan resources for document versioning (V), rendition (R), Full text indexing (Ft) and additional 2.5 KB of memory space for each version saved in repository (Ad):

$$V = docSize \times verNum \quad (2.1)$$

$$R = rendSize \times verNum \quad (2.2)$$

$$Ft = 0.3 \times docSize \times verNum \quad (2.3)$$

$$Ad = 2.5KB \times verNum \quad (2.4)$$

$$S_s(CMs) = (V + R + Ft + Ad) \times docNum \quad (2)$$

For Index server (Is), for each document version we need to plan additional storage space sized as 20% of document size:

$$S_s(Is) = docSize \times verNum \times 0.2 \quad (3)$$

Variables used in expressions above are as follows:

- verNum – number of document versions,
- docNum – total number of documents,
- docSize – document size,
- rendSize – document rendition size

Important point to consider during storage system dimensioning is the content storage time because after that period of time storage space used will be cleared.

Communications resources

Document management system functioning is based on standard protocols, both in intranet and internet communication. To perform data transfer operations between document management system entities, minimum required bandwidth of communication channel is 56 Kbps (EMC, 2012). It is understood that the higher communication channel bandwidth provides better system performance.

For optimum document management system operation (execution of operations over content repository: management, storage, distribution, caching, replication) recommended communication links bandwidth are shown in Table 3.

Table 7: Possible communication links and recommended bandwidth overview (EMC, 2012)

Link	Bandwidth
Content management server<->Database server	1 Gbps
Content management server<-> Application server	
Content management server<-> Indexing server	
Imaging Server <->Content management server	>=100 Mbps
Client workstation <-> Application server	>=128 Kbps ³
Client workstation <-> Content cash server	
Administrator workstation <->Content management server	>=128 Kbps
Client workstation <-> Imaging server	>=10 Mbps ⁴

4. EXAMPLE OF COMMUNICATION RESOURCES CALCULATION FOR SYNCHRONIZED CONTENT REPLICATION BETWEEN REPOSITORIES

In document management system with distributed repositories and content replication, the most important replication parameters are:

- Amount of objects that are replicated (for example, 5 objects with 2 MB size replicate faster than 10 objects with 1 MB size; the second option is much more frequent in practice).
- Number of replicated objects renditions. Rendition is a term describing the electronic representation of documents in document management system in a different format than the original (Matthew, 2003). For example, one document in Word format can have its representation (rendition) in PDF format in accordance with document life cycle.
- Size of the metadata per object that is replicated. Metadata are "data about object", describing the contents and their characteristics (Hudec & Büchler, 2011). Average metadata size is 2 KB per object.
- Replication time is the time for which the document should be replicated in other repository.

In practice, other, hidden, parameters affecting the network bandwidth should also be predicted. Those parameters are (Matthew, 2003):

- Latency which, in computer networks context, represents synonym for delay. Latency represents the time required to transfer the data package from one network location to another. (Usual value of this delay is around 20% of total time).
- Ethernet protocol overhead. As throughput (bandwidth) is the actual amount of data that is transmitted through network per time, overhead covers conditions that must be met in the transfer. Network transfer protocol is an example of overhead. Message sent will be accompanied by additional protocol information (protocol overhead). This additional information will occupy part of the link capacity and thus affect overhead. In practice, a maximum of 55% of bandwidth is being used to transfer content.
- Communication overhead (average value is 8%)

Communication resources calculation for synchronized content replication between repositories is done using following document management system repository parameters:

- there are two document management system repositories with content replication system
- each repository is accessed by 500 system users
- in average each user creates a new document / version⁵ within working hours (working time is 8 hours), this means a total of 1000 new documents / versions for a period of 8 hours, 125 documents per hour or 2.08 documents / versions per minute

³Recommendations for network connections speed between client computers and application servers depend on the number of simultaneously active users. For 10 concurrent connections, bandwidth may be less than 2Mbps, but it is recommended to have more than 256 Kbps.

⁴Recommendations for network connections speed between client computers (scan stations) and Imaging Server depend on the number of scan stations and number of scanned pages.

⁵Versioning is automated process that creates a historical record of the document. (EMC, 2012).

- replication is done in both directions (full duplex), and each document has one rendition
- in average document size is 1 MB
- the most common case in practice is that documents do not create linearly in working time. Usually, the first 20% of documents are created in the beginning of working day, 30% at the middle and 50% at the end of working day.

Based on given parameters below are calculations of communication resources for two cases of synchronous content replication between two repositories, with replication periods of 60 seconds in first case and 6 hours in second case.

Case one: synchronization period is 60 seconds

Network bandwidth is calculated according to greatest overhead time (at the end of working day, when 50% of documents are created), so it is necessary to cover a peak of 500 documents / versions per hour or 8.33 per minute. Because of simplicity, we will replicate 10 documents in one minute.

In average, 10 documents (with size of 1 MB) are replicated per minute (full duplex, 5 in one direction and 5 in another direction) with one rendition (0.5 MB in size) for each document. Therefore, the network must transport 0.125 MB of data every second, and that is 1 Mbps of network capacity. However, this is "theoretical" maximum.

In this case, latency is 12 seconds (20% of 60 seconds), so, in order to compensate for it, 7.5 MB of data have to be transferred in 48 seconds. Hence, the capacity of communication link must be:

$$\frac{7.5MB}{48sec} = 0.15625MBps = 1.5Mbps \quad (4)$$

When expand calculation with Ethernet/packet overhead of 45%, required network capacity is increased to 2.175 Mbps:

$$1.5Mbps \times \frac{100 + 45}{100} = 2.175Mbps \quad (5)$$

Additional 8% should be added to the communication overhead, therefore link bandwidth required for content replication between the two repositories, where the objects replication period is 60 seconds, is 2.35 Mbps:

$$2.175Mbps \times \frac{100 + 8}{100} = 2.35Mbps \quad (6)$$

Case two: synchronization period is 6 hours

In total, by the end of the working day 1000 documents / versions are created and have to be replicated within 6 hours, but no later than next working day starts. That gives us a total of 150 MB of data (1000 documents / versions of 1 MB size and the 1000 renditions of 0.5 MB size).

Provided that replication line is Full duplex, 500 documents will be replicated in one direction, which means that 75 MB should be replicated within 21 600 seconds (6 hours). So, required communication bandwidth is:

$$\frac{75MB}{21600sec} = 0.0035MBps = 0.028Mbps = 28Kbps \quad (7)$$

Including latency of 20%, an additional 4320 seconds must be compensated. This means that 75 MB must be replicated within 17 280 seconds. This is the speed of

$$\frac{75MB}{17280sec} = 0.00435MBps \approx 56Kbps \quad (8)$$

At this value it is necessary to add Ethernet / packet overhead of 45%

$$56Kbps \times \frac{100 + 45}{100} = 81Kbps \quad (9)$$

and 8% of communications overhead

$$81Kbps \times \frac{100 + 8}{100} \approx 87.5Kbps \quad (10)$$

So, for the content replication between two repositories, where the objects replication period is 6 hours, required link bandwidth is approximately equal to ISDN connections with bandwidth of 128 Kbps.

In this case it is necessary to add metadata calculation (approximately 2 KB per document).

6. CONCLUSION

Before establishment of enterprise document management system, it is important to make proper sizing of the system. That includes sizing number of users, number of repositories, their organization model and approximate amount of content that the system will manage.

Only on basis of system predetermined dimensions, it is possible to calculate required software, hardware and communication resources. This allows optimal functioning of system and reduces waste of financial resources.

USING IT TECHNOLOGIES FOR INTEGRATION BETWEEN PLANNING AND SHOP FLOOR LEVEL: A CASE OF THE OVERHAUL PROCESS FOR TRAIN BRAKING DEVICES

Danijela Gracanin¹, Branislav Stevanov² Zdravko Tesic³

¹Faculty of Technical Sciences, gracanin@uns.ac.rs

²Faculty of Technical Sciences, branisha@uns.ac.rs

³Faculty of Technical Sciences, ztesic@uns.ac.rs

Abstract: A brief overview of the development of systems for production planning and control is given in this paper, as well as an example of the development information system for the overhaul process of braking devices for train wagons. Modern market conditions are characterized by a very unstable, unpredictable and changing business environment. These requirements face companies with the fact that they must constantly improve their business practices and procedures in order to improve their business performance and remain competitive in the market. Likewise, companies must constantly share information with their suppliers, customers and partners and that information must be extremely safe. The integration and automation of the process of design, planning, scheduling and control are becoming increasingly important approaches that could lead the system into a state that imitates the human way of processing information and working in conditions of uncertainty. Since main problems are identified in communication between the level of business planning and the shop-floor level, management and operational decisions ought to ensure that the production process is in line with the dynamics of the product life cycle, processes and people in the company.

Keywords: material requirement planning, computer integrated manufacturing, enterprise resources planning, integration, shop-floor, production planning, production control

1. INTRODUCTION

Fast technological development, globalization, information technologies and competition are words which are very frequent in modern business. Companies have tasks to improve competitiveness, increase productivity, develop new products, reduce costs, improve relation with customers, etc. In order to perform these tasks, it's necessary to face the challenges of applying new technologies, methodologies, tools and knowledge that are in line with the time and progress of the market. Computer systems in general, and systems based on the network can be found even in the smallest activities.

In the past decades, management theorists believed that companies can and need strengthen relation along the whole supply chain, started from raw material to final customer (Norris, 2000). In 90s of last century, companies have began to use new technologies and accept Internet and other web based technologies in order to improve own business. Modern business environment and conditions don't allow companies to exist and develop as closed systems, but must be open to its environment, suppliers, customers and business partners. In order to provide information sharing between all relevant stakeholders, companies need developed and organized information system.

Modern trends in the application of new information and communication technologies in companies are focused on the integration of all activities in a unique, computer aided environment. The integration concept, which aims at providing the right information at the right time at the right place, concerns: business process integration, teamwork or computer work for concurrent design and engineering activities, increasing flexibility and interoperability of information, systems and people to force environment variability in the cost effective way. But, the main problem is caused by the heterogeneity of computer systems and applications that use the same data collected from business processes. The categories of functions have included planning functions, shop floor execution functions and machine/process control functions (Boucher & Yalcin, 2006). These functions are hierarchically linked because the upper level planning functions typically constrain the activities that are allowed at the lower levels. In companies with advanced enterprise integration, these levels are coupled through the network architecture and a set of common databases that hold the most current information and make it available to all functions requiring it.

2. DEVELOPMENT OF SYSTEMS FOR PRODUCTION PLANNING AND CONTROL

2.1 MRP - Material Requirement Planning

In the period from 1960 to 1980, most efforts have focused on the research and design of material flow within the company (Norris, 2000). In the sense of information, tasks such as receiving and realization of the orders were not optimized, because the information within the company has not transmitted on time and properly. First steps in systematization and editing of this process began in the 60th of the 20th century and the first result was material requirement system which is also considered as the antecedent of a system for integrated control of resources.

In the 60's, the focus was on achieving competitive advantage through cost, using the strategy of a large volume of production, minimize costs and keep stable conditions (Jacobs & Weston, 2007). Introducing of computerized system for determining the Re-order point, including the determination of economic orders satisfy the needs of companies in terms of planning and production management. Systems for material requirements planning are a key step forward to the process of material planning.

The first versions of these systems for MRP were expensive and large. First of all, they require more technical staff to operate with computers. The development of higher speed drives and larger capacity for data storage has enabled the further development of the integrated business process management. Over time, the approach is extended to the procedures of preparing operational plans, control of production activities, specifying the inputs / outputs for orders and communications in an integrated support system.

MRP systems have been characterized as an analytical procedure in which the individual requirements are created from independent requirements (Tescic, Gracanin & Mitrovic, 2008) based on data obtained from sales service or distribution. Based on individual requirements for components, MRP system determinates the gross requirements by surmising of requirements for components and their quantities. After that, the net requirements are calculated by subtracting the amount of parts already in stock and amounts that are already in the procurement process. The system consists of the following processes or steps (Figure 1):

- Material plans check in order to exclude those which are not currently required
- Net requirements calculation
- Calculation of the material amount needed to purchase with the aim to join in existing orders or requisitions
- Scheduling or deployment
- Define the sources of supply in order to make acquisition
- Define the requirements for the additional material based on bill of material

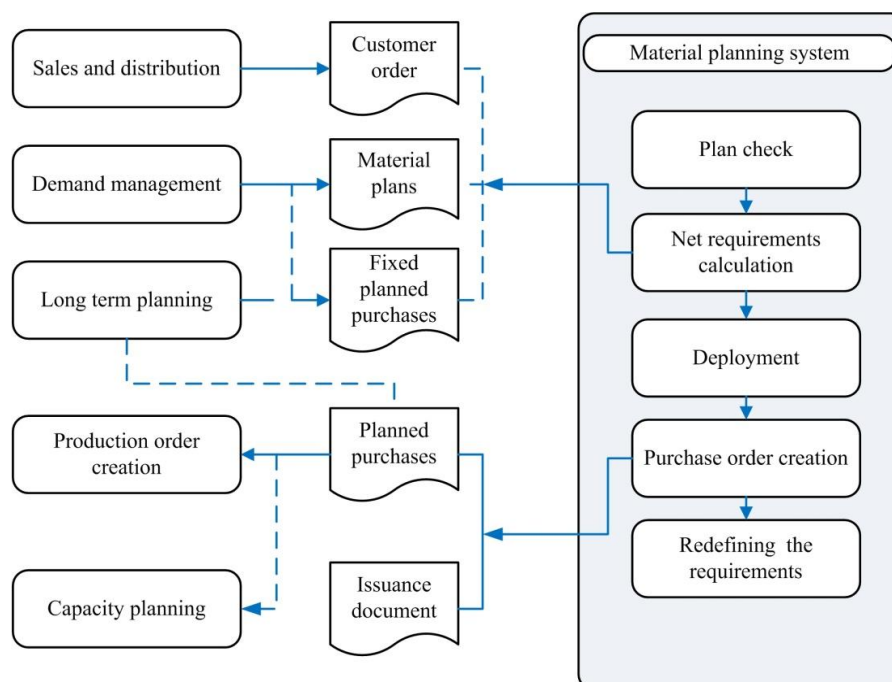

Figure 10: MRP processes

2.2 MRP II - Manufacturing Resource Planning

Manufacturing Resource Planning systems (MRP II) includes capacity planning and shop floor workers as well as the production needs. In the case of disability, this system allowed the planner to make changes to the plan implementation process within the existing capacity (Jacobs & Weston, 2007). This system allows the analysis of the consequences of different versions deployed enterprise resource plan and delivery of products, which was quite a lack of closed MRP systems. MRP II has expanded their usage to other areas such as marketing, production and finance. The most important, this was not only software system, but a combination of computer resources, human skills and the database. The emphasis was on the optimization of manufacturing processes with synchronization of material flows with production requirements.

One definition comes from the APICS Dictionary-a, (American Production and Inventory Control Society), which set standards of terminology over the years, and it follows that the resource planning for the production method of effective planning of all resources, the production company that uses units of measures for operational planning, the monetary unit for the financial planning and simulation supports the ability to answer "what-if" questions. It consists of various functions, which are linked together: business planning, sales and operations planning, production planning, material requirements planning, capacity requirements planning, and execution support systems for capacity planning and materials.

2.3. Computer Integrated Manufacturing - CIM

During the 80's, the performance of computer systems were significantly increased and cost reduced. This contributed to the intensive development of applicative systems in the field of product design and manufacturing technology (CAD-CAM systems). Computers have become an integral part of technological systems (machines), with the ability to manage work and machine movements, which is contributed to the development of computer numeric control machines, the robots and automatic guided vehicles.

The potential of computer systems, as an integral part of machines is contributed to the development of related and automated systems such as automated warehouses, flexible manufacturing cells, flexible manufacturing systems, as well as factory without people. These systems are set up as independent entities, often referred as islands of automation (Tescic, Gracanin and Mitrovic, 2008).

One of the main goals of computer integrated manufacturing approach is the automation and integration of entire business and production processes in an industrial company. The base of the approach is a Manufacturing Execution System - MES and its key component is a system for planning, scheduling and process control in production units of the company. This concept has created from practice and integrated processing of information about business and technical tasks in industrial processes (Dickerbach, Keller and Weihrauch, 2007). Research in this field started Harrington in the early seventies of 20th century. In his book, "Computer integrated manufacturing" (1973), Harrington has defined the following elements of this approach:

- Computer aided design
- Computer aided manufacturing
- Computer aided quality control
- Production Planning

Computer integrated manufacturing set up unique database by applying by applying a variety of applications, methods and techniques of product design and manufacturing flows, as well as connection with a business system functions (marketing, finance, human resources management) (Browne and all, 1988). According to Dorf and Kusiak (Dorf & Kusiak, 1994), the computer has an important role in integration of following functional areas of CIM systems: product design, tool design, process planning, numeric control machines programming, production planning and quality control.

2.4. Enterprise Resource Planning - ERP

The aim of the Enterprise resource planning is to integrate all the parts and functions into a single computer system, which will be able to service all of the specific needs and requirements of all parts of the company (APICS). It consists of software modules which are fully integrated into the system with a common database and there is no duplication of data. These modules cover a huge number of different functions of a company such as: marketing, finance, sales, customer support, human resources management and manufacturing. Disintegration is the sign of illness and integration is sign of health. All problems primarily come from one cause: the disintegration. Something isn't together, something doesn't work related. Therapy is - how to consolidate (Adizes, 2009). If the disintegration is cause of all problems, then the solution is integration. One of the main indicators of successful company is its full integration, which includes both, external and internal integration. Just as a unified entity, the company can develop products and implement services that meet customer needs. Effective and efficient management of production processes of the

industrial systems can be achieved by integration of the all functions and processes from top-level management to the shop - floor level (Zelenović, 1981).

Visibility in real-time and capabilities that provide integrated solutions has significant impact on improving of agility, quality and efficiency based on the collected data and execution of manufacturing operations through the exchange of information in the feedback to the ERP system. Total exploitation of ERP possibilities depends on its association with manufacturing units through the software applications that make the structure of the system for manufacturing activities control, as shown on figure 2 (Tescic, Gracanin and Mitrovic, 2008)

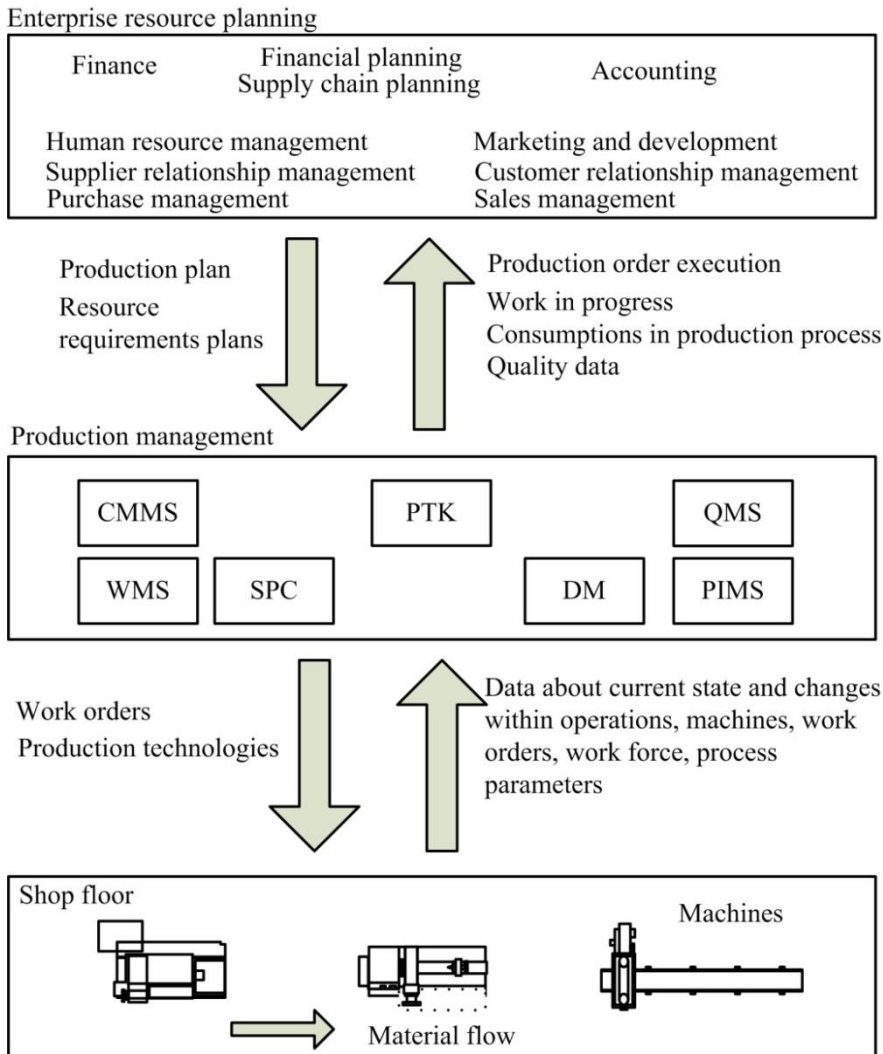

Figure 2: Shop floor, production management and general management

The characteristics of ERP system related to the business area are process-oriented, customizing to the company, modularity, independence and simulation. Briefly, the functionality of the ERP system is reflected in transactional processes (integrated data management), work flow management and decision support (Akkermans & Helden).

2.5. Enterprise Resource Planning- II generation

After several iterations of development and improvement, appearance of new generation of these systems was completely logical continuation, especially with the Internet as a business medium. With these systems, the information platform is extended to customers, suppliers and other business partners. While the first generation is adaptive technology, second generation can be categorized as a revolutionary technology (Norris, 2000). The adaptive technology are just a new generation of already existing technologies, while the revolutionary technology can be seen as those that change the way of life or way of doing business. With this

new generation of systems, companies are open to the environment and have a completely new way to communicate with clients. Web-based technologies give life and breath to the system for enterprise resource planning, which is a large and technologically complex and it is not always easy to discover its true value. ERP system is focused on improving the effectiveness and efficiency within the company, while the task of the second generation of the system is oriented to the environment and relations with customers and suppliers, as well as the promotion of products / services.

One of disadvantages of first generation is introduction of new function or activity which is not covered by the existing system. This constraint has seemed like a handicap of system, particularly with the rapid transformations in the organizational structure and functions. The second generation system was able to overcome this problem and provide greater coverage of functions and processes in the enterprise. The special significance of next-generation system is given due to the fact that they cover a number of industries, while the previous generation was more focused on manufacturing companies.

3. CASE STUDY

In this paper case study represents the overhaul process of train braking devices in company “Inter-Mehanika” from Serbia. “Inter-Mehanika” manufactures and gives services for both large government systems (EPS, Railways) and private companies (USS Serbia, Vagonka MINNiš, NIS installation, Inter-Gas.), and for all other smaller companies. Company consists of three parts positioned on three locations:

- company headquarters which include marketing, R&D, sales, purchase, and financial departments along with the specialised shop floor for repairing braking devices (K03),
- shop floor for repairs and maintenance of railway vehicles,
- manufacturing facilities for machining, locksmith-welding and plumbing works.

Hierarchical process structure is shown on figure 3.

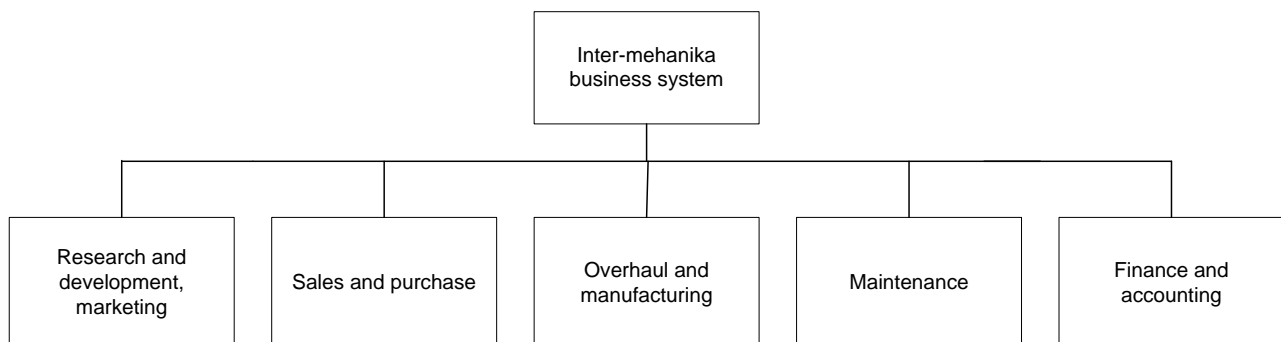

Figure 3: Hierarchical process structure

Train braking devices are overhauled in the specialized shop floor K03. The shop floor is fully equipped with technical and personnel for the repair, maintenance and reconstruction of all types of train brakes, distributors, metering valves, cylinders, regulators, cylinder-regulators and block cylinder regulators. The overhaul process begins with the reception and visual inspection of braking device which is then disassembled. Using the technical documentation for the overhaul process, device defects are noted and the parts that need to be changed are specified. There are two types of parts which can be replaced:

- parts which must be replaced every time the device comes to overhaul (rubber parts) and they are purchased from the supplier
- parts that must be replaced only if the inspection process shows defects of them (metal parts), and they can be purchased or more often they are manufactured in the manufacturing facilities of the company.

After the parts are prepared and changed the assembly process begins and after that the braking device goes to inspection and functional testing. The amount of documents and information regarding overhaul process is complex. Technical and technological overhaul documentation represents a manual for process of performing overhaul of braking device. The documentation contains detailed instructions for repairing brake device, a list of parts brake device, technical drawings of equipment, overviews of membranes and springs, time standards, normative for the materials and a document which serves for parameter input during braking device testing (Protocol). The instruction manual for the repairing of the devices defines in detail the procedure for disassembly, inspection and assembly of each device, with the necessary tools and measuring devices. Part lists give an overview of all parts of the device. Parts that are necessary to change during

repairs are separately labelled, as well as those that need to be replaced only when needed. The drawings give cross-section views of each part of the braking device, with labels for all positions. Overview of springs in the tabular view provides specifications for all the springs in the braking device (labels, wire diameters, spring diameters - inner diameter, the forces acting on the springs and spring length - free length and under pressure).

Overview of the membranes provides the technical characteristics of the membranes in a tabular view (labels of the membranes and their hardness). Also the parameters that the braking device must meet are defined. The parameters are presented in tables, and also there is a drawing that defines how to connect the braking device to the testing table. The protocol of the braking device testing includes results of the braking device. The time for repairs is defined by the time required for each operation (rough cleaning, disassembly, cleaning of the parts, control of the parts, defects inspection and finishing, assembly, testing and painting), and the total time is shown. Time standards exist for each device. Standards for required material contain defined amounts of paint, detergent, grease and other materials as needed for each part of the braking device. IDEF0 diagram of overhaul process is shown on figure 4.

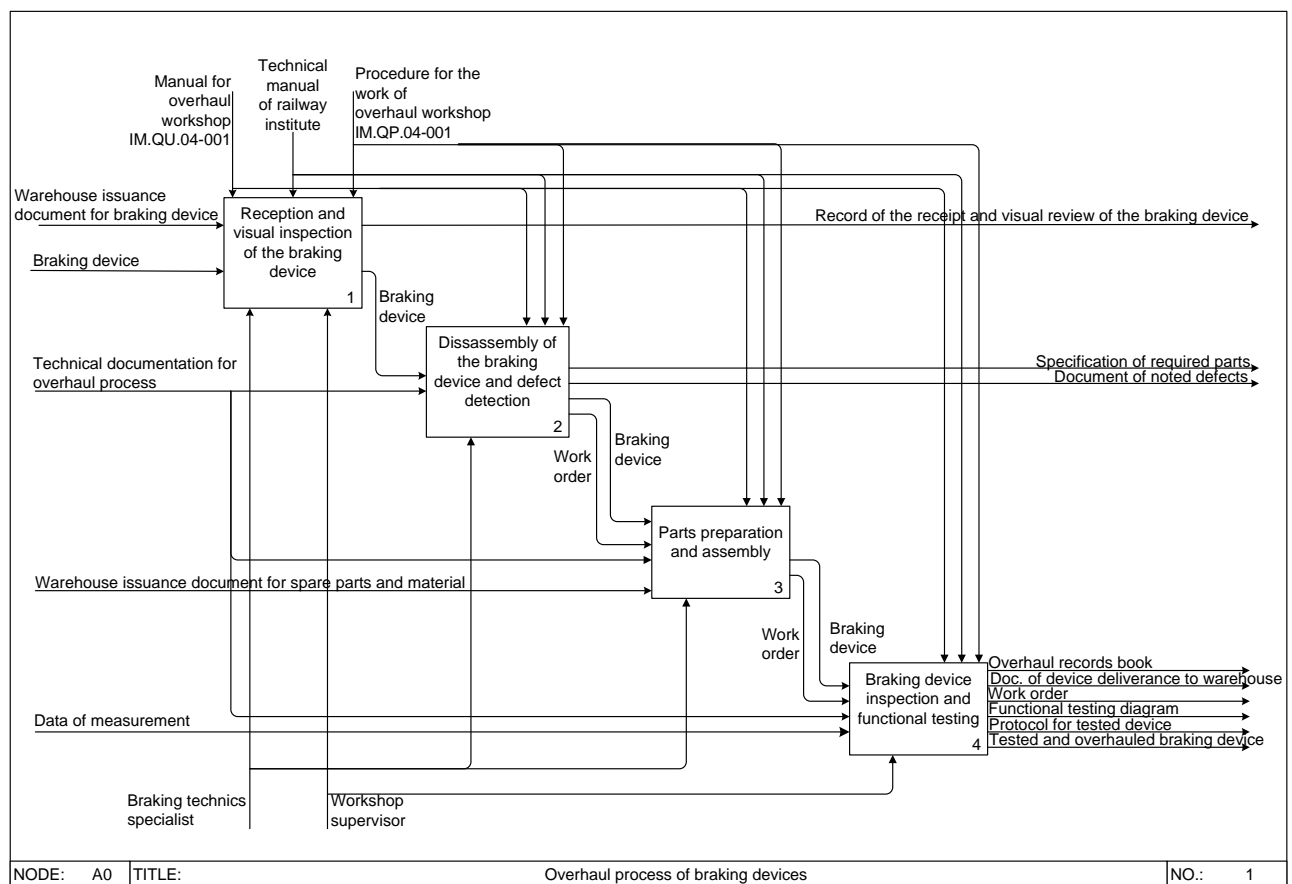

Figure 4: Overhaul process diagram

Testing of overhauled braking devices is made on testing station shown on figure 5.

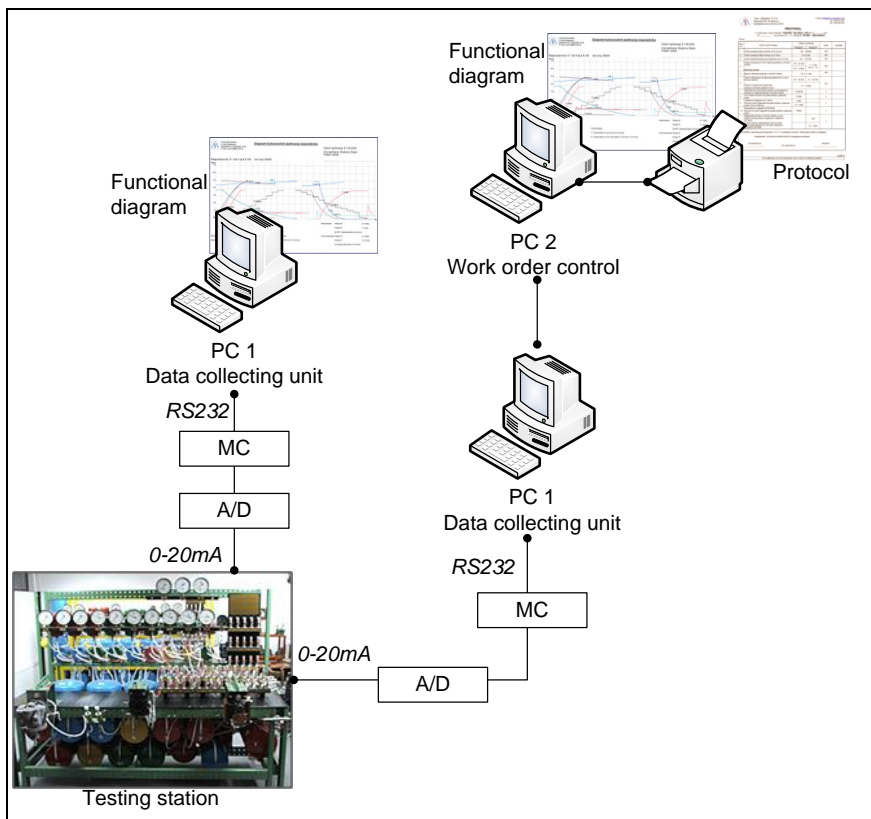

Figure 5: Testing of braking devices

During the test, the real system working conditions are simulated. Relevant parameters are examined (nominal pressure in the system, time of braking etc.) and the braking device is adjusted. Number of repeat tests depends on the number of settings that are needed to make the device and of the detection of possible defects that could not be noticed in the visual inspection of the braking device. Empirically, the number of tests carried out is not less than 15. Electric signal (0-20 mA) from the analog meter, which is a part of the testing station, is sent to 10bit A/D converter. A converter then turns continuous analog input signals into digital output signals. There are various procedures for this including successive approximation, counters, R-network comparators, dual-slope converters, parallel converters and multi-ramp techniques. Depending on the pressure, signal is converted to a number (0-1024) and through serial communication send on PC1. This process is also known as digitization. Program on PC1 then use a linear equation $Y=ax+b$ (a can have different values, b is constant and has value -1 which is atmospheric pressure), create a value of relative pressure and form a diagram.

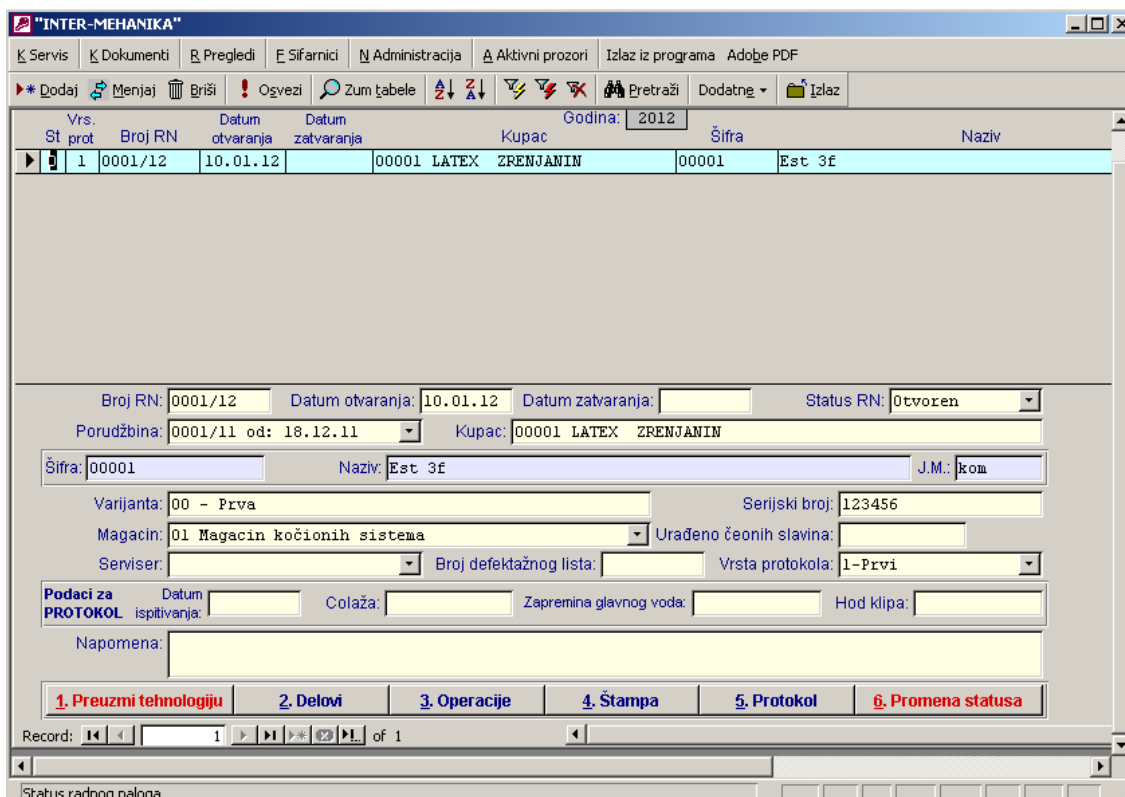

As a result of testing, the diagram captures the functional examinations from test equipment, and the data from the chart are enrolled in the testing protocol, which has a character of a certificate.

Shop floor K03 is poorly integrated with the other parts of the company. The conducted analysis of business process showed the following basic deficiencies in the performance of functions and processes:

- low level of integration between the processes and functions in the working system especially between incoming customer orders, K03 shop floor and warehouses (there is no tracking connection between work orders and customer orders, it is hard to track material, parts and tools consumption, there is no data acquisition and analysis from the shop floor etc.)
- process planning is missing,
- all documents are in paper form which is lowering the process efficiency,
- the lack of process analysis as a basis for decision-making procedures and settings.

The analysis showed the need for information system development. Application that integrates customer orders with work order control, shop floor activities and the final testing of the braking devices is developed using Microsoft Access and Microsoft SQL Server. The figure 6 shows input in the planning, execution and control of work orders in the overhaul process of the braking devices with the built-in connection with testing

station. The <Protocol> command enables downloading the results of measurements and the formation of the protocol document, which shows the final results of the overhaul process and can be sent to the customers.

The screenshot shows the 'INTER-MECHANIKA' software window. It features a menu bar with options like 'Servis', 'Dokumenti', 'Pregledi', 'Sifarnici', 'Administracija', 'Aktivni prozori', 'Izlaz iz programa', and 'Adobe PDF'. Below the menu is a toolbar with icons for various functions. The main area contains a data entry form with fields for 'Vrs. St. prot.', 'Broj RN', 'Datum otvaranja', 'Datum zatvaranja', 'Kupac', 'Godina', 'Sifra', and 'Naziv'. A table below these fields shows a single record with values: 1, 0001/12, 10.01.12, 00001 LATEX ZRENJANIN, 00001, Est 3f. Below the table are more form fields for 'Broj RN', 'Datum otvaranja', 'Datum zatvaranja', 'Status RN', 'Porudzbina', 'Kupac', 'Sifra', 'Naziv', 'J.M.', 'Varijanta', 'Serijski broj', 'Magacin', 'Urađeno čeonih slavin', 'Serviser', 'Broj defektažnog lista', 'Vrsta protokola', 'Podaci za PROTOKOL', 'Datum ispitivanja', 'Colaža', 'Zapremina glavnog voda', 'Hod klipa', and 'Napomena'. At the bottom, there are buttons for '1. Preuzmi tehnologiju', '2. Delovi', '3. Operacije', '4. Štampa', '5. Protokol', and '6. Promena statusa'. The status bar at the very bottom indicates 'Status radnog naloga'.

Figure 6: Integration through software

4. CONCLUSION

It could be concluded that these systems are not only the trend of information technology, but a necessity of modern business and a new vision of the modern company. Manufacturing is a very dynamic environment, and change and disturbances handling are high on list of research challenges. The cooperation between high-level planners and schedulers and the manufacturing execution system is virtually unexplored.

Case study presented in this paper is model of integrated processes in the industrial company with a focus on controlling the processes of repair and maintenance. The development process is required analysis and research of different approaches in the field of the industrial system characteristics and process identification. The integral information system that includes both business and part of production management and in the modern programming environment is designed. Future research activities will be focused on the further integration within "Inter-Mehanika" in the sense of connection this system with financial, commercial and R&D functions. For successful implementation of these systems is very important to select appropriate strategy and methodology for implementation and ensure the full involvement of all organizational levels and open communication among participants.

Abstract: *This paper describes the process of integration of mobile web applications with the Learning Contents Management System (LCMS). We present a way of developing web applications for mobile devices in the NetBiscuit platform which is implemented at the University of Novi Pazar. The process of implementation is based on the project management of e-learning, more precisely on the application of project management (through four phases: definition, planning, management and evaluation). It is designed as a combination of the project management phase which enables more efficient planning and performing online education with the procedure of design courses for e-learning.*

Keywords: *mobile applications, e-learning, NetBiscuit platform, LCMS, project management*

1. INTRODUCTION

In today's modern society, emphasis is placed on the availability of information which should be provided on all devices that users use to search for information. Therefore it is necessary to optimize web pages for mobile devices, and this trend is increasing fast. Using the mobile internet, customers receive the highest possible comfort in finding quick information that interests them. Some of the statistics that speak in favor of the development of this area are:

- 4 billion mobile devices in the world and out of that 1.08 billion are Smartphone's,
- by 2014. mobile Internet will overtake the use of the Internet through computers,
- 1/2 of all local searches are performed on mobile devices,
- 86% users of mobile Internet are using their mobile devices during watching TV,
- 2.7 hours per day - during which the average user spends on social networks (Facebook, Twitter...).

In response to modern trends of distance learning at the University of Novi Pazar is established combination of traditional education and distance learning. This type of learning represents a form of student support and supplements to the classical method of education using information and communication technologies (ICT). Values indicator of this system is to help students and teachers with ICT technology to easier overcome the teaching material. Apart from the implementation of e-learning at the University (Međedović, 2011) in classic web environment through a system of e-learning (Moodle and Google Aps) on this institution of higher education are formed and the shape of e-learning in the form of web applications for mobile devices. In the future, our web application will be developed to monitor the trends of modern education. One of the following steps in the development is the ability of electronic exam registration as well as filling the various types of forms, which will among the other things, reduce travel costs of students who do not live near the University.

This paper consists of three parts. In the first part we describe the method and platform development of University Web applications. In the second part, we specify the basic phases of project management and development of the application. In the third part is given a concrete integration process of mobile applications with the courses that are implemented in systems for e-learning.

2. DEVELOPMENT PLATFORM FOR MOBILE WEB APPLICATION

To develop applications for mobile devices, we chose Netbiscuits platform which provides fast and efficiently publishing web content through all available mobile platforms in the form of a Web site or the native application. This platform supports the publishing of web content to many types of mobile devices including smart phones, media tablet (mini-computers and phones at the same time) musical devices, game consoles, e-readers and even TV set-top boxes.

Netbiscuits retains its independence from any mobile operating system installed on the devices and provides optimization of Web content for each browser on the phone. This platform actually translates the code and adapts it to the browsers in order to present web contents.

Netbiscuits has integrated world classes of mobile devices in its platform which is connected to one rendering machine that deliver you optimized mobile Web applications on any mobile device. This platform uses the latest mobile technologies such as HTML 5, CSS and Java script, in order to create Web sites that users will experience as application (Petković, 2011). This platform provides the use of PHP and MySQL technologies to communicate with the database. In order to improve the user experience Netbiscuits provides optimization tools that enable the optimization of labels, CSS, images, audio and video content and provides their introduction on the basis the characteristics of each mobile device.

Netbiscuits content is optimized to reduce the load time for users who have access over the limited permeable scope. Netbiscuits has created a database that contains more than 6000 tested mobile device profiles from over 50 countries worldwide. In order to guarantee maximum coverage, reliability and quality of mobile sites and applications Netbiscuits does not use of any information or open source database. Database of this platform not only check the basic properties of each device such as the size of the screen but already have detailed information about the search capabilities media support, processing power or memory capacity of the device. Although mobile phones use different platforms and operating systems this web application adapts to any phone independent of who runs the startup (Schreiner, 2011). During development, we considered what is it that in relation to the primary web site of the information should be placed on the mobile web site which will certainly facilitate the University students.

While creating the application we were guided by the following rules:

- application should contain the most needed information for moving users
- navigation should be easy, fast and intuitive,
- rejection of the functionality, content and information that are not very necessary to the mobile web site reduces the time required to access the site
- speed access is also determined how the information and content is formatted and displayed to the end user.

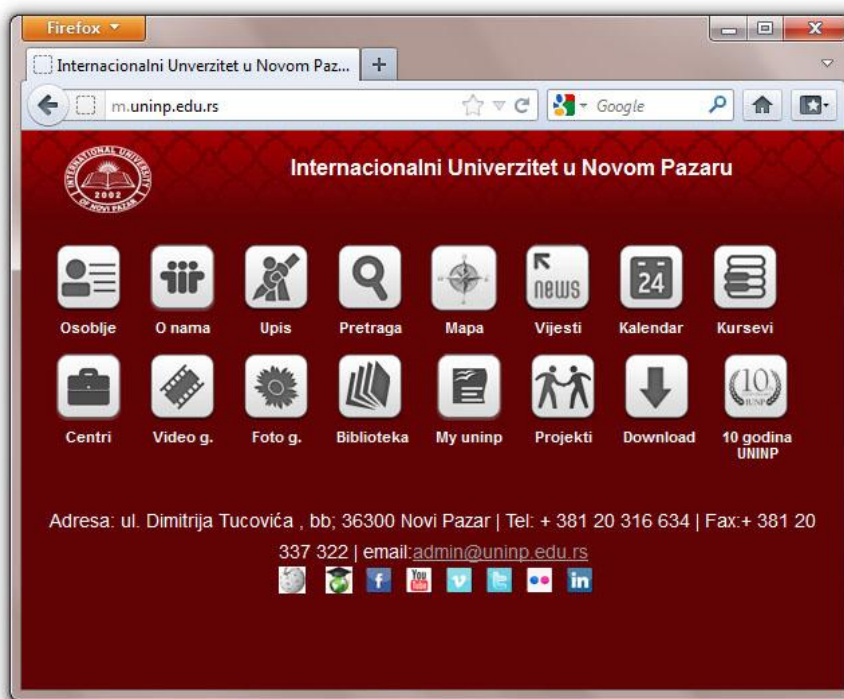

Figure 11: Home page of applications for mobile devices

As mentioned above, during development of web application PHP and MySQL technology is used under which the printed BiscuitML source code which is only understandable for the Netbiscuits platform. When it

comes to speed of navigation the use of mobile applications offer many benefits to students. All information that applications carries are already in local phone memory, thereby the speed is much higher than in the case where looking for any new information on the web site which requires additional time needed for data transmission over the Internet when you load and display the desired content.

A detailed functionality description of the University applications for mobile devices is described in our paper (Selimović, Saračević, 2012). In this paper we focus on system integration for e-learning with a mobile web application. In the following we describe the process of managing the project through its development phases.

3. PROJECT MANAGEMENT FOR DEVELOPMENT OF MOBILE WEB APPLICATIONS

Project management is a concept with the help of appropriate methods of organization, information technology, planning, management and control, performs a rational alignment of needed resources and coordination of necessary activities to realize a project in the best manner. The process of project management learning is a much broader concept of project management, instructional design, program leadership, team management and information technology.

The concept of project management of development of our applications for mobile devices is based on establishing efficient organization of data, that allows the best use of available methods of planning and control for effective project implementation with the emphasis on the better navigation, content, and easier communication.

3.1 Development phases of the concept of project management applications for mobile platforms

In this part of the paper we will present the basic phases of the e-learning. Firstly it is necessary to make a difference between the following concepts: processes, products and projects of e-learning. The process of e-learning involves the whole strategy of providing the knowledge using technology and networking. The product of e-learning is a package that comes with the completion of the project of e-learning.

A project of e-learning is an initiative to deliver or improve a separate package of the content of e-learning or to create, establish and maintain software or infrastructure to support e-learning process (Saračević, Mašović, Šemsović, 2011).

Figure 2 presents a model that is implemented through three phases in the design of the project: planning, design and development. Phase of design and development have their sub-phases which are in mutual interaction. During the design a prototype of application is created that can be reviewed and re-designed in the future iterations. In the development phase the implementation of received applications is being carried out as well as and its evaluation. There is also iteration between the phases of design and development.

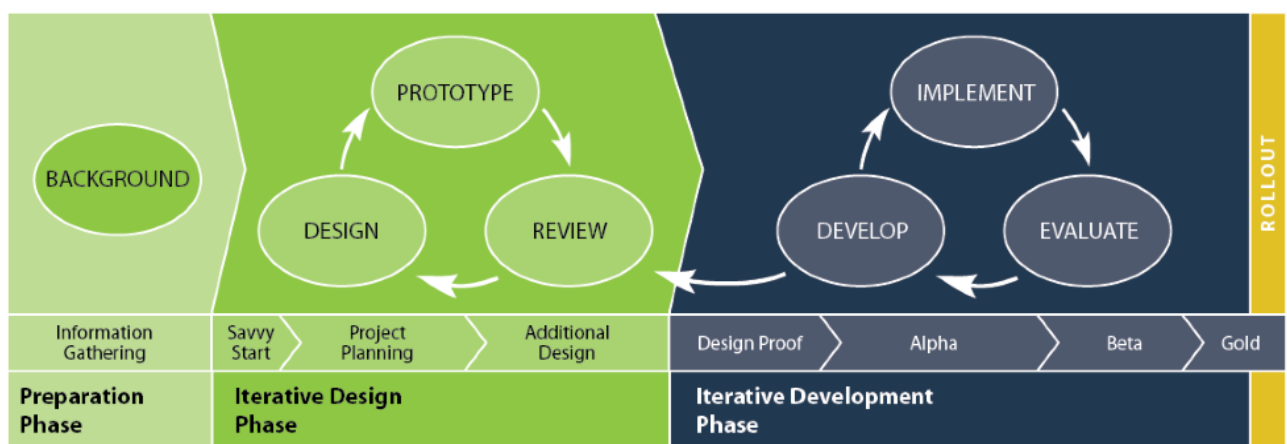

Figure 2: The development of applications based on the model 3-Phase (P-ID-ID)

The concept of project management and development of the application for mobile platforms based on the previously presented model can be defined through the following main steps (E-Lab, 2011):

1. PROJECT DEFINING is a phase that includes development of the project plan, its implementation and control changes, which is very important for the subsequent maintenance applications. In this phase the types of risks are defined for each phase of the project.
2. PLANNING is the phase of determining the scope and duration of the project. It performs the evaluation of individual activities, developing the project plan and control changes.
3. MANAGEMENT is a phase in which defined tasks are determined. It manages the risks, project scope, quality, cost, communication and resources.

- **management of project implementation** is actual monitoring of the implementation, recording and updating of actual data on the realisation (completed work, cost, duration) as well as monitoring of possible changes
 - **management of communications** is an important segment that includes communications planning, distribution of information, reporting about the project and its administrative closure.
 - **resource management** is the process of defining the resources needed for the project and their scheduling. It primarily refers to the selection of data that are used and imported from the traditional web site of the University.
 - **quality management** refers to planning and definition of measures for its implementation and control that is necessary in order to achieve desired quality of the results of the project.
 - **risk management** is the process of identification, analysis, planning responses to the risk and its control.
4. EVALUATION is the phase during which it conducts a formal evaluation of the actual value of the project, reports and documentation for the project are published to ensure the quality of the e-learning.

The project ends with a final report, which will serve in the realization of future similar projects.

4. SYSTEMS INTEGRATION FOR E-LEARNING WITH MOBILE WEB APPLICATIONS

Systems for support learning have experienced significant changes and passed many development phases and approaches and to the early learning system based on large computers with multiuser operating systems through the software system based on microcomputers developed for various computer platforms. Learning Management System (LMS) are the key applications in the model of electronic education or e-learning (Saračević, Međedović, Mašović, 2011). This kind of the system includes a set of functionalities that are designed to deliver, monitoring, reporting and administration of the learning content. One of these systems for e-learning is Moodle.

Despite the fact that the concept of Moodle architecture respects the principle of minimal consumption of resources and computer communication networks, there is a need to further simplify and optimize it. The reason for this is that mobile platforms used today, do not have available computer power or speed and bandwidth of modern internet connections. The result of attempting to respond to these requests was implemented as additional modules for Moodle environment (Saračević, Mašović, Selimović, 2011).

MLE – Moodle is a module that adds a Moodle installation the ability to access with mobile platform (mLearning). This module allows you to access on the system besides the usual, using the computer, and using mobile phones, smart phones, tablet computers etc. Mobile access is possible by using of a customized web pages or specially created applications for mobile devices. To integrate our web application with the LMS system – Moodle we used described supplement for open - source system (LMS) Moodle.

Supplement is copied into the installation file system of Moodle and then when you access to the system via mobile device browsers or with some special mobile phone application designed for learning on mobile phones (called the MLE phone client), MLE – Moodle recognizes the device and adjusts according to its performance. To log on the educational course you need to login on the mobile application.

Figure 3: Login form and students portal

M-Learning use the mobile phones as a medium for learning. Therefore the use of mobile phones as a medium it can be used anywhere. One possibility is to connect mobile web applications with Moodle, a system for e-learning which is customised to run on mobile devices. With MLE-Moodle you can implement some mobile learning scenarios. The mobile web applications are especially good for terrain trips where students need to complete quizzes or upload images / video / audio or written reports. creating locations based on the learning scenario for mobile tagging or integrated GPS. make a quick research and submit the results immediately in the classroom with mobile devices and see results immediately.

We will present an example of source code that uses the link to access the MLE-Moodle applications within the University. The main issue in this code is linking with the MLE-Moodle.

```
<container>
<column>
<?php
print ('<LIST class="mylinklistclass">
<items>
<item
href="http://d.uninp.edu.rs/blocks/mle/browser.php?xml=courses,c9-2">
</items>
</LIST> ');
?>
</column>
</container>
```

To demonstrate the functionality of MLE modules, we have listed Moodle course which was developed for the needs of University teaching. This course will be used to configure the module and it is necessary that the identical roles should be assigned at both courses. One such example is illustrated in the following figures.

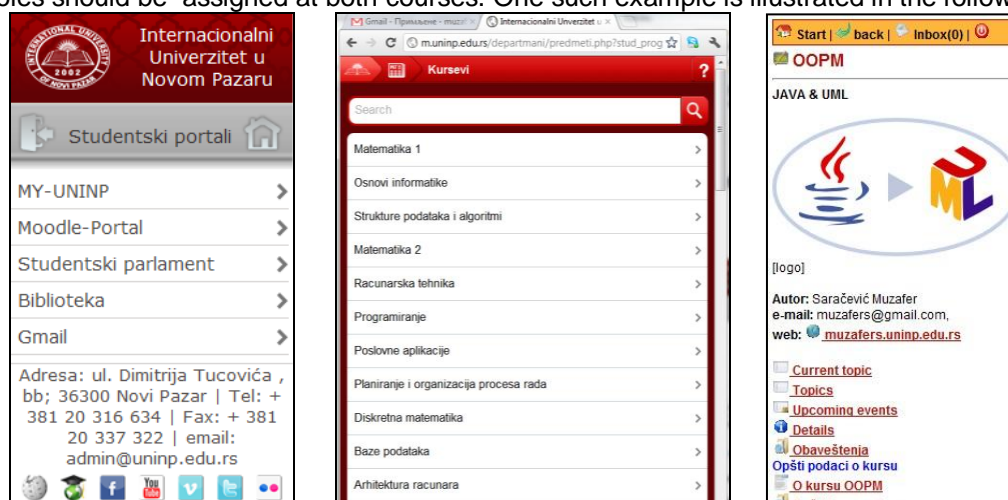

Figure 4: Loading procedure for Moodle course to applications for mobile platforms

Moodle has provided that, instead of solely classroom training is done it could also be done in our working rooms, MLE adds a new dimension to learning from any location, at any time, regardless of whether you have a computer with yourself (Mašović, 2011).

5. CONCLUSION

Without a doubt, the future of the internet lies in mobile platforms. With the appearance of Smartphone mobile devices internet has become more attractive to a wider audience. This mini Smartphone revolution cannot ignore changes in the habits of Internet users. This paper is a proposal of how to raise teaching in higher education institutions at a higher level and to allow students faster and easier access to the information.

This paper outlines some of the advantages of one model of the implementation of e-learning in higher education. We give proposals for application of project management in teaching improvement with emphasis on rapid development and high quality projects of e-learning. Product of e-learning which is implemented in this way requires a flexible content and simple interface customized to learning. The advantage of this way of implementation is that the method of creating courses for e-learning relies on the concept of a person's mobility. This process promotes the teaching approach in which the student is at the center of attention in any place at any time and thus achieves better study. The combination of traditional learning with the support of e-learning and m-learning is the best combination for the study. It is very important to apply described procedure of implementation at all educational institutions, because in this way the teaching will be raised to a higher level but also the level of student achievement.

CAN SERVICE FAULTS IN PASSENGER FLIGHTS BE PREVENTED? A PROPOSED FRAMEWORK

Ofer Barkai¹, Elad Harison²

¹Shamoon College of Engineering, Department of Industrial Engineering and Management, Bialik St., Be'er Sheva, Israel ; ofer@sce.ac.il

²Shenkar College of Engineering and Design, Department of Industrial Engineering and Management, 12 Anne Frank St., Ramat Gan, Israel; eladha@shenkar.ac.il

Abstract: The paper devises a new framework for implementing preventive service systems that aim at preventing service failures and complaints in air transport services. By proactively monitoring the provision of services to passengers and averting service failures, preventive service management decreases the volume of customer complaints and assists in enhancing service quality and airline reputation. The presented framework is based on extensive use of IT systems that continuously monitor the service infrastructure in a cycle of activities that includes detection and prevention of service failures, notification of service malfunctions and follow-up operations. The implementation and the value of the framework are exemplified in various scenarios that arise in the operation of commercial flights and often facilitate passenger complaints and discomfort.

Keywords: preventive service management, service faults, customer complaints, customer satisfaction.

1. INTRODUCTION

The eminent growth of the airline industry and air transport worldwide highlights the major economic and commercial importance of provision of qualitative and punctual flight services (Kim and Lee, 2009). The operation of services is challenging and complex, particularly in the airline industry, where large numbers of passengers continuously travel to multitude destinations worldwide and air transport services incorporate a broad set of resources, safety and work procedures.

Recent studies emphasize the importance of complaint management as a key factor for ensuring customer satisfaction and, in the longer term, customer loyalty (Homburg et al., 2010). At the same time, studies conducted on the subject of service recovery argue that most of the customers that confront service failures avoid complaining, especially before deciding to leave their service providers, and thereby do not provide service companies the opportunity to correct their negative experiences or compensate them for their damages (Chebat, Davidow, and Codjovi 2005; Sharma et al. 2010). Further, similar service failures often repeat themselves (either in same or different contexts) and more customers are exposed to service malfunctions that could have been prevented had companies enforced earlier service control mechanisms.

The recent and common practice applied by service providers that seek to improve their operations is complaint management. Complaint management includes scope of activities that encourage dissatisfied customers to complain, rather than remaining dissatisfied and spread negative opinions, correct their negative experiences and "convert" dissatisfied customers to satisfied and loyal clients (Fornell and Wernerfelt, 1987; Paul et al., 2009). However, the major drawbacks of complaint management is the exposure of customers to service faults and the requirement that customers contact their service providers and complain as a pre-condition for initiating complaint management procedures.

Preventive service management is a new and innovative framework that aims at improving customer satisfaction without exposing customers to negative experiences, by preventing service faults and the consequent customer complaints. The methodology is based on ongoing monitoring of the service infrastructure and processes and on discovery of conditions that may lead to potential service failures. Since continuous monitoring activities require intensive labor and may be very costly, we advocate the application of automated systems to carry out monitoring activities.

Preventive service management aims at guaranteeing consumer satisfaction as well as proactive elimination of events that may lead to potential service malfunctions by using human-based procedures and automated

systems. Indeed, prevention of failures was explored in the airline industry, considering, in particular, airline maintenance and safety policies (see for example Liou et al., 2008; Netjasov and Janic, 2008). However, little research has been dedicated to preventive practices that can enhance the quality of the service provided to passengers. Preventive service management suggests that by identifying, monitoring and preventing different factors and occurrences that result in service malfunctions, airlines can improve the level of delivered services and customer satisfaction, while sparing inconvenience and recovery costs.

2. PREVENTIVE SERVICE MANAGEMENT: A CONCEPTUAL FRAMEWORK AND METHODOLOGY

Preventive service management can be applied in a wide range of organizations, including airline companies. However, its application requires a coherent and constructed framework that addresses a broad variety of services and processes that support them. The methodology and the framework presented in this paper were constructed to accomplish the major aim of reducing the likelihood of service failures. This aim is addressed and met at large by establishing a model that addresses a broad spectrum of service related processes and organizational units on the basis of four major stages: detection, prevention, notification and follow-up (see Fig. 1).

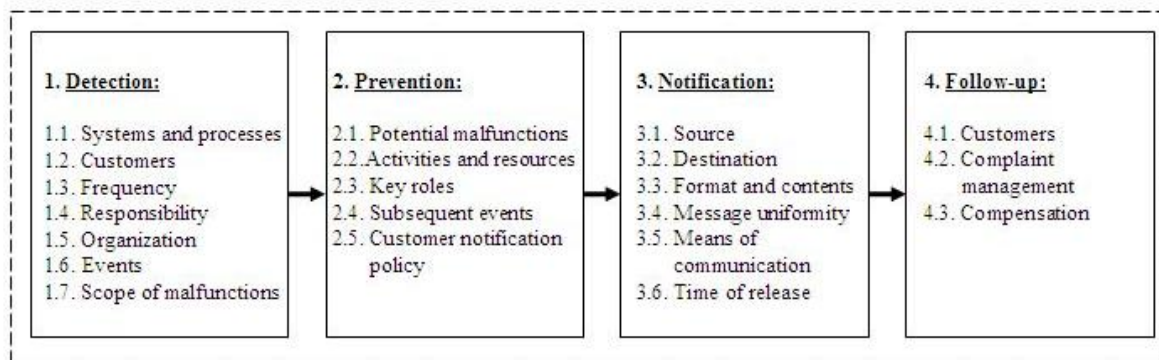

Figure 1: Stages of the Preventive Service Management process

Detection represents the stage of continuous monitoring of services to eliminate possible occurrence of dissatisfactory events. For example, airline companies may continuously monitor the state of major and minor aircraft maintenance problems to allocate replacement aircraft and team within a short period. Automation of the monitoring processes via real-time information systems provides broad coverage of the services in multiple destinations worldwide, while enabling the airline to economize on labor costs.

Service activities and information systems that carry out detection processes should address the following aspects:

- 1) The service operations, processes and related systems that should be monitored by the airline.
- 2) The population of customers for which detection is carried out (for example, business passengers, frequent flyers or all the passengers in a particular flight).
- 3) The frequency of operating detection activities (for example, hourly, daily or weekly monitoring of service processes).
- 4) Who is responsible for different detection operations.
- 5) The ways in which detection operations are organized and carried out, the information systems and the airline resources that they use.
- 6) Which events are defined by the airline as service malfunctions.

Prevention represents the activities that the airline implements to eliminate potential risk factors that affect the proper provision of services and their quality. In this stage, the airline carries out activities that proactively prevent the occurrences of service failures, such as emergency and contingency operations. In case planned service outages and maintenance operations are carried out, prevention includes the organization of activities and resources that can shorten the duration of service malfunctions and minimize financial losses.

Our framework consists of the following aspects of prevention processes:

- 1) Identifying potential service failures that may occur and articulating plans to resolve them in advance.

- 2) Allocation of resources and prioritizing necessary means to prevent service failures from occurring - The allocation of resources can also be decided on an economic basis: service providers can decide to invest in preventing only the failures that cause damages that surpass the costs of the resources, without taking into account downgraded service quality and reputation.
- 3) Key roles in the firm that should be informed about service failures that are prevented (major stakeholders within the airline, such as the CEO, technical experts and customer service managers).
- 4) Subsequent events that follow particular service failures and should be prevented.

Notification provides information about service failures to customers who are likely to be affected by it or to customers that the airline finds it important to alert about the problems and the major steps that are taken to solve them. Notifications may be delivered to customers in conjunction with the preventive operations that are carried out or may be activated after the prevention stage is completed. The proposed framework suggests that by applying notification in an automated way, the firm can address a large volume of customer calls in cases of widespread service failures. It is further suggested that firms should implement additional *active* notification systems that pro-actively contact customers and deliver notifications about expected service failures or failures that are discovered and can affect the operations of customers.

3. APPLYING THE PREVENTIVE SERVICE FRAMEWORK: PREVENTION OF POTENTIAL SERVICE FAILURES IN PASSENGER FLIGHTS

The most common passengers' complaints refer to the following categories (Weber and Sparks, 2004; Kim and Lee, 2009):

- Airline punctuality and convenient flight scheduling.
- Food quality and fulfillment of special meal requests (such as a vegetarian, Kosher or a children's meal).
- Proper and complete delivery and receipt of baggage at the flight destination.
- Cabin and check-in services.

Airlines can comply with a broad spectrum of service failures and malfunctions and prevent them by implementing proactive steps for monitoring and correcting service failures. The range of service processes and the failures associated with them begins when customers are ordering their tickets and ends when they leave the flight and collect their luggage. In general, the sources of service failures can be divided into three major groups: First, data on passengers or on airplanes are not streamlined between various information systems of the firm, resulting in maltreating customers despite the available information on their bookings and preferences. For example, a malfunctioning seat that is reported in the aircraft maintenance information system and is not removed from the ticketing system until it is fixed can create a problem to the passenger that purchased it and to the crew that should remove him to another seat shortly before take-off.

Second, passengers provide information via their bookings, but further know-how about their flight habits and needs that could ensure their convenience and satisfaction was not derived from their booking. For example, passengers that purchase children's tickets should not be allowed to choose seats near the exits, since children are not strong enough to open the exit doors in case of emergency. Hence, the ticketing system should prohibit choosing these seats when bookings that include a child are made so as to prevent the inconvenience of allocating different seats before the flight.

Third, due to lack of attention or mistakes of passengers or service providers, passengers are provided with inferior services than could have been supplied to them had these mistakes been automatically tracked and prevented. For example, if the passenger or the travel agent forgets to request special meals, the frequent flyer system can ensure via the purchasing history that the passenger usually consumes standard meals or otherwise contact the passenger before the flight to validate his choice.

Table 1 summarizes the various potential service failure events that can occur throughout the process of service provision in commercial passenger flights. As the various types of service failures do not depend on each other, airlines can choose to implement some or all of the proposed solutions to prevent them.

	Service failure description	Proposed solution
1	Unplanned flight delay - Delay of arrival to the destination and possibility of missing connection	Notification of passengers upon the event, the expected delay and instructions what actions should be taken. Preparation of dining and sleeping arrangement, if needed,

	flights	including passenger transportation.
2	Planned flight delay - Delay of arrival to the destination and possibility of missing connection flights	Notification to passengers about planned flight change (via SMS or phone). Rental of aircraft and crew, if needed. Frequent update of passengers.
3	Ticketing and seat allocation - Improper allocation of seats for babies, children and disabled persons by the ticketing system	Allocation of baby and parent seats by the ticketing system upon completion of a booking. Child seats would not be permitted next to emergency exits. Disabled persons ordering wheelchairs would not be seated next to emergency exits. Unavailability of seats due to technical problems requires notification of maintenance, temporarily removal from the ticketing system for upcoming flights and automatic allocation of alternative seats if purchased.
4	Flight manifest inaccuracies - Passengers do not appear in the manifest despite purchasing and receiving their flight tickets	Before flights automatically examining that the manifest and the passenger ticket purchases are identical. If mismatches were revealed, passengers would be provided with alternative seats.
5	Arrival of passenger luggage to a wrong destination	Receipt of contact details and address from passengers reporting luggage claims. Update of passengers via SMS or phone upon finding the luggage and coordinating its delivery. Installation of additional barcode readers in baggage compartments of airplanes to prevent wrong loading.
6	Flight time brought forward – Inconvenience and loss of Duty Free shopping time	Passengers are notified via SMS or by phone
7	Meals do not fit preferences of passengers (vegetarian, Kosher, etc.) due to travel agents' mistakes or passengers forgetting to specially order them	Automatic review of Frequent Flyer history can reveal mismatch between passengers' meal orders in the presence and in the past. Then, a company representative will call the passengers to ensure the accuracy of their present meal order.
8	Reduction of pre-flight waiting time	Luggage collection from the passenger's house (as a premium/standard service).
9	Animal transport – Lack of passenger's knowledge can impede the check-in process or would not allow transporting the animal.	Delivery of an email few days before the flight stating the procedures and requests in detail, including contact details of the airline's advisory veterinarian.
10	Confusion about the flight time due to mistakes and lack of attention	Redesign of the electronic ticket to highlight the flight date and time. Delivery of SMS with the flight details the day before.
11	General or specific seat malfunctions in the media system	Reporting the malfunctions to maintenance. Distribution of media players to passengers.

Table 1: Potential service failures in passenger flights and activities to monitor and prevent them

Among the various service failures that can be prevented by airlines, mismatch between passenger's meal preferences and the meal ordered for her (seventh category in Table 1) can occur due to mistakes in online booking or due to a travel agent's fault. This service failure can cause major inconvenience to passengers who cannot consume non-standard meals (due to medical or religious reasons), as most airlines offer them only if they were ordered before the flight. Fig. 2 exemplifies how this failure can be prevented by linking the various information systems and data sources of the airline. This process aims at ensuring that ordered meals match the preferences of passengers, indicated by data on their previous and recent flights. If no mismatch is found, the passenger receives by SMS his flight and meal details. Otherwise, an airline representative contacts the passenger to verify that the meal order matches her preferences and, if necessary, corrects it.

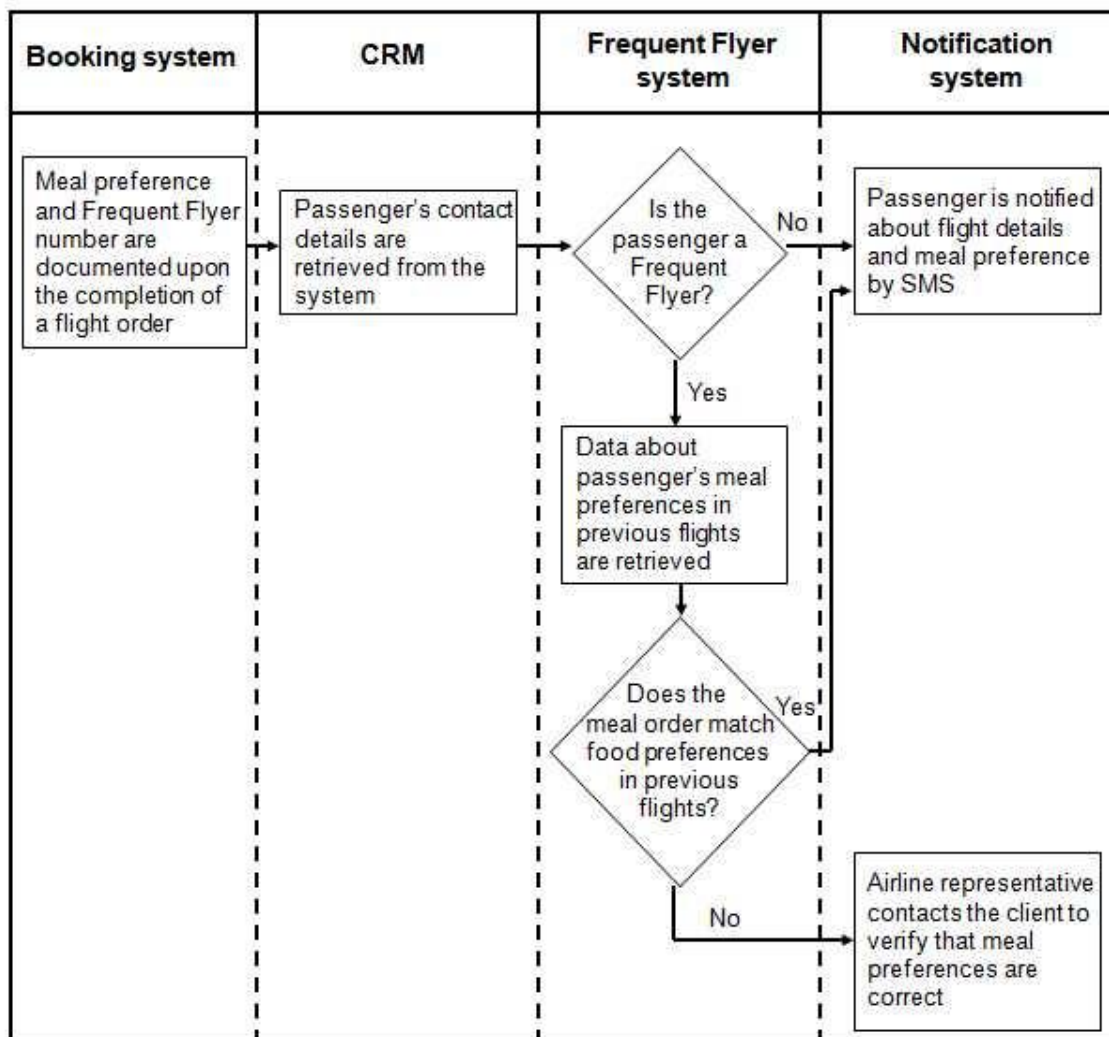

Figure 2: Preventing mismatch between meal orders and passenger preferences

4. CONCLUSION

The recent research literature on service and customer relationship management has largely focused on preserving customer satisfaction and addressing customer complaints as means for improving service quality. This paper takes a different approach towards the possibilities of improving the quality of services by proposing the preventive service management framework, which is based on monitoring the provision of services and eliminating potential service failures.

The airline industry was chosen to illustrate the application of preventive service management and its benefits as the operation of airlines and their revenues are largely based on the quality of services. Additionally, airline operations are sensitive to the emergence of service failures in multitude operations and contexts, for example as a result of technical malfunctions in aircraft cabin systems.

The presented methodology suggests that while the majority of services providing organizations, including airline companies, react to service malfunctions in an attempt to preserve satisfaction and loyalty of customers, service quality can be preserved in advance, hence sparing airlines the negative consequences of service failures. The methodology also advocates extensive use of information and communications systems. On the one hand, the use of information technologies enables airlines to enhance the degree and the quality of communication between them and their customers (e.g. by notifying them about their orders or any changes in the flight schedule). On the other hand, airline companies can produce larger value from data on aircraft procedures or about their customers' habits (e.g. by preventing ticketing of a broken seat or by identifying mismatch between an ordered meal and the customer's special food habits from past purchases).

Moreover, by using information and communications systems for automatic processing of information and for handling of potential service failure factors, airlines do not only enhance service quality but also substantially economize on labor and service recovery costs.

Abstract: *The subject of this work is exploring ways of traffic management by measuring the concentration of air pollution in urban areas. The goal of this research is to develop models of traffic management and air pollution. The method is based on air pollution 24-hour measurement and connecting monitoring stations with the Automatic Traffic Control System Centre. Based on the measuring results, signalling cycles are being activated in order to make city traffic diversion. In this way it is possible to manage air pollution in critical zones of the city and make traffic diversion to other city areas, which allows the improvement of air quality and pollution control within prescribed limits. Research results show that in the Case of Banja Luka City the air quality has improved 60 minutes after the suspension of traffic in endangered areas (city center). In order to maximize the effects of this method used for traffic management and air pollution control, it is necessary to define alternative city itineraries and implement a program of population education in due time. Results of this research can be useful for companies engaged in the manufacturing of specialized traffic management software and also help them create new specialized software for air pollution control and forecast.*

Key words: air pollution, traffic management, air quality, pollutant measurements, SAUS, APVJGP

1. INTRODUCTION

Economy, technology and car industry development caused the increased number of vehicles in urban areas. Environmental problems in urban areas of today are numerous, causing very serious health problems and influencing the psychology of urban living. In urban areas, such as Banja LukaCity, one of the main problems is undeveloped infrastructure. The Banja LukaCity has no roundabout. Two transit roads pass through the city causing the increase of the pollution. Technological aspect such as the structure of the city, taxi and vehicle traffic, type of vehicles, not implemented SAUS (System of Automated Traffic Management) and APVJGP (Automated Public Transport Surveillance) systems, partial air pollution measurement, bad traffic infrastructure (no separate lines for taxi and public transport) and finally climate and meteorological factors, have direct influence on air pollution.

Small traffic infrastructure and fairly old vehicles are just some of the elements causing the increased air pollution in the city. Air pollution is also caused by certain type of vehicles, in our case vehicles that are 15.7 years old (Euro 2 Standard), ([3]). The end result is ecology problems caused by increased pollution due to stop/go traffic waves and increased traffic during morning and afternoon rush hours. In order to solve the problem two possible solutions can be applied. The first is to set a traffic restriction which is not very popular solution for decreasing the air pollution in urban areas and traffic jams. The second is the method of traffic and air pollution control.

2. MANAGEMENT METHODOLOGY

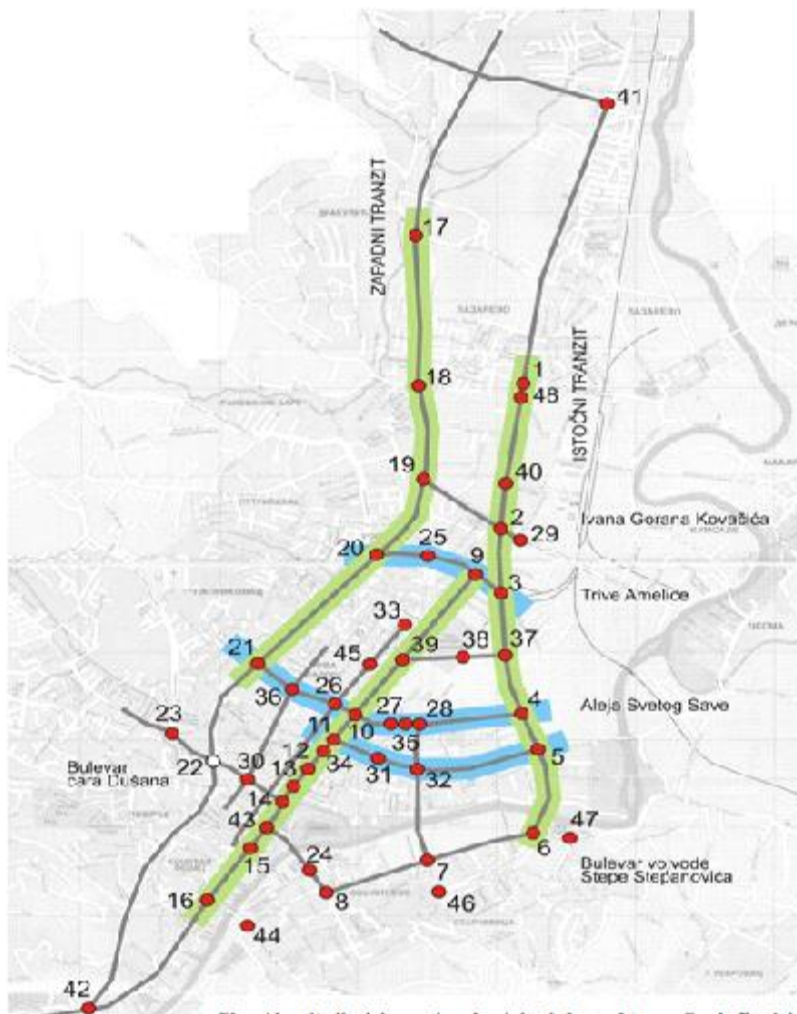

Air quality level in urban areas is determined by different geographical, climate, meteorological and other factors ([2]). Currently, the level of air quality in Banja LukaCity does not match health requirements, i.e. pollution has negative impact on its population. In general, measuring results of air quality in past 3 years indicate Second Class of air quality in Banja LukaCity area. Monitoring took place in 4 spots. Measuring results relating to pollution in the city centre (5th measuring spot) and measuring results relating to the pollution on no traffic day ([4], [6], [7]), show that the air quality keeps in range from Class I to Class IV., depending from the type of pollutant.

In order to apply the suggested methodology of traffic and pollution control, following actions are to be made:

- To install cable distribution system (DKR) throughout the city
- To integrate SAUS and APVJGP system
- To make a laboratory network for measuring the presence of each pollutant
- To install ArcGIS™ ESRI (Win/), Gis software-SelmaGIS
- To make professional teams for implementation of suggested actions
- To provide population education

3. THE ELEMENTS MODEL

DKR - Cable Distribution System represents an infrastructure system for data transfer and system management. This is very important issue because it also allows other elements of the system such as air pollution measuring units, air pollution street display etc., to be connected to data transfer system. For optical cable net (DKR), it is necessary to foresee a huge system which includes safety connections i.e. allows the system to function without the interruption.

Scheme 1: DKR - Cable Distribution System

The idea is to make the system work 24 per 7 and 365 days a year on online basis. Operating system must support audio or video data transfer i.e. alfa numeric information or services. It is of crucial importance to have this kind of system because it will allow the connection to the pollution monitoring network and sending information on current air pollution to street displays. In order to have emediate acces to all relevant dat,

SAUS system also must provide complete database of traffic and air pollution information as well as information on the other services.

SAUS system provides both location and graphic network preview i.e. georeference vector map of urban area including georeference chart of crossroads controlled by traffic light, parking and public garage area, street cabinets with active and passive equipment, street displays, pollution measuring units on video wall. A very important element of SAUS system is video surveillance of crossroads controlled by traffic lights and the detection. On specific locations it is necessary to install video cameras in order to achieve the following:

- Traffic and crossroad surveillance
- Driving direction of the vehicle detection (in case of driving wrong direction)
- Approaching of the vehicle detection
- Traffic jams detection
- Vehicle numbering
- Classification of numbered vehicles (it is the key element for pollution preview and the classification of pollutants is being done by Selma^{GIS} software)
- Lost cargo on the road detection
- Cross road and pedestrian surveillance

Video detection system provides detailed statistics for all required functions of detection cameras. It provides daily, weekly, monthly, quartal, 6-month and annual reports. All of this applies to air pollution statistics by pollutants). SAUS system architecture preview is given on Scheme 2.

SAUS system is advanced architectural information system for automatic traffic management (Scheme 2), that supports the following:

- reception, digitalisation and video formatting of the signal including the storage of all data related to video system and other peripheral elements such as temperature, air humidity and pollution level
- Broadcasting
- Data storage
- Client applications for video surveillance and system for independent diagnosis and maintenance

Monitoring and pollution measurement network consists of mobile EcoLabs that should be set on specific locations. Locations are determined based on traffic frequency i.e. spots with crowded streets and dense traffic during rush hours, when people are going to or coming back from work.

Monitoring and pollution measurement network is second phase in technical and organisational realisation of the model. Immediately after the realisation of SAUS system it is necessary to provide traffic counts on all crossroads and in a few iterations in order to get the exact figures of number of vehicles per hour or number of vehicles per crossroad. This will help define EcoLab locations for measuring of the pollution. [5]

Measuring Lab - APNA 370E, ([1]) has been used for continuous monitoring of atmospheric NO, NO₂ and NO_x. APNA-370 was selected because it uses an independent, internal dry-method to achieve the highest levels of sensitivity and accuracy. The dry method has been a preferred method for monitoring the atmospheric pollution, due to its minimal maintenance requirements and capability of continuous monitoring and instantaneous analysis of gas in its unaltered state. The APNA-370 uses a combination of the dual cross flow modulation type chemiluminescence principle and the referential calculation method. This gives it the advantages of the single-detector method plus the ability of continuous measurements of NO_x, NO, and NO₂. The design gives great stability and extremely high sensitivity (0.1 ppm F.S.)

APNA 370E is single rack-sized unit. For measuring of other pollutants such as CO, SO₂, O₃, LČ, ULČ, smoke and dust it is possible to connect mobile labs with the system.

LED panels are to be installed on city entrance and other city locations displaying different information but with its main purpose to inform the population about the level of the pollution (especially NO_x). LED panels are set on city entrances in order to give the information related to city traffic such as traffic jams, car accidents, directions, speed limit warnings, temperature (T °C), air humidity (rH %), air pressure (mb), etc. LED panels are matrix colour displays with 20 mm pixel distance which are resistant to moisture and other weather and climate factors.[5]

ArcGIS™ ESRI (Win/), GIS software-Selma^{GIS}

One of the most important elements of the model is the implementation of Selma^{GIS} software for graphic preview of pollutant emission on defined locations with mobile EcoLabs. Selma^{GIS} software is modular software supported by ArcMap™ as a part of ArcGIS™ ESRI information system Windows based [8]. User interface is Windows compatible and consists of:

- Emission Factory/Emission Database
- Digitizing Tool
- Meteorology Factory
- Terrain Factory
- AUSTAL2000

Figures for pollution emissions for each pollutant (NO₂, NO_x, PM10 etc.) in selected street can be obtained from Emission Factory SelmaGIS model. The system is used to determine pollutant dispersion in different seasons, vehicle structure which causes air pollution and meteorological conditions, type of source of air pollution (point sources: industries, energy production and heating industry), line sources (streets), diffuse sources (private heating, industries / energy production etc.). *AUSTAL2000* allows up to 300 x 300 grid points in the horizontal direction, i.e. the grid solution for simulation of region 25km x 25km.

Additionally AUSTAL2000 needs as physiographic parameters

- the topography height
- the aerodynamic roughness of the surrounding
- building information (building contours and building height)

AUSTAL2000 can treat the dispersion of the following gases: SO₂, NO, NO₂, NO_x (given as NO₂), Benzene, Chloroethane, Hydrogen Fluoride (given as F), NH₃, Hg

Meteorological conditions in defined area – When defining the model it is necessary to take into the account following meteorological conditions:

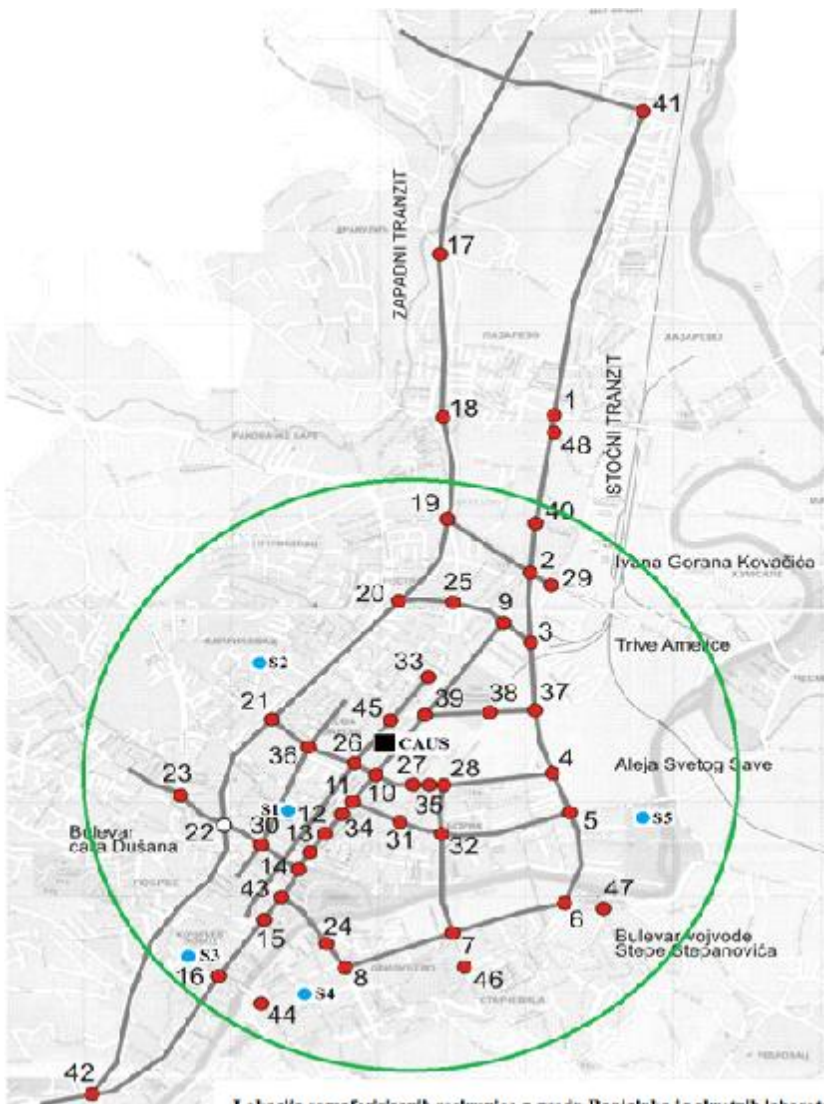

- Relative air humidity, (rH %);
- Air pressure, (mb);
- Wind roses, (direction, wind speed);
- Temperature, (C⁰)

Above given parameters are being taken from Hydrometeorological Institute of Republic of Srpska and have a great impact to pollutant emissions ([4], [6], [7]).

New public transport schedule, parking policy and raising the level of conscience of public transport users are of crucial importance for decreasing the air pollution up to 20%, in case of respecting public transport schedules. Constant reminding and education of the population allows rising of the level of their conscience and reducing the health problems caused by the pollution and increasing the percentage of using bicycle as a mean of transportation. New public transport schedule supported by SAUS has advantages such as pollution decrease, creating the pedestrian zones in the city centre and displacing parking areas out of the city centre to other urban areas. In order to finalize new public transport schedule it is necessary to change the old vehicles that are using liquid oil gas with new ones and, if possible, implement subway, tram or trolleybus transport system. The right means of transport should be implemented depending on the configuration of urban area and the financial resources and it is to be decided by the traffic performance study.

4. URBAN TRAFFIC MANAGEMENT BASED ON MEASURING AIR POLLUTION LEVEL

The method is based on air pollution 24-hour measurement and connecting monitoring stations with SAUS. (Scheme 2). Based on measuring results, signaling cycles are being activated in order to make city traffic diversion. This way it is possible to manage air pollution in critical zones of the city and make traffic diversion to other city areas, which allows the air quality to be improved and within prescribed limits. This method allows the implementation of automatic zero-zone i.e. no traffic zone in specific period of time.

Scheme 2: Traffic Management Model

The level of air quality in urban areas is determined by different geographical, climate, meteorological and other factors ([2]). Currently, the level of air quality in Banja LukaCity does not match health requirements, i.e. pollution has negative impact on its population. In general, measuring results of air quality in past 3 years indicate Second Air Quality Class in Banja LukaCity. Monitoring took place in 4 spots. Measuring results for city centre (5th measuring spot) and measuring results in during no traffic day ([4], [6], [7]), show that the air quality keeps in range from Class I to Class IV., depending from the type of pollutant.

Example: Bus line 14-9. This bus line covers the city center. As soon as pollution reaches its critical level with nitrogen dioxide concentration in the air, the SAUS system is to suspend bus lines 14-9 relocating the traffic to bus lines 14, 30, 22, 21, 20, 19 and 2. The measuring station (S3) that covers this line and city center is within SAUS system. Bus lines 21, 36, 26, 10, 27, 35, 28, 11, 31, 32 i 20, 25, 9, 3 would be suspended automatically and the traffic would be reallocated to bus lines 19, 2, 9 and to transit road lines , 2, 3, 37, 4, 5, 6, 7, 8, 24, 43, 15, 16, 42. City center would be covered only with city and taxi transport.

This was just a sample of city traffic organized based on pollution measurement results given by S1 station. Combining other measuring stations S2-S5 it is possible to make even more alternative itineraries depending on pollution level results. The most important element of traffic management is the infrastructure adjustment of city network necessary for alternative itineraries and pictogram plan for traffic allocation. Before the system is put into the function it is planned to conduct education campaigns in cooperation with the Ministry of Internal Affairs.

Measuring results on No Traffic Day (Scheme 3) and the day after (Scheme 4) during the period from September 22 to September 23, 2010

Scheme3:Results of measurements of nitrogen oxides in the day without traffic

Scheme4:Results of measurements of nitrogen oxides in the day with active transport

Years are determining second class of the air (Table 1). Taking into the consideration air pollution measuring hypothesis, measurements were done on the most frequent street in the Banja Luka City Center. Constant measurements are being done even during days with no traffic and in a specific period of time.

Table 1:Air Quality Classification

Pollutant Concentration in $\mu\text{g}/\text{m}^3$	Air Quality Class			
	Air Class 1 (low air pollution, relatively clear air)	Air Class 2 (risk zone)	Air Class 3 (high level risk zone)	Air Class 4 (critical zone)
SO ₂ (Sulfur Dioxide)	Up to 30	30 - 50	50 - 100	> 100
NO ₂ (Nitrogen Dioxide)	Up to 30	30 - 40	40 - 80	> 80
CO (Carbon Monoxid)	Up to 1000	1000 - 2000	2000 - 4000	> 4000
Black smoke or soot	Up to 20	20 - 40	40 - 60	> 60

Measurements being done on the day with no traffic and the day after with active traffic during the period from September 22 to September 23, 2010 ([4]) gave results as given in Table 1). Decrease of pollutants has been noticed during 2 hour period (10-minute measurements in 2010), especially nitrogen oxides. The values are double during the period with regular traffic. Scheme 4 and 5.

First Measuring Day took place on 22/09/2010 and it was the day with no traffic. An average NO₂ concentration during the measuring period was 28.232 $\mu\text{g}/\text{m}^3$. When comparing an active traffic and no traffic period the decrease of an average NO₂ concentration in the air was evident.

During 2-hour measuring period (no traffic period on 22/09/2010, 1100-1300) First Air Class was reached (zone of pollution border value with an average of $28.2325 \mu\text{g}/\text{m}^3$) with low polluted air, i.e. clean air. NO₂ concentration during a no traffic period was within both target and border value according to the Regulations of Border Air Quality Value ([5]).

Second Measuring Day took place on 23/09/2010 and it was the day of active traffic. An average NO₂ concentration during the measuring period was $45.282 \mu\text{g}/\text{m}^3$, maximum NO₂ concentration value $63.878 \mu\text{g}/\text{m}^3$. Based on the Decision of Pollution Air Protection in Banja Luka City ([2]), the air quality can be classified according to the following criteria:

During 2-hour measuring period (period of active traffic on 23/09/2010, 1100-1300)

3rd Class - High risk zone ([4]).

It is obvious that dense traffic in Banja Luka City Centre influences the air quality, which confirms NO₂ pollutant concentration during no traffic day measuring period. If we take a look at the graph with active traffic period results we can see that there is a significant increase of pollution with NO₂. The significant increase of pollutants is noticed even with other air pollutants.

If we make data crossing of time periods (with and without traffic, scheme 5) we can see that just after 60 minutes the air quality increases i.e.

Scheme 5: Crossed data measurements with and without traffic

This 60 minute period is a turning point when the air quality i.e. Nitrogen oxide NO₂ concentration level increases or decreases. Just after 60 minutes the air quality decreases to 2nd class. If we take into the consideration the fact that rush hours in Banja Luka City are between 07:00 and 08:00 and between 15:30 and 17:00, we can be safe to say that it is possible to manage air pollution efficiently both in the City Centre and other city locations, because the traffic infrastructure makes it possible. The highest level of air pollution was spotted in rush hour period between 15:30 and 17:00, when in short period of time large number of vehicles were on the streets. From the transportation aspect, it is necessary to coordinate alternative routes for vehicles. However standard itineraries for public and taxi transport would have stayed unchanged. In the AutomaticTrafficControlSystemCenter special itineraries would activate after the critical point, i.e. alternative lines for traffic redirection from the critical zone.

6. CONCLUSION

It is not completely possible to eliminate the air pollution in urban areas. However, it is possible to control it using air pollution measuring stations i.e. allocate polluted air throughout the city. With a support of networked measuring stations it is possible to make pedestrian zones (automatic pedestrian zone) between 1700 and 2400. This way the air quality could be improved to 1st class.

The air quality is determined by measuring results and its comparison to the standard, which helps define certain aims and take necessary steps such as:

1. Protection rate activation in critical situations (total traffic suspension using CAUS System, defining of pedestrian zone and Ecopass zone)
2. Population health risk estimation (traffic suspension)
3. Procurement of basic data for town planning (traffic infrastructure and itinerary planning)
4. Audit of citizen complaints on air pollution

Basically, air quality results taken on 5 different locations in past 3 years show that the air in Banja Luka City is of 2nd class. If we take into the consideration measuring results in S3 centre and the results on no traffic day (22/09/2010), the air quality vary from 1st to 4th class ([4]) depending on the type of pollutant. Finally, the results of the study show that it is possible to manage and control air pollution in urban areas.

Actions that can be taken in order to support these activities and help manage air pollution are closure of parking facilities in the city centre and supporting public and taxi transportation using price policies. Currently, the parking fee in the city centre is at least 5 to 6 times higher than in other city zones and restrictions on buses to remain in city centre other except on bus stations). Quality town management enables lower fuel consumption which decreases the pollution. The reason for that is that less time would be spent in searching for available parking space. Updated information on available parking spaces on public parking lots and public garages would be presented on crossroad displays and the data would be sent by Automatic Traffic Control System Centre.

Based on measuring station network it is possible to make pedestrian zone between 17:00 and 24:00 (implementation of automatic pedestrian zone) and this way improve the air quality to the 1st level. Decreasing the traffic frequency in the city centre would help bus and taxi drivers to drive on schedule, which would also decrease air pollution.

A study allows surveillance and present reading of air quality with immediate traffic dispersion in urban area. Also, the study shows that diagnostic analyses and air quality measurement depends on meteorological conditions. In this case, wind rose has a big influence as well.

Abstract: *The goal of this paper is to show possibilities of using Google Maps technology for the planning and realization of special events like mountaineering actions. Google Maps is a powerful, user-friendly managing tool which offers geographic information and gives possibility of choosing between various views such as Traffic, Map, Terrain and many others. The presented software features specification is divided into two packages. The first one consists of features which are important in the mountaineering actions planning phase, and the second one contains functionalities that can help in performing the action itself. Some of the presented features represent addition to the existing outdoor navigation software. While proposed functionalities are not supposed to support complex mountaineering expeditions which demand very serious pre-trip logistics and planning, they can be used as an auxiliary tool in some logistic segments.*

Keywords: *GoogleMaps, special event, mountaineering, planning, mountain hut, mountain peak, tracks*

1. INTRODUCTION

For performing all special events, especially hiking actions, the most important thing is good preparation and organization. In cruel conditions, like they are on mountain, you can never be sure that everything will go according to plan, but there is a way to largely control this situation. Using information and communication technologies you can speed up preparation itself and ensure quality plan execution. In that way you can predict and prevent many potential dangers which can occur in action performing. In this, we must note that, no matter how we planned all undertaking in detail, mountains still hide certain danger that can, more or less, violate the plan. Our plan can be great and worked out in detail, but there are things we can not affect in surroundings like these, primarily weather conditions but also other natural factors. The goal is not to eliminate situations like these, but to reduce its influence on minimum.

The reminder of the paper is structured as follows. Section 2 presents Google Maps technology through its main characteristics, additional technologies and different case studies. In section 3 we will define our problem for which we will use presented technologies and try to recognize all user requirements. In section 4 related work is discussed. Finally, Section 5 provides the conclusion and gives outlook of further research directions.

2. BRIEF OVERVIEW OF GOOGLE MAPS

Google Maps is a web mapping service application and technology provided by Google. This program is a virtual globe with a map and geographic information. You can view close up maps of any place in the world. This service is offering powerful, user-friendly mapping technology and local business information -- including business locations, contact information, and driving directions. Google Maps are flat maps that function within a web browser, and it offers several different views of the landscape, including Street, Traffic, Map, Satellite, and Terrain.

It was launched on February 8, 2005. Interesting thing is that Google Maps satellite images are not updated in real time; they are several months or years old. Google Maps uses a close variant of the Mercator projection, which is a cylindrical map projection that became the standard map projection for nautical purposes because of its ability to represent lines of constant course, known as rhumb lines or loxodromes, as straight segments. While the linear scale is equal in all directions around any point, thus preserving the angles and the shapes of small objects, which makes the projection conformal, the Mercator projection

distorts the size and shape of large objects, as the scale increases from the Equator to the poles, where it becomes infinite. If the earth were perfectly spherical, the projection would be the same as the Mercator. Google Maps uses the formula for the spherical Mercator, but the coordinates of features on Google Maps are the GPS coordinates based on the WGS 84 datum. The difference between a sphere and the WGS 84 ellipsoid causes the resultant projection not to be precisely conformal. The discrepancy is meaningless at the global scale but causes maps of local areas to deviate slightly from true ellipsoidal Mercator maps at the same scale. This difference maybe is not significant but consequence is not that meaningless. Because the Mercator projects the poles at infinity, Google Maps cannot show the poles. Instead it cuts off coverage at 85° north and south. This is not considered a limitation, given the purpose of the service because there are no roads at those latitudes.

Like many other Google web applications, Google Maps uses JavaScript extensively. As the user drags the map, the grid squares are downloaded from the server and inserted into the page. When a user searches for a business, the results are downloaded in the background for insertion into the side panel and map; the page is not reloaded. Locations are drawn dynamically by positioning a red pin (composed of several partially-transparent PNGs) on top of the map images. A hidden IFrame with form submission is used because it preserves browser history. The site also uses JSON for data transfer rather than XML, for performance reasons. These listed techniques actually represent Ajax techniques.

Google TECHNOLOGIES

There are many technologies based on Google Maps. In this paper we will mention just some of them.

Google Ditu - Chinese localized version of Google Maps and Google Local services. In order to be compliant with the requirements of Chinese law, Google had to remove or modify some Google Maps features in Google Ditu. Google Ditu does not allow overlay of user-generated content from Panoramio, YouTube, Wikipedia and webcams. Google Ditu shows the disputed border areas between China and India as being part of China, while on Google Maps those disputed areas are shown inside dotted lines.

Google Moon - displays the points of landing of all Apollo spacecraft to land on the Moon Google Mars.

Google Sky - an online space mapping tool that allows users to pan through a map of the visible universe, using photographs taken by the Hubble Space Telescope.

Google Rider Finder - displays the current location of all supported vehicles of the participating services in major U.S. cities, including Chicago and San Francisco, on a Google Maps street map.

Google Transit - public transport route planner, or we can say the service that calculates route, transit time and cost, and can compare the trip to one using a car.

Google Biking Directions - possibility to search for biking directions on Google Maps. Optimal routes are calculated from traffic, elevation change, bike paths, bike lanes, and preferred roads for biking. An optional layer also shows different types of biking paths, from bike-only trails to preferred roads. This service is available in the US and Canada.

Google Street view - provides 360° panoramic street-level views of various U.S. cities.

Google Aerial view - consists of angled aerial imagery, offering a "bird's eye view" of cities. This feature was available only to developers via the Google Maps API. In February 2010 it was introduced as an experimental feature in Google Maps Labs.

Google Latitude - feature from Google that lets users share their physical locations with other people. This service is based on Google Maps, specifically on mobile devices. Some concerns have been expressed about the privacy issues raised by the use of the service.

Google Flu Shot Finder - allows users in the United States to identify locations where both the pandemic H1N1/09 virus and seasonal flu vaccines are available near a given address or ZIP code.

MonopolyCity Streets - live worldwide version of the game Monopoly using Google Maps as the game board.

Google My Maps - lets users and businesses create their own map by positioning markers, polylines and polygons onto a map. The interface is a straightforward overlay on the map. A set of ninety-one pre-designed markers is available, ranging from bars and restaurants to webcam and earthquake symbols. Despite these, there is possibility to add your own markers. Polyline and Polygon color, width and opacity are selectable. Each element added to My Map has an editable tag which can contain text, rich text or HTML. Embeddable video and other content can be also included within the HTML tag. Created map you can embed into your Web site by copying and pasting map link into your HTML Page.

TECHNOLOGIES THAT CAN BE USED IN COMBINATION WITH GOOGLE MAPS

Google Maps has a great possibility and represents an astonishing discovery of 21st century. Even though, by combining it with other technologies, we cannot harm it, we can just improve it. In this section we will list only a few of many other technologies that can be used in combination with Google Maps. These can help us in export and import all important data from and into database, respectively.

Google Fusion Tables (or just Fusion Tables) is a Web service provided by Google for data management. Data is stored in multiple tables that Internet users can view and download. Google Fusion Tables lets you store, share, query and visualize data tables with pie charts, bar charts, lineplots, scatterplots, timelines as well as geographical maps. Data is exported in a comma-separated values file format. It offers a REST API to run SQL-like queries to manage tables (create, delete), manage data rows (insert/update/delete), and query the table for all rows that match spatial or data conditions. The results of queries can be a .CSV or used in the Google Maps API or Google Chart Tools.

Oracle Spatial forms a separately-licensed option component of the Oracle Database. Oracle Spatial aids users in managing geographic and location-data in a native type within an Oracle database, potentially supporting a wide range of applications — from automated mapping/facilities-management and geographic information systems (GIS), to wireless location services and location-enabled e-business. The spatial component of a spatial feature consists of the geometric representation of its shape in some coordinate space — referred to as its "geometry".

NEW SIGNIFICANT FEATURES

In 2011, Maps and Earth cataloged the massive earthquake in Japan, local businesses and museums joined Street View, and Maps went inside buildings to help you get your bearings in airports, shopping malls, and big box stores across the United States. The most significant features of Google Maps in 2011 are:

- Google Maps kicked off 2011 with some new 45-degree imagery for 10 U.S. cities, including Albuquerque, New Orleans, San Antonio, and Tucson. The 45-degree images in Maps are aerial photographs taken from a 45-degree angle that offer better views of a location than the grainy satellite imagery.
- After the devastating and subsequent tsunami that struck Japan, Google sprung into action to provide fresh satellite imagery of areas that had been heavily impacted.
- Google included a Person Finder to help locate displaced persons, as well as a collection of Google Maps with information about electricity black-outs, road conditions, and emergency shelter locations.
- After tornadoes ripped through the southern United States, Google added new satellite imagery to Google Earth and created a collection of tornado touchdown reports in Google Maps.

- New Place Pages feature that lets you take a 360-degree photographic tour of store interiors such as Nashville's Gruhn Guitars and Comics Toons N Toys in Tustin, California.
- Partnering with transit agencies in Boston, Portland, San Diego, and San Francisco, Google Maps in June launched a feature that let you find out if your bus or train was running on time in real time. Live transit updates let you see live departure times for your bus or train, as well as service alerts. Transit updates are accessible on your PC or on a mobile phone running Android 1.6 or higher.
- Google also added an extremely handy feature to Google Maps that let you download a specific map area to your Android mobile phone for times when coverage is spotty and you can't get online to access Maps.

CASE STUDIES

In order to improve their business, many companies have adopted Google Maps and other listed technologies. In this section we will mention just some of the most famous companies that became even better thanks to these technologies. Those companies are:

- **Tracker Fleet tracking** – leading provider of vehicle tracking with over one million security fleet telematics systems fitted in the UK enables customers to monitor and manage their fleets quickly and effectively Google Maps API was an effective way to make it easier for customers to view information about its vehicle fleets and wanted to investigate displaying historical data on maps that would traditionally appear in a written report or spreadsheet.
- **UniCredit** – one of Europe's largest banking institutions, wanted to add geolocation features to its website including a service to help customers find nearby branches, as well as a tool for linking users to information on the bank's products and services. In addition, they wanted to connect customers with consultant agents in different offices.
- **DHL** - as part of the world's leading logistics group, DHL implemented a mobile-computing system to fully utilize courier routes, reduce the carbon footprint of deliveries, and to improve its Express Same Day Service in UK. DHL used GPS technology to give dispatchers accurate, real-time visibility of courier locations. DHL Same Day chose Google Maps API Premier that lets corporate users build and integrate fully interactive Google Maps on public and internal websites. The couriers' GPS coordinates are now integrated into Google Maps and displayed on plasma screens in the service centers.
- **Toyota** – decided to create a pilot website which would be entirely optimized for mobile devices. The goal was to create a full mobile version of website instead of a scaled down, simplified version of the current website. Location-based services are one of the great advantages of the mobile internet, so they decided to use Google Maps on both main and mobile sites.
- **Apple** – this famous IT Company also added possibilities of Google Maps on their Web site. They use it for adding more useful information for every their store, such as: opening hours, exact address, description how to get to their store, driving directions.
- **Zipcar** –deals in renting cars in Boston and on their site you can find Zipcars near you with all types of cars that are available by entering your address, work address, best friend's address or neighborhood. You can also learn more about the cars, like how many groceries or friends you can fit safely inside.

There are many other companies that are using possibilities of Google Maps for various purposes. Such as fire break, determining how many of acres are affected, when evacuation has started and so on. Other companies are using it for trip planning. There you can see all viable transportations with evaluation of time arrival and cost for each elected type of transportation. You can also enter parameters that are important to you, for choosing adequate medium. Some of them are: minimum time, minimum transfers or minimum walking, acceptable walking distance, are you a person with special needs and so on.

3. PROBLEM DESCRIPTION

In this chapter we will see what is necessary for planning some special event, like mountaineering. We must note that as mountain climb is harder and more serious, that more logistics is needed.

Before departure itself, you should determine all information that is necessary for surviving in cruel conditions. Primarily you need detailed description of location. This is related to existential questions that concerns mountain hut, its structure, capacity, existence of drinking water and so on. The most important thing is to determine not only the distance between every point of interest (in further text POI) and place in which you are situated, but also all routes that lead you to the desired place. The point is not to choose any of existing routes, but to determine, depending on position, the best and the closest route that will take you to the final destination, whether it's mountain hut, water, parking place, mountain service, mountain peak itself or something else. Before departure you also need to know what the length of the route is and how many hours of walking is expected. Needed time primarily depends on age and physical predispositions of mountaineer, but also there are many other influential factors like weather conditions, season, group size, gender, etc. Considering all key influential factors you can predict needed time to conquer some mountain massif. The key element in situations like this is good communication. For navigation on those places, of great importance, is possibility of using GPS gadgets. Before departure itself you should examine ability to access GPS, signal quality, network coverage and availability of various services.

Considering previous exposure, we will state all identified user requirements:

- Defining POI (hut, peak, parking, mountain service, medical help, restaurant) and all important information
- Defining tracks
- Description of tracks that lead to mountain peak
- Evaluation of hiking time
- Length of route between two points of the segment

4. FEATURES DESCRIPTION

In this chapter we will present software features specification according to problem description given in previous chapter. We must emphasize that suggested solution is based on using Google Maps technology. Realization of features that we will give in this paper will provide quality planning and realization of mountaineering actions. These features represent addition to existing outdoor navigation software and not their surrogate. Proposed functionalities are not supposed to support complex mountaineering expeditions which demand very serious logistics and planning, but can be used as auxiliary tool in some segments of logistics.

Functionalities of this software can be divided into two packages. In the first package are features that cover mountaineering actions planning phase and the second consists of functionalities that can be helpful in performing action itself. In further text we will present all identified features.

Planning phase features (first package) consists of following:

- Defining POI types
- Defining POI (hut, peak, parking, mountain service, medical help, restaurant)
- Maintaining data about hut facilities
- Defining and maintaining information about peak approaches
- Maintaining approaches grade values
- Attaching GPS tracks to defined approaches
- Maintaining hiking time for approach route

Second package consists of following functionalities:

- Searching and displaying all tracks to the mountain peak that have intersection in defined diameter from actual GPS position
- Ranking of obtained tracks depending on given criterion which can be: minimal distance to the track switching point, the lightest weight track, the shortest hiking time remaining, etc.
- Getting information about time left from actual position to the peak. For this purpose embedded average hiking time table and weighting coefficients that depend on approaching grade value are used
- Getting information about number of left track segments, their grade value and estimated time left for their overcoming

Logical data model of presented solution is given in Figure 1. In data modeling process, extended entity-relationship technique is used.

950

For realization of defined features Google Maps will be used. All Geocoding and other information is stored in database with Oracle Multimedia (if we are using Oracle Spatial). Data can be displayed by reverse engineering addresses into Geospatial Co-ordinates using the Google Maps API. Hereinafter, are figures that describe how Google Maps can be used for displaying information about hut, peak and track.

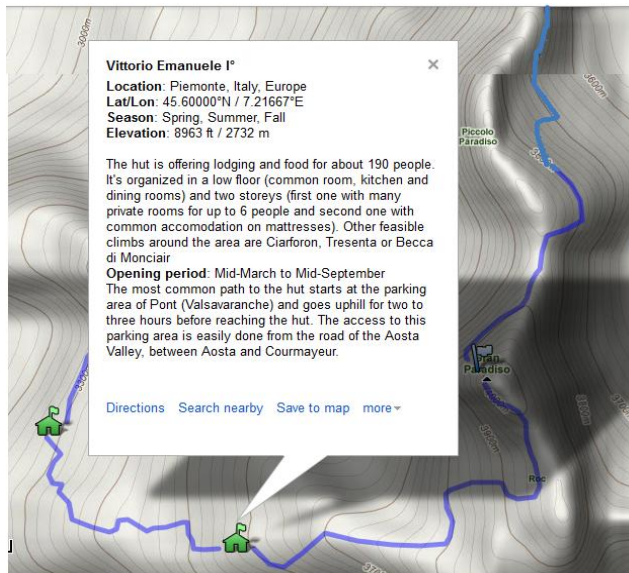

Figure 2: Info about mountain hut

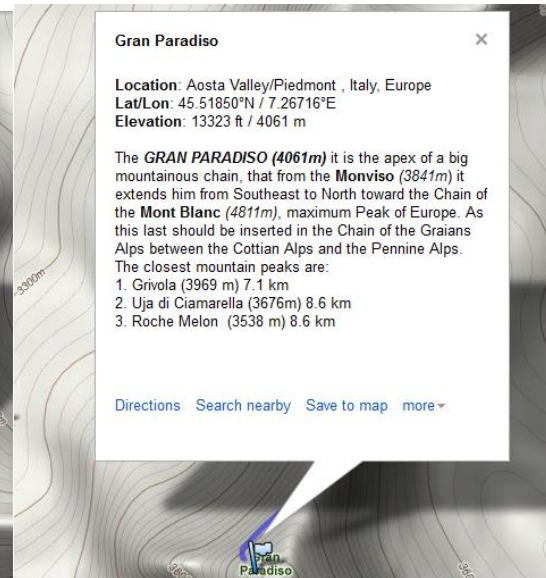

Figure 3: Info about mountain peak

On figure 2 are a couple of huts and defined peak. This figure presents all information that is important for the hut. Hut has its name, location (latitude and longitude), seasons in which it is available, elevation, short description and opening period. Figure 3 presents mountain peak. It has its name, location, elevation, brief description, and list of closest peaks. Blue colour is for tracks. On figure 4 is information about standard NW face route that leads from hut on figure 2 to peak shown on figure 3. Each route has total distance between two defined points, level of difficulty, track description and site for further information.

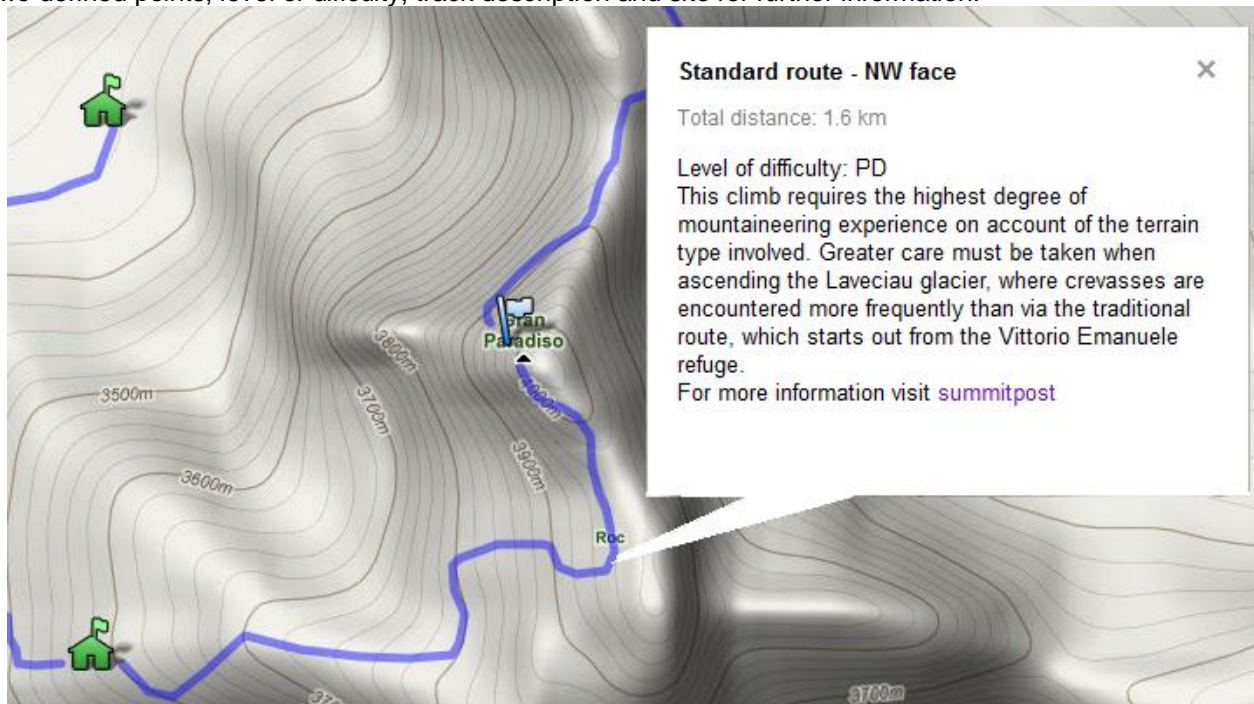

Figure 4: Info about NW face route from mountain hut to peak

5. CONCLUSION

The goal of this paper was to show possibilities of using Google Maps technology for planning and realization of special events like mountaineering actions. For defined problem and identified user requirements we have given software features specification and data model of presented solution. Our goal for the future is to improve suggested solution and to work on its realization. We do not want to replace existing outdoor navigation software, but to use its possibilities and add some new features that are important in planning and realization special events, in this particular case, mountaineering actions.

Abstract: *Information and communication technologies (ICT) in contemporary business are becoming an important means of creating and maintaining a long-term competitive advantage. On the other hand, multinational companies, being drivers of globalization and internationalization, implement ICT in their business strategies. This mode of operation leads to the creation of global markets and the internationalization of trade. The aim of this paper is to highlight the role that ICT play in the creation of global markets and the internationalization of trade. For this reason, the focus is on the innovations that are brought with the information and communication technologies, global market and trade conditions in the "new-to-digital" economy, as well as on the positioning of Serbia in terms of "digital" economy and information society. By using relevant statistical data, the goal is to determine where Serbia is in the implementation of ICT for business purposes.*

Key words: *information and communication technologies, global market, internationalization of trade, innovations, "new" economy*

1. INTRODUCTION

Market globalization and internationalization of trade marks the end of the 20th and early 21st century. Multinational companies (MNCs) as drivers of globalization recognize information and communication technology (ICT) as a resource for competitive advantage and increase business performance. Hence the effort MNC leader in the global ICT market to implement in business strategy, while recognizing them as agents of globalization. Internet adoption in MNCs leads to reengineering the entire supply chain, developing new business formats to trade in goods, services and capital. It is produced and traded to a business partner does not see. It affirms the concept of a virtual (electronic) transactions, electronic commerce, virtual supply chain, marketing and Internet marketing information systems on the Internet. Electronic commerce and electronic sales channels that were in the eighties mentioned in MNC visions "have brought" a new concept of business economics known as the "digital economy". "Old Economy" driven resource gives way to "new economy" (knowledge economy), whose main resource of knowledge - innovations and info. Furthermore, MNCs, former leaders of the "old economy", accept the challenges of the "digital economy" and develop electronic business. The degree of acceptance of ICT reveals the level of information (lack of) literacy and transnational cooperation "of national-international" stakeholders: owners, managers, employees, suppliers and society as a whole. Furthermore, the globalization of markets and internationalization of trade reveal (in) ability of local managers to implement ICT in marketing-management strategy. In terms of "new economy" open questions: how to position the national economy into regional and global economic integration? how to master the secrets of the Digital Agenda "information society" by the EU as a "pre-accession commitment," the candidate countries for entry into its market? And how to master the secrets of "network economy" as a polygon in which MNCs "measured" force "global player"? The European Union is still in the framework of the Stabilization and Association Agreement (SAA), recognized the insufficient development of ICT in Serbia, as a limiting factor for the development of "information society", on the one hand, and Web-digital economy, on the other. To this end the EU's economic policy makers in Serbia set up a digital "tasks" including pride of place belongs to the development of the concept of electronic commerce, "the digital-Internet (Web) economy" and "information society". As the Serbian, the first of March 2012, granted candidate status for EU membership, and the Digital Agenda Project "informational society" becomes priority number "one".

2. INFORMATION AND COMMUNICATION TECHNOLOGIES – A PREREQUISITE FOR INCREASING THE COMPETITIVE ADVANTAGE OF COMPANIES IN CONDITIONS OF GLOBALIZATION

Modern information and communication technology (ICT) and their use in operations of multinational companies (MNCs) and other operating system feature of the globalization in the 21st century. The

development of microelectronics, production and use of computers enabled the transition of industrial society to information society. With the development of ICT leads to convergence of traditional forms of international business operations carrier, on the one hand, and computer science, on the other hand. Multinational companies seeking the possibility of diversification of business has been recognized ICT as factor in raising the competitive advantage. Hence the efforts of companies in the global market leader that implements ICT in business strategy while recognizing them as agents of globalization. Government and management of MNCs countries try to encourage the development of innovative activities in electronics and communications.

2.1. INNOVATIONS WERE BRING BY INFORMATION AND COMMUNICATION TECHNOLOGY

Scientific and technical progress in the field of micro-electronics and applications of information and communication systems, such as: EAN system (European Article Numbering), scanning (bar codes), and a computerized collection of the so-called point of sale. POS (Point of Sale System), electronic transfer of funds so. EFTPOS system, electronic payment cards, electronic transfer and exchange of business data so. EDI (Electronic Data Interchange), electronic transfer and standardization of business documents so. EDIFACT (Electronic Data Interchange for Administration, Commerce and Transport) and the SWIFT system (Society for Interbank Financial telecommunication), leading to the re-engineering of the international carrier business, affirming the concept of global information and communication strategy.(Chaffey, Mayer, Jolnoston, Ellis-Chandwick, 2000)

With the development and implementation of Internet, multinational companies recognize the information-communication innovation as a resource to increase competitive advantage and business performance in the global market. Internet adoption in MNCs leads to reengineering the entire supply chain, developing new business formats to trade in goods, services and capital. It is produced and traded to a business partner does not see. It affirms the concept of a virtual (electronic) transactions, electronic commerce, virtual supply chain, marketing and Internet marketing information systems on the Internet.(Turban, Mc Lean, E., Wetherbe, 2003)

Electronic commerce and electronic sales channels that were in the eighties mentioned in the visions of MNCs "spawned" a new concept of business economics known as the "digital economy". "Old Economy" driven resource gives way to "new economy" (knowledge economy), whose main resource of knowledge - innovations and information. Furthermore, MNCs, former leaders of the "old economy", accept the challenges of the "digital economy" and develop electronic business (e-business Eng.). It is the "displacement" (transfer) of the traditional business functions: purchasing, sales, logistics, physical distribution, marketing, finance, customer services, and cooperation with business partners on the Internet. Electronic procurement and sales overcome spatial and temporal barriers; MNCs and management with emphasis on marketing information system (MIS) to inform consumers about the properties of the "package deals" that can satisfy their needs, desires and expectations. Through large and expensive projects, such as: a) Business-to, business (B2B commerce between business systems), which includes not only business between parent companies and subsidiaries, but also other companies and supporting entities such as banks, insurance companies, customs, shipping organizations, financial institutions, etc.), b) Business-to-consumer B2C. This model of e-business is focused, mainly, on the sale marketing products and services. The best-known company of its kind in the world is Dell, Amazon-com, e Bay, c) Business-to-Administration B2A, d) Consumer-to-Administration C2A. This, the model is increasingly promoted by the European Union to reduce the complicated administrative procedures between administration-citizens. He served makers "global society" as a platform for the development of "information society", e) Consumer-to-Consumer C2C f) Consumer-to-Business C2B. Example of e-business model was developed by Price.Line.com where the customer says the price at which to buy the product, and the seller is trying to deliver the product in accordance with the request, g) Government-to-Consumer G2C (government to citizens and others). In this model, e-business recognizes the desire by the Government (Administration) of the developed countries to a global society and make the information developed "in hand" approach to all.(Clinton, Gore, 2000)

This does not exhaust the list of innovations that bring with them information and communication technology. Along with information and communication reengineering of production and transfer of the global market sphere there is a kind of electronic revolution in the financial market. Based on EDI and the Internet promotes the concept of electronic financial markets, and in the forefront of electronic exchanges. Trading on the stock exchange is carried out based on a software-hardware package. Formed a sort of reversal of spreading primarily personal computers and then connect them to the Internet as a global communication

medium. Information and communication technologies broke the physical, linguistic and administrative barriers in the movement of goods, services, capital and labor in the global market.

3. THE GLOBAL MARKET IN CONDITIONS "NEW-DIGITAL ECONOMY"

Chronologically speaking, the process of globalization of markets and the internationalization of trade carried out in phases. Leaving aside this time in an exhaustive listing of the most important carrier (driver) globalization-internationalization, the different stages of development we intend to look at the final stage of which is the "seal" the "new economy".

Are there new managers for the "new economy"? With the development and application of ICT and novelty that brings scientific and technical progress and changing the nature of conducting global business. Computers and electronics modify the current traditional business and marketing-management skills. Development and application of the Internet in the late 20th century affirms the concept of electronic (virtual) business and the new managers for the Internet "digital economy" parallel changes in the nature of global competition on the market. Besides price and quality of goods and services comes to the fore and the implementation of marketing innovations that bring with them information and communication technology. Multinational companies are becoming promoters of modern information and communication systems and the "masters" of the global market. Electronic data interchange and business documents based on EDI and the Internet has enabled multinational companies to connect with their affiliates, on the one hand, and business partners and subcontractors across the globe, on the other. It creates a model of "network economy".

The term "network economy", "digital economy", "knowledge economy", is used to refer to "postindustrial society". These are concepts ("landmark"), which separate the "old economy" (resource-driven economy), and "new economy" (knowledge-driven economy and information). Furthermore, in theory a few years ago started using the term "new economy". (Milovanović & Veselinović, 2009) It is a young (tentatively named) new scientific paradigm to explain the whole range of economic, social and cultural changes brought with them the information and communication technologies, where pride of place belongs to the Internet. Rarely characterized in textbooks, technical papers, in scientific meetings, the term "new economy" there are different interpretations of this phase of globalization. The literature has not yet crystallized attitude, whether the "new economy" or is it just a new phase of development of the current economy.

Leaving aside other aspects of the "new economy" (socio-cultural, environmental and ethical), as a permanent current topic, we can say that the innovation that brings scientific and technological progress of the most recognizable determinant of economic phenomena. Seen from this perspective the "new economy" is a qualitatively higher level (benchmark) "old economy". It served Pjatkovskom (2009) to the question of whether there is a "new economy" answer "if we agree with the fact that economic growth is still largely based on the traditional economy, then we can say that the" new economy "in the true sense of the word does not exist ". (p. 396) However, if the other "new economy" look like a set of economic phenomena and mutually conditioned processes based on IT technology, which means new ways of doing business and further economic development, then we can say that there is a qualitatively different pattern of economic development. This definition links the "old" and "new economy" in the sense that the "new economy" is still just a form of expression of technological and economic development. Another group of theorists led by Gordon (2009) believes that the term "new economy" will always be written in quotation marks because it does not exist as such. (p. 397) There are only new production technology and distribution that each time a qualitatively different impacts on the way this business. According to them faster economic growth in the U.S. in late nineties of the 20th century is the result of "new economy" has increased productivity in the sector of information and communication technologies, supplemented by cyclical effects of higher levels of investment.

It can be finally concluded that the ICT architect of the "new economy". The challenges of ICT are accepted by multinationals companies, the leaders in the global market. Due to the different pace of implementation of ICT in business strategy leads to technological and economic gap between the companies. The differences are more noticeable if the development and application of technological innovations seen at the global level. The digital divide that already exists between the developed North and the underdeveloped South, will lead to further technological and economic divide between these countries. Generators "new economy" and lead to the division of the company globally recognized companies and parochial type. Through this prism, and in terms of further penetration of ICT should consider the future trends of globalization.

4. TRADE IN THE ERA OF "NEW-DIGITAL ECONOMY"

With reference to contemporary theory and practice, we see that the progressive development of the ICT is coming closer to the international carrier business, on the one hand, and ICT, on the other. Multinational companies recognize ICT as a factor in raising the competitive advantage and improve business performance. Hence the effort MNCs, global market leader is in implementation of the (ICT) in business strategy and promoting themselves as the creators of the "new economy". (Daning, 1998)

Development and application of the Internet leads to a kind of global business reengineering. Multinational companies internationalize their operations affirming the concept of electronic (virtual) business. There is a virtual transfer of business of MNCs. Parent companies open their branches (daughter companies) around the world, where the spatial distance business partner is no longer a limiting factor in business.

4.1. "MOVING" RETAIL NETWORK TO THE INTERNET

Modern ICT abolishes the last geographic barrier between the participants in the global business. Information and communication technologies and their services, such as the Internet becomes a platform on which the traffic of goods and services. Retail chains leaders "traditional economy" such as Wal-Mart, Marks & Spencer recognize ICT as an important determinant of internationalization of trade in the era of "digital economy". (Turban, McLean, Wetherbe, 2003) It comes to the "migration" of the retail network in the traditional trade institutions to the Internet. These retail chains develop the retail network "brick and mortar" and open Internet e-store, known as retail sales on a "click and mortar". Commodity exchanges are digitalized. Information and communication technology and standardized trading rules internationalize the stock market trading. (Dugalić, Štimac, 2005) Thanks to ICT London Metal Exchange has become a global stock market. Internet-Web economy has made the London Metal Exchange to trade on her "accredited" electronic brokers from around the world. On this basis, trade moves from mechanical to electronic Internet-stage development. This does not exhaust the list of innovations that ICT brings. It develops and occurs: e-money, e-payment card, e-check, e-payment and e-business documents (purchase orders, invoices, records of quality and quantity of goods receipt, goods and documentary letter of credit, customs declaration, etc.), which increasing the competitive advantage of companies in the global market.

Digital Economy (the "new economy") requires change-management and marketing skills. It affirms the concept of electronic (Internet-virtual) virtual marketing and management. (Kolaković, 2011) Network Economy becomes a global range within which MNCs "weigh" their forces. The national competition's authenticity "tests" the global test site. In other words, the global market is becoming a national evaluator of business strategy. In the global market is checked and implementation of ICT strategies in the marketing strategy of the business system. In doing so, we must not forget the fact that ICT reversed model "parochial" production and trade. New ICT reveal the level of information (lack of) literacy of local stakeholders: owners, managers, employees, suppliers and society as a whole. Therefore, the appearance (exit) of local managers in the global market easily reveals their (un) preparedness for the implementation of ICT in national business strategy. Examples of this abound. One of the key is the digital divide between the developed North and the underdeveloped South.

Financial markets, financial institutions and financial conditions of the participants in the "digital economy" given the epithet of "virtual". Stock Exchange becomes a virtual financial "conglomerates" in which electronic trading brokers from different web sites. Distances financial student is no longer a limiting factor in the business, came to the fore of the global strategy of the financial markets.

5. SERBIAN SECRET TO MASTERING THE "NEW ECONOMY" AND THE INFORMATION SOCIETY

Digital processes re-engineering of all areas of business are present in the world and the EU more than half a century. Innovation that brings scientific and technical progress has changed the traditional way of conducting all business activities have. Pride of place in the digital re-engineering of the national and global socio-economic scene was given to ICT. With the development of the Internet as the latest phase of information-communication restructuring "traditional model" of life and work, changes and socio-cultural view of society. It promotes the concept of information society on the one hand, and the world becomes a "global village", on the other.

Depending on the level of ICT in business, is the differentiation of national economies in the following directions:(Porter, 2000) a) Globally oriented economy, b) regionally oriented economy, and c) Locally

oriented economies. The global decentralization of socio-economic activities will be digitally literate privilege which would exclude from the regional and global socio-economic information and unprepared scene of the national economy, in this case, the national economy from the group c.

Through this prism should be considered and the development of information society in Serbia. It is a national project to harmonize our information and communication infrastructure with the "Digital Agenda". The development of ICT, electronic communications and their implementation in the socio-economic development strategy of the Serbian society is one of the EU requirements.

The European Union has recognized the insufficient development of ICT in Serbia as a limiting factor for the development of "information society", on the one hand, and Web-digital economy, on the other. The development of digital communications and information society is an important factor to increase national competitiveness and improving the business climate and quality of life of citizens. To this end, EU economic policy makers in Serbia following sets of digital "tasks" as follows: (Izveštaj Svetske banke, 2009) 1) digitization of telecommunications infrastructure, 2) that the Internet is widely available, 3) fast, cheap and secure Internet, 4) development of broadband Internet, 5) Web development economics, 6) the introduction of digital television, 7) development of the industrial sector of electronic communications equipment, 8) development of mobile services, 9) the introduction of number portability, and 10) effective access to information and knowledge.

This does not exhaust the list of EU demands Serbia on the path to mastering the secrets of the "information society" and the "digital economy". It is necessary to market liberalization of fixed telecommunications network and the elimination of "double" as a bottleneck of information and communication environment. Emphasizes the development of broadband Internet access, because the current data, only 6.36% of users using this approach, which is below the EU average (23.9%). The development of "information society" and the "digital economy" requires change of public, utility and real sectors. It involves the use of ICT in the following areas: a) Public administration (e-government), b) Health (e-health) c) Judiciary (e-programs sponsored), d) Education, science and culture (e-science and e-culture), e) Distance learning (e-learning).

A special segment of "information society" and the "digital economy" is a national concept development of electronic commerce. Feeling is the best person for the development of the concept of electronic commerce Ministry of Commerce of Serbia within the project "Strategy and Trade Policy of Serbia," (Grupa autora, 2009) a special emphasis placed on the development of this new segment-digital economy. Emphasis is placed randomly on the development of e-commerce. Reasons for this are more. Primarily, the internationalization of trade and globalization of markets is impossible to imagine without the instrumentality of ICT in the marketing strategy of retail chains. Electronic trade models, such as (Ćuzović & Ivanović, 2010) B2B (Business-to-Business), B2C (Business-to-Consumer), B2A (Business-to-Administration), C2A (Consumer-to-Administration), C2C (Consumer-to-Consumer), C2B (Consumer-to-Business), G2C (Government-to-Consumer), P2P, make the platform on which the traffic of goods-services-capital-information in international business. Computers and electronics are becoming the architects of the "new digital-trade."

Bringing the end of the discussion on this topic should be said that in Serbia, created institutional conditions for the development of "information society" and the "digital economy". When you speak, especially bearing in mind that Serbia has adopted the Digital Agenda: (Grupa autora, 2010) 1) Development Strategy of electronic communications in 2010. Until 2020, 2) Strategy for Information Society by 2020, 3) development of e-government strategy for the period 2009-2013., 4) Law on Electronic Commerce, 5) Law on Electronic Signature, 6) Law on Electronic Documents, 7) Law on secrecy, 8) data Protection Act and the personality and 9) Act on Organization and Jurisdiction of the fight against high-tech crime.

It is the harmonization of our socio-economic environment with the requirements of the Digital Agenda of the EU "Information Society" and "digital-Internet economy." For the implementation of the Digital Agenda Serbia estimated the amount of five billion Euros.(Grupa autora, 2010) Funds for implementation of these projects will be provided by international organizations, donations, and through public-private partnership.

5.1. POSITIONING OF SERBIA IN CONDITIONS OF "NEW ECONOMY" AND INFORMATION SOCIETY

Speaking of the "Information Society" and "digital economy-Web economy" in Serbia is not possible without the answers to these questions, like: what is the level of development and application of the Internet? Where Serbia is today in terms of implementation of the Internet for business purposes? After the answers to these

questions, we will try to look at digital-Internet positioning Serbia to the EU, on the one hand, and Global positioning on the other hand.

Starting from the research objectives in the following presentation we will try to rely on the available empirical-statistical data look "digital-Internet" positioning of Serbia in the EU and the global environment.

Table 1: Overview of the population of Internet users by region in the world

Region	Population (2011)	Users of Internet (31.12.2000.)	Users of Internet (2011.)	Users of Internet (in %)	Increasing of users of Internet (2000-2011)	Users of Internet by regions
Africa	1,037,524,058	4,514,400	118,609,620	11.4 %	2,527.4 %	5.7 %
Asia	3,879,740,877	114,304,000	922,329,554	23.8 %	706.9 %	44.0 %
Europe	816,426,346	105,096,093	476,213,935	58.3 %	353.1 %	22.7 %
Middle East	216,258,843	3,284,800	68,553,666	31.7 %	1,987.0 %	3.3 %
North America	347,394,870	108,096,800	272,066,000	78.3 %	151.7 %	13.0 %
Latin America	597,283,165	18,068,919	215,939,400	36.2 %	1,037.4 %	10.3 %
Australia	35,426,995	7,620,480	21,293,830	60.1 %	179.4 %	1.0 %
Total	6,930,055,154	360,985,492	2,095,006,005	30.2 %	480.4 %	100.0 %

Source: <http://www.internetworldstats.com>

According to estimates, about 30% of the world uses the Internet population. This number is significantly higher if the watch-developed regions of the world, such as North America, where 78.3% of the population uses the Internet, Oceania (Australia), where 60.1% of the population uses the Internet, and Europe where 58.3% uses Internet population. In less developed countries, the percentage of Internet users rarely exceeds 20% of the total population. However, most Internet users today are located in Asia, about 44% of the total number of users worldwide. This is partly explained by the fact that Asia is a continent with the most population, but it is the percentage share of Internet users in relation to the total population far behind North America, Oceania and Europe. Also, many underdeveloped regions have high rates of growth of the Internet, which can be partially explained by the statistical phenomenon of a low base. It speaks to their importance to use the Internet to grow in the future. (Bjelić, 2008)

The most important limitation of the number of Internet users worldwide continues to represent the costs to invest in equipment to connect to the Internet infrastructure. In addition to computers and need to find appropriate software to enable Internet access, as the very poor strata and remains an obstacle. However, widespread use of cell phones, even in the poorest regions of the world, and allows the use of Internet services. This is one of the reasons for the increase of Internet users, even in underdeveloped parts of the world. (Bjelić, 2008)

Table 2: Users of Internet in EU

Region	Population (2011)	% of world population	Users of Internet (2011.)	Users of Internet (in %)	Increasing of users of Internet (2000-2011)	Users of Internet by regions
European Union	502,748,071	7.3 %	338,420,555	67.3 %	258.5 %	16.2 %
World without EU	6,427,307,083	92.7 %	1,756,585,450	27.3 %	558.9 %	83.8 %

Total	6,930,055,154	100.0 %	2,095,006,005	30.2 %	480.4 %	100.0 %

Table 4: Users of Internet in the candidate countries for EU accession

The candidate countries for EU accession	Population (2011)	Users of Internet (2011.)	Users of Internet (in %)	Increasing of users of Internet (2000-2011)	Users of Internet in Europe
Croatia	4,483,804	2,244,400	50.1 %	1,022.2 %	0.5 %
Island	311,058	301,600	97.0 %	79.5 %	0.1 %
Macedonia	2,077,328	1,057,400	50.9 %	3,424.7 %	0.2 %
Montenegro	661,807	294,000	44.1 %	n/a	0.1 %
Turkey	78,785,548	35,000,000	34.9 %	1,650.0 %	7.3 %
Total	85,657,738	38,603,400	34.9 %	1,509.8 %	8.2 %

Source: <http://www.internetworldstats.com>
Table 5: Users of Internet in Serbia

Country	Population (2011)	Users of Internet (2011.)	Users of Internet (in %)	Users of Internet in Europe
Serbia	7,310,555	4,107,000	56.2 %	0.9 %

Source: <http://www.internetworldstats.com>

In Europe, 58.3% of the population uses the Internet, which is less than in North America and Oceania. Looking at the most developed countries of Europe, the countries that make up the European Union, we can see that the percentage of people who use the parking it is 67.3% and 16.2% of all Internet users worldwide. The percentage share of Internet users in the total population in the EU may be important also to notice the difference. On the one hand, as Sweden with 92.4%, Netherlands with 88.3%, Denmark with 85.9% as the country where the highest percentage of Internet users. On the other hand is Romania with 35.5%, 38.7% from Cyprus and Greece with 46.2% as the EU member states that have the least percentage of Internet users in relation to the total population. If we look at the candidate countries for EU membership, we note that Iceland leads the world in the percentage of Internet users in relation to the total population, even with 97.0%, followed by Macedonia with 50.9%, 50.1% from Croatia, Montenegro with 44, 1%, and at the end of Turkey with 34.9%. Compared with the candidate countries for EU membership, and some newer EU member, Serbia with 56.2% of Internet users in relation to the total population has a good basis that this number will soon be above European average.

6. CONCLUSION

Modern information and communication technology (ICT) and their use in operations of multinational companies (MNCs) and other business systems lead to the globalization of the seal of the 21st century. Multinational companies seeking the possibility of diversification of business has been recognized ICT as a factor in raising the competitive advantage. Scientific and technical progress in the field of micro-electronics and applications of information and communication systems, such as: EAN system, scanning (bar codes), POS, EFTPOS system, electronic payment cards, EDI, EDIFACT and SWIFT system, leading to the re-engineering of carrier international business, affirming the concept of global information and communication strategy. When it comes to our country, the European Union has recognized the insufficient development of ICT in Serbia as a limiting factor for the development of "information society", on the one hand, and Web-digital economy, on the other. The development of digital communications and information society are a significant factor in increasing national competitiveness and improving the business climate and quality of life of citizens. To this end, EU economic policy makers in Serbia following sets of digital "tasks" as follows: 1) digitization of telecommunications infrastructure, 2) that the Internet is widely available, 3) fast, cheap and secure Internet, 4) development of broadband Internet, 5) Web Development Economics, 6) the introduction of digital television, 7) development of the industrial sector of electronic communications equipment, 8) development of mobile services, 9) the introduction of number portability, and 10) effective access to information and knowledge. Starting from these requirements, in Serbia are created institutional conditions for the development of "information society" and the "digital economy". When you speak, especially bearing

in mind that Serbia has adopted the Digital Agenda: 1) Development Strategy of electronic communications in 2010. Until 2020, 2) Strategy for Information Society by 2020, 3) development of e-government strategy for the period 2009-2013., 4) Law on Electronic Commerce, 5) Law on Electronic Signature, 6) Law on Electronic Documents, 7) Law on Secrecy, 8) Data Protection Act and the personality and 9) Act on Organization and Jurisdiction of the fight against high-tech crime.

RATIONALIZATION OF POSTAL NETWORK IN SERBIA USING INFORMATION TECHNOLOGY⁶

Ivan Tričković¹, Dragana Šarac² Ivana Bajić³

¹Faculty of Technical Sciences in Novi Sad, ivantricko@gmail.com

²Faculty of Technical Sciences in Novi Sad, dsarac@uns.ac.rs

³Faculty for Traffic and Communications Management, Berane, CG, ivana.bajic@fmsk.me

Abstract: *The development of technology leads to changes in people's daily communication. The Internet and mobile phones have become the communication tool of the modern man. New ways of communication are redesigning interfaces for providing postal service. Such advances in technology should be monitored because they could completely change the current way of conducting postal services. This work is about implementation possibilities of informational technologies in the process of postal network rationalization.*

Keywords: *post, information, technology, virtual, counters, network, rationalization*

1. INTRODUCTION

Idea of implementing information technology in the post, so far, was about post operability and increasing the availability of financial services to existing clients. Former applications of these technologies have not increased the availability of postal network units. Since 2003 the number of posts in Serbia has not significantly increased. Due to unprofitability problems of postal network in rural areas, post offices are being shut down and postal service reduced.

New trends in the development and providing of universal postal services impose the need to increase the number of posts and regular provision of postal services throughout the territory of the country. This is of course a challenge for the universal service provider, in Serbia that is the Post of Serbia. One of the solutions that is imposing is the use of IT in the realization of virtual post counters in rural areas. If we know that 70% or more costs of the operator are labor costs, then solutions with virtual counters are acceptable.

Introduction of virtual counters can significantly increase availability of postal network. By implementing a virtual post counter, users would constantly be served 24 hours, 7 days a week, regardless of postal office hours. The question arises whether all postal services may be provided in electronic format. Many of the services are established through the implementation of physical activities: supply and delivery of postal items. However, interfaces can change from the extent that the letters could be converted into electronic form to the extent of ensuring full postal service that allows physical receipt and delivery of mail.

2. INFORMATION TECHNOLOGY AND POST

Automation of technological processes in post offices, took place gradually. In 2009 were automated nearly all the post offices in Serbia, as shown in Chart 1.

⁶This paper is derived from research within the project funded by the Ministry of Education and Science of the Republic of Serbia, under the name of "Reengineering the operator network of the universal postal service, with the organizational synergy of governmental and economic resources" (TR36040)

Chart 13: Postal Automation

Post of Serbia, was the pioneer in introducing new advanced technologies. Information technology in Post of Serbia was introduced among the first in the world. Historical overview of information technology in the Post of Serbia is given in Table 1.

Table1: Implementation of information technology in Post of Serbia

Period	Implementation
1929-1950	1929. First of franking machines "Francotyp" in Belgrade.
1950-1960	1950. Franking machine "Hasler" and "Postalija".
1960-1970	1969. NCR446-Account Processing timer reduced from 30 to 10 days. 1967th IBM360th 1966th Machines for the reception of postal referral "Kienzle", and consignments booked "Camp. "
1970-1980	1979. Teller machine, "Kienzle 1200". 1974th Rent IBM CICS programming language. 1972nd IBM 370/135. 1970th Service EOP ..
1980-1990	1988. Olivetti M19, Fujitsu DX2100. 1984th Computer system TIM-100 -Mihajlo Pupin Institute. 1983rd Teller EDS90 computer system. 1982nd Terminals for Payment Bunker Ramo. 1980th IBM4341 in Novi Sad
1990-2011	2011. Post TIS. 1999th Post Net WAN network based on Internet technology. 1995th ON-LINE from PS. The 1991st Olivetti- Energodata PC386 and PC486, KIS, LAN, IBM3090

The biggest slowdown in further development of the postal network, are post offices in rural and village areas. Low demand for services and low population density in these areas make difficult to provide basic postal services. Nobody needs unprofitable network, but there is an obligation to provide it to every populated place and the population living in these low density areas is no exception (Kujačić, M., 2005) Attempts to solve the problem by introducing a post office by contracting local offices of different purpose, did not yield the desired results. In remote areas, reception and delivery of mail is carried out once a week. In order to perform the simplest service, you need to wait a week!? The solution is to get to the nearest post office. In district of Jablanica and Pcinj 10 villages go on one mailbox, in Zlatibor and Raska 7 villages go on one mailbox. On average in Serbia without Kosovo and Vojvodina, three towns go on one post. In Vojvodina, one town goes on one mailbox.

The use of information technology in solving the problem of providing services in rural areas is still in its infancy. In the world there are examples of using self-service automated machines and mobile post office in the process of reception and delivery of mail to sparsely populated areas. In our country, they are poorly used. For the purpose of postal network rationalization and analysis of resource utilization in Post of Serbia, we tested the possibility of introducing virtual counter in rural areas in Republic of Serbia.

3. VIRTUAL COUNTERS IN POST OF SERBIA

Virtual post office counter can be implemented as a self-service machine for the provision of financial services (ATM), with additional interfaces for the provision of postal services (receipt and delivery of postal items). Also, virtual post office counter can be implemented by using the Web sites that can, in addition to tracking sent postal items, offer the opportunity to perform some of the postal service. What is common in these ways of using virtual counter is that the user is not limited to working hours of postal units and may demand service regardless of time, day or night. Virtual post offices in rural and sparsely populated areas, close to highways..., can appear as ATM, POS system or terminal or be conceived as home banking, videotext, info kiosk.

ATM (Automated Teller Machines) is a self-service banking device that allows credit card use. Some of the functions that can be done using the ATM are cash withdrawal, making deposit, transfer of funds to other accounts, payments from different accounts, insight into the accounts. In relation to the micro location of installation, ATMs can be:

- "lobby" - posted at the entrances;
- "indoor" - in the counter hall and post office
- "outdoor" - at the entrances of public institutions and in the busy places

There are two types of ATM:

1. "off-line" devices, which are not connected to the central computer rather than working independently through units for reading and decoding of plastic money card and credit card.
2. "on-line" devices, which are connected to the central computer via a computer network, so that the system of protection and control is simplified.

External design of the ATM is composed of:

- small display;
- small keyboard with a few buttons;
- slot for the card, the card is placed during the operation of an ATM;
- slots for money with oval desk, which puts money (the investment), or from which it receives the money (at withdraw).

ATM configuration is reflected in the existence of the module that prevents unauthorized use of ATM and modules for encryption and decryption. Modules are tailored to work with standard international cards VISA, EUROCHQUE, SIBS ... This kind of use of modules is important in the tourist areas (eg, Zlatibor district) because it allows the use of ATMs to foreign tourists.

POS systems are self-service systems that can be owned by post office, banks and retail network. One POS system consists of the following components:

- POS terminals;
- concentrators;
- communications network;
- Switch Center;
- banking and / or post account systems and
- alternative systems for authentication checks, credit and debit cards.

POS terminals are classic or modified electronic - cash register system to provide terminal function and are associated with concentrators. In addition to basic functions, these terminals have a hardware add-ons that allow reading of the magnetic and electronic records from credit and debit cards as well as reading bar codes. Self-service POS terminals can be built where they can achieve their primary function of network availability to users of postal services. (Wincor Nixdorf, "ProCash 2150xe, ProCash 2150xe USB", 2006)

Home banking systems provide users of banking services financial transactions using personal computer, telephone and videotext system in your home without going to the post office. The development of Home banking system affects the development of telephone network capacity.

Videotext allows using postal service at home. This system enables direct transfer of resources, information and orders via the telephone network, without writing financial documents. The development of videotext system is affected by the telephone transfer because this system of self-service financial transactions looks like the ATM device, which has no possibility of cash payments. Videotext terminals in the system can be computers or TV sets, but for this system is necessary to introduce a special telecommunications system for the phone transfer and a device for videotext on the actual computers.

Payment via the Internet is an important factor in implementing the virtual counter through a Web site. For many smaller and larger companies, payment of goods and services via the Internet offers significant advantages. The Internet has become an efficient and cost effective distribution channel and the opportunities provided by the Internet market is still not fully exploited. (M. Hassinen, 2007). There are

different ways of electronic payments via the Internet that do not require physical presence of user in post office. Customers for this type of electronic payments are using credit and debit cards from banks that support such a pricing system. In addition to using credit and debit cards, there is the option of paying through PayPal account and E-Gold. Electronic payment system has general and specific security requirements. Such a system should be:

- safe and to ensure privacy, authenticity and confidentiality,
- easy to use and understand by the buyers and sellers,
- clear for bank's management,
- suitable for different types of currencies,
- low-cost implementation.

Equipment for purchasing over the Internet is extremely expensive, and Visa and MasterCard have strict procedures for obtaining technical certificates for these jobs. They prescribed the use of 3D Secure technology, which significantly reduces the risk of fraud with credit cards on the Internet. The system provides full security to all parties in a financial transaction because it also makes the chain in which is the bank that issued the card, the cardholder, a merchant who receives payment, the bank in which the merchants account is, international payment system Visa and MasterCard.(Y.A. Au & R.J. Kauffman,2006)

Info Kiosk is a self-service device designed for effective marketing, e-business, e-communication, that can provide a variety of information and services without the presence of authorized workers. All parts of kiosk are placed in housing that is planned and designed to resist negative outside influences. Within it is usually a computer that controls and operates the device. Depending on your operating system, it is created an application that will adequately respond to customer requests. User is interacting with a computer without using a mouse or a keyboard, but the touch screen, while some types of kiosks have integrated keypad, smart card reader for identification and payment, a printer, a device for receiving and issuing currency... For kiosk to connect to the existing information system, it is used standard network components (Milovanović, G., 2010). There are three types of these devices:

- Point of Information - the most frequently used type of info-kiosks, which is intended to provide specific information in different fields. Users of these devices can take over, but cannot affect the information provided by the kiosk.
- Point of Service - is an enhanced version of previous devices, in which a user can request and obtain the required service at a kiosk.
- Point of Sale - devices that provide buying of individual items.

Info Kiosk presents advertise and access database and tells status, reserve resources and terms, issues membership cards, certificates, instructions, account delays and interest, chooses the currently most favorable conditions. It can also give the latest news, give program of events, offer pictures and multimedia messages, marketing messaging, Internet access, exchange electronic mail (Mailing), access to the Internet, exchange e-mails, deals in tourism, recommended books, theatre, hotel, restaurant (taking into account the former interest), printed forms... It can be used for anonymous surveys and voting, it may possess information about the city, streets, buildings and office layout. Kiosk does not hire new work force, but decrease the current. It is a means accepted by all organizations that want to meet the increasing needs of the population for the rapid and timely information. Info kiosks have found broad application in the post. Main advantages of info kiosks are:

- vast amount of information which can be reached easily,
- users receive useful information that they cannot influence.

Info kiosk will be a quick and easy way to allow users access to a wide range of information. Info kiosks are of special importance because it provides a standardization of services. Using the info kiosks post would be permanently at the service for users, with fewer employees. For users of postal services, information kiosks can provide information on distribution counter, types of services, pricing, procedures, complaints, special offers and campaigns, discounts, access to the Internet or databases of general interest...

Developed postal administrations use kiosks to receive mail and sell postal packaging and valuables. In Serbia the information kiosks have emerged in the form of ATM devices to supplement the account of mobile phone and charge for parking spaces. Postal Savings Bank has set a kind of kiosk used to edit the order of

serving customers. Belgrade municipality is also planning to introduce info kiosks through which citizens would be provided with information on status of their case and about the work of municipal services. Also, information kiosks can be placed on the frequent location so that customer would be completely served. JP Informatika Novi Sad has implemented info kiosks in their offices, and the Web site offers its customers the following features:

- guide to the city government (city government for utilities, city government for transport and roads, the city administration of urban planning and housing services, city administration for social and child protection, the city administration of inspection, the city government of general affairs),
- virtual register
- unified billing receipts (insight into the account ...),
- assembly building
- electoral registers,
- statistics from general data,
- insight into unified receipts traffic,
- on-line loans.

Automatic postal center is the name of U.S. Postal Service automatic teller. This device allows you to perform as much as 80% of services provided by post. The basic functions of these devices are:

- receiving letters and packages;
- payment by credit cards;
- sale of postage stamps;
- providing additional services and information;
- Search postal codes;
- determine the weight and price of items;
- prepare forms and confirmation of receipt;
- issuance of billing statements.

Thanks to this device, the U.S. Postal Service since 2004 achieved revenue that was higher than planned.

U.S. Postal Service, in addition to traditional demands for the postal services, issues passports through a unique Web portal, enables on-line shopping of postage stamps, pay postage for packages and letters from your computer, changing addresses, calculate postage, etc..

The postal administration of France - LaPoste in cooperation with the French company, IER has developed and installed in the framework of its postal network a new self-service interactive kiosk Lisa 2. On the territory of France in the 1200 post offices there has been installed 2100 kiosks with a tendency of further expansion.

It is planned to implement Lisa 2 kiosks in Germany and Switzerland because the experience of implementation in France shown good results in the quality of service and cost-effective use of the counter. Software used on this kiosk is extremely flexible in terms of pricing attitudes, change currency and banking requirements that are specific to different postal administrations.

Singapore Post has implemented new automated service S.A.M plus (Self-service Automated Machine), which provides up to 50 applications available for different services. Self-service machines are installed at 90 locations in Singapore mainly in the halls of apartment buildings, hotels, restaurants and are primarily intended for specific groups of users. This system is available 24 hours and has the following features:

- Cash withdrawals
- Payment of bills and utilities,
- Reception and delivery of shipments in the domestic and international traffic,
- Buying and booking air tickets,
- Payment of fees for traffic violations,
- Returning borrowed books from libraries,
- Donations for humanitarian organizations,
- Payments for insurance companies,

- Delivery of groceries,
- "Leave for delivery" through which the user can give the shipment to be delivered to the recipient the next day until 17:00h.

4. CONCLUSION

Rationalization of postal network operations is possible by using modern information technologies. The aim of this approach is:

- decline in the share of labor costs in total production costs of postal services and
- increased availability of postal network.

Currently in Republic of Serbia more than 66% of posts are in rural and village areas. It is urgent to rationalize the network in terms of costs. Also, 35% of addresses where delivery is conducted belong to a wider and the widest delivery area. In this area the delivery is done from 1 to 3 times per week. In terms of accessibility it is necessary to increase the number of postal units and increase the number of deliveries per week. PostTis computer network owned by the Post of Serbia is an important resource in the realization of these objectives.

The implementation of virtual counters in rural areas requires extensive work by the Post and the wider community. This is a complex project that requires also the presence of hardware and software support. Education of virtual counter users is a prerequisite for their introduction.

Abstract: *E-business strategy as a part of general business strategy is becoming a key element for effective and cost-efficient market penetration. This paper analyses the main factors that must be taken into account when developing and redesigning a web store, focusing on the current situation in the online Serbian market. The authors conducted a research of 479 websites in Serbia that provide electronic commerce services to determine all necessary features for a fully operational web store. The following features were identified: payment options; shipment and delivery; conditions of use; privacy notice; and the presence of a shopping cart. The results obtained provide several recommendations which should be taken into consideration when designing a commercial e-strategy. Firstly, it can be observed that over 85% of the examined websites do not have any payment option and below 20% of them do not have an e-cart feature for processing electronic commerce. Secondly, out of all the observed web stores, over 25% do not have any delivery options available. Finally, more than half of the websites do not have information provided on website regarding conditions of use and privacy notice. The Internet is an option but only if there is an adequate strategy.*

Keywords: *e-commerce, e-business, website, web store, e-strategy*

1. INTRODUCTION

Numerous changes in the environment, globalization of markets and economic regionalization have contributed to the substantial shifts in the business of many companies in the world, causing it to begin to think and act in new ways. Expansion of the Internet and creation of network among companies and public administration led to major changes in the manner and efficiency of business systems. In recent years, the quality of electronic business transactions is also significantly improved. All of that contributed that e-business strategy become a part of general business strategy. This integration is generating synergy while in return, organisations becoming effective and cost efficient in market penetration. In the process of forming a corporate strategy to respond to the challenges of environmental change, normative thinking requires that a company should analyze its industry forces and value-chain activities in order to identify opportunities for IT innovation (Changa, Jacksona & Groverb, 2003). They also strongly recommended that companies must clearly recognize their e-commerce initiatives as an integral part of t strategic objectives and carefully evaluate their customer and competitor base, as a part of strategic thinking in order to reap more benefits. The quality of electronically business transaction has also significantly improved in recent years and thus increases the importance of e-commerce. Industries get a new form under the influence of digital dimensions (Laudon & Traver, 2010). From the beginning of the commercial Internet use, in the mid 90's, are formed and changed business models, market and communication framework of electronic business and commerce implementation. Since then, there is a question: where should be turned all the participants in the process of e-commerce? The only answer is that they must turn to building trust (Turban, King, Lee, Liang & Turban, 2010). Information Technology, Internet and e-commerce have a powerful impact on productivity and management in general. One of the key advantages of the Internet is located in the area of electronic commerce (Jobber & Lancaster, 2006).

A recent study by Hausman and Siekpe (2009) found that computer factors are necessary antecedents to online shopping, albeit indirectly through attitudes toward the site and flow. In addition, they point out that website features should be considered primary in every site design to generate positive perceptions of usefulness while avoiding irritation. From the practical point of view, web design is critical in building customer relationships, facilitating customer support, and converting visitors into customers in the online environment (Ghose and Dou, 1998).

Statistical Office of the Republic of Serbia (2010) showed that only 4.9% of respondents using Internet to conduct a commerce. According to Internet World Stats (2010), in Republic of Serbia 55.9% of population are using Internet.

This paper analyses the main factors that must be taken into account when developing and redesigning a web store, focusing on current situation in online Serbian market.

2. KEY FEATURES OF WEB STORE

Unlike traditional information systems, e-commerce systems contain characteristics of both an information system and marketing channel (Hausman & Siekpe, 2009). Effective web design requires examination of both these factors from the users' point of view to ensure web stores provide required elements. Key dimensions for Web site quality in past research show that design, content, entertainment, usability, reliability, interactivity, security, privacy, trust, product value, delivery. Prior research has found that design of a quality website, as part of e-business strategy, has become a key element for success in the online market (Hernández, Jiménez & Martín, 2009.). They also pointed that accessibility, speed, navigability and content are important features which determine website quality. In the sense of consumer purchase intention, three groups of factors are identified as relative important: technology, shopping and product (Chen, Hsu, Lin, 2010).

A different research by Eastlick, Lotz and Warrington (2006) found that strongest relationships leading to online purchase intent were those between trust in and commitment toward an e-tailer and between firm reputation and trust. Privacy concerns influenced purchase intent with strong negative effects, both directly and indirectly through trust (Eastlick, Lotz & Warrington, 2006). Ranganathan and Ganapathy found, based on a questionnaire survey of 214 online shoppers, four key dimensions of B2C web sites: information content, design, security, and privacy. Though all these dimensions seem to have an impact on the online purchase intent of consumers, security and privacy were found to have greater effect on the purchase intent of consumers (Ranganathan & Ganapathy, 2002).

Another research investigated the relative importance, when purchasing goods and services over the Web, of four common trust indices:

- third party privacy seals,
- privacy statements,
- third party security seals, and
- security features (Belanger, Hiller & Smith, 2002).

Belanger, Hiller and Smith (2002) also investigated the relationship between these trust indices and the consumer's perceptions of a marketer's trustworthiness. The findings indicate that consumers' ratings of trustworthiness of Web merchants did not parallel experts' evaluation of sites' use of the trust indices. The results revealed that when making the decision to provide private information, consumers rely on their perceptions of trustworthiness irrespective of whether the merchant is electronic only or land and electronic. Privacy and security features were of lesser importance than pleasure features when considering consumers' intention to purchase (Belanger, Hiller & Smith, 2002). Both consumers and vendors perceive privacy concerns in terms of information control: who has access to personal data (disclosure), how personal data are used (appropriation) and what volume of advertising and marketing offers arises from the use of personal data (intrusion) (Cases Fournier, Dubois, Tanner).

Jarvenpaa and Todd (1996) investigated impact of the World Wide Web on consumer shopping behaviour. They gathered consumers' reactions via an open-ended survey using a sample of 220 shoppers, and related the reactions to the factors of product perceptions, shopping experience, customer service, and perceived consumer risk, which they had identified from the existing literature on retail patronage behaviour. The shopping experience by consumers was reported to be generally enjoyable, but at the same time frustrating. In the study it has been found that consumers could perceive the potential for time savings and reduced effort compared with traditional forms of shopping, but that, at present, goal-directed shopping was difficult. Overall, the results of this study suggest that World Wide Web vendors need to think more about how they perform on the factors known to affect consumer behaviour; namely, product perceptions, shopping experience, and customer service (Jarvenpaa & Todd, 1996).

3. METHODOLOGY

Authors performed identification and targeting of web sites in Serbia to determine which of them provide the service of electronic commerce. Research was conducted during the first half of 2011. The general level of search was performed by inserting following keywords into a web browser: internet shop, internet business, internet shopping, e-shop, e-commerce, e-shopping. After the search process final list of 479 web stores was created and content analysis was conducted. In the research authors used features of technology and shopping factors, as found by Chen, Hsu and Lin (2010). According to Hausman and Siekpe (2009) following features were identified:

- payment options,
- shipping and delivery,
- conditions of use,
- privacy notice, and
- presence of shopping cart

4. DISCUSSION AND RECOMMENDATIONS

It has been noticed that Serbia increased its presence of the Internet and new technologies through which it is possible to achieve a large number of transactions. Internet infrastructures developing but it is not used enough. In recent times, utilization level of servers, which is a significant data, is very small.

Table 8: Web site location

		Frequency	Percentage
Serbian hosting		159	33.2
International hosting	American and Germany hosting	228	47.6
	Other international hosting	89	18.6
Total		479	100

This research show that 67% web sites use hosting services from international providers. In the last several years, difference between quality and price of domestic and international hosting system is reduced. International hosting services has advantage due to reliability, higher quality and cost than the local systems.

Figure 14: Web site location

4.1. Payment options

Table 2: Payment options

		Frequency	Percentage
Not determined		5	1
Does not exist		415	85.6
Exist	Banca Intesa	26	5.4
	PayPal	5	1
	Western Union	3	0.6
	Moneybookers	9	1.9
	2CO	17	3.5
	QVoucher	2	0.4
Total		479	100

Almost 87% of websites focusing on e-commerce do not use any payment provider, 8% of websites focusing on trade collected over a foreign provider, while only 5% of web stores using the provider from Serbia.

4.2. Shipping and delivery

Table 3: Shipping and delivery

		Frequency	Percentage
Not determined		4	0.7
Does not exist		125	26.4
Exist	PTT	62	13
	DHL	19	4
	FedEx	5	1
	Own delivery	32	6
	Some other carrier	232	48.9
Total		479	100

27% of websites do not have any Shipping and delivery option, 6% of web stores are delivering products by themselves, and 67% are using carrier service.

4.3. Conditions of use

Table 4: Conditions of use

	Frequency	Percentage
Not determined	2	0.4
Does not exist	255	53.2
Exist	222	46.3
Total	479	100

The research showed that 53% of web stores does not contain the terms of use, which usually serves as an explanations of how to shop over the internet.

1.4. Privacy notice

Table 5: Privacy notice

	Frequency	Percentage
Not determined	21	4.4
Does not exist	260	54.3
Exist	198	41.3
Total	479	100

More than a half of identified web stores do not have indication of security in the form of privacy notice.

1.5. Presence of shopping cart

Table 6: Presence of shopping cart

	Frequency	Percentage
Does not exist	85	17.7
Exist	394	82.3
Total	479	100

The research showed that 17.7% of web stores do not contain presence of shopping cart at their web site.

5.0. Recommendations for electronic business strategy development - web store case

Firstly recommendation is that current or future web stores in the Republic of Serbia must implement any kind of payment over internet. Weather it is a bank system for online payment processing, payment providing or paypal system. This problem has to be addressed to proper government body in order to create fair climate for implementation of payment options at web stores. Secondly, web store vendors have to include presence of shopping cart at their web stores in order to be identified as electronic commerce subjects. Thirdly, current or future web stores must implement delivery options in order to be able to provide complete service for e-customers. Especially, delivery have to be reliable and on time, because these factors are essential for customer satisfaction. Finally, as all prior research found that trust and privacy are very important elements of web store, Serbian e-vendors must pay more attention to the conditions of use and privacy notice at their web stores. Chen, Hsu and Lin pointed out that the protection of privacy is imperative for online transactions (Chen, Hsu, Lin, 2010). Both consumers and vendors perceive privacy concerns in terms of information control: who has access to personal data (disclosure), how personal data are used (appropriation) and what volume of advertising and marketing offers arises from the use of personal data (intrusion) (Cases, Fournier, Dubois, Tanner). Also, Belanger, Hiller and Smith said that a privacy statement can enhance the perceived trustworthiness of e-vendors.

5. CONCLUSION

According to research results it can be concluded that e-commerce situation in Republic of Serbia is alarming. Internet is an option but only if there is an adequate strategy.

Electronic Commerce in Serbia is certainly a possibility to achieve a model that would bring the benefit of vendors (faster and more efficient sales), customers (faster, more efficient and better shopping) and government (more money in the budget to shop online, increasing turnover, starting a business), only if all advantages of new technology is used in the right way. Further research should pay more attention consumer protection, antitrust and unfair competition, the fight against corruption, fight against the illegal import and export of products from the country. It is important that new technologies help facilitate the launch of a new business and self-employment. Electronic commerce increases the degree of innovation and competitiveness through the use of new technologies and increased visibility of operations.

Further research will be oriented on e-vendors and e-customers in order to identify main problems of e-commerce in Serbia.

Abstract: *Relational databases have been in use for many decades. Integrated with SQL language, this database technology is very efficient with flat records. Recently, there has been increasing actualization of data stores that do not exclusively use SQL language, called NoSQL databases. Some examples are Amazon's Dynamo and Google's BigTable. These systems should give advantage in executing statements with large, complex data types. Based on the collected system performance results, the aim of this paper is to compare relational with NoSQL systems and to decide which of the two is better for certain use. The paper analyses both systems from Oracle. Performance comparison was conducted in controlled, experimental conditions, with flat and complex data types. Based on results, it can easily be concluded that each system demonstrates excellent performance depending on different data types that were used.*

Key words: NoSQL, RDBMS, system performance comparison

1. INTRODUCTION

Database management systems based on the relation model become dominant in the last quarter of the last century. During the seventies the first commercial systems based on the mentioned model appeared and since then they have been widely use, usually as the only acceptable possibility for a system that has to provide access to large number of clients (Kriha W. 2011). Although there were different attempts to create a system which would replace relation systems, such as creating object and XML database, those technologies were not accepted from the users side nor have achieved proportionate share of the market such as relation systems (Kriha W. 2011). Mentioned alternatives were accepted by relational systems and they continued its life mostly as a integral part of relational systems (eg. Object-relational database). The best indicator for that is almost everyday usage of the word “database” which represents synonym for “relational database”.

Organisations that their business based on web and offer new or improved existing services have appeared about ten years ago. List of those type of organisations include Amazon.com which enabled popularization of B2B web sales, Google that has brought a revolution in information searching on the Internet, also MySpace, Facebook, LinkedIn and Twiter which enabled connecting people using “social” networks.

Although the trend of exponential growth of newly created data was evident, mentioned companies with its expansion contributed additional emphasize need for rapid manipulation of data, efficient storing large amount of data, usage of data with complex structure and their interconnection (Perdue T. 2012). By extremely large datasets often are consider event based transactions that occur in chronological order, for examples weblogs, shopping transactions, manufacturing data from assembly line devices, scientific data collections, large multimedia object etc. Amount and complexity of data have influence on time needed for displaying and manipulating with data.

NoSQL movement was initiated by the listed companies, primarily Google with their system BigTable, Amazon with Dynamo and Facebook with Cassandra, all in order to create database management system (DBMS) which would have performance and high speed of response as top priority, but with possibility inconsistencies of data in certain moments. Actualization of NoSQL solutions initiated a polemic of advantages and disadvantages of these two approaches for creating DBMS. Users and database administrators are splited into two groups. First one consist followers of relation database management system (RBBMS) and second one followers of NoSQL system. The primary goal of this work is to compare relational and NoSQL solution of the same manufacturer and to analyze advantages and disadvantages of these two possibilities for solving certain number of business tasks. Viewed from the aspect of IT manager, there is challenge giving preference to one system compared to the other i.e. benefits of usage of each of

them for appropriate business needs and requirements. This study should show to whom is each of systems intended.

The remainder of the paper is structured as follows. Section 2 gives an overview of different characteristics of RDBMS and noSQL systems. In section 3 design of experiment, used for performance comparison of these two systems, is introduced. Section 4 provides experimental results for RDBMS and NoSQL system and results analysis. Section 5 provides conclusion and suggest which system is better for certain business purpose, depending of amount and type of data in use.

2. GENERAL CHARACTERISTICS OF RDBMS AND NOSQL SYSTEMS

There are a certain group of characteristics of NoSQL databases that are universal and applicable for all solutions regardless of specificity of their functions or way of storage. In this part basic features will be shown. Within these basic features central part occupies CAP theorem (Consistency, Availability, tolerance to network Partitions) created by professor of Berkley University, dr. Eric Brewer. CAP theorem represents acronym of the word Consistency, Availability and tolerance to network Positions. This theorem says: "You can have at most two of these properties (Consistency, Availability, Tolerance to network Partitions) for any shared-data system" (Brewer E. 2000). Service that has consistency, as its feature, operating fully or not operating at all. It can be said that distributed system is available if any request accepted by the correct node must be followed by response of the system. Only fully crash of network (partition tolerance) can cause incorrect functioning of system. CAP theorem is proved in 2002 by Seth Gilbert and Nancy Lynch from MIT University. Gilbert and Lynch in his proof have used if their proof the word atomic (nuclear) instead of consistency. The term consistency they define as the existence of a clear sequence of operations that makes all operations were executed as they were done at once (Gilbert S, Lynch N. 2002). Reasons shall be reflected in the fact that consistency, strictly speaking, describes the property of database transaction which provides establishing relationships between all the data, as determined by pre-defined limitations. It is describing the letter "C" from ACID properties of the transaction. Unlike consistency, Bewer this term has used in term of atomicity, the letter "A" from ACID. Mentioned terminology discrepancy, according to some experts, was created as a result of creating practical creation of an acronym (Browne J. 2012).

Some basic features of each NoSQL database are derived based on CAP theorem. In contrast to relational databases, which own ACID characteristics, NoSQL databases have BASE features. The features that every transactions of relational database in execution has to have are:

- Atomicity – requires that all operations of the database should successfully complete or none
- Consistent – transaction transforms database from one consistent state to another and consistency is defined by constraints. During the execution of transaction consistency can be compromised
- Isolation – during the execution of two or more transactions in the same time their effects must be isolated. These effects must be the same like effects of some of their serial execution.
- Durability – serious failures of the system can not affect durability of results of completed transactions

Web with its content that offers (wiki, blogs, social networks, etc.) constantly increases amount of data that needs to be analyzed, processed and forwarded. Organisations who use mentioned content of web need to determinate their own requirements regarding performance, reliability, availability, consistency and durability. CAP theorem, as already mentioned, allows connection of only two characteristics, not three: atomicity, availability and tolerance to network partitions. However, for more and more applications, especially in large web and electronic stores, availability and tolerance to network partitions are more important than strict atomicity. Mentioned applications must be reliable which leads to availability and redundancy (also distribution between two or more nodes, since many systems work on "cheap and unreliable machines" which increase scalability also). These characteristics are hardly achieved using ACID features, so the usage BASE features has started to be applicable. According to Dr. Brewer, BASE approach is restricted with importance of consistency and isolation from ACID features and has emphasized availability, "gracious degradation" performance (Brewer E. 2000). Acronym BASE consists of the following characteristics:

- Basically available – system can have this characteristic even if some of its parts are not available
- Soft-state – system must not be consistent in every moment
- Eventual consistency – system will be in consistent state at some point of time. After some time, all nodes are consistent, but that may not be the case at some other point of time

NoSQL databases have also one more feature, which is very important. That is scalability. The general definition of scalability is that is the feature of the system, network or process to properly respond to increasing amount of work (Bondi A. 2000). NoSQL databases support horizontal scalability. This represents possibility of adding new nodes to the system, eg. movement from one web server on the server tree.

Categorization of NoSQL databases is usually done according to way of storage. In the beginning, with development NoSQL database there were dominant two solutions, Google's BigTable and Amazon's Dynamo. According to that there were only two categories and these two solutions were belonging to these categories. But, in time, the number of solutions has increased, thus has increased also number of possible types of storing data in NoSQL databases. That leads also to the growth in number of categories. Although on the Internet and in the literature can be found divisions which have different number of categories (some authors have made even nine categories) (Hoff T, 2012), most of them uses four or five categories. The categories are: key/value databases, databases based on a column, databases based on a document, graphs databases and object databases.

Object database can be seen as particular case of relational databases. Because of their (non) presence in practice, they are classified as object-relational databases or relational databases which have support for object types. Comparative overview and comparison of RDBMS and databases based on graphs clearly showed that between these systems there are differences in speed of query execution and it is hard to done general conclusion about effectiveness one in favor to another. (Vicknair & Macias, 2009).

Databases based on key/value principle of storing data have simple model: map/directory that enables customers to ask and require key value. Besides data model and API, this type of NoSQL database offers high scalability, but on the other side consistency suffer. That is the reason why most solutions in this category does not support neither complex ad-hoc queries nor analytical functionalities (there is no support for join operation neither for aggregate functions). Usually, the key length is limited by number of bytes and mostly there is no limits on possible values.

This type of database exists for a long time, but the most number of classes of NoSQL database appeared in last few years and were inspired by Amazon and Dynamo. They are based on hash table. Hash table is data structure which uses hash function for mapping an identified key with its assigned values. That provides access specific data for a certain key and avoiding searching through a large amount of data. By that immediately is allowed access to required data which significantly improves performance. This type of NoSQL database is important because one of their representatives will be tested in the further work.

3. DESIGN OF EXPERIMENTS

Presence of RDBMS system more than four decades has caused that RDBMS establish as completely dominant type of data storage in theory as well as practice (Vicknair & Macias, 2009). Today it can be found a big number of solutions from various manufactures in the market and also in use. From the other side, NoSQL solutions although much more younger than RDBMS solutions, experiencing expansion in last few years. The reason for that is popularity of companies which have initiated this movement: Amazon, Google and Facebook.

Two systems selected for testing are Oracle XE 11g (representative for RDBMS) and Oracle Kvlite 1.2.123 (representative for NoSQL). The question which solutions between these two system is more effective in favor to another is imposed. If there is no solid answer to previous, question which solution is better for use depending of amount and types of data may be consider.

The subject of this research is the performance comparison of these two systems. Since lite versions are widely intended for personal needs as well as for SME (primarily small and micro companies and that is defined by act of the European Union) (European Commission 2012) these systems own a certain number of restrictions regarding the number of tables that can be created, the number of used nodes and etc.

Performance is very complex concept and may include a big number of variables. In this study, one variable will be considered, comprehensible to users. It is speed of statement execution.

Potential impact on the speed of statement execution had to be eliminated and because of that all the tests were done on the same hardware, same computer, the local instances of the database and has not been used any type of optimization (triggers, indexes, partitioning, etc.). For database access it was used the same environment, NetBeans 7.1.1.

Executed statements are based on the most frequently used data types both for small or micro enterprise and private individuals. Those statements include manipulation of predefined types i.e. character data, numeric data and Date data type. Besides that there was executed statement for more advanced use of database. Specifically, statements for images manipulation was used and it was expected that NoSQL system shows the advantages of using key/value principle. Statements are labelled as I1 – insert predefined data entry; I2 – insert images; S1 – selecting predefined data; S2 – selecting images.

4. EXPERIMENTAL RESULTS

The experiment was realized in 40 series. Each statement was repeated in 40 iterations, then the minimum and maximum result values were removed and was calculated average value for remaining 38 iterations. Cache memory was emptying during the measuring to remove caching data in the memory i.e. to remove potential influence to results. Generation of the data was used in the statements. Statements that were used for manipulation with data consisting predefined types also generated values of numeric, character and date type, while statements that were used for manipulation with images also chose random picture from the predefined collection of images. Statements I1 and S1, for entry and display the values of predefined data types were conducted in series with 1.000 n-tuples, then with 10.000 n-tuples and finally with 100.000 n-tuples. The time was measured in milliseconds. The result is shown in Table 1.

Table 9: Statements with predefined types

	N1.000		N10.000		N100.000	
	Insert (I1)	Select (S1)	Insert (I1)	Select (S1)	Insert (I1)	Select (S1)
Oracle XE (RDBMS)	91	115	915	1.096	8.992	10.558
Oracle Kvstore (NoSQL)	739	683	3.841	3.720	30.171	48.133

Next two graphs are showing how number of records affect execution time of I1 and S1 statement, respectively. Left graph shows how increase of number of records affects required time for statement I1 execution. Even with a increase to a 100.000 records, RDBMS is still dominantly faster then NoSQL system.

Picture 1: Execution time for I1 statement

Picture 2: Execution time for S1 statement

Right graph shows how increase of number of records affects required time for statement S1 execution. Like with previous statement, situation with S1 statement is almost the same: even with a increase to a 100.000 records, RDBMS is still dominantly faster then NoSQL system.

The results from Table 1 were expected. As it can be easily seen, RDBMS was much more faster than NoSQL solution. The greatest difference was during the entry of small amount of data (over 8 times higher speed). After increasing number of n-tuples big difference still remains (RDBMS is over 4.5 times faster). Explanation of results can be found in the fact that characteristics of the relational model (RDBMS is based on that model), are expressed during the storing the „simple“ type of data which can be easily stored in a table.

Statements I2 and S2, for entering and displaying files, in the specific case, have been conducted in series with 10 n-tuples, then with 100 n-tuples and at the end with 1.000 n-tuples, because of the duration and number of repetitions. Times are measured in milliseconds. The result is shown i Table 2.

Table 2: Statements with images

	N10		N100		N1.000	
	Insert (I2)	Select (S2)	Insert (I2)	Select (S2)	Insert (I2)	Select (S2)
Oracle XE (RDBMS)	667	2	4.425	5	36.377	44
Oracle Kvstore (NoSQL)	32	22	232	90	2.654	839

Next two graphs are showing how number of records affect execution time of I2 and S2 statement, respectively. Left graph shows how increase of number of records affects required time for statement I1 execution. In contrast to previous two statements (I1 and S1) statement I2 which is used for inserting images, shows a big difference between two systems, in favor of NoSQL system. Almost in same manner like RDBMS in previous statements, NoSQL was dominant in executing I2 statement. Even with a increase to a 1.000 records, NoSQL is still dominantly faster then RDBMS system.

Right graph shows how increase of number of records affects required time for statement S2 execution. In contrast to previous statement, RDBMS again shows dominant advantage in speed of executing S2 statement, which is statement with select command.

Picture 3: Execution time for I2 statement

Picture 4: Execution time for S2 statement

Results from Table 2 which are related to the commands for displaying data (here we mean of displaying byte representation of object, not the picture itself) clearly show dominance of RDBMS in relation to NoSQL solutions. Explanation for that is itself relational model and its advantages in work with flat data. However, when we are talking about pictures entry it is evident that NoSQL database is dominant. This result demonstrates the greatest advantage of NoSQL databases: the possibility of applying hash table principles (store data about key which shows the actual values) and possibility of sharing operations of writing in more nodes. NoSQL database consists of nodes for storage which consists of one or more nodes for replication. Greater number of nodes for storage leads to increasing of the number of nodes for replication. Between those nodes it is possible to share write operation which directly influences in lower speed of data writing. It could be expected additional reduction time of data entry in more advanced version of the software with possibility of defining a huge number of nodes for storing.

5. CONCLUSIONS

Conducted experiment, in fact, confirmed the results that could be expected before the test. It should be noted, once again, that this test was included two systems for small and micro enterprise, and private individuals. These solutions are available on the Oracle web site and can represent a cheap version for all users who are ready to make some compromises.

Taking into consideration all above it can be concluded that the relational database convincingly quicker executes statements, especially those with predefined types. Oracle XE response was almost immediate and that is especially expressed when displaying small number of data. The interesting fact is that, ignoring resource and hardware limitations, RDBMS was able to insert 100.000 records in less than 9 seconds, which is the result for every applause. With increasing number of n-tuples outcome has not been changed, so with 100.000 records XE system was much more faster than NoSQL system.

On the other hand, NoSQL solution did not have any chance against relational model when it comes speed of statement execution with standard data types. NoSQL enables access to the database only through its API. To be sure that both systems have the same conditions it was used NetBeans environment for connection and work with both databases. However, SQL language (with „select“ and „where“ commands for display and „insert“ for input) is so efficient that NoSQL integrated „put“ and „get“ methods can not be compared to it. But, NoSQL was extremely convincing where we expected so. During the storing images in the database efficiency key/value principles came to the fore. Oracle's solution is based on that. As already

mentioned, defining additional nodes for storage and replication would certainly had influence on reducing statement execution. Relational model with its BLOB objects could not be comparable with NoSQL solution in this segment.

During realisation of test, a problem was shown with Kvlite system. Inconsistency was expressed, which certainly is not welcome and must be thought as disadvantage of NoSQL system. In several occasions there were situations that data which have been entered in previous iteration in NoSQL were not possible to be seen or to be accessed. Also there were situations where the data that have been already deleted still remained in the database. That was possible to see during new entries.

After analysis of results the question that could be raised is whether the organisations should adopt NoSQL systems. The answer is obvious. If primary product of organisation is not social network (like Facebook, LinkedIn) or system where the speed of retrieving information is vital (like it is for Google, Amazon) then NoSQL solution is not acceptable. Inconsistent data still cause catastrophic consequences in many businesses. NoSQL databases have narrow range of use, but as these tests show they are really effective in situations when their usage is necessary. With 100.000 flat records that have been tested RDBMS still stays effective and faster solution. The question is whether average small or micro enterprise has a need to manipulate with greater amount of data than mentioned? One more question can be raised is who really has a need for NoSQL? Is that a small or micro enterprise that should be represent targeted market for tested lite versions of software? Concentrating on the one relevant aspect of performance, as a fundamental criterium for delivering fast and consist data, the answer is definitely negative. For the most number of users of small and micro enterprise relational database still meet all requirements of business. Even if it is used over tens and hundreds of thousands records they still represent faster and more reliable solution then NoSQL system.

Abstract: *This paper discusses the management of cloud computing-based infrastructure for e-learning at a university level. The main issue in a modern e-learning system is to provide scalability and reliability of educational applications. The primary goal of the research is to develop a model for management of the cloud computing infrastructure for e-learning. A private cloud was implemented within the existing infrastructure at the Faculty of Organizational Sciences, University of Belgrade. The described solution is comprehensive and includes all cloud computing service models. Additionally, a description of features and management resources is provided for each service model.*

Key words: *cloud computing, infrastructure, e-learning, management, private cloud*

1. INTRODUCTION

With rapid increase in the number of users, services, educational content and resources required, educational institutions and their e-learning systems face new challenges in design and deployment of IT infrastructure for e-education. Modern information and communication technologies provide means for increasing efficiency, flexibility and cost-effectiveness of e-learning systems. The users of e-learning system have a need for including different resources into courses. These resources require more data and resource-demanding processes, such as interactive video, virtual worlds, modeling and simulations. Current, traditional, IT infrastructure used for the great majority of e-learning systems is not able to answer to all teachers' and students' requests and needs in effective and economical way.

One possible solution is investing in new equipment with the goal of enhancing existing IT infrastructure. This approach enables that an educational institution provides required technical resources for successful implementation of a distance learning system. The main con of this approach is economical unprofitability. The process of adding new physical resources to an existing IT infrastructure is expensive and durable. IT infrastructure, resources and business processes are able to provide flexible on-demand services to teachers and students in the e-learning process and they need to be innovated and optimized permanently.

Developing new technologies, growing the number of available services and participants of e-learning system showed many disadvantages of implementation of traditional IT infrastructure for e-learning systems in scope of learning institutions. The goal of each educational institution is to add new visions and technologies which permit qualitative, efficient and economical implementation of an e-learning system and its management. IT infrastructure is a backbone of e-learning systems and their deployment and maintenance requires certain expenses. During the initial acquisition of computers and network devices, it is needed to observe whether the features of scalability and expansibility of components are available. Desired level of expansibility is actually hardly to acquire because of infrastructure components' constraints. E-learning systems based on classic IT infrastructure consider that one server is used only for one service. Beside of the impossibility of physical expanding of servers and upgrading the performances, there are also problems related to software updates.

If we invest a big sum of money for buying a high-performance expandable server and if that server works with 20% or less of its capacity, the phenomenon of low utilization occurs. That means that educational institutions have greater expanses and also more time is required for maintaining, repairing and administration of many physical servers. Distance learning system can be implemented by using Moodle software solution in a virtualized environment (Barham et al., 2003). In that way, software consolidation is performed and the paradigm "one service = one server" is avoided. However, despite of organizing databases for storing all options and information about this system, new problems are system availability, improving performances, managing and fine tuning of the virtual environment. It is clear that it is necessary

to implement a tier for managing virtual infrastructure and virtual resources into this system to facilitate obtaining reliability, security, scalability and economy of the system (Vujin, Radenković, Milić, & Zrakić-Despotović, 2011).

2. CLOUD COMPUTING INFRASTRUCTURE

Cloud computing is an area of computing that refers to providing customers with highly scalable IT capacities as a service via the Internet. ("Cloud computing: benefits, risks and recommendations for information security," n.d.) (Parameswaran & Chaddha, 2009) (Sultan, 2010). It is an abstract, scalable and controlled computer infrastructure that hosts applications for end-users (Badger, Patt-corner, & Voas, 2011). Services and data coexist in a shared and dynamically scaled set of resources (Srinivasa, Nageswara, & Kumar, 2009). Virtualization is one of prerequisites for the realization of cloud computing and the main feature of cloud computing is its scalability (Dong, Zheng, Yang, Li, & Qiao, 2009) ("Cloud Platform - CA Technologies," n.d.).

The architecture of the private cloud is based on flexible federations of servers, storages and networking (Cerbelaud & Huylebroeck, 2009). Virtualization provides efficient resource usage through separation of abstract platform from IT infrastructure. Model of a private cloud enables a large number of users to share resources and leads to higher level of resource usage and cost effectiveness. Within an e-education system, this approach leads to a perception of limitless IT capacities, where services can be used according to users' needs. Architecture of a private cloud enables active planning and monitoring capacities in real time, so that infrastructure can dynamically be scaled to support high loads of users' requests. In this way, a balance between the need for agility and costs of unused capacities is easily achieved. The model of IT infrastructure enables continuous availability of e-learning services, even in cases of interruptions within the infrastructure itself. Permanent availability is achieved through an architecture of redundant IT infrastructure and application of standardized procedures for automated management. E-learning services are provided with the same level of quality independently of when or from where they are accessed to. High level of quality and functionality is achieved by standardization of system components, including physical servers, network devices, storage devices, re-sources, etc.

The security of e-learning IT infrastructure model is divided into three layers (Cayirci, Rong, Huiskamp, & Verkoelen, 2009):

- Infrastructure security – by applying security technologies and by controlling all architectural layers. This control is performed by assigning access rules to users, processes and IT components and by applying the principle of minimal privileges for accessing the user account. By using this strategy, users are always logged in with minimal privileges needed for normal functioning. Administrator privileges are used only by user authorized for administrative tasks;
- Accessing applications – considers using secure application access by applying identity management system;
- Accessing computer network – considers applying standard security tools and procedures.

Flexibility and other features of the model are achieved thanks to virtualization which separates operating systems, data and applications from physical hardware. Following processes are identified by this abstraction:

Automation of processes,
Resource management,
Organizing components,
Service management,
Personal services.

Automation layer consists of basic automation technologies and a set of commands and scripts which perform tasks, such as starting or stopping virtual machines, server restart or applying software updates. Modularity of this approach enables simplifying of software development, removing bugs and maintenance.

Management layer consists of tools and services which are used for organizing, using and managing of IT infrastructure components. In almost all cases, there are different tools for hardware, software and

application management. Management layer is used for performing following tasks: reserving storage resources and networks, operating system applications and application tracking. The key features of this layer are remote access, tracking each IT infrastructure component and tracking of dependencies of all infrastructure components.

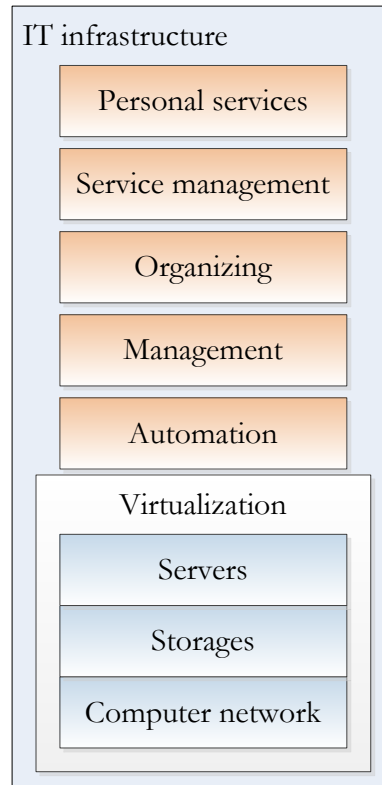

Figure 15: Layers of the infrastructure model

Organizing layer uses advantages of automation and management layers and it represents an interface between organization and its infrastructure. It is a layer which needs to provide designing, testing, deployment and tracking of complex business processes where the system components are integrated.

Service management layer needs to provide answers for solving incidents, problems and it needs to perform control by using best automation examples, such as Microsoft Operations Framework (MOF) and IT Infrastructure Library (ITIL). Service management by using the concept of integrated service management reduces unneeded and expensive deadlocks and it improves the quality of e-learning services.

Personal services provide user interface which can be used for accessing and managing services and assigned resources. By using access control based on user roles, several parts of system administration are being delegated.

3. CLOUD COMPUTING INFRASTRUCTURE MANAGEMENT

To provide better system scalability and to introduce new services for students, this model includes cloud computing infrastructure. The cloud computing architecture is based on physical infrastructure (Doddavula & Gawande, 2009)(Foster, Zhao, Raicu, & Lu, 2008). This is an example of a private cloud model, because the owner of the physical infrastructure is an educational institution. Beside of creating and managing the private cloud, public cloud interface is included in this model, as well(Foster et al., 2008). This model permits expanding of IT e-learning infrastructure with commercial infrastructure and commercial resources when request for resources are greater than the number of available resources or the performances of servers are not sufficient(Velte, Velte, & Elsenpeter, 2009).

Main components a private cloud include resource pool: servers, storage, and network. Server pools include physical resources, such as CPU, memory, network interfaces, graphical adapters, and storage units, which are all building blocks of virtual machines(Qian, Luo, Du, & Guo, 2009). Network pool includes address

services and package delivery between physical infrastructure and virtual machines. This component includes physical and virtual switches, routers, firewalls and virtual private networks. Storage resource pool refers to data stored in a private cloud. Storage resources need to be connected in a network in order to support migration of virtual machines across servers. Virtual hardware is presented to virtual machine's operating system by hypervisor(Raichura & Agarwal, 2009).

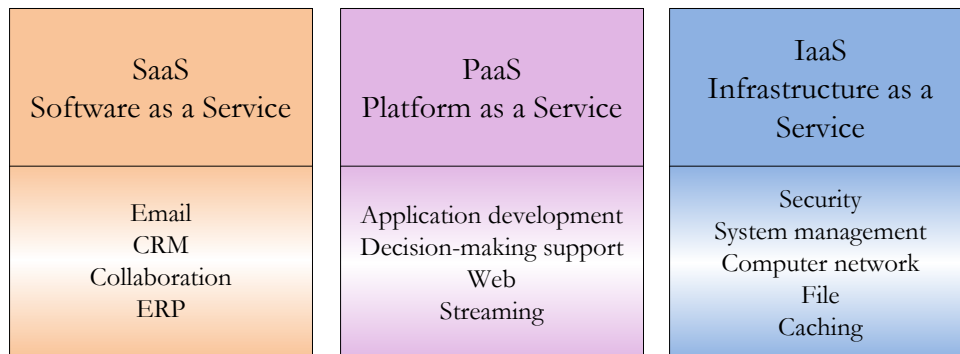

Figure 16: Types of delivering services

Primary goal of a private cloud is to decrease time and money necessary for deploying new hardware and software. In this way, new services can be deployed more quickly(Dong, Zheng, Xu, et al., 2009). Private cloud can provide its' users with infrastructure as a service, platform as a service and software as a service.

Infrastructure as a Service approach means that following components are delivered to users: CPUs, clusters, virtualized servers, memory, networks, storage and system software(Doelitzscher, Sulistio, Reich, Kuijs, & Wolf, 2011). Organization of these components is user's obligation. IaaS offers standardized infrastructure at the organization level. User organizes, manages and tracks delivered resources by using a standard logical interface for creating and changing the configuration, as well as for acquiring information related to the infrastructure, integrally. Availability of resources is performed by using of shared infrastructure components and the virtualization technology. Instead of providing new hardware for each new application or service, virtualization permits sharing of hardware resources and allocating them to a larger number of applications, which increases effectiveness and capacity usage and decreases expenses(Chine, 2009). Via administration interface, it is possible to increase or decrease volume of infrastructure, to move virtual machines by cloning or migration in the real time(Mahmood & Hill, 2011)(Rao & Sasidhar, 2012).

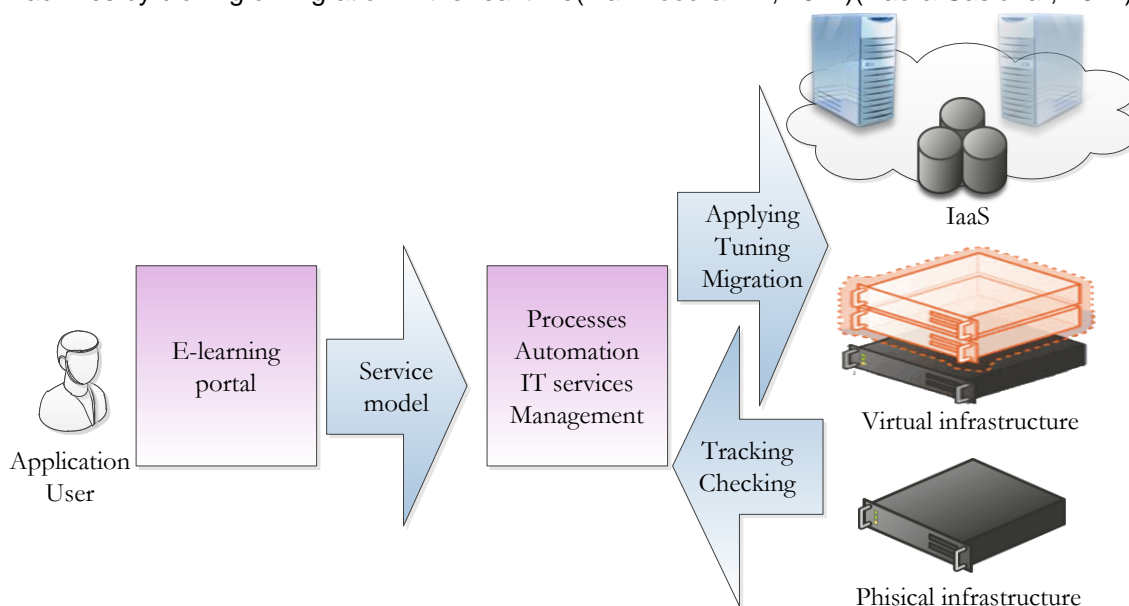

Figure 17: Delivering IaaS

It is possible to manage virtual infrastructure components by using administration interface or by creating automation scripts and commands which are started at special moments which are defined. Private cloud model enables high mobility and availability of the infrastructure and services, which creates an environment

where it is possible to track and to move application from development and testing phases into the production phase. After moving the application into the production phase, it is possible to deploy storage of these applications to a dedicated image repository.

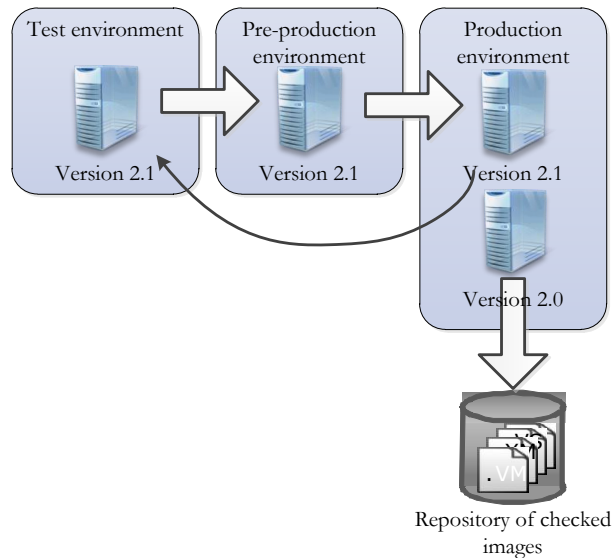

Figure 18: Mobility of infrastructure and services

Delivering and managing of virtual infrastructure resources as infrastructure enables that educational institution permits reservation of resources and their delivering to students. Students can design, implement and simulate computer network and network services. When the work is done in this environment, resources are being released and returned to pools of private cloud's available resources.

Figure 19: IaaS in e-learning

Model of PaaS through a private cloud also provides possibility to deliver platform as a service to end users. Platform as a service includes operation system, middleware, and development tools. On virtualized servers, users can run their applications, or develop new applications, but they cannot manage or configure operation systems, hardware or other infrastructure resources (Vouk, Sills, & Dreher, 2010). This way of delivering the application is convenient because of easy usage customization and application scalability. (Tian, Su, & Lu, 2010).

Platform as a service gives an educational institution an opportunity to provide each student with a virtual computer that they can use during the course of study (Schaffer et al., 2009). Through web interface, a student can manage virtual resources from the repository of platforms and choose a platform they want. After starting the image of a platform, a student can use all resources supported within that platform. After the platform is shut down, the image of the platform is stored in the repository and the student can use it later. It

is also possible to create repository of platforms for each subject, where students who study this subject can start the platform and use tools and applications related to that course. After a class, images may or may not be saved, depending on the concept of the course.

Figure 20: PaaS in e-learning

Finally, the model of a private cloud gives possibility to deliver software as a service. Unlike traditional application that need to be installed on a user's computer, software as a service presents one instance of the software that can be used by multiple users

With big cloud provides, users acquire perception of seamless cloud capacities, where limits are defined by providers' rules or contracts. However, there are no real limitless capacities, only an illusion created through optimized and efficient usage resources (Buyya, Yeo, & Venugopal, 2008). Educational institutions usually own less IT capacities comparing to cloud provides, therefore it is not always possible to provide all users with requested resources anytime. Therefore, requests need to be prioritized, and users need to be provided with possibility to reserve resources for specific period of time. Model of a private cloud must also provide a sophisticated system for resource scheduling (Rittinghouse & Ransome, 2009).

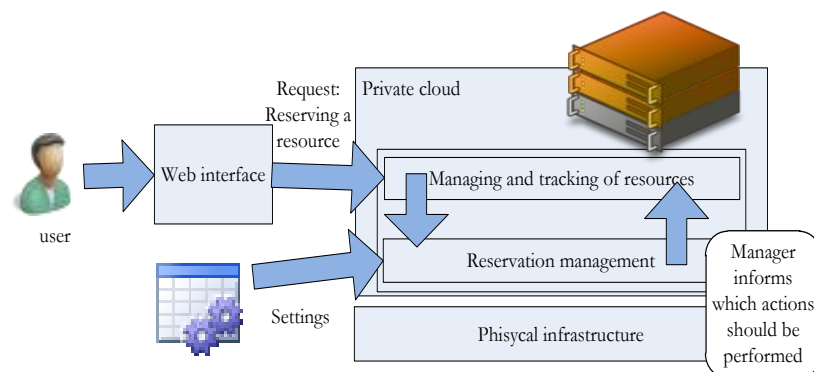

Figure 21: Allocating resources and making reservation of resources in the private cloud

Despite of current components for managing the resources of cloud computing infrastructure, a module which enables resource management via Android application is developed, as well ("Cloud computing: benefits, risks and recommendations for information security," n.d.). This module uses current cloud computing infrastructure and it is integrated with LDAP directory where students' accounts are located. It uses web services, which enables developing other applications in the future. Target users of this application are students of the Faculty of Organizational Sciences. They can run predefined images with installed operating system and required software, which is used in teaching process.

4. CONCLUSION

Cloud computing is emerging area that enable high educational institutions to use the existing software and hardware resources in more effective way. However there are not many papers that deal with cloud computing education in e-learning. This paper introduces a model for management of cloud computing

based infrastructure for e-learning. One of the most significant contributions of described model is that it solves problems of scalability with a more efficient use of existing resources within the private infrastructure.

Future research is directed toward cloud computing applications in developing e-education infrastructure with focus on: implementing a system for centralized identity management and research that will be include evaluation in real e-learning system.

Abstract: *This paper presents a strategic matrix of quality and product innovation (QPI) - a tool for strategic analysis of enterprise environment, in order to identify relevant aspects, assess their impact on business performance, and take appropriate strategies. The strategic matrix QPI is designed for strategic management for the purpose of positioning the product within a product range from the standpoint of competitiveness, and defining strategic and tactical choices of products priority in terms of future treatment. A prototype tool is implemented in MS Excel, and the positioning of products within the product range of the company is interpreted graphically. In the assessment of the strategic position, relevant product dimensions are involved, including: volume, price, quality and innovative features. The strategic matrix QPI is created and its implementation is managed by the marketing office.*

Keywords: *strategic management, tools, quality, innovation, product*

1. INTRODUCTION

From a strategic standpoint of view, the analysis of enterprise environment is applied for the analysis and evaluation of its environment (external and internal) for a specific period of time, to identify all relevant aspects, as well as assess their impact on business performance, and is used in order to make adequate corporate strategy. A number of tools and techniques are used for this purpose today, including: questionnaires, measurement of value for consumers; BPEST analysis, BCG matrix, McKinsey GE Matrix, Ansoff's matrix, process development map; SIPOC diagram, analysis of business models; key resources and capabilities of enterprises map; analysis of critical success factors, and others (Coulter, M., 2008).

This paper presents strategic matrix of quality and product innovation (QPI) that represents a realized prototype software tool for the analysis of companies environment, and also implemented model of strategic tool for the analysis of the production program of company - portfolio of products. The tool is primarily designed for strategic management, in order to strategically position each individual product within the product range, and is used to determine the strategic and tactical choices of products priority (Covin, Slevin, Schultz, 1994), to make decisions regarding of dealing with it in the future (volume, pricing, resource allocation, quality improvement, innovation, etc.). The positioning of products within the product range in the company is interpreted graphically with the help of strategic matrix QPI. In forming a strategic assessment of the position, the relevant dimensions of the product are involved, including: volume, price, quality and innovative products. From the organizational point of view, strategic matrix QPI is created and its implementation is managed by the marketing office. Software tool is implemented in MS Excel, and its structure, inputs, the method of their preparation, method of assessment of relevant characteristics for the evaluation, outputs, and the possibility of its application, are explained in more detail below.

2. THEORETICAL AND METHODOLOGICAL BASIS OF STRATEGIC MATRIX

Theoretical basis

Quality and innovation are two important factors that determine the competitiveness of products. This claim is clearly confirmed by the results of theoretical analysis (Krstić, Bojković, 2011), from which we can conclude that between these two phenomena - the quality and innovation of business systems, there is some connection, which is reflected in the fact that both phenomena have strategic importance for business

system and give a joint contribution to the level of competitiveness, and also are complementary factors of competitiveness of products, and ultimately of the business system.

Quality, in this context can be defined as the set of all good qualities, characteristics or values of the goods or services, which enable to meet the established, indirectly stated or implied needs of stakeholders. This definition integrates external and internal quality of the product. The external quality of the product as a measure of satisfaction is related to the main features of products / services and can be measured in relation to expectations. Internal quality of the product includes the ability of business systems to carry out the implementation of the product from the first attempt, with minimal degree of nonconformity, and in an efficient manner. Strategic QPI matrix includes the following features of products quality, namely: quality, cost, design, safety, maintenance, reliability, standardization, environmental criteria, ease of use, transportability, recyclability.

Innovation in this context can be defined in accordance with (Tether, 2003) as "the successful use of ideas, or guidance of ideas into profitable products, processes, services or business practices." Strategic QPI matrix includes the following categories of product innovation, including: marketing innovation, product/service innovation, process innovation for product realization, organizational innovation for product realization and business model innovation for the specific product.

Program basis

In the introduction to this paper the most important tools and techniques used today for the strategic analysis of enterprise environments are listed. From the standpoint of program implementation, commercial software packages developed on an Excel platform are most commonly used today (*Excel4Marketing Toolbox, 2012*), such as: BCG Matrix, Perceptual Mapping/Positioning Maps, Marketing Metrics and Dashboard Report, Benchmarking, Radar Charting, Performance Gap Analysis, Pareto Analysis and Pareto Charting, Ansoff Matrix, Trend Chart, McKinsey GE Matrix.

The strategic matrix QPI, which is presented in this paper, is built on similar program foundations as the above mentioned software packages (it is also implemented in Excel), but differs from them by theoretical soles.

3. PRACTICAL IMPLEMENTATION OF STRATEGIC MATRIX

The strategic matrix QPI consists of the following constituent modules, as follows:

- Organization,
- Data entry,
- Assessment of factors,
- Calculation,
- Output,

which are hereinafter more elaborated.

Module: Organization

Within this module relevant information regarding the organization's work with the Strategic QPI matrix are presented, as follows: input data for calculation, production program- portfolio of products, determining the weight factors, assessment of product quality characteristics, assessment of the level of product innovation, outputs, and the purpose of the matrix output. The application of this matrix is in large measure determined by the organization or the manner in which the necessary data are to be collected. Since the data are collected within the company, and partly externally, the role is here entrusted to marketing service.

Module: Data Entry

Within this module are entered input data for the formation of strategic QPI matrix, which is actually related to the definition and assignment of the production program, which is subject to strategic analysis. The data is retrieved as follows: product number, product model and planned quantities of certain products. In doing so it automatically calculates the value of each production in absolute terms and in percentage (Figure 1).

DATA ENTRY					
Product/service					
Number	Model	Quantity	Price (din)	Production value (din)	Relative production value (%)
Product 7	TT7	7000	123	861000	61.4
Product 6	TT6	6000	42	252000	18.0
Product 2	TT2	3000	50	150000	10.7
Product 8	TT8	400	240	96000	6.8
Product 1	TT1	230	134	30820	2.2
Product 3	TT3	1100	5.5	6050	0.4
Product 5	TT5	470	7.5	3525	0.3
Product 4	TT4	280	11	3080	0.2
			Sum	1402475	100

Figure 22: Data Entry

The program provides 8 products, but it can be expanded as needed, however the expansion may require the expansion of other modules. The user is offered practical instructions for proper sorting of the entered data.

Module: Assessment of factors

Within this module, the assessment of relevant factors is implemented. The assessment factors includes assessment of the weight factor, the assessment of product quality and determination of the level of product innovation (Figure 2).

Weighting factor (weight) is awarded to participants in brainstorming or users surveyed by the person who manages the creation of strategic matrix.

Assessing quality characteristics of products can be done in two ways, depending on the organization of matrix creation, as follows:

1. Through a brainstorming organized within the company, and attended by experts for specific areas of product quality. Each of the experts makes its own range of products from 1 to 10 based on characteristics that evaluates;
2. Through research based on surveys of users in terms of quality characteristics of each product individually, ranging from 1 to 10, conducted by marketing service. As the assessment of quality characteristics are used to middle-grade quality characteristics of the individual products, which are formed in the summary report of research.

ASSESSMENT OF FACTORS									
Assessing product quality characteristics		Grade 1-10							
Quality	Weight factor	Product 1	Product 2	Product 3	Product 4	Product 5	Product 6	Product 7	Product 8
		TT7	TT6	TT2	TT8	TT1	TT3	TT5	TT4
1 Price	10	3	1	5	2	3	4	1	7
2 Design	15	2	2	1	3	4	2	1	3
3 Safety	25	1	3	1	3	4	5	4	1
4 Maintenance	1	10	2	1	2	3	4	1	5
5 Reliability	4	5	3	1	1	6	4	2	5
6 Standardization	5	1	2	1	6	6	4	1	5
7 Ecological criteria	15	2	9	7	8	6	6	6	5
8 Ease of use	5	2	9	8	3	9	6	1	3
9 Transportability	5	8	2	2	9	6	2	9	4
10 Recycleability	15	10	3	1	2	5	1	1	1
	100	44	36	28	39	52	38	27	39
Assessing the level of product innovation		1= unchanged		2=modified		3=new			
Inovativnost	Weight factor	Product 1	Product 2	Product 3	Product 4	Product 5	Product 6	Product 7	Product 8
	%	TT7	TT6	TT2	TT8	TT1	TT3	TT5	TT4
1 marketing model	25	3	2	3	3	1	1	2	1
2 product/service model	30	1	2	1	2	1	1	1	2
3 process model	10	3	1	1	1	2	3	3	3
4 organization model	5	2	2	3	2	1	1	1	1
5 business model	30	1	3	1	1	6	2	1	1
	100	10	10	9	9	11	8	8	8

Figure 23: Assessment of factors

Assessing the level of product innovation is done by the company experts for specific areas of innovation of products, each of the experts makes its own range of products from 1 to 3 (1 = unchanged, 2 = modified, 3=new product) based on models of innovation (marketing model, product/service model, process model, organizational model, business model).

Module: Calculation

Within this module (Figure 3), based on input data and the estimated factors, the calculation of the relevant values is done, necessary for the formation of strategic matrix.

Product quality factors			Calculation of relevant values																	
			product quality																	
Quality			Weight factor		Product 1		Product 2		Product 3		Product 4		Product 5		Product 6		Product 7		Product 8	
1	Price	1	30	3	90	1	30	5	150	2	60	3	90	4	120	1	30	7	210	
2	Design	2	15	2	30	2	30	1	15	3	45	4	60	2	30	1	15	3	45	
3	Safety	3	10	1	10	3	30	1	10	3	30	4	40	5	50	4	40	1	10

score			100	175	220	160	185	260	150	145	150									
Relevant values of product innovation					3.25		4.6		2.8		3.55		5.8		2.5		2.35		2.5	
					TT7		TT6		TT2		TT8		TT1		TT3		TT5		TT4	
					6.52		4.32		4.82		5.06		7.54		5.54		2.98		6.8	

Figure 24: Calculation of relevant values

Module: Output

Within this module, based on the calculation of relevant values, the output of strategic matrix QPI is formed (Figure 4).

Figure 25: Output

The strategic matrix QPI is a two-dimensional matrix, whose dimensions are quality and innovation. Products from the production program of the company are positioned inside these dimensions of matrix. Circle diameter determines the volume of product production. In this way, the strategic position of each product is visually determined. Higher value on the vertical dimension of the matrix indicates the positioning of the product from the standpoint of innovation, and higher value on the horizontal dimension of the matrix indicates the positioning of the product with regard to quality, while the larger diameter of the circle indicates the higher value of products production volume.

4. CONCLUSION

In this paper, a developed prototype software tool for analyzing strategic environment of companies is briefly presented.

The aim of strategic QPI matrix is to facilitate making of relevant policy decisions regarding the quality management and product innovation management within the production program of business systems, by strategic positioning of each product.

Strategic matrix QPI enables management function to designate the strategic and tactical choices of products priority in the analysis of the life cycle of the production program.

Because of its easy-to-use user interface and graphical displays, the further development of strategic QPI matrix is viewed in its incorporation into EIS (Executive Information Systems) or ERP systems (Enterprise Resource Planning), enriching them with yet another strategic management tool.

Abstract: *This paper will present the Spring framework and EJB technology, which are used for enterprise application development. Subsequent to the technology presentation, a review of ISO/IEC 9126 standard will be given. Standard ISO/IEC 9126 is used for defining the software metrics for measuring the performances of a software system. In accordance with a case study, the aforementioned technologies will be evaluated using the software metrics that are supported in the software package Swat4J.*

Keywords: *Spring, EJB, ISO/IEC 9126, software quality, software metrics*

1. INTRODUCTION

We are being witnesses of very fast technical-technological development. This is especially expressed in the field of software engineering. In this sense, a great number of software technologies intended for solving various problems emerge on the scene. For example, there are technologies intended for development of enterprise applications: Spring and EJB technology. The fact is that Spring introduces a completely different approach to the development of complex applications, and that it represents the alternative to EJB technology. Also, the indisputable fact is that the EJB technology (which is de facto standard in the process of complex applications development) has significantly progressed in the EJB 3.0 versions (Graudins & Zaitseva, 2006).

However, standards are being defined in the field of software engineering. For example, the International Organization for Standardization – ISO, has defined the standard ISO/IEC 9126 (ISO/IEC 9126, 2003) used to precisely define the software quality. The attributes of quality of software system, as well as of software metrics are defined in this standard. On the basis of these attributes it is possible to perform the static analysis of the software system.

The subject of this paper's survey is the comparative analysis of two already mentioned contemporary software technologies (Spring and EJB technology), which are used in development of enterprise applications.

2. ENTERPRISE JAVABEANS (EJB)

Enterprise JavaBeans are actually Java EE components that implement the EJB (Enterprise JavaBeans) specification. They are written in the Java program language, and represent the components executed on the server's side and, as a rule, encapsulate business logics of the given application. Enterprise beans are executed within the EJB container, which represents the executive surrounding of application server (Pieber & Spoerk, 2010).

Enterprise beans significantly simplify the development of large, distributed applications:

- EJB container provides services on the system level, such as transaction management and security of enterprise beans, so that software engineers could concentrate on solving business problems
- EJB components are performed at the server's side, so that client does not contain business logics of the application. This is the reason why engineers and designers engaged in development of presentational layer do not have to take into account neither the implementation of business rules nor approach to the system of managing the database
- Enterprise beans are quite transferable components, so that it is possible to compose different applications that will use the already existing EJB components. These applications could be performed on every Java EE server, but only if it supports Java EE specification and the standard API

Table 1: Types of Enterprise JavaBeans

Type		Purpose
Session	Stateless	Performs certain tasks for the client; optionally they could implement web service
	Stateful	
Message-Driven		It acts like a listener for a certain messaging type, such as Java Message Service API

We could say that EJB technology has following features (Pieber & Spoerk, 2010):

- EJB technology represents de facto standard in the process of developing the complex applications
- EJB uses good features of application server (e.g. declarative transaction management, security)
- Using Entity classes of EJB technologies outside of application server
- EJB technology takes over good features of other technologies
- EJB technology in the new EJB 3.0 version is significantly simplified and advanced
- It requires using the EJB container

3. SPRING FRAMEWORK

As it has already been pointed out, Java in the function of platform offers exceptional possibilities. Even more, today there are numerous Java specifications (Java Specification Request, JSR) which solve different kinds of problems.

Spring framework has found an immense application in the development of enterprise applications. It practically enables everything that EJB also performs, but it does not require the usage of EJB container (Graudins & Zaitseva, 2006). For example, it is possible to use Apache Tomcat servlet container. The application which is developed by using this framework is significantly clearer, and it contains less program code. The framework works off many things in the background, so that in this way we obtain applications that are quite simple to maintain. In addition, Spring facilitates the work with other frameworks (for example, Hibernate, iBatis, JDO). In this way it enables not only the use of standard Java technologies for approaching relational basis (JDBC), but of modern tools for mapping relational entities into objects (ORM) as well (Arthur & Azadegan, 2005).

Spring is not a solution for all problems, but it definitively facilitates the development of JEE applications. In the time of its emergence, many people didn't neither admit nor understand that the development of JEE applications faces many problems (Singh et al., 2002). However, Spring has a completely fresh and new approach, and it most certainly influenced the change of many people's opinion. After all, the fact is that the new EJB3 specification took over many ideas from Spring.

Spring enables the integration with great number of technologies. Some predefined implementations could also be used here (for example, Spring possesses the Spring Web MVC implementation). It is often said of Spring that it represents the lightweight container, which could be performed on the application server, or in servlet container⁷.

We could say that Spring technology has following features (Pieber & Spoerk, 2010):

- It does not require using the EJB container
- It contains the Spring MVC framework that could be used while developing web applications
- Possesses JDBC mechanism for persistency
- Spring enables the integration with ORM frameworks (e.g. Hibernate, iBatis)
- Spring enables declarative transaction management
- Spring enables the integration with other Web MVC frameworks (e.g. Struts, JSF)

⁷Lightweight containers are actually containers that use the Inversion of Control (IoC) principle in order to work with business objects of the system in a non-intrusive way.

4. SOFTWARE METRICS

ISO (International Organization for Standardization) and IEC (International Electrotechnical Commission) represent international organizations whose activities are directed towards establishing international standards in different areas. The standard ISO/IEC 9126 (which studies software metrics) is especially important for software engineering. It includes four parts (Kanellopoulos et al., 2010):

- ISO/IEC 9126-1 studies the Quality model
- ISO/IEC 9126-2 studies External metrics
- ISO/IEC 9126-3 studies Internal metrics
- ISO/IEC 9126-4 studies Quality in use

Before the beginning of using software system, it is needed to evaluate it by using software metrics. This evaluation is based on business goals related to usage and managing the software in a specified technical and organizational environment. Standard ISO/IEC 9126 is used to define the software metrics that are used for measuring the performances of software system. This standard is also used to define the attributes of software system, and then adequate metrics are being defined for every attribute (Schackmann, 2009).

Swat4j (Swat4j, 2012) is the software tool intended for following and managing the activities of development and maintaining the software system that is being written in Java program language. It is based on the principles of the ISO/IEC 9126-1 (Quality model) and ISO/IEC 9126-3 (Software Product Quality, Internal Metrics) standards (Laval et al., 2008). Following software quality attributes are defined by this software tool:

- Testability
- Design quality
- Performance
- Understandability
- Maintainability
- Reusability

In addition, the software tool could be used for finding the potential bugs in the program. Over 30 metrics are integrated within the Swat4j (metrics are adjusted to characteristics of Java program language), and over 100 industrial standards that relate to the best practice rules in writing the program code (Laval et al., 2008). According to predefined model of software quality, several metrics are linked to every attribute of software system, i.e. there are several rules in writing the program code. In the other hand, one metric/one rule could apply to more than one attribute of software system, which is showed in Figure 1.

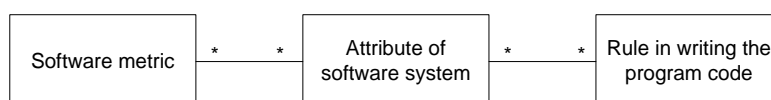

Figure 26: Relation between attributes of software system, software metrics and rules in writing the program code

We could say that Swat4j contains following groups of metrics:

- Object-oriented metrics – they enable the measurement of object projection quality, as well as of couples and dependence between objects, as well as of some other principles (Kanellopoulos et al., 2010):
 - Weighted Methods Complexity (WMC) is defined as a sum of complexity methods
 - Response For Class (RFC) defines the set of all methods that can be invoked in response to a message to an object of the class
 - Lack Of Cohesive Methods (LCOM) represents the measure of mutual connection of methods
 - Coupling Between Object (CBO) is based on the idea that one object is related to some other object if one object uses the features and methods of that other object (for example, the method of the first object uses the methods or appearance of the second one)
 - Depth of Inheritance Tree (DIT) – The depth of a class in the inheritance hierarchy is defined as a maximal number of levels starting from the observed node to the tree's root
 - Number of Children (NOC) - Calculates the number of direct sub-classes of the observed class/interface in the class hierarchy

- Complexity metrics – The complexity of a system or its components represents the difficulty of understanding the software system, or the components of the software system. We differentiate following metrics for determining the complexity:
 - Cyclomatic Complexity – McCabe - The cyclomatic complexity of the software system is measured by calculating the number of decision points or conditional statements of the observed program language
 - Halstead Complexity Metric - serves for measuring the complexity of the module directly from the original program code by using operators and operands
 - Maintainability Index metric – Represent the quantitative measure intended for measuring and following the maintenance in order to reduce or terminate the system's tendency towards entropy of program code
- Code metrics – The mentioned metrics represents specialized metrics which enables the specific insight into quality of the program code. These metrics are used in combination with one, or more than one specialized metrics such as object-oriented metrics, or complexity metrics. In addition, we can observe these metrics in four different levels: the Method level, Class level, File level, and Package level

5. CASE STUDY

A case study was created for needs of this research by using the Larman's method of software development. CRUD operations are implemented for all objects that are defined in the data model shown in Figure 2.

Figure 27: Case study data model

The case study we have just demonstrated was realized by using Spring and EJB 3.0 technologies. Software metrics supported by the software package Swat4j are used for static analysis of this case study. The emphasis is primarily set on the object-oriented metrics, complexity metrics and maintainability index metrics. On the basis of performed analysis, following data on Software quality model are obtained:

Figure 28: Software quality model – Spring

Figure 29: Software quality model – EJB

The graphical display of quality model of this case study, developed by using the Spring framework, is presented in the Figure 3. As we can see, Design Quality (8.78) and the Reusability (8.51) attributes are lower graded. In the other hand, Figure 4 represents the quality of model of case study developed by using

EJB technology. As we can see, lower grades are awarded to the Design quality (7.53) and Reusability (8.98).

However, it is important to point out that the value of the Design quality attribute in EJB technology is less than comparing to the Spring framework (7.53 to 8.78). Oppositely, the value of Reusability attribute is higher than in EJB technology comparing to the Spring framework (8.98 to 8.51). Other attributes are quite equally graded.

Based on the obtained attribute values in the model of software quality, we can say that the application developed by using the Spring framework is better designed comparing to application developed by using the EJB technology. And contrary, the application developed by using the EJB technology has greater possibility of re-use comparing to the application developed by using the Spring technology.

Based on the performed static software analysis, we can reach following conclusions on the observed technologies:

- The set of class responses is well defined
- Methods are well designed and not complexed
- There is a lack of method's cohesion within classes. We should discuss the option of dividing some classes into several classes
- Classes are poorly coupled
- Classes inherit greater number of classes then they should. The number of inherited classes should be reduced, or discuss the option of using the composition instead of inheritance
- By using these technologies, we get easy to maintain applications

6. CONCLUSION

This paper shows the basic concepts of EJB 3.0 and Spring technologies. Both Spring and EJB enable the development of complex (enterprise) applications, but approaches are slightly different. The fact is that both technologies have their advantages, but disadvantages as well.

Based on everything that was stated in this paper, we could say that EJB technology has following features:

- EJB technology represents de facto standard in the process of developing the complex applications
- EJB uses good features of application server (declarative transaction management, security...)
- Using Entity classes of EJB technologies outside of application server
- EJB technology takes over good features of other technologies
- EJB technology in the new EJB 3.0 version is significantly simplified and advanced
- It requires using the EJB container

After the survey of EJB 3.0 technology, we've given a short survey of the Spring framework. We have presented the components of the Spring framework and their purpose. In this context, we determined that the Spring technology has following features:

- It does not require using the EJB container
- It contains the Spring MVC framework that could be used while developing web applications
- Possesses JDBC mechanism for persistency
- Spring enables the integration with ORM frameworks (e.g. Hibernate, iBatis)
- Spring enables declarative transaction management
- Spring enables the integration with other Web MVC frameworks (e.g. Struts, JSF)

Based on the previous research, we have concluded that the Spring framework enables the exact same things as EJB does, while it is not necessary to use the EJB containers. Applications written by using the Spring technology could be performed within the application server. However, applications written by using the EJB technology could not be performed without the application server. Also, Spring facilitates working with other frameworks (it could integrate with ORM frameworks, as well as with Web MVC frameworks). However, the fact is that the EJB 3.0 technology has overtaken many good characteristics of the already existing technologies. Good features of the Spring framework had been used (for example, the support for IoC concept had been added) and Hibernate framework (annotations added, as well as support for mapping

the classes into POJO entities for simple securing of persistency). In this way, the technology is significantly improved and simplified. Many operations are made automatic and the container carries them out in the background (without the explicit invitation coming from user). In addition, the use of Entity classes of EJB technologies in this new specification is made possible and outside the application server.

After the survey of EJB 3.0 and Spring technologies, we've given the survey of ISO/IEC 9126 standards used to define the quality of the software system. This standard comprises of four parts: ISO/IEC 9126-1 (used for defining the software Quality model), ISO/IEC 9126-2 (for defining External metrics), ISO/IEC 9126-3 (for defining Internal metrics) and ISO/IEC 9126-4 (for defining Quality in use). For needs of this research, the case study has been completely planned, and two realizations were given: one by using the Spring framework, and the other by using the EJB technology. These two applications represented the base for performing static analysis of the software (software metrics that satisfy the ISO/IEC 9126 standard is used). Results of the static analysis of Spring and EJB technology are shown in Table 2.

Table 1: Spring and EJB quality model

	Testability	Design quality	Performance	Understandability	Maintainability	Reusability
Spring	10	8.78	10	10	10	8.51
EJB	10	7.53	10	10	10	8.95

Based on the obtained values of attributes in the model of software quality, we can say that the application developed by using the Spring framework is better designed than the application developed by using the EJB technology. However, application developed by using the EJB technology is easier to re-use comparing to application developed by using the Spring technology. Based on the metrics value, we have reached the following conclusions on observed technologies:

- The set of class responses is well defined
- Methods are well designed and not complexed
- There is a lack of method's cohesion within classes. We should discuss the option of dividing some classes into several classes
- Classes are poorly coupled
- Classes inherit greater number of classes then they should. The number of inherited classes should be reduced, or discuss the option of using the composition instead of inheritance
- By using these technologies, we get easy to maintain applications

We have an impression that the EJB technology slowly evolves. The fact that technology progresses and takes over good features of other technologies is praiseworthy indeed. In this context, many companies have been engaged in the development of new Java EE specification. In addition, we believe that the Spring technology is completely opened for expansion towards other technologies.

WHERE ARE WOMEN IN IT SERBIA?

Ana Pajić¹; Dragana Bečejski-Vujaklija²

¹Faculty of Organizational Sciences, University of Belgrade, Serbia, ana.pajic@fon.bg.ac.rs

²Faculty of Organizational Sciences, University of Belgrade, Serbia, draganab@fon.bg.ac.rs

Abstract: *Rapid development of information systems and technologies calls for the establishment of gender equality at all levels. The issue of women's underrepresentation in information technology has been recognized, yet the number of women is still disappointing. The study is implemented through an online survey, where a link was distributed via email to women who work at jobs related to IT, in the IT sector or other organizations.*

Initial results indicate that women are outnumbered in Serbia and they face certain challenges and obstacles that men do not. The aim of the paper is to point out the necessity of a declining gender gap in information systems and technology in Serbia, in order for it to take advantage of the overall potential of a fast-growing market.

Keywords: *gender gap, women in IT, retention of women, gender stereotypes, female computer scientists*

2. INTRODUCTION

For more than a few decades information systems and technologies have changed the world and interpersonal relationships, improving quality of business processes, facilitating access to information and creating new forms of communication. They have led to changes in various spheres of social life, becoming one of the most dominant technology in today's world. The modern, competitive and profitable business cannot be imagined without the use of information technology.

Fast development of information systems and technologies had a huge impact on employment, as well as women's employment. On the other side, a disparity between women and men has persisted in the requirement and retention of women at all levels of information technology [IT], particularly in the highest corporate and academic positions. There is still established perception that it is a traditionally male dominating profession and employers prefer more male ICT professionals. Women face different challenges and barriers in this so-called "male" field.

Facing continuously with different stereotypes, through childhood and schooling time, girls don't recognize technology as perspective career. IT sector, which is growing continuously, are seen as boring activity which is not worth getting involved with. Is it female lack of interest or lack of support and long-term stereotypes that keeping women away?

Despite a number of obstacles, some women succeed at the top of IT. As Fahmida Y. Rashid (2011) pointed out "the bulk of female power seems to be concentrated in the vice presidents, COOs and CTOs. Women tend to be second-in-command and leaders of major divisions. That's not a bad place to be, considering where women were only a few short years ago". Unfortunately these women are rare examples, but only with the real role models and good work learning environment the situation can be improved.

Therefore, this study will be addressing this issue. Paper goal will be to assess the general status of women in IT profession in Serbian market.

The basic question to be answered is where the women are in information technology in Serbia, as well as does the market referring differently male computer engineers than female. We want to investigate gender gap in IT field, in order to awake community and government how serious the problem is and to get involved them in solving it.

The starting point is the survey we conducted among female population working in the field. The main results will be presented in this paper, which could be a good starting point for further research and case studies.

3. LITERATURE OVERVIEW

The issue of women's underrepresentation in information technology, whether in school, higher education, or industry, has been studied in many ways over several decades. It is receiving growing attention not just from

scientists, but also in industry. A number of firms and institutions have recognized the problem, women are facing with, trying to discover its very complicated nature.

Gender Gap in IT has been known since as far back as 50s, with appearing of first dedicated electronic business computer (Hicks Marie, 2010). In early computing, women had been mostly involved in advertising to sell data processing equipment and as data processing labour force. The image of woman as low-cost, unskilled worker was then created and seems to left significant mark on further female professional position in the field.

From the 1950s through the mid-1960s, the primary roll of female worker was to demonstrate power of early office machine quite easy to use. The photographs of female workers on adverts, standing by and working on machine, shared the message „although the electronic computers they use “are so complex,” nonetheless, “a girl can be taught how to work in only ten minutes”“(Hicks Marie, 2010, p.7-8). Machine was tending to complete complex tasks, where low skill and inexpensive replaceable labour can use it. Therefore, routine jobs were dedicated to female worker. In 1960s, women raised their voice and tried to improve their position on the market, convincing community to see them not as „cheap labour but as qualified technicians“(Hicks Marie, 2010, p.8). Despite this effort, employers continued to perceive women as unreliable, not committed to a career worker, meant to be on lower-level positions. They were more demonstrators instead of real computer workers. Unfortunately, in 1970s culture norms were more changed and women started to be use as a sexual object in commercials, focusing on their bodies, which more marginalized them.

Picture 1: The advertisements appeared in early computing

Today's situation is quite better. The number of women in science and engineering was growing, yet men continue to outnumber women, especially at the upper levels of these professions. But recent studies in USA showed that the number is dropped in last few years (Swift Mike, 2011). The percentage of women in IT is declining despite the programs that specifically addressed young women. The research from June 2002 (James Justin, 2010) presented the same results for countries around the world. India was the only exception, where programming is seen as better option in comparison to working in a factory or a farm.

Different theories and empirical studies concentrate on the question why there is a lack of women within the IT profession. Ellen Spertus (1991) have come to the conclusion that not just the problems resulting from working in primary male environment, but also the different ways in which children are raised can influence a girl not to pursue an interest in technology. She highlighted the existence of different expectations for men and women based on culture. Bearing in mind the words of eminent computer scientists, Professor Dame Wendy Hall, “girls still perceive computing to be “for geeks” and that this has proved to be “cultural” obstacle,

so far impossible to overcome" (Shepherd Jessica, 2012), we can conclude that cultural stereotypes of gender skills, abilities and competences are well-established in academic and corporate world.

On the other hand, there is an opinion that women are not quite aware of variety of options IT career has to offer. Mostly women think that IT is mainly about programming and not explore creative parts of the field, which can be more interesting and inspiring for them (Morton Ella, 2005).

Furthermore, it is not enough just to encourage girls to pursue IT career but also to stay within for long-term. Women face difficulties with keeping up with new coming technologies in everyday changing environment, when they make a decision to have a family or to take maternity leave. However, technology itself provides more flexibility with opportunity for working from home via Internet.

4. RESEARCH RESULTS

The main focus of this research is to look at the state of job and working environment satisfaction among women participating in IT sector in Serbia. Data was collected through online survey, where the link was distributed via email to women who work at jobs related to IT, in organizations where IT is core work or others. The survey is posted on the website <https://docs.google.com>.

The research was conducted in March 2012 and initial results are presented in this paper. The results should be used for information purposes and be considered as good base for further in-depth comprehensive study of women in information systems and technologies. We used statistical software SPSS version 11.5 to process survey results.

The number of participants involved in the survey is 182, with different educational background and working experience. They are connecting through the interest in technology and science. For the purpose of presenting them, we start with the main variables which can have significant impact on final results.

In Figure 1 we can see participation rates by age, with the age groups as defined in survey. Most female participants are young. The vast majority (72 percent) of women are below the age of 35 years old. Only 14.8 percent are over the age of 46, and about one-half of those individuals are over 55 years old.

Table 10: Age range of participants

	Frequency	Percent
Below 25	24	13.2
26-35	107	58.8
36-45	24	13.2
46-55	18	9.9
Over 55	9	4.9
Total	182	100.0

Furthermore, the examination of company profile variable is quite interesting. As we expected most participants (53.3 percent) are coming from companies where IT is core business work. 17 percent of them are working in service industries and substantial number of women is in the companies related to education. Figure 2 provides a view on outcomes for this independent variable, which impact on results would be discussed in next section.

Leading companies are failing to capitalize on the talents of women in the workforce, according to the report (Saadia Zahidi & Herminia Ibarra, 2010). Lack of women's participation in the workforce can cost the billions of dollars every year developed and growing fast economies. For purpose of monitoring gender gap in IT

sector in Serbia, we observed the percentage of women in companies working at IT related jobs. The rate of IT female professionals in the labor force can be seen in the graph (Figure 3). Not surprisingly, only 33 participants responded that in their companies, women present over 50 percent of workforce.

Table 11: Company profile

	Frequency	Percent
Education / Training	20	11.0
IT core business	97	53.3
The public sector	12	6.6
Service industries	31	17.0
Other	22	12.1
Total	182	100.0

Table 2: Company profile distribution

	Frequency	Percent
below 1%	14	7.7
1-5%	16	8.8
6-10%	13	7.1
11-20%	33	18.1
21-50%	73	40.1
over 50%	33	18.1
Total	182	100.0

Table 12: Frequency of women's percentage

Figure 31: Frequency of women's percentage in companies

The leading discussion in this field is regarding different career challenges female IT workers face than their male counterparts. Moreover, there is existing assumption of fewer women at high level positions with responsibilities of leading complex projects. Is this mean that being the women represent disadvantage in getting a job? 85.7 percent of women responded on this question with negative answer. They don't consider men have an advantage on women in getting a job in IT industry. The distribution of responses is more or less even in all age groups and it is presented in Figure 4.

On the other side, the statement that women don't so often lead complex projects is not completely confirmed. Around 27 percent of participants say that no women in their companies get to lead a complex projects. It is more emphasized among younger population, where one-half of respondents below 25 years old say the same (Figure 5). Performing Chi-square test, we made comparison among these two and company profile variable. Outcome show statistical significant relationship between profile of participants' companies and their responses regarding gender discrimination in getting a job. The corresponding probability is 0.001, which is lower than the conventionally accepted significance level of 0.05 or 5 percent.

Figure 32: Gender difference in getting job

Figure 33: Women lead complex projects

The brief statistical analysis of gender pay gap shows that women are equally compensated for their work compared to men. There is not substantial difference in wage among IT workers in Serbia in the opinion of research participants. Slightly disagreement can be observed in younger age groups, particularly in group between 35-45 years old. The differences become non-significant as we move up a group (Figure 6).

The similar results are obtained regarding appreciation of women in IT. Around 24 percent of responders are not satisfied with the treatment from the employers and coworkers. Mostly it is visible in the group between 36-55 years old. The response overview is showed using Figure 7. Undertaken Chi-square test shows an important influence of company profile variable on equality in appreciation of both genders. The corresponding probability is 0.02. We can say that there is a tendency of it to affect also payment equality, which should be confirmed with extended empirical data.

Figure 34: Gender pay gap

Figure 35: Appreciation of women in IT

5. CONCLUSION AND FURTHER WORK

The study analysis indicates that more proactive guidelines need to be implemented in order to bring a balance in the participation of women in ICT. Women and men are still divided by their perceptions of growth opportunities and compensation levels. Reducing gender gap for technology worker is a slow process and a big challenge.

Pursuing the objective of obtaining relevant data regarding status of women in IT profession in Serbia, we have presenting following:

- undertake a descriptive study to characterize the independent variables, such as number of women working at IT related jobs in responders companies expressing as a percentage (values presented in Figure 1, 2 and 3).
- in order to understand behaviour and obstacles women facing in IT career, we assess attitudes and opinions of responders regarding gender stereotypes and commonly used statements over women discrimination in IT world.

Results show that the majority of involved women believe in equality between women and men in getting job, leading complex project and payment. As already mentioned, we observed the statistical significant correlation between company profile variable and distribution of responses regarding gender payment gap, women appreciations and differences in getting a job. Therefore, we can't ignore the other part of the population which disagrees with them.

In spite of the encouraging findings of the current study, we identified a number of weaknesses. A limited number of data values were collected during the execution of the survey, due to the limited amount of time and the number of subjects. We may consider the quality of data collection to be not enough for deep comprehensive analysis. Furthermore, we asked subjects firstly for their personal opinion, came from their experience, which should be reviewed with more data in the future. The results of this research should therefore be interpreted only as findings and good basis for further projects.

In view of the brief analysis of the gender gap statistics in IT Serbia, it is important to continue research on this population as studies provide essential information about experience women facing. We intend to conduct more of field studies in cooperation with other institutions and to analyse the representation of females enrolled on studies at Belgrade University.

Abstract: *This paper considers the complex relationship between managerial strategic choices and business performance in a dynamic international environment. This topic is extremely current in the conditions of the world economic crisis and is relevant for companies, as well as in the final instance, for economic growth. The goal of the paper is to indicate the key aspects of company performance improvement as the result of successful realization of a chosen strategic option in international business. Comparative analysis of the approaches and results of empirical research points to a variety of implications of strategic managerial decision-making on performance and also to the expressed multidimensionality in this field. Dynamic approach and focus on considering qualitative and quantitative aspects of the analyzed connectedness in an international framework is necessary.*

Keywords: *strategic option, international business, managerial choice, company performance improvement, international competitiveness, innovative strategic orientation*

1. INTRODUCTION

Managers in international business must make decisions about entering a certain foreign market, and introducing new products and services, which is reflected in the selection of an appropriate strategic option. The company should reinforce its strengths in order to face the challenges of a rapidly changing external environment for which discontinuity is the norm. Analysis and prediction of changes in business environment help to successfully create strategies and conduct business towards improving performance in the future period. In any case, the international environment has an important impact on the company, which largely depends on the dynamics of the environment. It is also necessary to consider variety of its factors – social, economic, political, cultural, technological, ecological. Managers must take into consideration the acceleration of business competition activities, shortening the product and service life cycle, shifting of economic power between countries and regions, desegregation in many business spheres, increasing uncertainty and operations in a more volatile contemporary world. There is an important tendency for companies, especially in certain types of product and service fields, to use the flow of information in order to create a competitive advantage in foreign markets, especially in conditions of intensification of knowledge based competition. The use of communication technologies is of increasing importance in the realization of strategic options in the international business.

The global economic crisis has influenced a change in the strategic approach of many managerial teams, as well as factors of creating strategic advantages in an international framework. The strengthening of the role of the state in the economic sphere, protectionist tendencies and the necessity of considering national differences and adapting to local conditions must be taken into consideration. Increasing significance of product and process innovation, product and service customization and resource allocation of companies to strategic priorities is evident in contemporary business. The expanding role of cost management and price competition imply the importance of the creation of an appropriate pricing strategy. Generally speaking, the complexity and dynamics of the contemporary environment demand a flexible approach to strategic options and an effective managing of strategic changes.

A particular challenge for managers is the selection and realization of a strategic option which will lead to the improving of company performance. This is essential from the aspect of economic development, but also for the enhancing of dignity and reputation of the business on a global scale. For the managerial profession what is becoming crucial is multidisciplinaryity, as well as development of new approaches, methods and techniques of modern management, new ideas and creativity. Also, attention should be focused on the

¹This paper includes the research results of the author realized on Project record no. 179081 financed by the Ministry of Education and Science of the Republic of Serbia.

connection between strategic management and performance management, with the appropriate information support. The importance of economic knowledge is also now center stage, including both microeconomics and macroeconomics, which relates to production and service industries, with their focus on more intensive, successful inclusion in international business in the complex dynamic environment of the second decade of the 21st century.

2. MANAGERIAL STRATEGIC CHOICES IN CONTEMPORARY INTERNATIONAL BUSINESS

Companies must reexamine their strategic choices as a response to changes in the environment. Starting from the altered economic landscape, adaptation is necessary of the following functional strategic components: market and products; operations and innovations, organization and people; identity and reputation (Ghemawat, 2010).

As regards market and products as strategic components, companies in developed countries should reconsider the manner of customer targeting. The second challenge is related to pricing pressures. The necessity of lowering prices has been influenced by the economic crisis, fall in purchasing power and surplus of capacity, and the expansion to poorer markets, both domestic as well as foreign is also contributing to this trend. Finally, companies must develop products and services fundamentally different from previous ones, taking into account local differences, such as consumer preferences, price sensitivity and infrastructure, as can be seen from the example of the company *Nokia*, which developed a mobile phone, intended for rural communities in India in accordance with their particular local needs. Possible adjustments are likewise expressed through the focusing on underserved market segments throughout the world.

The domain of business operations is specific by its tendency to shorten and simplify supply chains, and adjustments often imply rethinking the scope of offshoring. Another characteristic is importing process innovation from the emerging economies. In addition to this, high-tech firms especially have a pronounced tendency to move R&D where the researchers and market growth are present. As regards organization and people, it is becoming more important in the case of multinational companies to re-create country manager functions and develop a globally representative talent pool (Ghemawat, 2010). From the aspect of developing strategic options of multinational companies the possibility of having dual headquarters— one in a developed Western country and the other in Asia is becoming up-to-date. Certain adjustments are needed in the domain of reputation as a strategic component, such as building a strong corporate identity, emphasizing belonging to a corporation and restoring the general reputation to a business in the contemporary world in the conditions of the economic crisis.

Manager must respect the fact that many industries are being transformed by the fast development, acceptance and application of innovation from the sphere of information and communication technologies (ICT). Especially noticeable are changes in the field of expanding service sectors. From the viewpoint of companies and the economy, the influence of ICT on lowering transaction costs is now foremost. The location of the company in the case of creation of an ICT cluster is also becoming important. In creating an appropriate competitive strategy in the conditions of digital economy, managers should reexamine the position of the company in relation to competitors in the sphere of e-business (Milićević, Ilić, 2011). Abilities of the firm in the domain of information and communication technologies must be objectively considered, as well as the need for financial resources. Development in the field of mobile communications is becoming important.

In the recent period the importance of strategies that help to outthink the competition is stressed. Leaders in companies that have applied this strategy spot an opportunity in the environment which others do not, intelligently choose and quickly react to this new strategic option which basically disrupts the established market relations. Traditionalists are defeated in an environment in which business competition is undergoing a fundamental paradigm shift (Krippendorff, 2012). Specifically, breakthrough companies are creating a new strategic reality by seizing asymmetric advantages. Examples of these companies are *Apple*, *Microsoft*, *Google*, *Tesla Motors*, *Vistaprint*. Strategic creativity here is important as the result of a new way of thinking which through acting differently, in the final instance, leads to the reshaping of particular industries. As a result, performance of hypergrowth companies is often considerably improved as reflected in an increased market share, income and profit. The original strategic approach and following new paths in the altered environment have led to the global business success of companies *Dell*, *Facebook*, *Amazon*, *L'Oréal*. What is characteristic and often stands out is the power of coordinating things outside the company itself in implementing innovative strategies.

In modern strategic management in Asia, but also throughout the world, starting from hypercompetition, the common practice of creating and realizing strategies is often linked with the classic work of the Chinese writer Sun Tzu *The Art of War* (Sun Cu, translation 2009). It is typical of these approaches to treat the market as a battlefield and it is of key importance to realize the strategic option which will defeat the competition, especially in conditions when supply exceeds demand.

In this context it is important to consider the essentially different approach to strategic options expressed in the concept "blue ocean strategy" created on the basis of a detailed empirical study of 150 strategic moves spanning more than a hundred years and thirty industries (Chan Kim, Mauborgne, 2005). Here the metaphor of a red and blue ocean is used for different market spaces. "Red oceans" refer to the known market space where industry boundaries are defined and accepted, and the competitive rules of the game are well known. As the market space gets crowded, prospects for profits and growth are reduced (blueoceanstrategy.com). According to this concept, tomorrow's leading companies will succeed not by battling competition, but by creating the blue oceans of uncontested market space. Even though some blue oceans were created beyond existing industries boundaries, many were created with new game rules from within red oceans by expanding existing industry boundaries. A typical example is the Canadian company *Cirque du Soleil*, which successfully created new market space that made the competition irrelevant through a strategic orientation towards an alternative form of entertainment for a new group of customers. There will always be red oceans in the environment, but companies, by creating blue oceans, followed by a new aggregate demand, can use the new opportunities for development and realizing profit, i.e. improving performance, and this strategy is defined as value innovation. It implies a leap in value for the enterprise and for its buyers and is based on differentiation and low costs, i.e. improved efficiency, which implies a "win-win scenario" (Chan Kim, Mauborgne, 2005). In contemporary conditions of ICT development in international business, the blue ocean strategy execution in mobile industry is becoming particularly relevant.

3. CONNECTION BETWEEN THE STRATEGIC ORIENTATION OF A COMPANY AND BUSINESS PERFORMANCE IN THE INTERNATIONAL ENVIRONMENT

It is necessary to constantly examine the external international environment in order to timely observe the signs of possible unfavorable economic trends, demand saturation, technology substitution, consumption structure change, and social discontinuities. If there are indications that a certain foreign market won't be profitable in the future period, the company shall seek an opportunity on a new market or on a more narrow market segment.

In order to be successful, a company must create value for its customers/service users and other relevant stakeholders in a distinct manner through competitive positioning and by offering an integral service. Strategy is defined also as the skill of creating value which offers a conceptual framework based on which managers can identify chances of providing value to clients with the company attaining profit. In this sense the strategy is seen as a way for the firm to define its operations and integrate resources, including the intangible ones.

Considering the importance of business performance improvement from the aspect of survival, and especially the development of companies in the world economic crisis, the focus is on studying the relationship between strategy and different aspects of enterprise performance. In this context, besides the profitability ratios, newer approaches and models of measuring performance of a contemporary company must also be considered, especially the advantages offered by the creative application of competitive benchmarking (Miličević, 2005). In designing a specific system of measuring performance as the result of realization of a particular strategic option, the interests of internal and external stakeholders should be considered.

It is important to stress the role of the Balanced Scorecard - BSC as the original model of measuring company performance (Kaplan, Norton, 1996). Application of BSC and strategy maps is especially current from the aspect of increasing the importance of knowledge as an intangible resource which often leads to important innovation and in this sense BSC enables the successful overview of results from innovation and learning perspective. Innovation can result in lower costs, differentiation or faster response to opportunities and threats from the external environment, where the core competence and abilities of the organization must come to the fore.

Employees can effectively implement a strategy when they fully understand it and when they realize how they can contribute to future business success. It is especially important to have communication between managers and employees and cooperation. In this context the newer approach through "performance-driven organization" is more relevant as it integrates the performance of employees and the performance of organizations (Siffler, 2006).

The empirical study of the relationship between strategy and performance is relevant, determining the business strategy from the aspect of pursuit, achievement, and maintenance of competitive advantage in an industry (Morgan, Strong, 2003). In this manner strategy is linked to the outcome of strategic decisions of managers. Multidimensionality is implied in the assessment of business performance with the incorporating of the driving forces of future growth. The manner in which the business strategy content is expressed in a company is determined differently, namely as a strategic fit, strategic predisposition, strategic thrust, strategic orientation or as a strategic choice.

In assessment of business strategies the comparative approach is affirmed which evaluates the strategy based on numerous traits and dimensions common to all companies. It surpasses the empirical limitations typical of the classification approach for strategies and starts from the following six dimensions of strategic orientation which have been developed from several angles in literature in the field of strategic management: *aggressiveness*, *analysis*, *defensiveness*, *futurity*, *proactiveness* and *riskiness* (Morgan, Strong, 2003).

Aggressiveness as a dimension of strategic orientation of an organization is primarily linked with using and developing resources faster than the competition. In markets characterized by turbulence and intense competition aggressive strategic behavior should improve organization performance through increased sales and profitability. This dimension entails a clear orientation towards sales which emphasizes the importance of increasing the market share and plays an important role in direct confrontation with competitors in order to defeat them. *Analysis* relates to the capacity of creating knowledge and securing the process of organizational learning. It reflects an organizational approach to problem solving formed by understanding the internal and external environment context. It has been observed that in turbulent international environment the successful managers are those who base their decisions on more information, considering a larger number of alternatives and seeking more advice in decision making. The level of business performance can depend on the ability of the company to retain its existing competitive position with a slight emphasis on development outside its business field or market. The dimension of defensiveness is characterized by a high degree of strategy specialization, stronger focus on the defense of the existing area and belief that expert knowledge in a certain field leads to a high level of business performance. In endeavoring to secure a high level of business performance, the organization is seeking a market position which it is able to defend from the competition. The *futurity* dimension implies that in conditions of considerable environment changes, the existence of a long-term vision is a strategic imperative for preserving a competitive market position. Such an orientation secures the basis for understanding the pattern, form and scope of potential changes in the competitive environment, industry and market. *Proactiveness* reflects innovative behavior and the tendency of the organization to take advantage of the observed opportunities, experiment with change and assume the so-called "first-mover" actions. This dimension of strategic orientation enables the creation of a competitive advantage on the basis of a proactive approach to seeking new products and markets. Organizations with such a strategic orientation realize a high level of performance based on their responsiveness to market signals, access to rare resources, customer and user loyalty and strong commitment to innovative improvement of business. *Riskiness* as a dimension of strategic orientation can be specified as possible gains or losses which are the result of an implemented action. The allocation of resources is very important and can be the key parameter in making decisions related to the choice of a competitive strategy (Morgan, Strong, 2003).

Empirical research regarding these dimensions of strategic orientation and business performance of companies was conducted on a sample of 149 medium and large production high-tech companies. The influence of these dimensions of strategic orientation of companies on business performance was examined which were presented through a combination of the following indicators: accounting-based items – return on investment and sales growth; market-based items – market share, customer satisfaction, competitive position and customer retention and "overall firm performance" as a generic indicator (Morgan, Strong, 2003). The results of this research showed that companies whose strategic orientation was based on futurity, analytical skills and abilities but also defensive tactics achieved the highest level of business performance. On the other hand, also relevant is research that indicated proactivity, preference towards risk and aggressiveness as very common dimensions of strategic orientation of many successful companies,

especially linked with intrapreneurship practice. Thus we must consider the connectedness of an entrepreneurial strategy and firm performance (Dess, Lumpkin, 1997).

The results of cluster analysis are relevant, according to which four basic types of innovative strategic orientations are differentiated, based on which businesses can be classified into four groups: (1) product innovators or current pioneers – companies with the highest rate of introducing new products and relatively high allocations for research and product development; (2) process innovators – firms with the highest costs of research and development, that enter target markets relatively early; (3) late entrant non-innovators – the least innovative, with the lowest rate of introducing new products and relatively small research and development expenditures; (4) former pioneers – businesses that are currently not innovative, viewed from the aspect of introducing new products and allocations for research and development (Manu, Sriram, 1996).

The relationship between the innovative strategic orientation type and the following business performance indicators: return on investment, cash flow of investment, cash flow from operations, market share, relative market share, market share growth is important in international management. The results of research of this connection are specific (Manu, Sriram, 1996). A characteristic of the first group of companies, product innovators, was weak financial performance such as return on investment and cash flow due to high costs of this strategy, but the growth rate of the market share is very high. Process innovators were better than product innovators regarding financial performance, however cash flow was unsatisfactory. Firms from the third group – non-innovators realized a very low market share, as their strategy was not designed for acquiring a strong market position (Manu, Sriram, 1996). Former pioneers had superior performances according to all indicators, except market share growth. Excellent marketing and financial performances of this organization were realized on the basis of a superior market position which stems from the fact that these companies first appeared on these markets and had built a good image, and sometimes were successful franchisors, especially on an international scale.

Research results have shown that companies, instead of the complete realize around 60% of their strategies' potential value, due to losses and problems that occur in strategy planning and implementation. (Mankins, Steele, 2005). According to the research of these authors, average performance loss in strategy realization is 37%. The loss structure is as follows: 7.5% - inadequate or unavailable resources, 5.2% - poorly communicated strategy, 4.5% - actions required to execute not clearly defined, 4.1% - unclear accountabilities for execution, 3.7% - organizational silos and culture blocking execution, 3.0% - inadequate performance monitoring, 3.0% - inadequate consequences or rewards for failure or success, 2.6% - poor senior leading, 1.9% - uncommitted leadership, 0.7% - unapproved strategy, 0.7% - other obstacles, including inadequate skills and capabilities (Mankins, Steele, 2005).

The fact that in international business many high-performing companies have succeeded in closing the strategy-to-performance gap owing to effective planning and strategy realization is certainly positive. This complete and effective planning and execution process has contributed to the great performance of companies such as *Cisco Systems*, *Dow Chemical*, *3M* and *Roche*.

Price competitiveness in international markets is important, so the application of an adequate pricing strategy for a product or service is relevant. The example of the company *Apple* is illustrative as its new pricing strategy is considerably different from its strategy in the previous period. The company *Apple*, which was once known as a leader in the high-tech sector for its high prices, recently began to defeat the competition with a new strategy based on lower prices. Innovations, such as products like iPhone, iPad and the ultra-thin MacBook Air notebook are justifiably considered the key generators of the rebirth of the company under Steve Jobs. Analysts believe that the new pricing strategy has considerably contributed to having this company, besides loyal users of *Apple* products, win over a broader circle of consumers. Aggressive pricing is the results of *Apple's* ability to use its growing manufacturing scale to push down costs for parts for their devices which are saleable throughout the world (N. Wingfield, 2011).

4. CONCLUSION

In conditions of limited resources and great pressures on increasing efficiency and effectiveness, the importance of strategic planning in international business becomes apparent, i.e. making managerial decisions about the desired goals and strategies that will realize them. This implies the importance of successful connectedness of managerial strategic choices and business performance in a dynamic

international environment. This topic is extremely current in conditions of a world economic crisis and is relevant both from the microeconomic and macroeconomic aspect which relates to the export performance and economic development. The results of the research presented in this paper pointed to key aspects of business performance improvement as the result of a successful realization of the chosen strategic option by managers. Comparative analysis of the approaches and results of empirical research has stressed the variety of implications of strategic managerial decision-making on performance, as well as the pronounced multidimensionality in this domain. It has been shown that a dynamic approach is needed as well as a focus on reviewing quantitative as well as qualitative aspects of the analyzed connectedness in an international framework.

It stems from this that updating the company performance measurement system is necessary, as company itself is complex and changeable, with the apparent dynamics and complexity of external general and operating environment. From this aspect it is important to respond to managerial demands for a measurement system that supports the selected strategic option and links it with business operations. In large companies this is particularly useful, especially considering the possibility to better review the performance of certain organizational units and their contribution to realizing the business results of the company as a whole.

Besides experience and creativity, in the reexamining of the relationship between the strategic choice and business performance improvement, also important is the multidisciplinary knowledge from different fields such as corporate and competitive strategy, investing, value for owners, managing international business, development and innovation of products/services, operational management, organizational culture, human resources management, managing customers as stakeholders, leadership, ICT management.

Generally speaking, the connectedness of the application of a certain strategic option and the improvement of business performance in conditions of a rapidly changing modern international environment implies the integration of performance measuring in the sense of simultaneous consideration of different performance indicators with a deeper insight into their mutual relations. Parallel theoretical research, consideration of practical problems and particular solutions have led to an operationalization of different conceptual performance indicators in an international framework. Having this in mind, it is necessary to consider concrete results of a company, which in practice means the acceptance of the contingent approach. The information aspect is also important i.e. obtaining data for testing the given interdependency as well as appropriate software support. An integrated approach can entail the translating of performance indicators of an organization considered in a strategic sense into performance indicators of the operational type of individual employees, which means into a form of action plans. This incorporates the application of the technique "management by objectives – MBO" which has shown to be effective in many companies in the world. In practice it is necessary to set priorities and systematically analyze the connectedness of strategy realization and performance improvement, with continuous dedication of managers and employees, as well as their proactive approach.

Abstract: *Emerging markets strengthening in the international trade and investment flows, including BRICS as the most important, change positions of key players in the world market. BRICS countries are a threat for both the developed and developing countries, because they shift investment focus and raise the competitiveness bar. Their markets are, at the same time, an opportunity for successful positioning of transnational or multinational companies assuming the model of their business strategies to the challenges of the emerging markets. This paper examines the specificity of business strategies of the successful companies in emerging markets.*

Key words: *business strategies, emerging markets, BRICS, capability, capacity, risk*

1. INTRODUCTION

Emerging economies are low-income, rapid-growth countries using economic liberalization as their primary engine of growth. They fall into two groups: developing countries in Asia, Latin America, Africa, and the Middle East and transition economies in the former Soviet Union, East Europe and China. Private and public enterprises have had to develop unique strategies to cope with the broad scope and rapidity of economic and political change in emerging economies.

With a combined labor force of more than 1 billion people, BRIC (Brazil, Russia, India and China) have always had the potential to be key players in the global economy. Rapid economic growth in recent decades has enabled BRICs to begin to tap this potential. With a large population base and relatively low per capita income, role of this group of countries in the world economy, is only likely to increase over time as they narrow their gap with advanced countries in income levels.

² This Research Paper was the part of the project "Advancing Serbia's Competitiveness in the Process of EU Accession", no. 47028, in the period 2010-2015, financed by Serbian Ministry of Science and Technological Development.

Figure 1: BRIC in the global economy, 1991-2015
Sources: IMF and World Economic Outlook, October 2010

The world population in 2011 was estimated at 7 billion people. Almost three out of every seven people in the world today live in BRICs. Although the share of these countries in world population is projected to decline over time, similar to that of the United States and the Euro Area, it will remain a multiple of that of the United States and Euro area combined and could eventually supports economies that are commensurate to BRICs human resource base (Issouf, Yongzheng, 2011).

Regarding growth, since the early 1990, BRICs have more than doubled their share in global output. BRICs GDP (based on market exchange rate) are now the third largest in the world after United States and the Euro area. According to the IMF projections, BRICs GDP will surpass that of the Euro area before 2015 (Issouf, Yongzheng, 2011).

Finally, BRICs exports have been the most dynamic in their integration into the world economy. Over the past two decades, BRICs share in world exports have nearly tripled, overtaking that of the United States and catching up rapidly with that of the Euro area. The growth of BRICs imports has been less spectacular but still very impressive -nearly doubling their share in world imports over the past two decades and should catch up with the United States soon (Issouf, Yongzheng, 2011).

Investment focus move to emerging markets has made their economic development more dynamic, strengthen trade position and greatly sharpened the competitive environment in these markets. According to the latest UNCTAD report (UNCTAD Report, 2011), BRICS countries (Brazil, Russia, India, China and South Africa) were among the biggest recipients of greenfield investments in period 2005-2011. This equally applies to the value and to the number of individual greenfield investments. Number of investments ranged in South Africa from 29 to 65, in Brazil from 34 to 102, in India, which is recorder with China, from 191 to 358, in Russia from 133 to 192 and in China from 141 to 330 of individual investment.

Recent research by the World Bank about profiles of countries according to certain indicators of the attractiveness of foreign investment such as the ability and the safety of investments in certain sectors (especially in those of interest to investors on a global world trends), start up their own business, taking of land for lease for greenfield investments, judicial experience in that country etc.) indicate that the profiles of BRICS countries, of most aspects, are above average and recommend them for FDI and in the future. On question, in which developing countries is your firm presently investing, BRICS countries take leading positions, in this order: China, India, Brasil, Russia, the fifth place is Poland, and a sixth take South Africa. Each second asked investor said that investing in China and each fourth in South Africa. (World Bank Group, 2011).

2. STRATEGIC EXPANSION IN EMERGING MARKETS

For more than a decade now, multinational companies have flocked into emerging markets under the banner of globalization to access low-cost sourcing in high growth economies. Many of these companies have established fairly successful operations and realized significant cost arbitrage. According to the survey of 247 executives from consumer and industrial product companies performed by Deloitte during 2009, it can be concluded that companies are increasingly making emerging geographic markets a centerpiece of their global business model. Over the next three years, 88 percent of companies plan to expand their presence in emerging markets; 50 percent of companies expect 20 percent or more of their global revenues to have their origins in emerging markets; a third of these companies plan to place more than 20 percent of their investments in these regions (Deloitte survey, 2009).

Figure 3: Top three strategic objectives for establishing functions in emerging markets
Source: Deloitte, Rethinking emerging market strategies: From off shoring to strategic expansion, 2009

The main reason of expansion to emerging markets is not only presents in low-cost centres, but for large number of multinational companies it means establishment of core functions of their value chains in these regions. Cost savings is still a key motivator, but market expansion, speed to market and access to the talented human resource become important decision making factors. Companies also spread their investments across multiple locations in order to diversify their investments across geographies. Also, they strive to broad the scope of their business in emerging economies; large number of them established commercial operations in addition to their manufacturing endeavours. Firstly, they try to generate more income from sales activities and secondly, they realize that material sourcing can be more payable and important. The companies' future returns will depend on emulating global business models in emerging markets. Recent research shows that there is strong correlation between the sort and number of business functions a company establishes in emerging markets and the percentage of global profits that come from these regions. According to the Deloitte's survey, a one third of the companies with five or more business functions in emerging markets earn 20 percent or more of their global profits from that market; companies with only a single operation derived 10 percent or less of their global profits from emerging markets.

Last period was characterised by some important changes in relation to the main trends in emerging markets: raw materials and production costs have become higher that had negative influence on the financial positions of the companies which main reason for entering emerging markets was cost savings. Those companies that declare market expansion as their key objective recorded increase in their global market share. Consequently, companies, that are not capable to keep pace with changes in emerging markets, will not be a part of global business model and their results in emerging markets will be unsatisfactory. Obviously, business operations in emerging markets became more complex: companies strategically shift specific functions of their value chains in order to realize new objectives: growth, innovation and sustainability. From a strategy standpoint (see figure 4), three factors determine the emerging market business model: capacity, capability and risk (Deloitte survey, 2009).

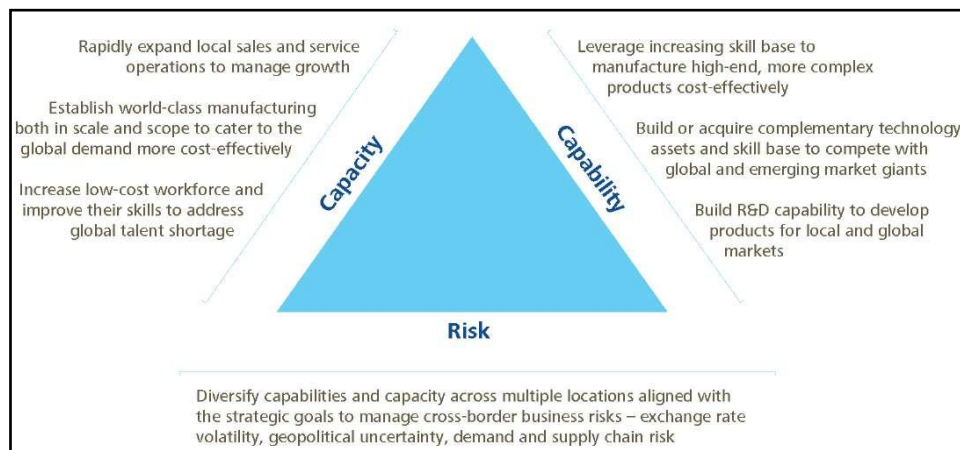

Figure 4: New strategies for emerging markets

Source: Deloitte, *Rethinking emerging market strategies: From off shoring to strategic expansion*, 2009

2.1. Capacity

Despite financial crisis and recession in large number of the world's economies, developing economies like BRICS will continue to be the pillars of global GDP growth. It is not easy task to satisfy consumers in developing countries, so companies have to aggressively target these economies to achieve their growth targets. Strong understanding of the market, culture and local constraints are crucial for introducing products to new regions. Some companies need even several decades to achieve this capacity. Business operations in emerging markets allow companies to take advantage of favorable currency arbitrage and build capacity for local and international markets.

Expanding the scale and the scope of production capacity became important issue. As it is in *Deloitte's survey (2009)* noticed "for example, the demand for consumer and industrial products in BRIC countries has grown exponentially in the last few years". (p.7). Consumer demand in emerging markets became very similar to the demand of developed countries so the companies will need to grow their capacity for product development and manufacturing if they want to increase local demand. Recent trends show that some companies transform their business in emerging markets into export hubs by increasing manufacturing capacity to account for both local and international consumers.

2.2. Capability

Capability means that companies are ready to move from assembly and low costs parts production stage to more complex business functions stage in order to upgrade their value chain. Multinational companies diverted its activities trying to build more complex, engineered products for local and global markets. For example, South Korean Hyundai Motor Co. recently started commercial production at its second engine plant in India in an attempt to drive up small-car sales in one of the world's fastest-growing auto markets. Hyundai, the world's sixth-largest automaker, aims to make its India plants the global hub of its compact car production (Deloitte survey, 2009).

Multinational companies became more aware of capability of emerging markets: they try to enhance their product or service offerings, either through acquisitions or alliances with local companies. On the other hand, multinational companies will extend their capability accessing to the new talents in emerging markets which are characterized with low cost, well skilled and good educated workforce. Some of them see emerging markets as good chance to improve or to supplement their capabilities in research and development. The world's largest steel company, Arcelor Mittal, was found a state-of-the-art R&D facility in Kolkata, India which will not only bolster the company's R&D capacity, but represent also the capabilities they need to enter the fast-growing, lucrative field of engineering consultancy. *Kumar, Runa Rajeev and Rakhi Mazumdar (2010) said that "additionally, the new facility will take advantage of the huge gap between supply and demand for consultancy jobs in that part of India: the company has recruited some 300 people to occupy the 25 000 square foot facility"* (p.12).

2.3. Risk

Last but not least factor that will determine the emerging market business model of multinational companies is risk. Strategic expansion of business involves cross-border business risks and companies have to take all necessary steps that will enable them to create a sustainable cost and revenue structure across geographies. Besides political, regulatory, market and increasingly geopolitical risks, that can also have a hand in the successes and failures of companies' endeavors in other countries, cross-border business risk has several forms of challenges: exchange and interest rate volatility, operational stability issues and experience. Fluctuating exchange rates may not allow companies to remain competitive in highly price-sensitive markets which are typically for emerging economies. The uncertain future of emerging market currencies adds risk to projected profits and cash flow over the long term. Operational stability is one of the greatest concerns among companies in emerging markets; mistakes and wrong decisions can easily jeopardize hard-won companies' reputation. Abandoning emerging markets due to such risk factors is clearly not a viable solution, but one of the crucial things is that companies have to manage risks absolutely proactively. Companies with more experience tend to do a better job of extending their value chains in emerging markets because they have deeper business relationships and understanding of local markets needs and relations and cultures. As it is in *Deloitte's survey (2009) pointed out "finally, careful consideration of strategic objectives that account for capability, capacity and risk can go a long way in choosing the right region"* (p 10).

3. WINNING IN EMERGING MARKETS

Emerging markets in Asia, Latin America and Eastern Europe are delivering some of the strongest revenue and profit growth for global makers of fast-moving consumer goods (everything from snacks to toothpaste) despite concerns that lower prices translate into lower profits. Emerging-market leaders like Coca-Cola, Unilever, Colgate-Palmolive, Groupe Danone and PepsiCo earn 5% to 15% of their total revenues from the three largest emerging markets in Asia: China, India and Indonesia (Shankar, Ormiston, Bloch, Schaus and Vishwanath, 2008).

Until the past few years, emerging markets were a relatively low priority for the leading consumer products companies with a few exceptions, even though these markets are home to about 85% of the world's population. With growth slowing in the mature markets of North America, Japan and Western Europe, some consumer goods companies have figured out how to tap into the purchasing power of a new and growing middle class (which has rising income, credit cards and access to personal loans) in these emerging markets. So, the question is how we can make differences between losers and winners?

Successful companies are willing to break away from business as usual. They adapt western marketing and business management practices to local customs and develop the resourcefulness to overcome inevitable barriers. Winners have consistently followed the six hard rules in emerging markets which includes participation in the mass market, than localization of 4Ps, management of costs aggressively, building local team; selectively conquer the local market and staying at the course. In first step they go beyond premium to achieve scale in distribution, manufacturing and brand building. After that, the winner move to the next step which include localization of production on the basis of consumer insights, mastering the dynamics of local distribution and placement, pricing at so called sweet spots and aggressively investment in promotion of the brand. When they take initial position on local market, than start to manage cost which means to avoid too much specification and reduce overhead. In the process of building a local team the winner empowers local management and minimizes regional span breakers. Also, they try to provide local management with global

career paths as well as to ensure that expatriates have long-term commitment. After that, expanding distribution base and acquisition with local product and brand may be very important. At the end, the winner considers an emerging-market organization and sustains investment while targeting near-term profitability (Shankar, Ormiston, Bloch, Schaus and Vishwanath, 2008).

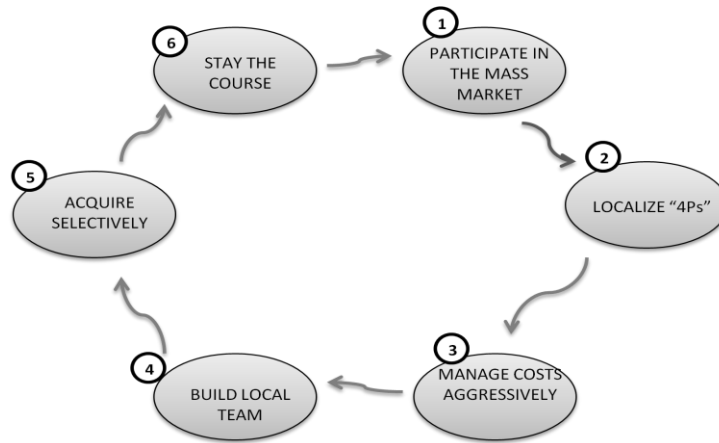

Figure 5: Keys to emerging-market success

Source: Satish Shankar, Charles Ormiston, Nicolas Bloch, Robert Schaus and Vijay Vishwanath, *How to Win in Emerging Markets*, MIT SLOAN Management Review, Harvard Business School, April 2008

Primarily, the emerging-market winners enter the mass market to achieve scale in distribution, brand building and operations. Multinational companies in developing nations targeted niche premium segments those that traditionally delivered the highest profit margins. They often were stuck with low growth, while local players were expanding rapidly in the low-end segments. As local companies moved into the premium and near-premium market segments, multinationals realized that the mass-market opportunity was too big and important to ignore, in other words they needed to enter the mass market for both the opportunity and to play defense.

Second business strategies include localization at every level. Competitors have several incumbent advantages, including, consumer understanding and loyalty, lower costs and home court advantages with government regulators. But by taking the time to learn and master local market complexities, multinational companies can gain a competitive edge. That often requires fundamental changes to the product offering switching to significantly smaller pack sizes, using unconventional distribution channels and developing products in local flavors, to name a few. Localizing also means taking an aggressive approach to brand building. That was the foundation for example for Coca-Cola's dramatic success in China, where it leads all carbonated soft-drink sales, with a 51% market share led by its Coke and Sprite brands against PepsiCo's 30% share. Now, China is Coca-Cola's fourth-largest market, approximately 5% of its worldwide sales. Therefore, the crux of all localization strategies is pricing which implies a price that is competitive in the local marketplace and that also delivers a profit (Shankar, Ormiston, Bloch, Schaus and Vishwanath, 2008).

Between the traditional premium and low-end market segments is the large and flourishing market for "good-enough" products, with higher quality than low-end goods but affordable prices that still generate profits. Feeding the good-enough market requires aggressive management of costs. Winners look at everything they can control to shift the competitive dynamics in their favor, from changing the specifications for packaging material to imposing greater operating efficiency to lowering overhead and using local equipment. For multinationals catering to the premium end of the market, a strategic acquisition can help slash costs enough to make them competitive. Example is Colgate-Palmolive Co. investment of \$21 million for a 40% stake in Sanxiao, a low-cost toothpaste brand in China. Colgate's benefits multiplied when it started using the factory as a worldwide distribution center (Shankar, Ormiston, Bloch, Schaus and Vishwanath, 2008).

Also, for better business success the winner sometimes make local acquisitions just to be sure to have a strong business fit. A strategic acquisition can accelerate a multinational's entry into an emerging market by adding popular local brands to its product lineup, broadening its reach with a stronger distribution network, providing a local talent pool and lowering operating costs. Again we can take Coca-cola as an example.

Coca-Cola acquired the Russian beverage group Aquavision, giving it state-of-the-art, expanded production capabilities. The move builds on Coca-Cola's previous purchase of Multon, the leading Russian fruit juice maker.

Like final business strategies which the leaders use maximization of their investments by building dedicated emerging-market capabilities. This enables them to approach each emerging market with strategies crafted to distinguish the characteristics they find there from the established practices they pursue in developed economies. For example, the French food conglomerate, Groupe Danone, has substantial presence in major emerging markets in Asia such as India, Indonesia and China, which share several common characteristics. The company has learned a lot from operating in these markets, such as positioning brands to appeal to local consumers, using low-cost Asian production equipment, keeping a tight lid on overhead and changing the specifications for packaging and raw materials to produce "good-enough" products. These lessons have been effectively cross-pollinated across the various emerging markets in which Danone operates (Shankar, Ormiston, Bloch, Schaus and Vishwanath, 2008).

CONCLUSION

The crucial moment for definition and choice of emerging market strategy is where and which business functions of the value chain the companies will establish. As one of the most complex business decisions, it needs to be aligned with the general strategy of the company rather than country rankings by macro-level indicators. Companies need to do more with less to stay competitive and improve products and speed to market. They must align their strategic objectives with the capabilities and market potential that locations can offer bearing in the mind significant opportunities for revenue growth of the local markets.

Succeeding in emerging markets is essential if multinational companies are to defend and increase their share of the global market. With consumer markets in Asia and Eastern Europe growing at double-digit rates, multinational companies are moving fast to build their brands and the expertise to manage them in emerging markets. Even more, it is generally accepted that how successful companies are in emerging markets is a critical indicator of how they will be successful in the world.

³University of Belgrade, e-mail: mladenc@fon.rs

Abstract: *This paper describes specific relations between Romanian and Serbian economies, especially the foreign trade impact, some structural characteristics and the recent trends during the last years. The foreign trade is one of the important activities of the national economy, providing factual transaction, change of ownership of products, and thus outlining the actual goods. This activity is seen as an isolated one, can grow exponentially an economy on the long term, but sometimes may go bankrupt during a short term, also. The first section describes Romania's economic evolutions during this recession period, underlying the significance of the foreign trade in the national external balance of Romanian economy as a new EU member. The second section analyzes the Serbian Economy during the same period as a pre-adherent country to EU. These sections also analyze the concentration or specialization process in the structure of Romanian and Serbian foreign trade using statistical methods, indices and coefficients. A final remark is about the forecast of the two economies which underlines that the sustainable and vigorous growth in the new context becomes somehow impossible, as a Romanian and Serbian reality and a goal within the timeframe of 2012-2013.*

Key words: *foreign trade, structure of import and export flux, Gini-Struck coefficient, concentration / specialization of foreign trade, indices' method.*

1. INTRODUCTION

The foreign trade is one of the most important activities of a national economy, providing factual transaction, change of ownership of products, and thus outlining the actual goods. Between Romanian and Serbian economies there are some similar and structural characteristics and some recent and mutual trends, during the last years. Either Serbian or Romanian economies participate in international trade, under the impact of recession and new restructuring process, the first economy during a specific pre-accession period and the second one during a difficult post -accession period to the same European Union.

The trade balance represents the synthetic expression of the degree of economic efficiency in each of this economy recorded in foreign trade activities, and shows the results of nationwide activity, as well as the place it occupies at Union European and international level, revealing the real competitiveness of its goods. The foreign trade activity seen as an isolated one, can grow exponentially an economy on the long term, but sometimes may go bankruptcy during the short term, also. The analyses of foreign trade focus on: a) the methods that describe the costs of export and import and highlight the importance of specific transactions; b) the methods of analysis of an external and globalized balance; c) the methods quantify the impact of the scale economies, underlining the major technologies' role in foreign trade; d) the method of game theory; e) the statistical and econometric methods for identifying and testing the different trends of the products to export and import; f) the specific empirical methods focusing on the specificity of import and export prices; g) the method of quantification of value and physical degrees of coverage and the net term of transfer between the external trade flows etc.

This paper describes and uses the classical version of the last mentioned method based on Serbian and Romanian economies (Korka and Tușa, 2004; Anghelache, Mitruț, Isaac-Maniu and Voineagu, 2009; Săvoiu, 2011), and improved with statistical instruments for measuring concentration – diversification. The result is called the extended method of exchange ratio indicators (Săvoiu and Dinu, 2012), and it has been already used in statistical and economic analysis.

The phenomena of concentration - diversification are assessed structurally, but also correlated with reference limits by using the Gini - Struck coefficient or index, as a statistical and mathematical solutions, continuously replicated since the appearance of that instrument, up to the presett moment, passing

successively through indices of the following types: Hirschman, Herfindahl-Hirschman, Grubel-Lloyd, Brühlhart, Greenaway, Neven, Hine-Milner, Sternberg-Litzenberger, Hannah-Kay, Finger-Kreinin, Andreosso-O'Callaghan, Gini-Struck in the curve ABC, (Hirschman, 1964, Grubel and Lloyd, 1971, Finger and Kreinin, 1979, Lilien, 1982, Curry and George, 1983; Neven, 1995, Sternberg and Litzenberger, 2004; Andreosso-O'Callaghan, 2009, Esteban and Ray, 2011; Săvoiu, Dinu and Tăchiciu, 2012).

The evolution of a national economy can be shown by foreign / external trading, through the balance of the export and import fluxes, as well as the dynamics of that balance, which has a direct impact on the level of the gross domestic product and that of foreign debt and here are included the following statistical instruments: a) the index of the value exchange ratio (the index of percentage coverage of imports by exports - ICXM); b) the index of the gross exchange ratio (the "gross barter" terms of trade index - IGB); c) the index of the net exchange ratio (the "net barter" terms of trade index - INB), known as the terms of trade index; d) the foreign trade price shears – FTPS); e) the effect, in absolute value, of the deterioration of the net exchange ratio (the absolute value of the losses - ΔVL); f) the purchasing power of exports index (IPPX); g) the factorial terms of trade index (IFTT).

Making use of the statistical instrument of Gini - Struck (G-S), the article identifies the trends and specific limits in processes of concentration and diversification in the export or import flows in Serbia and Romania

$$\text{Coefficient } G-S = \sqrt{\frac{n \sum_{i=1}^n g_i^2 - 1}{n-1}} \quad (1)$$

2. APPLIED METHOD, SOME RESULTS AND DISCUSSIONS

2.1. Developments and trends of Romania's export and import developments and trends

Due to the fact that the European Union is the main commercial partner of Romania, a country that became, after January 1 2007, its member, it is obvious that the external trade flows of our country depend, mostly, on the member countries of the European Union, between the years 2004 and 2010 (three pre-accession years and three other post-accession years), they accounted for between 69.5% and 74.3 %, of its total volume. In relation to import, the member states of the EU accounted for shares between 63.2 % and 73.3%, which shows that imports' dynamics was a much more upward one (in fact ¾ of Romania's balance of trade deficit stems from the EU member states as well).

Table 1: Romanian foreign trade, between 2004 and 2010

	2004	2005	2006	2007	2008	2009	2010
	Million Euro						
Exports (X)	18935	22255	25850	29549	33628	29116	37293
Imports (M)	26281	32569	40746	51322	56337	38897	46802
$\Delta = X-M$	-7346	-10314	-14896	-21773	-22709	-9781	-9509
	out of which with the European Union, in %:						
Exports (X_{UE})	72.9	69.5	70.5	71.98	70.4	74.3	72.2
Imports (M_{UE})	64.9	63.2	68.71	71.29	69.1	73.3	72.5

Source: Romanian Statistical Yearbook, 2011, NSI Edition, Bucharest.

The recession has diminished the negative impact of net exports in GDP as the only favourable effect of a major impact: in Romania, the balance deficit already has a continuous upward trend from about 8% to about 14% of GDP between 2004 - 2008, only to change sharply, to below 10% in 2010 (although the share of exports declined with 5 % in the same year 2010, the imports had a more severe setback).

Table 2: The most important statistical indicators according to the method of exchange ratio, in Romania, between 2004 and 2010

	2004	2005	2006	2007	2008	2009	2010
Previous year = 100%							
General evolutions of export and import

Some of the major aspects describing the reactive external trade profile of the Romanian economy before and under the impact of recession are the specific elements of the analyzed indicators:

a) in the peak period of the recession, the volume or the index of quantity of the export increase maximally, the export prices fall, the price scissors is maintained as potential, while the volume of imports decreases much more, import prices are reduced at a maximum intensity;

b) the “gross barter” terms of trade index (IGB) reflects a sharp deterioration in the exports slightly delayed almost a year (in fact Romania certainly supports other partner economies, by paying the wages and profits incorporated in the imported goods, while failing to ensure the entire survival of the entrepreneurs and employees in its own economy);

c) the “net barter” terms of trade index (INB) emphasizes a shift from recording the effect of “rises” in absolute terms to quantifying in relative terms, a process that is more severe at the entrance in the recession as Romanian economy does not have a “critical” mass of internationally competitive products;

d) the difference in point of percentage rate between export and import price index tends to “zero” during the recession;

e) the signal generated by the purchasing power of exports index or IPPX, though it is a limit where imports had to be stopped, was by no means an important decision-making tool, which gave recession the character of a natural regulator in this respect. (Săvoiu, Dinu and Tăchiciu, 2012)

The impact of recession has changed structural trends of export and import flows of Romania, between 2001 and 2010, and identifies the persistence of both flows within the area of excessive concentration, according to the Gini-Struck index values in the curve ABC-Struck (Săvoiu, Crăciuneanu, Ţaicu, 2010). Even the trend for the four years prior to recession was one of the diversification, recession resumed the high level at the beginning of the decade under review, with however some positive aspects by the densification of both flows on the categories of manufacturing intensive products. The sources of imports and the destinations of exports also see a natural process of concentration in the destinations by groups of countries (by increasing trade with the European Union, and Europe as a whole), conforming to the political options to integrate the national economy.

Table 3: Annual values of the indices of concentration of exports and imports, in 2001 and 2010 in Romania

Categories of products	The structural values of g_i and g_i^2 determined through Gini - Struck							
	2001				2010			
	Export		Import		Export		Import	
	g_i	g_i^2	g_i	g_i^2	g_i	g_i^2	g_i	g_i^2
Mineral products	0.069	0.0048	0.144	0.0207	0.055	0.0030	0.110	0.0121
Food and agricultural products	0.038	0.0014	0.078	0.0061	0.084	0.0076	0.084	0.0071
Chemical products	0.064	0.0041	0.127	0.0161	0.095	0.0090	0.169	0.0286
Metallurgical products	0.133	0.0177	0.073	0.0053	0.119	0.0142	0.109	0.0119

2.2. Serbia's export and import developments and trades

In the last decade of the past century Serbia's foreign trade knew an unfavourable period that had three major causes: a) shifting from planned economy to the market economy, losing traditional economic partners in the former socialist bloc; b) the dismemberment of the former Yugoslavia and the wars that followed in the region led to the loss of commercial partners from the former union republics; c) the economic sanctions imposed by the European Union and the United Nations.

As a CEFTA member state since 2007 and especially after December 22nd, 2009, when it officially applied for membership to the European Union, entering a pre-accession stage comparable as trends with Romania between 2004 and 2007, Serbia provides unambiguous and methodologically unitary statistical databases. Unfortunately, they are still expressed in US dollars, and leads to the necessity of analyses that exploit relative indicators or Gini-Struck type indices.

The CEFTA (The Central European Free Trade Agreement) membership, held by countries in the South-Eastern Europe, allows Serbian companies to export duty free on a market of almost 30 million consumers. Serbia is the only country outside the Community of Independent States which has a free trade agreement with Russia, since 2000 (http://www.siepa.gov.rs/site/en/home/1/importing_from_serbia/trade_regulations/). Serbia also concluded such a free trade agreement with Turkey and with the EFTA member states (Switzerland, Liechtenstein, Norway and Iceland). From the point of view of the product, the structure of Serbian exports is in 2010 as follows: intermediary goods account for approx. 2/3, consumer goods for approx. 1/4 and capital goods almost 1/12 of the total volume. (http://www.siepa.gov.rs/site/en/home/1/importing_from_serbia/foreign_trade_data/foreign_trade_by_commodities/).

Table 4: Evolution of Serbia's foreign trade in the period 2004-2010

USD thousand

	2004	2005	2006	2007	2008	2009	2010
EXPORTS	3522424,6	4480801,5	6426633,9	8824013,1	10972201	8342909,5	9793048,1

Source: Statistical Office of the Republic of Serbia

The chart of this evolution is presented in Figure 1.

Figure 2: Serbia's export, import and balance of trade deficit

For the period 2004-2010 we can notice the diversification of Serbian foreign trade demonstrated by the continuous decrease of Gini-Struck coefficient values. This evolution is shown in table no. 5.

Table 5: The values of Gini-Struck coefficient for Serbia's foreign trade

	2004	2005	2006	2007	2008	2009	2010
Total Exports	0.3215	0.3417	0.3567	0.3341	0.3162	0.2770	0.2844
Total Imports	0.3175	0.2957	0.2972	0.2554	0.2543	0.2407	0.2354
Exports to Romania	0.7544	0.5955	0.5851	0.5151	0.4379	0.4343	0.4331
Imports from Romania	0.3863	0.3171	0.3563	0.4101	0.3578	0.3692	0.3406

Source: Composed by the authors based on data of *Statistical Office of the Republic of Serbia*

We can notice that the values of Gini-Struck coefficient are higher for the commerce with Romania, than those for the total foreign trade of Serbia. The conclusion is that in the case of commerce with Romania there is a higher concentration. However, there is also a tendency of decreasing values for this coefficient in the case of Serbian-Romanian bilateral trade. In 2011, Romania was Serbia's fifth export partner, with 6.9% of the total Serbian exports. In relation to imports, Romania holds the 6th place with 4.4% of the total value of Serbian imports. In table no. 6 is presented a detailed situation of bilateral commerce in 2010.

Table 6: Serbia's trade with Romania in 2010

	TOTAL IMPORTS	596567.8	100.000	0.20439834

Source: Composed by the authors based on data of Statistical Office of the Republic of Serbia <http://webzs.stat.gov.rs>

For Serbia's exports to Romania in 2010, the Gini-Struck coefficient is calculated below:

$$G - S_{2010} = \sqrt{\frac{n \sum_{i=1}^n g_i^2 - 1}{n-1}} = \sqrt{\frac{10 \times 0,26882014 - 1}{10-1}} = 0,4331$$

In the case of Serbia's imports from Romania, the Gini-Struck coefficient has a smaller value:

$$G - S_{2010} = \sqrt{\frac{n \sum_{i=1}^n g_i^2 - 1}{n-1}} = \sqrt{\frac{10 \times 0,20439834 - 1}{10-1}} = 0,3406$$

In relation to Serbia's exports to Romania, in the period 2004 - 2010, there was a continuous decrease in the value of the Gini - Struck coefficient, which proves a diversification trend.

3. A FINAL REMARK

Smaller or less developed economies like Romanian or Serbian cases cannot afford scale interventions and policies in the competition and trading on international markets and Serbia and Romania's behaviours can be no exception to this truth. The extensive method seeks, through the additional information, to help a prompt and accurate response in times of crisis and recession, a reaction that can always be improved. The prognosis of the two economies underlines that the sustainable and vigorous growth in the new context becomes somehow difficult or even impossible, as a Romanian and Serbian reality and a goal within the timeframe of 2012-2013.

Abstract: *This paper focuses on the study of the importance of culture for creative management and the expansion of creative industries in Europe, which represents a current and challenging area that requires an integrated and dynamic approach. The multidisciplinary nature of this topic in conditions of development of information and communication technologies in the environment of the new economy were a starting point. The results of Internet research of the authors are also presented. The ways in which cultural diversity in Europe can be encouraging to the development of creative management and for creative organizations performance improvement have been shown. The focus is on the results that stem from this.*

Keywords: *European culture, creative industries, innovations, European creative management, Europeana, international environment, business performance*

1. INTRODUCTION

Different aspects of human life and managerial practice, as well as their changes, are linked with culture. In this sense culture includes values, ideas, attitudes and symbols that shape human behaviour and are passed on from generation to generation. It encompasses the material and immaterial environment which people build and nurture. In order to understand the complex and multidimensional nature of culture, it is necessary to examine elements such as: language, religion, desirable behaviour, customs, material products, norms, beliefs, aesthetic criteria, education and social institutions.

From the position of creative management, it is important to differentiate between two views of culture. Culture in the final instance relates to the totality of knowledge and practice, intellectual and material, of a particular society or specific group. In this respect culture is relevant as a component of the external domestic and international environment of a company, as well as the organizational culture itself as part of the internal environment of the production or service firm. Culture often implies an entire range of artistic and philosophical works and creations. In this case management in the field of cultural and art organizations (museums, libraries, theatres, endowments, archives) stands out, which can have an international dimension. Culture is studied from the aspect of economics as a so-called non-economic factor of economic development on the one hand, and from the other culture as a collection of mainly non-profit organizations, although they can be profit oriented, especially certain segments. In relation to this, cultural product placement is important considered through this other aspect, which often implies the existence of an international market.

It has been stressed that societies are entering the post-industrial age, and culture the postmodern age. Today, less than ever before, is there "givenness" and even less "givenness once and for all". Any value judgment, definition or pattern is questioned and differently interpreted. An idea, content and trend in art change with the use of new media. Alternativity, as one of the principles of postmodernism, represents the core and meaning of creative impulses in culture. Culture is linked with the domain of speed and technology. The aims of an industrial society largely relate to mass consumption, while the information society is characterized by a great intellectual creativity which entails the action oriented information, the importance of ideas and dominance of intellectual capital, which is in the focus of creative management. From the macroeconomic aspect, the goal of sustainable development is typical with emphasis on social welfare and

³ This paper includes the research results of the author realized on Project record no. 179081 financed by the Ministry of Education and Science of the Republic of Serbia.

human values, linked to a focus on a new development criterion the GNW (gross national welfare), i.e. an advanced welfare society in which not only ecologic demands shall be fulfilled but also the human need for self-realization.

Culture is extremely important in the new creative economy of the 21st century based on ideas, information, knowledge and images. The interaction of culture, creativity, innovation and business is implied. This has implications on creative management, which incorporates rationality, creativity but also risk, especially in conditions of a turbulent environment and economic difficulties on a global level, but also at the level of regional economic integrations.

2. SPECIFICITY OF EUROPEAN CULTURE IN AN INTERNATIONAL FRAMEWORK

A characteristic of European culture is that it is often perceived as specific in a global framework by managers that manage international business, and originate from other cultures. We must keep in mind that, on the other hand, European culture is associated with variety, both from the aspect of tradition, but also from the angle of contemporary practice considering the European Union (EU) member states, and those that are not i.e. all European countries along with the challenges of multicultural creativity of contemporary Europe. There are different concepts and approaches to contemporary European culture (Stich, 2000).

What is implied by "European" refers to the period from Antiquity to the second decade of the 21st century, and the history of the idea of Europe as a cultural domain has not been linear. Especially analyzed is the period of European culture from 1848 as a historical turning point i.e. in the sphere of culture from the period of the Enlightenment and Romanticism, with the acknowledgment of a particular evolution from the Modern to the Postmodern period and further and also incorporating differences such as the Avant-garde and popular culture (Winders, 2001).

From the perspective of creative management, especially important is the symbolism of Europe and the different aspects of product design and packaging, visual firm identity, promotion in different media, as well as communication associated with it. The symbolism of Europe is also expressed in the design of the euro banknotes. It is believed that the Greek poet Hesiod, who lived in the late 8th and early 7th century BC, first used the name Europe. The starting point is usually the ancient myth of Europa, a girl sitting on the shoulders of the god Zeus, in the form of a bull, a scene which has been depicted by many European painters, and later accepted as a symbol by managers in some advertising campaigns.

The number twelve on the emblem and flag of the EU with twelve stars on a blue background is explained as the traditional symbol of completeness and unity, and the circle of stars represents unity and harmony among the peoples of the EU (<http://europa.eu/>, 2012). *The Ode to Joy* by L.V. Beethoven from his Symphony No. 9 has been accepted as the European anthem. The colour blue represents continuity from Antiquity, since remains of the colour blue have been found on ancient sculptures that depicted the Europa myth (Schmale, 2003). The EU motto is *United in diversity*, and diversity refers to differences in culture, tradition and language. *The European Agenda for Culture* wishes to promote: cultural diversity and dialogue; culture as a catalyst for creativity and innovation and culture as part of the EU's international relations. *The EU's Culture programme* (2007-2013) should realize the following main objectives: to promote **cross-border mobility** of those working in the cultural sector, to encourage the **transnational circulation** of cultural output, and to foster **intercultural dialogue** (<http://ec.europa.eu/culture/>, 2012). As part of the European Capitals of Culture initiative two cities are European Capitals of Culture each year. Beograd's application for the title of European Capital of Culture 2020 is important in the context of European cultural space.

The symbolism of Europe is expressed also in the design of the banknotes. The euro banknotes depict, depending on the denominations, the architectural styles of Europe's cultural history. The front side shows gateways, which are linked with the spirit of openness and cooperation, and the reverse bridges as the symbol of communication among Europeans, as well as between Europe and the rest of the world (<http://www.ecb.int>, 2012).

In this context it is important to stress that relying on the variety of the developed artistic practice throughout Europe, in the recent period there has been a particular development of culture and art management, which is relevant for many organizations with a long tradition in this field, including managing new projects, managing special events in the sphere of culture and art, especially festival management. Also characteristic is the focus on management related to profit organizations in the field of culture (publishing, music

production, film industry, etc.) which in many cases have over longer time periods achieved successful artistic and business results on an international scale. What is necessary is the strategic approach to project management in culture (Milićević, Vasić, Ilić, 2010). Cultural industries in Europe represent an important source of income and jobs. The importance of recent authentic development in European film and media culture in a global setting is stressed (Højbjerg, Søndergaard, 2006). Of particular importance is the successful development of cultural tourism and a typical example is Saint Petersburg (<http://gov.spb.ru/culture>, 2012). The City of London is characterized by a specific blend of business, finance and culture (<http://www.cityoflondon.gov.uk>, 2012).

3. CHALLENGES OF CONTEMPORARY CREATIVE MANAGEMENT

Creativity is considered extremely important for success of the innovation process in an organization. The concept of creativity itself is complex and defined in different ways. Creativity can be defined as the generation of novel and useful ideas for the organization (Muñoz-Doyague, González-Álvarez & Nieto, 2008). This implies that it must be relevant to the organization's goals and some value should be gained in the future period as the result of creativity. The connectedness of management of change, innovation, creativity, knowledge management and business performance is important in this.

In the context of rapid changes in the environment, creative management is linked with the 21st century as the synthesis of two related fields of knowledge, on the one hand newer management studies, and on the other, creativity as an interdisciplinary field. This means that creative management is the study and practice of management, drawing on the theories of creative processes and their application at individual, group, organizational and cultural levels (Xu, Rickards, 2007). Creativity in business is manifested in several areas – generating ideas, development of products and services, creating innovation, formulating strategies, increasing competitiveness, cost control, acquiring new knowledge, marketing, human resource development. Creative organizations represent the outcomes of creative management. The successful development of creative management in Scandinavian companies is a good example of this.

It is typical that creative management is linked with Postmodernism, along with the tendency to combine it with elements of Modernism. Creative management is compatible with the postmodern, largely open understanding of the world, which implies heterogeneity, informality, differentiation, seeing things through "images". The orientation towards long-term innovative development of an organization is present. From the perspective of managerial practice it is important to consider both continuous and radical change; objective knowledge and intuition; predictability and experimentation; product and company development; capital and knowledge driven development; single and multiple solutions; contingency and determinacy; reducibility and holism (Nyström, 1998). The interaction between firm development and product development is emphasized in business, which has shown to be important in market placement of new, unexpected products as results of new knowledge, especially in the case of consumer electronics, software, cosmetic products, which in the interaction has lead to considerable development of the companies that have launched these new products.

The cultural sector in the economic sense is linked with the production and distribution of cultural goods and services. It includes the visual arts, performing arts, museums, libraries, archives, archaeological sites, film, video, radio, television, video games, music, book publishing, press publishing, while in the case of creative industries it also incorporates advertising, architecture (especially architectural services), design (including product design, graphic design, fashion design). For creative management in these industries it is extremely important to consider the particular influence of culture in the context of development of information and communication technologies (ICT), digital economy, mobile business and knowledge society. Chiefly owing to the expansion of the ICT sector, there are new opportunities and challenges for the development of creative industries. Also characteristic is the approach of some Scandinavian countries, where in practice the recently affirmed "the experience economy" has now taken centre stage which elicits an experience from the customers consuming the physical products and services. This above all relates to different areas of art, including the market of artworks and antiques, artistic crafts, heritage, but also to design, software, entertainment, tourism, sport and implies that managers are closer to societal demand. Culture has a positive effect on creating an emotional experience. It has a role in innovative design and emotional branding.

Cultural diversity in Europe can be encouraging for creative management, for generating new ideas and developing products and services with economic value which also contribute to promoting prosperity of people and improving the quality of life. It is necessary to consider the influence of culture on the formulation

and realization of business strategies of European companies in conditions of a contemporary complex international environment, and especially in implementing strategic changes. Culture in the business sphere is present through cooperation, communication as well as through social networks on the Internet. Viewed as a whole, companies and institutions throughout Europe provide many cultural offers. There is talk about the affirmation of the Renaissance model as regards the personality of manager. More and more designers are included in managerial teams. Also companies are hiring creative people, especially artists, who spend time with employees, affirming esthetical values, which are becoming more important for many buyers of their products. On an international scale success was achieved with products bearing the names of famous European artists, and a typical example of this is the car Picasso of the French company Citroën which has launched the slogan "Creative technologié" (www.citroën.com, 2012) and Mozartkugel (www.mozartkugel.at, 2012) as part of the special offer of the city of Salzburg and its developed cultural tourism with Mozarteum University and the world-renowned Salzburg Festival. Many European companies are encouraging the work of artists, especially regarding contemporary art. A specific connectedness of business, artists and brands is being created, and the prints of photographs of artists, philosophers and works of art on products of mass consumption (especially clothes, leather goods and furniture) are becoming more common. Art works are exhibited in office space and are part of the interior of modern European firms, which is relevant for the employees as well as the customers, who with consuming the products and services, increasingly also expect an experience.

4. EUROPEANA AS A RESOURCE FOR DEVELOPING CREATIVE MANAGEMENT IN EUROPE

Europeana.eu a portal of digital objects of Europe represents a place on the Internet where millions of digital objects from libraries, museums and archives of European countries are available to Internet users. The Internet presentation allows searching the virtual content of over 20 million objects made available to users by 1500 institutions from 33 countries (europeana.eu, 2012). *Europeana* represents the central point of building content and availability of digital material related to the cultural and scientific heritage of Europe and thus is a very important part of the efforts of building a new creative economy in the territory of Europe. The importance of *Europeana* is reflected in the vast funds invested in its development which were earmarked in the budget of the European Commission for this purpose in the period until 2020. *Europeana* was opened for users in November 2008, and continuous support to its promotion has always been present (Purday, 2009). It has enabled the exploring of digital resources of Europe's museums, libraries, archives and audio-visual collections. Items include images, texts, sounds and videos.

In this sense *Europeana* represents an important basis for the development of creative management in Europe. This basis is twofold since the availability of materials encourages the creativity of the managers themselves, but also provides support to the development of a vast range of virtual services related to cultural and scientific heritage. The managers themselves in the process of creative management of an organization enrich and expand their knowledge, and the wealth of materials from different European countries encourages the mental associative and comparative processes, as well as the development of new ideas, which is crucial for the success of creative management. Access to the design of *Europeana* is such that it gives impulse to the creative use of materials available for users and development teams. The metadata model - EDM (*Europeana Data Model*) used to describe this materials has been created with the idea of encouraging innovation and the new use of materials through the creation of special applications (Doerr, Gradmann, Hennicke, Isaac, Meghini, & van de Sompel, 2010). This lays the important foundation for affirmation of creative management in Europe, since the development of applications which will efficiently utilize digitalized cultural heritage requires a high degree of creativity in all processes linked with managing an organization that develops such applications.

Innovativeness which can be developed in the process of planning and designing services based on the wealth of materials available on the *Europeana* portal was best demonstrated during the competition entitled "Programme for *Europeana*" held in four European cities in June 2011 (Highlights from Hack4Europe! Roadshow, 2012). Poznań, Barcelona, London and Stockholm were hosts to over 85 programmers from companies belonging to the sector of information and communication technologies and creative industries. The programming resulted in 48 applications, the most prominent being applications for mobile devices, applications with components for social networking and games, and applications for permanent content storage and its visualization and applications for integration with Wikipedia. Such events illustrate possibilities offered by *Europeana* regarding the development of creative ways for connecting users and the data that they need, available on the *Europeana* portal.

5. CONCLUSION

From the aspect of creative management the implications of culture on product/service development, communication, and branding are important. There is talk in Europe about a return to the idea of the Renaissance man, with many talents, skills and a broad knowledge base, involved in the arts, and science. Also current is the consideration of the expansion of creative industries from the aspect of overcoming the economic crisis and raising employment levels. The forming of creative clusters is being intensified as part of the European cultural space.

One must have in mind that creative management is crucial for the development of all European industries considering the connectedness of industrial fields and the increasing relevance of creativity as a factor of competitive advantages in a global setting. In the focus is the relationship of creativity as a multidimensional process and innovation, as well as creative approaches to marketing and strategic changes at the company level.

Cultural diversity in Europe can be encouraging to the development of creative management and for creative organizations performance improvement. On the side of output this should result in the development of new products and services that have an economic value, but also contribute to increasing the prosperity of people. Cultural products such as music, films, electronic books and magazines in the conditions of the new economy and ICT development in the 21st century in many cases have contributed to increasing competitiveness and the business success of many European companies in the contemporary international environment.

Viewed as a whole, the domain of connectedness of culture and European creative management is complex and full of challenges. Culture influences the creative capacities of organizations. It opens new issues which are qualitative in nature, above all linked with talent, vision, valuable ideas, novelty, differentiation, but also important are quantitative aspects, especially those related to measuring managerial creativity. Managing the corporate imagination and creative management processes as a whole should certainly contribute to business performance improvement in the future period.

Abstract *International negotiations represent a very complex practice during which the negotiators encounter diverse cultural particularities which are brought into the process by their partners. In order to conduct the process as efficiently as possible, and, of course conclude it, negotiators should keep to certain principles which will give the negotiating process a much better chance for success. The overall goal of negotiation is to arrive at a solution acceptable to all parties involved. Increasing knowledge about negotiating partner is a way to become a more effective cross-cultural negotiator. Negotiation approaches differ considerably due to culture. Since international managers spend such a large amount of time negotiating, it is important to understand the negotiation process and how culture influences it.*

Key Words: *Negotiations, culture, negotiating strategy, negotiating process, negotiating style.*

1. COMPETITIVE IMPORTANCE OF BUSINESS NEGOTIATIONS

One of the most difficult, but also the most important tasks for international managers is successful planning, conducting and concluding the negotiating process. International negotiations are very complex and difficult since they include encountering different laws, regulations, standards, business practices, but first of all, cultural particularities which are 'brought' into the process by negotiators. It is very naive to enter the international negotiations believing that 'people are similar wherever they live, and that they behave in a very predictable way'. The negotiating style which has proved efficient in home environment, can be completely incompatible with the values, beliefs and attitudes of those who belong to other cultures. Each of them is shaped by its belonging national culture, geography, history and political system.

Negotiating is a process in which two or more parties try to reach an agreement which will bring them a mutual benefit (Acuff, 2008). By bringing closer their attitudes, the interlocutors try to create a situation which will enable creation, maintenance and further development of the relationship.

The negotiating process is conducted in stages. The negotiations should not be the confrontation of strengths, but the series of stages, starting with the preparation to reaching an agreement. The process should be defined in a way that primary goals as well as tactics and behaviour to be conducted are clear at every moment.

As it has already been mentioned, the negotiating process should result in a solution which is acceptable to both parties. However, there are different types of optimal outcomes in practice. The type of negotiations will primarily depend on the negotiating power of the participants, the issue discussed, as well as the personality of the negotiators. Also, each party 'starts' with their best alternative of the possible agreement (BATNA – 'Best alternative to Negotiated Agreement').

In the modern multicultural environment, negotiators should emphasize the integrative negotiations (Acuff, 2008), which is the most consistent with the win-win tactics. In order to reach an integrative outcome, each party has to understand the interests, preferences and priorities of the interlocutor. The subject of negotiations should always come first, and the development of the options which are mutually beneficial should be followed by a maximum objectivity (Acuff, 2008).

There is no universal 'recipe' for the success of cross-cultural negotiations, but the knowledge of dynamics of the process itself, the implementation of the proper strategies and tactics, as well as the acceptance of cultural diversities as a challenge which can 'open the door' to a further long-term cooperation has proved to be the best solution.

1.1. Business Negotiations Principles

International business negotiations represent a very sensitive field. Norms, values, beliefs and attitudes of the negotiators are completely culturally based – they behave and think differently. Each party has its expectations and goals, which are often different, but not irreconcilable. Unless the diversities are coordinated properly, the process will probably not pass its first stage. However, with the mutual respect of certain principles, participants will give a much better chance to the success of the whole negotiating process (Rakita, B., 2006).

- Before the beginning of negotiations, we should find out as much as possible about the members of the other negotiating team. Also, we should make sure that the number of members in the negotiating team is the same as in the other party. Thus the feeling of superiority of any party will be annulled and the negotiations will start in the atmosphere of equality. Changing the team members during the process should be avoided (except when absolutely necessary) since this will disturb the initial trust established, as well as the possible formation of a long-term business relationship.
- We should always get acquainted with the differences related to time, punctuality and the course of dealing with the activities. Negotiations cannot properly develop unless the mentioned points are considered and adopted. It is absolutely certain that a wide range of differences will appear in the field of interlocutors' corporate cultures.
- Establishing and maintaining a good interpersonal relationship is fundamental for the success of negotiations in many parts of the world (China, Japan, and Korea).
- In the situation when you do not speak the language of the other negotiating party, the first step is to find a good interpreter. But, during meetings, you should always address the interlocutor not the interpreter. He will translate from the 'background' while the interlocutors will, even if they speak different languages, establish a better contact talking face to face. The main task of the interpreter is to translate the meaning correctly and precisely, without omitting even the slightest details.
- Before the beginning of the negotiations, you should inform the interlocutors about the accomplished business results and experience. It is advisable to send a CV, necessary information about the company, as well as the list of the key topics to be discussed during the negotiations. In some cultures, especially Asian, it is very important to know all business achievements and the status of the interlocutor (Adler, N.J., 2002). The above mentioned information becomes even more relevant when negotiations are to be conducted by a woman – unless she has a good CV, she will not be taken seriously enough.
- The success of negotiations depends largely on patience. Reconsidering and discussing certain topics and issues sometimes represents a test of knowledge, politeness and the overall commitment to the process.
- The whole course of negotiations should be well prepared in advance. Each phase should be worked out in detail, and action plans should be created but always with a degree of flexibility. The negotiating process is filled with highs and lows and sudden twists. A good negotiator should consider all the changes as a challenge and get the maximum benefit from them.
- In the case of misunderstanding, further development of the events should be slowed down. Instead of continuing the discussion, you should locate the root of the problem, analyse it and work on solving it together with the other party. If the problem is not solved, you should let the other party get out of the process with 'due respect'.
- When a negotiator chooses a strategy, the next step is to balance it properly – you should always stick to the desired goals with necessary adaptability to your interlocutor and his culture.

1.2. The Influence of Culture on the Choice of Negotiating Strategy

The configuration of cultural dimensions determines the interests and priorities of the negotiators, and thus the choice of the appropriate strategy (Brett, J.M., 2007). When the interests and priorities are 'located', the negotiator chooses a strategy which represents a general approach to the negotiating process and it includes a set of behaviour which will lead to a desired outcome.

Basic cultural values and assumptions explain the differences in determining the interests and priorities (Brett, J.M., 2007). For example, companies that come from cultures with long-term orientation will always tend to build a noticeable presence on a new market and at the same time create a positive image. The motive for penetrating new markets is never to achieve short-term profitability. On the other hand, companies

from cultures with short-term orientation will focus all their strengths on generating a maximum short-term profit.

The strategy chosen by the negotiators is also influenced by the culture they come from (Brett, J.M., 2007). *In the case of confrontation strategy*, we deal with the choice of directness and/or indirectness in communication. Thus there is a direct strategy where a negotiator clearly states his interests and priorities, and indirect, which is characterized by a higher level of non-verbal communication. In the *motivation strategy*, negotiators state and underline all their interests, starting from the personal ones to the expectations of the outcome of the negotiations. The *Influence strategy* reflects the negotiator's use of power which largely depends on the best alternative of the possible agreement (BATNA) (Ury, W., 2003). The power is directly linked to the available satisfactory alternatives so it will be demonstrated by the party which possesses it. When BATNA is not attractive enough, a negotiator will depend on the other party much more, which automatically diminishes his influence on the further development of the process. In the *informative strategy* negotiators decide on how much information, as well as on the way to convey it to the other party, which directly determines the type of agreement which will be made. It can also be direct and indirect.

The members of individualistic cultures usually use motivation strategy together with setting very high goals and underlying the achievement of personal interests. They often refuse acceptable agreements if they do not meet their interests and demands completely (Brett, J.M., Okumura, T. 1988). However, the above mentioned sometimes non-negotiable attitudes, lead them to a situation where they come out of the process as the inferior party. In general, cross-cultural studies and research which deal with the comparison of the main characteristics of negotiators from individualistic and collectivistic cultures, show that the former are much more oriented towards strategies which, above all, provide the fulfilment of exclusively personal goals. On the other hand, negotiators from collectivistic cultures behave in much more cooperative way.

Cultural dimensions of egalitarianism and hierarchy influence the choice of strategy in which the possession of power is manipulated (Moran, T.R., Harris, R.P., 2004). Negotiators from egalitarian cultures (e.g. USA) believe that the power in negotiations comes from available information about the knowledge of the other party's best possible alternative (BATNA). However, if the process develops normally, they seldom resort to its direct use. On the other hand, negotiators from hierarchical cultures (e.g. Japan) believe that the power comes from various sources – status, persuasion ability, knowledge of the other party's best possible alternative and alike, and they use it much more. Their behaviour is characterized by the use of different types of power as well as tactics to influence the other party.

Directness or indirectness in the use of informative and confrontation strategy is determined by communication context. Negotiators from low-context cultures present information directly; e.g. American negotiators will act frankly in order to learn as much as possible about the interests of the other party, but they will also present their preferences and priorities very clearly without 'saving' information. Japanese negotiators, as members of high-context culture, are characterized by indirect approach. They present their priorities and interests in series of proposals.

2. Cultural variations in negotiation styles

Each culture has its own style of negotiation. Internationally, it is expected from negotiators to know the styles of interlocutors, in order to reach mutually useful agreement, as well as to avoid misunderstanding and keep further business collaboration.

Recognition and adaptation to the interlocutor's style has a direct impact on the success of a negotiation outcome. Generally, in practice, a large number of negotiation styles are established, but the following styles could be stated as fundamental: direct, analytical, motivational and mediating style (Brett, J.M., Okumura, T., 1998).

Direct style (persuasive) is characterized by the use of a phrase that points to urgency, directness, and speed at job performance. Since this style always insists on the efficiency of final outcome, negotiators who use this style often want to have control over others, and to keep strictly to the defined plan and to present their suggestions accurately. They rarely make any concessions. Since they always want to win, their appearance is persuasive, insisting on interlocutor's agreement.

Analytical style is characterized by aspiration to achievement of mutual understanding. Therefore, it always insists on logical sequence of events. Negotiators who use analytical style always stick to their priorities, and never make concessions if they can disorder them. They also try to induce the interlocutor to the conclusion, but without the use of overemphasized, direct insisting and persuasion.

Negotiators who use motivational style consider the mutual benefit as the main goal of the process. They always try to understand their interlocutor, since 'the good idea' is considered to be more important than precise agendas and abundance of information. Therefore, this style is characterized by creativity and enthusiasm. Negotiator - motivator considers himself smart, since he never closes the door in front of some new solutions.

Mediating style is characterized by aspiration towards consensus and good relationship between negotiating parties. Interlocutors who use this style will always listen to the other side and share the same opinion. Also, the efficiency of work is not of the most importance. The most important thing is to make an agreement, as well as further improvement and open perspective for mutual cooperation.

It is obvious that direct and analytical styles are characterized by the use of 'firm tactics' (the use of open threats, demands, sanctions, open approach to persuasion), while motivational and mediating styles comprise the use of 'soft tactics' (Brett, J. M., 2007), (insisting on friendly relationship, feeling of community and reciprocity, indirect approach to persuasion).

Generally, variations in the styles of negotiation are widely exposed in the following fields (Brett, J. M., 2007): 1) Rules in the process of negotiation 2) Selection of a negotiator, 3) Decision making process.

Cultural variations in the negotiation process

All cultures both explicitly and implicitly influence the behaviour of their members. They respect the established rules, no matter if they are about private or business life. The acquired rules reflect in the field of a negotiation process, - the way of running the process depends on cultural predispositions of negotiating sides. However, the biggest number of distinctions in the process of negotiation is visible in the domain of atmosphere by methods of approach and styles of communications characterized by specific cultures.

The atmosphere of a negotiating process is created by negotiators' sides, manifesting the behaviour which is culturally specified. French, Spaniards, Latin-Americans and Japanese consider negotiations as a social ceremony, which has its participants, protocol, time-frame, ethical principles related to the process of discussion, as well as the specified final outcome.

Members of Anglo- Saxon cultures (Americans, British, and Australians) have more pragmatic approach. The most important of all is the achievement of the 'economic goal' and constant focus on professional approach. American negotiators, regardless of their always friendly, open appearance, insist on an efficient and fast decision making process. For them, the agreement that brings the mutual benefit presents the main goal which they want to reach as soon as possible, neglecting the protocol. They send technically competent people to negotiations, who present concrete facts to interlocutors. Their directness and facts in outline make interlocutors often see them very harsh negotiators. Confrontations and verbal competitions are considered to be the challenge which can produce more constructive solutions (Moran, T. R., 2004).

French people experience negotiations as a ceremony, and forum during which they can demonstrate their acumen and logical way of thinking. At the very beginning of negotiation they show distrust to the interlocutors. With regard to historical heritage and their participation in a large number of international negotiations, members of this culture consider themselves as very experienced negotiators. A team leader is always the best orator, highly educated and self-confident. French negotiators are always ready for debates, and present well formulated solutions.

Japanese negotiators believe that socialization with interlocutor presents the integral part of the process. Since they insist on achieving long-term relationships, the reached agreement presents the beginning of the process of mutual adaptation. Members of this culture consider that it is important to create a relationship based on confidence, harmony and implicit understanding. (Moran T. R. Harris, R. P., 2004).

Approaching methods in the process of negotiation are also influenced by the core culture of a negotiator. There are two basic methods: width method and depth method. The first one insists on facts, details, written word, quantity of documentation, while the second one is focused on long-term relationships, relationship quality, given word.

American negotiators suppose that it is necessary to pass through the phase of agreement before reaching the final contract. Members of this culture are preoccupied by possession of facts and statistic data, and similar to French, they pay much attention to written contracts and agreements. Pronounced word or given promise is not of great importance to them. Therefore, the focus on quantity is obvious; the quality of relationship is put on the second place. Since time is money they do not use it over-excessively, even though they withhold important detailed explanations to the interlocutor.

Japanese negotiators consider that a negotiation already implies implicitly a large amount of details, so in their negotiating scenario there are no specific outcomes and facts defined in advance. They even try to avoid getting into great details, trying to give width to the agreement that will be specified during the process of negotiations (March, R., 1985, April). Japanese believe that the most important thing is to agree about main principles of both interlocutors, always making possibilities for new alternatives of the outcome which would bring benefit to both sides. Since the further cooperation is based on mutual confidence and agreement, a given word or a promise is sometimes much more appreciated than the signed agreement?

Communication style typical for members of American culture is characterized by positivism and openness (Scott, B., 2005). They usually start the communication process with assumption that the English language will be used during the whole session, which has shown to be one of the biggest shortcoming. The use of translator usually brings them in a situation to be late in discussion, since the other side often uses English actively or passively, which gives them time to think about the stating points. Furthermore, they insist on the use of a logical argumentation as well as on warning and pressure techniques even when interlocutors give no assent. They present their ideas clearly, considering the silence as unpleasant or as a sign of a problem.

Japanese make an impression of being easily persuaded negotiators, since they are apparently very passive. Reactions to interlocutor's presentation are usually based on expression of affirmative signs with different non verbal signals. They use period of silence in communication, during which they think calmly, expecting the other side to accept their behaviour completely. Generally, Japanese transfer only 10% of a message verbally, giving preference to non verbal communication. Even when they express themselves verbally, they are prone to indirectness, using phrases such as 'maybe', 'probably'... (Scott, B., 2005). Regarding the constant aspiration towards harmony maintenance, Japanese negotiators are almost never aggressive. Their communication is characterized by positivism and politeness.

Members of French culture often insist on their mother tongue to be used in a negotiation process. Negotiators from other cultures regard them as the most complicated European interlocutors. The French often use "no" in communication and they reject deals and compromises. They usually bring up all the information at the beginning of the process (which they also expect from the other party), and afterwards they establish their own principles and a way of thinking. They do not accept additional exposition of information, believing that the interlocutor has been hiding it up to that moment. Therefore, to the other negotiating party, they always appear as inflexible opponents (Kremenyk, V.A., 2002). French negotiators, who are always "furnished" with right arguments, take pleasure in debates, confrontations and competitive behaviour.

2.1. Variations in choosing a negotiator

The diversity in communication styles is also manifested within the purview of choosing a negotiator. The criteria for the number of negotiators that will make a team, on what grounds they will be chosen and connected, who will be a team leader, whether the authority will be strongly emphasized and similar issues, vary from culture to culture. By the way of choosing a negotiator and the structure of a negotiating team in general, the actual corporate culture of an organization can be clearly discerned.

American negotiators exclusively focused on the goal of efficiency, hold that a team should be as small as possible (sometimes even represented by a single person). In comparison to negotiators' age structure from many cultures, American negotiators belong to the youngest. They already take a prominent position in a team in their early thirties, sometimes even in their twenties. Women are often included in the structure of a team, although a small number of them hold highest managerial functions (Kremenyk, V.A., 2002).

Generally, the major criterion for the choice of a negotiator who will enter a team is represented by the level of their technical expertise. The criteria for the choice based on age and social status are considered completely irrelevant.

Americans always perceive their team as of a leader, applying so called “John Wayne” strategy. They are of the opinion that there is not a problem that they cannot solve. (Kremenynk, V.A., 2002).

Members of a French negotiation team are usually chosen by social and professional status criteria (Kremenynk, V.A., 2002). Regarding the fact that the tradition is highly esteemed in France, the existing relations are very important, not only family relations but also social and academic as well. The similarity between the members of a team (regarding the above stated criteria) is exceptionally emphasized and significant, and on the other side, it has an influence on the very way of managing the process. As opposed to other European countries, the above mentioned similarity is of the utmost significance in the structure of French teams.

Members of a Japanese negotiating team are usually in their late thirties, led by a senior leader. The choice of a negotiator in a team is based on their status and knowledge, the presence of women is very rare, while a leader is being chosen according to the age criterion. They will never send a small team to do negotiations. In most cases, they are striving to include representatives of various functions in a team, which will, in their opinion, automatically bring a competitive advantage to them.

2.2. Variations in the process of decision making

Every culture imposes certain characteristic thinking and reasoning patterns to their members, and accordingly, also ways of decision making. Generally, the very concept and acceptance of truth is different when we compare Eastern and Western culture clusters. In Western countries it is considered that the truth will be revealed by proper application of certain scientific methods. Therefore, if Aristotle's way of thinking is followed, all problems will be efficiently solved. In Eastern cultures, Taoist's way of thinking is adopted. The truth is an “active agent” and it can never be revealed by simple application of scientific methods. It can be reached in different ways, but also, it can have different forms.

The above mentioned variations are reflected in the way the decisions are made. American negotiators see each session as a process of problem solving, even when a problem does not really exist. What is also typical of them is that they do not negotiate all outcomes at the same time. They decompose them, solving them in a certain order, each in its own turn. What is very important to them is that they know who makes decisions in the other team, so that they target all proposals to a person in charge. During a negotiation process, they mostly use utterly rational way of thinking, utilizing all facts available. In this way, the other party is always exposed to a certain dose of persuasion based on being strongly “equipped” with information.

Within French negotiating teams, decisions are brought in a centralized way, by the highest authority. Generally, the French care a lot about the security of a decision that has been made, so while trying to keeping it safe, their behaviour can often be described as conservative. Also, in contrast to the American, they always set long-term goals.

The concept of decision making that is valid in Western countries is hardly applicable in Japan. In this country consensus-based decision-making process is used. Every employee that is potentially affected by the decision will participate in the consideration of its adoption or refusal. Hence, everyone has the right to express their opinion. Also, there is a constant feedback between the top management and employees in terms of prompt delivery and exchange of information relevant for joint decision-making. Top management holds in high esteem expert opinion of the middle-level management. Japanese negotiators make conclusions slowly, but once they reach them, they bring them into effect rapidly. Generally, once they make a decision based on adequate background information, they always stick to it. In contrast to them, within a Chinese negotiating team, an “exclusive right” of making decisions belongs only to the highest authorities, while other members are often not even asked for their opinions.

3. Instead of conclusion - Improving the process of cross-cultural negotiations

There are fundamental differences between national cultures related both to goals and behaviour during a negotiation process. Thus, it is always a current issue in what way a cross-cultural manager will most efficiently solve a potential problem rooted in great cultural diversification.

Firstly, an imperative in the contemporary business environment is to understand and accept as much as possible the culture of a partner negotiator. Once we are familiar with the culture of our interlocutor, and the way it influences the style of negotiations, it is much easier to understand characteristics of a specific situation. All data related to the interlocutor's organization, as well as their previous experience in cross-cultural negotiations should be taken into consideration. Afterwards, their needs, interests and desired goals should be re-examined and then compared and adjusted to our own. Negotiators must always bear in mind that there are great differences between intra- and inter-cultural negotiations. The approach that proved successful on a national "field" should never be taken as a benchmark for global success.

Author Stephen Weiss (Weiss, S.E., 1994) states that negotiators can choose a negotiation strategy according to their cultural similarity with an interlocutor. Accordingly, they will increase the possibility of maximizing the outcome of negotiations. Thus, in a situation of a *low-level cultural similarity*, the wisest thing to do is hire an agent, advisor or a mediator. *Middle-level cultural similarity* implies constant mutual adjustment – for example, American negotiators should know in advance that with any member of an Eastern culture they will never make an agreement rapidly. Negotiators, whose cultures are to a certain extent similar, may also choose so-called adaptation approach. In this case, considering the limited knowledge of specific characteristics of the interlocutor's culture, the whole process is being precisely coordinated. It is determined in advance who will talk to whom, what language will be used, how much information should be brought up and shared, as well as what interests, priorities and expectations related to the outcome of negotiating are. *High-level cultural similarity* implies full acceptance of the interlocutor's cultural characteristics. The existing differences are put aside and they become irrelevant, and so, the process is being personalized. The interlocutor is observed as an individual, not as a member of some other, unknown culture. This type of strategy enables mutual empathy and respect be improved, which represents the basis for creating any kind of long-term cooperation. The effect symphony is a strategy where both parties are willing to enter a negotiating process without exclusive predispositions imposed on them by the local culture. Therefore, they enter the process broad-mindedly, ready for certain renunciations, adjustments or adoption of completely new approaches. Cultural differences are put aside and together they create a new model of negotiations which suits best both parties' interests and priorities.

Moral, ethical and social responsibility are becoming more and more intensified when we take into consideration that there are contacts between different cultures on a global scene. Thence, when the question of ethics is applied to the field of cross-cultural negotiations, a motto that is desirable to be adopted is: 'Do as you would be done by'. However, corruption, lying, disclosing secrets or covering information relevant to the outcome of negotiations, still, for most parts, represent the reality in a field of negotiations.

The above mentioned diversity of national cultures constantly imposes an ongoing question of convergence and/or divergence on negotiators. As the knowledge of other cultures is considered almost essential, a convergent approach to doing negotiations seems like a logical solution.

However, cases where negotiations need a divergent approach are not rare. Members of different cultures often retain specific negotiation ways and patterns. Deeply rooted cultural behaviours are very hard to change, even when there is a strong possibility for overlapping with the interlocutor's behaviour and negotiation style. Still, another reason for divergence is a belief that an adopted (culturally specific) negotiation style is considerably more effective than the styles of other cultures (so one cannot expect that the interlocutor will change it).

Abstract: *The world economy prevails that the greatest merit for the development of powerful nations of the world is due to strong management. Changes occurring in the overall living as a result of the emergence of new technologies and information systems inevitably led to changes in management with managers giving guidance as individuals to find their place in the structure of the organization, and their knowledge and skills in the best possible way to fit into the overall setting. With the advent of globalization, the boundaries of organizations disappear; with its growth and expansion they exceeded local, regional and national frameworks and developed throughout the world. The scope of such management activities significantly increases and gets complicated so that managers also become experts on development and organization, planning, linguistic styles and multinational cultures, and mediators. Through its universality management allows fine organization and structuring of available resources to achieve effectiveness and efficiency, thus achieving the higher performances leading to najprisutnata reality before which set the modern concepts of management. The broad framework of its diversity does not limit nor narrows the possibility of freedom in creating the organizational and hierarchical structure, which opens the field for modeling okrozhuvanjeto. Big impact has management in the development of the economy is indisputably proven. Management throughout human history was constant companion and motor shekel which dragged and still pulling ahead in the new development. Good implementation of features enables management and economy of the Republic of Macedonia to engage in international business activities.*

Keywords: *management, internationalization, globalization.*

1. ALTERNATIVE POSSIBILITIES OF GLOBAL MANAGEMENT IN THE EFFECTIVE AND EFFICIENT UTILIZATION OF AVAILABLE RESOURCES

Taking into account the knowledge that today are available to science and practice indisputably is proven that the importance of the management in the development of a society is of particular importance. The management throughout the human history was a constant companion to the development and motor force that influenced and is still influencing to the direction of new development.

Today in modern scientific thought is widely accepted that the greatest merit in development of the most powerful countries in the world is due to strong management. The changes occurring in the overall living as a consequence of the emergence of new technologies and information systems inevitably led to changes in the concept of management where managers have a the final word in giving guidance how the individual should take its place in the structure of the organization and with its knowledge and skills in the best possible way to fit in the organizational setting. With the advent of globalization, national characteristics of organizations are lost and they with their growth and spread beyond local, regional and national frameworks with widely disseminated throughout the world. In such circumstances the scope of management significantly increases and complicates and managers are also profiled in experts from several areas: the development and organization, planning, linguistic styles and multinational cultures, mediators and others. Through this universality, the management provides organization and fine structure of the available resources to achieve effectiveness and efficiency, and thus exercise of the higher performance of the organization that is leading to the modern concepts of management. The broad framework of its diversity does not limit nor narrows the possibility of freedom in creating the organizational and hierarchical structure, which raises the most optimal box modeling environment.

From this aspect is undisputed that the successful implementation of managements' functions enables the economy of the Republic of Macedonia to join to the international production systems.

Today, to live and survive in a world of strong competition among businesses worldwide, presupposes a respect of the imperative that every manager needs to apply, and that is to know quickly and decisively to bring key decisions about the organization he leads. Adoption of strategic decisions often carries with it risks that can have long term implications to the operations of the company. The critical and difficult strategic decisions are actually everyday operation of business entities, in often limiting conditions regarding the flow of capital, investment in training and development, lack of resources or forced savings because of poor economic conditions. Each decision that will be made by the manager is strategic because it needs to maximize the economic impact of existing resources and it can be determined by action that would have the lowest risk, and thus bring maximum profit organization in general.

From here we can conclude that the strategic decisions depend on the character of each individual and that is what gives individuality to their essence. The strategic decisions of the executive and other managers are the choices that determine the direction where an organization will move from which derives its success or failure. In today's business world that is changing rapidly, it must be followed by quick adaptations in the domain of strategic decision making.

Analyzing the experiences of the practice can not even be concluded that today on national, much less on international level there is no single approach to the process of strategic decision making, or defining the term for them, because not every strategic decision or the its process fits every situation, organization or person. From here the existence of extensive and detailed explanations of techniques and approaches, and even established frameworks through which the process of making strategic decisions. The results of the process of making strategic decisions, as such, should be able to evaluate, and thereby the results or success that comes as a future can be measured by the results from the previous period. However, gaining experience with the making of strategic decisions not only to evaluate the possibility to compare the effects achieved with the results achieved in the past, but the process becomes important by itself, because of the experience that it is acquired and its application in the future. Such comparisons are important because they allow improving of the position of the management team for new insight into decisions. Therefore it is said that the process of making strategic decisions turned into art for by managers familiar with his reaction to new and unexplored situations and conditions, that is how we understand these situations and how they define the problems for which decision-makers. Besides experience, which is undoubtedly there and formal techniques for making strategic decisions that help managers to improve the functioning of the organization, to prepare for new and unknown situations imposed by the environment which is constantly and rapidly changing.

Following the dynamic development of global economic processes inevitable conclusion is that any executive, but the basic knowledge and skills, should have capabilities to initiate and create their own ideas and solutions, to understand the environment in acting, his organization (business and economic), to recognize the causes of problems, comply with the principles and the principles that make up global management, and thus has its clearly defined strategic thinking, which is expressed and implemented through the adoption of effective and sound strategic decisions.

According to scientific thought global management is a universal activity and under the general concept is a special form of management that uses the factors of environment and internal factors on performance in the world market.

The success of Global Management is the advantages of multinational companies using the strategies, functions and principles of it, realize maximum efficiency in operation, optimal management and long-term stability.

The basic features of global management: strategic planning, international organization, international personnel policy; international communication, negotiation of international operations; culture of international operations.

These functions are accomplished the ultimate goal, which is a competitive advantage in business or national economy. Today as a brake on this tendency occurs more external factors, such as: competitors, resources, technology, suppliers, consumers, labour supply, economic conditions, legislative, political, governmental, socio-cultural, international and other conditions.

The modern way of doing business, which is characterized by destruction of national barriers do not refer to the connection of global management, competitiveness and market, something which again suggests a

whole system of chain reactions, which arise as a consequence of their mutual interaction. The importance of competition policy for the national economy and the fact that all activities of the European Union are based on the belief that the competitiveness of companies is a prerequisite for successful performance of European businesses internationally.

2. MULTINATIONAL CORPORATIONS AS INVESTORS IN MACEDONIA

To date in the Republic of Macedonia (RM) were made numerous analyzes in order to discover the reasons - why Macedonia is not attractive for multinational corporations (MNC). Out of them comes almost unique conclusion that still can not speak to the overall stability of the security and political climate, corruption, contract enforcement, unpredictable government policies, inefficient judicial system, fully constructed tax system and the small market is one of the biggest reasons that deter foreign investors to choose RM as preferred destination for their business activities. MNC Macedonia seen as the country where there are still unresolved property rights, changing policies, long decision-making process at central and local level, inadequate banking services and underdeveloped and insufficient infrastructure.

As one of the few advantages of Macedonia for potential foreign investment, experts say the good location of land transport links, educated and cheap labour and open trade regimes.

Analyses show that the strategic task of the country should be achievement of the gross investment rate of around 25%, which is based on part of domestic savings, but most foreign investment. The priority should be attracting MNCs, mostly through independent projects of foreign investors, or through our partnerships with domestic firms.

In Macedonia there is no institution that can analyze the quality of foreign investment by MNCs in the country for the simple reason that no such data exist. What we have official institutions are data from the National Bank of Macedonia (NBM), which posted total foreign investment by year and by country.

With a large percentage of the total investments in Macedonia, part of Cyprus, Liechtenstein, and a few years investments have started to come from British Virgin Islands, Marshall Islands, Cayman Islands. These countries, due to tax exemptions present in them, the world's known as a "tax haven". Companies seeking to avoid taxes in their home country establish their own subsidiaries in these countries and by investing them in other countries.

3. INVESTMENT POLICY AND MNC

Investment policy is an economic category that considers key and one of the most important factors of economic development - investment. From their size, structure and efficiency of use is determined process of economic development of a country.

Therefore the investment policy is the most important part of developing macro-economic policy and plays an important role for economic growth of national economy and achieving higher levels of economic development of the country as a whole. Considering the goals of economic development, investment policy determines how to most effectively achieve the goals of development in each stage of development of national economy.

From here you can:

1. First Investment policy means a set of government measures that affect the realization of investment activity, i.e.
2. The second The investment policy includes measures and instruments relating to investment and economic development.

Depending on which level relate distinguish two levels of investment policy as follows:

- Investment policy head of government;
- Investment policy run businesses.

Basically, the role of government is to create a favourable environment for investment and businesses to make specific investment decisions. Therefore, no special instruments of economic policy that would have pertained only to the investment policy, but the measures and instruments of investment policy and overall measures that concern and economic policy.

In a market economy country does not interfere directly in the investment decisions of business entities. On the other hand, the instruments of monetary policy can affect the volume of money in circulation in order to encourage investment. In this regard recent example is the decision of the National Bank to limit the amounts of funds that banks can use to purchase treasury bills, or auctions for the same from one week down to once a month (Regulations and Decisions from the National bank of the Republic of Macedonia, Retrieved from <http://www.nbrm.mk>). Although this decision banks reacted immediately, the Central Bank left its stance defending the same with the explanation that this way the banks will remain more free resources that they will place in the economy which is generally known that there is a lack of liquidity means.

The instruments of fiscal policy can affect the acceleration of depreciation and the rate of reinvestment, and customs policy on the price of imported technology.

4. DEVELOPMENT POLICY OF THE GOVERNMENT AS A PREREQUISITE FOR THE CREATION OF ATTRACTIVE CONDITIONS FOR FOREIGN DIRECT INVESTMENT (FDI)

According to the Programme of the Government of the Republic of Macedonia (Programme of the Government of the Republic of Macedonia, Retrieved from <http://vlada.mk>) prepared a Public investment Programme in Macedonia 2010-2012 (Public Investment Programme in Macedonia 2010-2012, Retrieved from <http://www.finance.gov.mk/files/u1/PIP-2011novo.pdf>).

Starting in 1995, in the Ministry of Finance is established a database of investment projects of public infrastructure of the Republic of Macedonia, based on data submitted by the competent ministries and who constantly innovate.

In preparing the program is removed from the conclusion that actions taken to intensify the reform process in the country, especially the transformation processes in the public sector seeking to accede to the application of appropriate methodology in the implementation of public investment planning and monitoring their implementation.

In preparing the program takes into account development policies in the sectors and priority infrastructure projects contained in the Programme of the Government of the Republic of Macedonia for the period 2006 - 2010 year (Programme of the Government of the Republic of Macedonia 2006-2010, Retrieved from <http://archive.vlada.mk>). Enclosure Programme 2010-2012 the contribution of the Government in implementing the strategy to increase investments of MNC in the country, will be expressed, primarily by organizing, supporting, regulating, promoting and encouraging development activities, and adoption of appropriate legal and economic regulations.

Government of the Republic of Macedonia emphasized the priority given to creating conditions for successful implementation of the Stabilisation and Association Agreement with the European Union (Stabilisation and Association Agreement with the European Union, Retrieved from <http://www.sep.gov.mk/Default.aspx?ContentID=24>) and the Treaty with the World Trade Organization (Treaty with the World Trade Organization, Retrieved from <http://www.wto.org.mk.mk.gd/>).

These agreements, along with contracts or agreements with other countries in the region and beyond a free trade constitute a solid basis for increased economic cooperation with foreign countries, qualitative restructuring of the economy, and thus the total development (Free Trade agreements, Retrieved from <http://www.mchamber.org.mk/%28S%28tqvesj45khgpdrcnusici45%29%29/default.aspx?lId=2&mId=83&smlId=0&cId=0&pId=1>). This would lead to improvement of inflow of foreign direct investment by MNCs in Macedonia.

Republic of Macedonia, a small country with proclaimed permanent orientation towards open market economy, the priorities of development puts other forms of economic cooperation with neighbouring and other countries, especially member countries of the European Union.

In 2011, macroeconomic stability in the country was successfully held. The exchange rate is stable and inflation is controlled framework. Given that the Republic of Macedonia continue to be plagued by lack of capital investment, despite an increase in national savings, strategic goal and priority of the government is creating conditions for greater inflow of foreign investment.

In this connection, the Government is making efforts to improve the domestic environment, in terms of increased investment activity of MNCs, particularly by creating favourable conditions for attracting foreign direct investment.

One of the key benefits of the system state that "a priori" go encourages investment and certainly a legal certainty to investors (M. Andonovski (2010) Institutional Assumptions for Improving the Conditions of Business in the Republic of Macedonia. Prilep, R. Macedonia: Economic faculty - Prilep).

The same investor in the country, will be provided by completing reforms in the judiciary, promotion of arbitration (Laws and Regulations for the Economic Chamber of Macedonia, Retrieved from <http://www.mchamber.org.mk>) or non-judicial dispute resolution (Law on Mediation, 2009, Retrieve from www.pravda.gov.mk/download.asp?id=253), more efficient provision of capital creditors through appropriate means of providing payments and creation of legal prerequisites for eligibility ownership of property by foreign persons, and others.

Despite their determination to continue with economic reforms, will be very difficult for the country to persist in their efforts without a recent twist in the field of real investment and production.

Special investments of MNCs in infrastructure is vital especially for:

- reducing unemployment and poverty
- increase the competitiveness of national economy
- higher economic growth, and
- balanced regional development in order to intensify the process of European integration of Macedonia.

5. TARGET GROUP OF INVESTORS AND TARGET SECTORS FOR PROMOTION

From the analysis and comparison of the Republic of Macedonia in terms of region, can perform positioning of the target groups of foreign investors and target sectors that still need to focus in future promotional activities:

1. Medium and large enterprises (firms) of adjacent and nearby developed countries, who need to expand production;
2. Multinational companies that are not yet present in the region;
3. Multinational companies that are already positioned in neighboring countries;
4. Companies or firms that are main foreign trade partners of Macedonia, i.e. firms that have successfully cooperated with Macedonian companies.

According to previous experience and considering the current level of FDI of MNCs, the most important are those sectors where Macedonia has its own experience and knowledge, and it would be: the sector of industry of food and beverages sector of metal industry, the Department of Energy, the telecommunications sector, and lately the tourism sector.

STRENGTHS AND WEAKNESSES OF RM IN TERMS OF ATTRACTING FDI AND STRATEGIC ALLIANCES

Strengths:

- Solid political and macroeconomic stability
- Relatively favourable tax environment
- Level of privatization and a sound level of realized economic reforms
- Renewal of existing and creation of new institutions
- Restructured and privatized banking system
- Developed telecommunication infrastructure
- Solid level of high-educated staff
- National treatment of foreign investors
- Relatively low tariff rates
- The existence of free economic zones
- Short takes time to start a business
- Ability to use tax breaks and incentives

Weaknesses:

- Poorly developed infrastructure in general
- Still insufficient recognizable locations for attracting FDI
- Limited natural resources
- Implementation gap in the primary key laws
- Bad judicial system
- The size of the market
- Administrative barriers - long procedures for obtaining the necessary licenses to perform activities at the local level (building permits, frequent changes to the purposes of land etc).
- Poorly developed technological base in the sectors
- Low level of know how (especially managerial skills)

6. CONCLUSION

From the above it can be concluded that the field of creating conditions for attracting foreign investment and thus increase the level of globalization of Macedonian economy of multinational Plan of Macedonia and more opportunities and favourable conditions are available, i.e.:

- Commitment of the Government program of economic development, responsible fiscal policy, and creating a favourable environment for attracting FDI
- Further development of financial markets
- Development of strong institutions for attracting FDI
- Adjustment of legal regulations concerning labour relations in accordance with EU standards
- Borrowing in the international financial institutions and investment Concession for the construction of capital infrastructure facilities
- Creation of a fully liberalized fiscal system to attract FDI
- Further strengthening of the banking sector
- Reforms in education in accordance with the needs of the development departments of the Republic of Macedonia.

ENHANCING COMPUTER MEDIATED COMMUNICATION BY APPLYING CONTEXTUALIZATION TO EMAIL DESIGN: A CASE STUDY

Adi Katz

Department of Industrial Engineering and Management SCE College of Engineering, Israel, adis@sce.ac.il

Abstract: *This paper deals with communicational breakdowns and misunderstandings in computer mediated communication (CMC) and with ways to recover from them or prevent them. The paper describes a case study of CMC conducted in the company Artigiani. We observed communication and conducted content analysis of e-mail messages, focusing on message exchanges between customer service representatives (CSRs) and their contacts. In addition to task management difficulties, we identified communication breakdowns that result from differences between perspectives, and from the lack of contextual information, mainly technical background and professional jargon on the customers' side. We examined possible ways to enhance CMC and accordingly designed a prototype for an e-mail user interface that emphasizes a communicational strategy called contextualization as a central component for obtaining effective communication and for supporting effective management and control of organizational activities, especially handling orders, price quoting, and monitoring the supply and installation of products. Designers of systems that support distant communication and collaboration may find practical ideas to apply.*

Keywords: *Computer-Mediated-Communication (CMC), Computer Supported Cooperative Work (CSCW), e-mail design, Communication Breakdowns, Miscommunication, Contextualization, Mutual Understanding*

1. INTRODUCTION

Computer supported cooperative work (CSCW) and computer mediated communication (CMC) are most crucial in the activities of today's organizations. Organizations need to achieve goals that one person cannot accomplish alone, and knowledge that is collected by individuals should be reserved for the general use of the organizational community. Now, workers need more than ever to share knowledge, and are involved in joint activities that require the support of information systems. Communication is at large extent in the form of computer mediated cooperation, and computerized applications ascribed as groupware (group support systems that include shared environments, whiteboards, electronic group calendars, chat rooms and more) facilitate communication and improve coordination. The overall success of organizations is certainly dependent on CMC that need to be designed to achieve a high level of mutual understanding (hereafter MU) and minimal communication breakdowns.

Although e-mail is the most widespread mode of CMC at work, e-mail client software is poorly suited to support the collaborative quality of the organizational tasks, which results in a pernicious problem of people suffering from email overload (Bellotti et al., 2005; Whittaker, 2005). Users get frustrated with their e-mail because they feel overwhelmed by the high volume of messages. It seems that current structures within e-mail clients prove inadequate, especially for high-volume e-mail users. There is need for reinventing the e-mail client, moving it from the current electronic analog of physical mail to a tool that allows users to manage all of their digital communications. New visualizations of the information contained within e-mail inboxes are a key piece of the solution (Rohall, 2001).

The Problem of Communication Breakdowns

Communication problems are potentially present in organizational processes, which involve cooperative work between workers coming from different occupational backgrounds. The differences in language and knowledge eventually create a situation of distance between individuals who need to communicate in order to complete their tasks successfully. Therefore, the organizational process could be facing a problem of miscommunication that might lead to low performance and therefore to its failure.

On the one hand, collaboration between workers who come from diverse functional backgrounds is essential in organizations (Fischer, 1981). On the other hand, communication processes that involve individuals who come from different organizational occupations, domains or methodologies and hold different kinds of knowledge, impose certain demands and requirements on the form of messages exchanged between them (Sommerville et al, 1996). Research has shown that communication is more efficient when people share

greater amounts of common ground and when integration between individual member contributions is achieved. However, achieving integration will be more challenging if group members start from different practical realities - e.g. come from different functional backgrounds. Common to all situations requiring the communication of contextual information is the likelihood of being misunderstood because of information the speaker possesses but the listener does not. Such situations are more likely to occur in computer mediated team work than in face-to-face teams (Cramton, 2001).

Contextualization

Current communication theories suggest that communication breakdowns may be reduced by contextualization, i.e., an adaptive communication behavior of providing the explicit addition of contextual information to a core message to ensure effective communication. Communicators contextualize in order to overcome communication difficulties arising from perspective differences. The lack of contextualization has been named as one of the most frequently occurring problems in communication between distributed workers (Cramton, 2001; Hinds & Bailey, 2003). The decision to contextualize involves trade-offs between the benefit of gaining better communication and the costs in terms of the cognitive resources it requires. The cognitive effort required for the act of contextualization is particularly heavy on the e-mail author in CMC, because information transfer, especially complex information, is less efficient than in richer media (Kraut et al., 2002). Although the degree of context required in an e-mail message depends on the recipient, it is the sender (author) who must determine the context that the message provides, as well as its depth. Hence, the adaptive behavior of contextualization is at the sender's discretion. A sender who senses a problem in communication has motivation to contextualize in order to gain mutual understanding.

It has been reported that the impacts of contextualization on MU and on performance are contingent on whether communicators share or differ in their perspectives: contextualization increases MU and performance in cases of different perspectives, but it does not increase MU and even decreases performance in situations of shared perspectives. In other words, contextualization is only effective when needed and counterproductive when not needed (Katz & Te'eni, 2007). However, message senders are not always effective communicators, and are not always aware of the difference in perspectives with their recipients and therefore may use contextualization inappropriately.

In order to contextualize appropriately, a speaker needs to be engaged in an additional communication behavior, perspective taking, which is metaphorically depicted as the act of stepping into the shoes of the addressee. In task-oriented situations, one's ability to orientate to the perspective of the other person enables him to assimilate and integrate information using the other's frame of reference and leads to higher MU (Tan, 1992). Perspective taking is a cognitive skill that varies among individuals and requires cognitive effort (Dickey et al., 2007). In addition, people tend to rely on their own perspective when communicating because it requires less cognitive effort (Horton & Keysar, 1996; Keysar et al., 2000), or overestimate the degree to which others' perspectives mirror their own (Krauss & Fussell, 1991). It was found that cognitive load has a detrimental influence, as it disrupts monitoring and adjustments and leads to rather standard messages that are not adapted to the perspectives of the addressees (Roßnagel, 2000; Horton & Keysar, 1996).

In customer service situations, customer service representative (CSR) may use fixed, predefined messages to present a generic corporate image to those outside the organization (Adria & Chowdhury, 2004). This makes it difficult for strangers to develop shared understanding of context, which is crucial for communication effectiveness (Dickey et al., 2007). In addition, customers are sometimes unable to take a CSR's perspective because the CSR refers to things outside the customers' experiences. In such cases, sessions can break down and end without resolution.

Contextualization in e-mail Communication

We looked at previous work in CMC that stress the need for reinventing e-mail, and put our focus on contextualization as a central component for enhancing effective communication. We concentrate on two existing features from previous work, embedded links and visualization of message threads and added additional features (introduced in the design section).

Contextualizing with embedded links

Knowledge organization deals with issues of how to best store knowledge so that it can be retrieved when relevant. Users need to get to the right knowledge at the right time, and must be aware of the relevant

knowledge that is available to them at each task. The idea of tying knowledge to action is aroused from the fact that workers do not have the time to actively seek organizational knowledge, and therefore it would be far more effective if the knowledge could find them (Schwartz, & Te'eni, 2000).

KMail, a knowledge-enhanced e-mail designed to enhance collaboration, is a remarkable example for a tool that ties organizational memories (OM) effectively to organizational actions using contextualization (Schwartz, & Te'eni, 2000). KMail is a URL-based OM that enables the linking of knowledge to ongoing communication to achieve successful communication by helping users to appropriately adapt to communication by assessing perspective differences.

Contextualization with message threads (conversational trees)

Collaborative tasks are not discrete but iterative. As a task evolves, users have to combine task related information in incoming messages with prior relevant information. Prior messages are important because they contain context that is critical for interpreting the current message (Whittaker, 2005). Messages should be viewed as elements of a conversation rather than as independent or solitary. An e-mail conversation, also known as a *thread*, is typically defined as the tree of related messages that arises from the use of the reply operation (Venolia & Neustaedter, 2003). This interconnectedness of e-mails is not fully exploited in conventional e-mail clients. Conversation threads in e-mail allow users to see a greater context of the messages they are reading, remind users that a conversation is in progress, recording the state of a discussion, and collating related messages automatically (Kerr, 2003). A full visualization of a message thread clearly displays a message along with all its previous related messages and therefore provides better context for understanding the meaning of the current message. Therefore we treat threading as a form of contextualization, since it adds layers of information about the communication's history.

Threading is useful for both recipient and author. At the recipient's side, contextual information reduces the likelihood of misunderstanding the meaning of messages. For both, contextualization by thread visualization reduces cognitive demands on memory by eliminating the need to recall past issues and other conversational elements. At the author's side, threading serves as reference of the common ground achieved in the conversation until the current point, and allows him to expend less effort in building the current message. The author assumes that the recipient already knows or has access to previous information and therefore can choose not to contextualize, sending only the core message and drawing the recipient's attention to relevant context whenever necessary. This allows a relatively parsimonious (economical) communication pattern, requiring less message exchanges and enabling the creation of shorter messages, because most of the information needed is already presented in the thread.

Innovative ideas that go beyond the limited context preservation by threading widely used in e-mail programs can be found in the literature. Examples are: an advanced email prototype with a complex branching reply tree (Venolia & Neustaedter, 2003), an integrated e-mail client with visual separators in the Inbox list using "pivoting" and threads (Kerr, 2003, Kerr & Wilcox, 2004), and a combination of a tree based model with a timeline model to produce useful tracking of conversations (Rohall et al., 2001).

2. ARTIGIANI AS A CASE STUDY OF CMC DIFFICULTIES

The current study is about designing effective CMC to enhance good communication. Our objectives were to first evaluate communication processes between CSRs and their business clients, with a special attention to communication breakdowns to find the types of contextual information that help resolve breakdowns and miscommunications, and then find possible ways to enhance effective CMC and finally implemented our ideas in the design of an e-mail prototype. We examined communication processes in an Israeli company named Artigiani, as a case study of an organization with massive email message exchanges. Artigiani specializes in designing and manufacturing affixing (metal fixtures or accessories such as handles, hooks and hangers).

Case Study Steps

To evaluate the existing communication in Artigiani, we conducted the following activities in a time range of about two months: observations; one-to-one interviews; and collection and text analysis of 60 e-mail messages.

Consequently, we roughly distinguish between two purposes for contextualizing:

- Task management: Contextualization for improving the worker's ability to effectively manage his organizational activities and tasks, and to improve related decision making.
- Communication: Contextualization for improving CMC, i.e. achieving a high level of MU and minimal occurrences of communication breakdowns.

Findings

The first meeting between a customer service representative (CSR) and a customer is face to face; the following communication is usually via e-mail. Although CSRs are in contact with customers and business clients via telephone and face to face encounters, there is a massive activity of e-mail message exchange. E-mail is the preferable communication channel to handle various organizational activities (e.g. negotiating with suppliers, orderings products, quoting, scheduling the supply and installation of products, etc.), especially because of its ability to document and maintain written proofs. We were interested in the exchanging of messages between CSRs and customers, and also with professionals such as carpenters, contractors, architects, interior designers, and suppliers. Inasmuch profitability of businesses depends on maintaining current customers and attracting new ones; customer service is an important part of every business organization. Customers are satisfied when they receive personal and prompt service. The likelihood of a business to lose customers due to bad experiences with CSR reinforces the goal of achieving good communication between them. Although important, this study is not about developing and refining effective customer service skills, but is about designing effective CMC to enhance good communication between CSRs and business clients.

We now briefly describe the difficulties of task management and communication in Artigiani.

CSR's Task Management Difficulties

CSR's in Artigiani spend much time in managing of pending tasks. They are involved in various parallel activities related to customer service and handling orders, such as management and documentary of customer files, responding to telephone calls, monitoring orders, negotiating with suppliers, quoting, scheduling the supply and installation of products and so forth. CSRs are in great pressure to respond quickly to e-mails, and the activity of managing their tasks is experienced as a stressful one, because of the high volume of incoming messages. They are constantly involved in deciding about priorities of activities, and in addition they tend to lose important items when they need them (such as previous message exchanges, and documents that they wish to attach to outgoing messages). They are required to manage ongoing activities over time and need to handle numerous schedules and reminders. The time range for an order is thirty days in average, and during this range communication regarding an order or client is not continuous. However, CSRs need to quickly associate items, events, files or messages to them. This makes the task of managing orders and treating clients and customers cognitively demanding.

For the sake of tracking and managing orders, information is filed into physical office folders. The process of collecting and filing is inconvenient, tedious, and requires the investment of time and consistency. Thus, workers tend to neglect this activity and as a result information can be lost. In addition to arranging information in physical folders, CSRs constantly arrange files in their metaphorical desktop folders on their computers and in their e-mail folders. Mentally retrieving the location of needed information is cognitively demanding on the long term memory, and constantly searching for information in e-mail folders is tedious and time consuming. It is clear that CSRs in Artigiani have problems of effectively maintaining and using various types of knowledge, thus the value of the information is lost. CSRs do not have a clear visualization of all the parties involved in a conversation, nor do they have easy access to the contents exchange in the conversation by each member. Clearly, difficulties to reach information in a timely manner affect work quality, especially the quality of customer service. Because e-mail communication is a-synchronic in its nature and not continuous, it is difficult to keep track of orders and to effectively handle them.

An e-mail system that supports easy access to contextual information items that are related to pending tasks can be of great help for managing the overwhelming high volume of incoming messages and activities.

Communication Difficulties

Observations, interviews and text analysis of e-mail messages revealed that the main activities of CSRs are handling orders facing customers and suppliers, stock checking, price quoting, and answering technical questions. We discovered that the vast majority of miscommunications occur in communication between

CSRs and customers, and that the main source of communication breakdowns is the differences between the perspectives of CSRs and customers, derived especially from the lack of technical background and jargon at the customers' side. While communication between CSRs and professional contacts such as designers and carpenters is more parsimonious, CSRs need to include a mass of contextual information in the message when communicating with customers. Often, it is necessary for CSRs to communicate with customers via telephone over cases in which communicators fail to overcome breakdowns that emerge in e-mails exchanges. In some cases, communication failures were so severe, that they damaged the ability to effectively treat an order, and the whole deal was canceled by the customer. Cases as such undoubtedly harm the organization's profitability.

Text analysis of email messages demonstrate CSRs' tendency to use egocentric and standard expressions when communicating with clients. Keeping in mind that contextualization requires cognitive effort and is time consuming; we claim that the aforementioned cognitive overload of CSRs influences their little tendency to contextualize.

3. DESIGN

In this section we present our prototype of an e-mail user interface designed for CSRs in Artigiani.

Our e-mail design reflects an attempt to follow an avenue for reinventing e-mail, which was suggested after a survey of a vast body of work accumulated over the past 3 decades in the e-mail literature. The survey retrieved three perspectives that need to be assembled simultaneously to support activities in the design of future e-mail clients: *individual*, *communicative*, and *socio-organizational* (Ducheneaut & Watts, 2005). We will refer to the three perspectives when we describe our e-mail features.

Contextualization must rely on organizational knowledge for two components: 1) Knowledge to provide additional context layers around action; 2) Knowledge to identify conditions in which to contextualize messages (Schwartz & Te'eni, 2000). Accordingly, our e-mail design roughly distinguishes between two purposes for contextualizing; supporting task management and enhancing effective communication:

- **Task management:** Contextualization for improving the user's ability to effectively manage his organizational activities and tasks.

We dealt with design issues of how to best implement the idea of tying knowledge to action; in other words, how to best organize and display knowledge so users can easily get to the right knowledge at the right time at each task. This purpose is closely tied to the Ducheneaut & Watts (2005) *individual* level reflected in the e-mail as file cabinet metaphor, in which e-mail design extends human information processing capabilities.

- **Effective communication:** Contextualization for achieving a high level of MU and minimal communication breakdowns.

We dealt with two questions regarding contextualization:

- **When?** We designed an e-mail prototype that would help users to identify the conditions in which contextualization is necessary and encourage them to do so.
- **What?** We designed an e-mail prototype that would help senders to identify what types of information is required for the receivers to understand the message. Metaphorically, senders should be able to easily build the contextual bridge above the cognitive distance between them and the receivers.

We present two screens (Figures 1-2) that show the main features that are designed to achieve effective task management and effective communication. For convenience, we separated between these two different purposes, but it is important to note that some features support both.

Task management: knowledge to provide the additional context layers around action

Figure 1 presents a screen layout from our e-mail prototype with an incoming message from a customer. The layout is divided into four panes: 1) incoming messages (inbox list); 2) message content; 3) OM related to the message; 4) thread view. When a message is selected in the inbox list (pane 1), different contextual information of that message appears in the three remaining panes.

Incoming messages (inbox list)

The incoming message pane resembles current e-mail programs. Messages are separated according to arrival dates, and basic information of each message is displayed (arrival time, sender and subject).

Three icons may appear next to messages: an icon of a message thread for messages that belong to a message thread, the familiar attachment icon, and flag icons that express urgency. The latter meets the need for effectively managing pending tasks and task prioritizing. The system parses the text of incoming messages and flags selected messages as most urgent, when identifying urgent expressions and punctuation marks (e.g. "critical", "urgent", "ASAP", "quickly", etc.) or when identifying content that is considered high priority (e.g. activities such as orders). Flags and priorities are considered as a design component of the *communicative* level in the Ducheneaut & Watts (2005) framework.

Organizational memory (OM) for tying context layers to action

Our prototype borrowed the main feature of kMail, which is the creation of OM views. The idea of tying OM to e-mail messages resembles the "contextual data" design component, related to the *socio-organizational* level in the Ducheneaut & Watts (2005) framework. We elaborated Schwartz and Te'eni's (2000) idea of associating OM views to outgoing messages, by proposing OM views also for incoming messages. For example, in Figure1, an incoming message from a customer was parsed, and the words "item number 126" were associated with a memory item of a figure of a door handle, and therefore were hyperlinked to an OM view. Implementing the idea of tying knowledge to action, this addition helps CSRs manage the numerous pending tasks which arrive with incoming messages. Though we differentiated between effective task management and effective communication, OM supports both. In addition to helping CSRs to better handle their tasks, the probability for MU is raised by the fact that incoming messages are associated by hyperlinks to the relevant information needed for the CSR to understand their meaning.

Message threads

Thread visualizations are associated with the *communicative* level in the Ducheneaut & Watts (2005) framework. Following previous work, we designed graphical representation of message threads to highlight all parties involved in a conversation, and to have an easy access to the contents exchange in the conversation by each member. We used different colors for different professional groups (CSRs, carpenters, contractors, architects, interior designers, suppliers and customers). To produce a useful tracking of conversations, our threads are located on a timetable, following the work of Rohall et al. (2001). In figure 1, at the 4th pane, for each message on a thread we inserted a button to access the sender's profile for more details. This encourages the user to take the contact's perspective before replying or making relevant decisions. In designing message threading, we adopted from a list of key qualities characteristics that are most relevant and useful for effectively managing CMC and organizational activities at Artigiani: chronology, relationships, compactness and attribute highlighting (Kerr, 2003).

The preliminary phase of text analysis of a message's helped us expose important attributes that are extremely useful for quickly finding particular messages or assessing the state of a thread. Users can effectively locate all messages that were sent by a particular person; sent on a particular time range (day, week, month); or ascribe to a certain milestone (distinguished stages such as orderings, production and supply). Organizing information by categorization of the main milestones of customer care in Artigiani is an important feature for lowering the cognitive complexity sensed by CSRs. We used colours to group and distinguish between certain messages, contacts, and milestones, for a quick and simple identification. Using identical colors to group elements helps reduce cognitive load. Highlighting attributes by coloring nodes and locating threads on a timetable spare the need to click on messages on a thread to see who communicated, when, and at what stage.

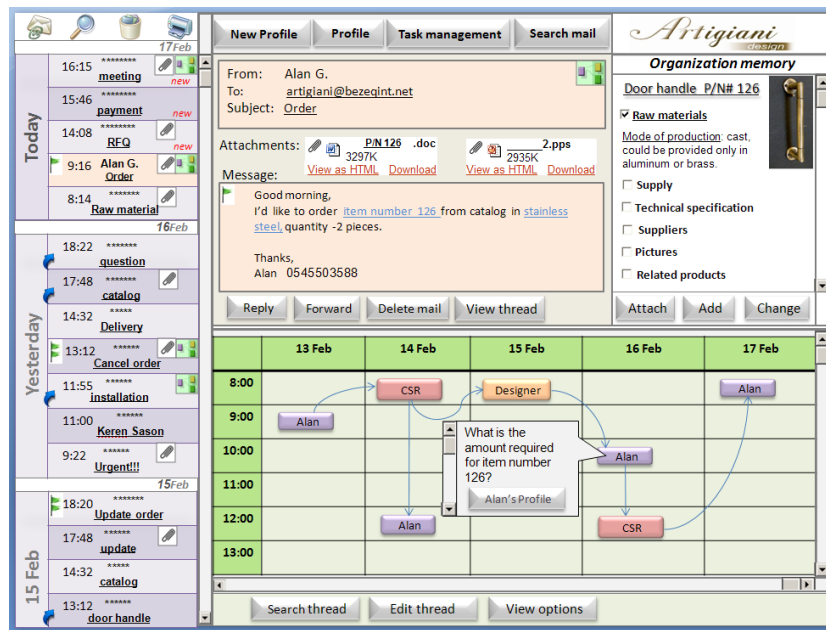

Figure 1: Contextualization with Embedded Links and Threading Visualization

Effective communication: knowledge to identify when and what to contextualize

As aforementioned, contextualization is only effective when needed and counterproductive when not needed. We are also aware of the fact that message senders are not always effective communicators and are not always aware of the difference in perspectives with their recipients. Therefore, our prototype includes two main elements that are aimed to ensure appropriate contextualization.

Organizational memory (OM) for effective communication

Whenever a CSR composes a message, the system will retrieve all the relevant information from the OM and will offer hypertext links to the OM for the CSR to confirm validate or modify before message transmission. At the recipient's side, the message will arrive with hyperlinks to relevant OM views. As kMail, there is use of knowledge about senders and receivers to match their profiles and estimate their distance. Embedded links in outgoing messages are automatically created based on the distance detected. When calculations of sender-receiver distance find similar profiles, MU can be achieved with a relatively economical message exchange, with few embedded links, if any. Embedded links to OM not only encourages contextualization when necessary, but also helps users to contextualize what is necessary.

Profile Cards

"Profiles" can offer in-depth information about each individual an e-mail user is corresponding with, to enrich the understanding of whom they are dealing with (Tyler & Tang, 2003). We implemented profiles cards to minimize the distance between communicators. An example is shown in figure 2. User's can create contextual information about contacts, and then use them as an important reference in order to dispel ambiguity around their perspectives when composing messages to them. Unlike embedded links, which are system generated and therefore formed automatically, profiles enable the user to actively seek for relevant information about contacts, and then to consciously decide on to whom to contextualize what. In addition to basic customer information, profile cards contain the customer's "categories of interest". The CSR can use this information effectively as common ground for a smooth and efficient communication, and for providing customer-centered service; for example, he may identify the preferred design style of the customer and offer him complementary products. Also, profile card contains attachments to all the files that were gathered for this contact.

Transition between views presenting different layers of context

Users can quickly transfer between different layers of context by manipulating the display characteristics. As shown in figure 2, a user can choose between a graphical or textual display of information, switch resolutions of detail from a daily to an annual view, through weekly and monthly views, and also choose to present a specific time range. A user can request to see more "drill down" presentations to access documents that belong to different milestones (for example, regarding an order, CSRs can see all documents that were saved: quotes, orders, manager approvals, manufacturing, etc.) Sorting documents by themes that are derived from critical organizational activities (milestones), is in line with the notion of "Thematic components" that connect *communicative* and *socio-organizational* levels (Ducheneaut & Bellotti, 2003; Ducheneaut & Watts, 2005) and with "Workflow systems" that are appropriate for organizational tasks that have a predictable structure (Whittaker, 2005). Users can transfer between views that display threads of e-mail conversations, specific messages and e-mail attachments. In figure 2, a CSR chose to display all messages exchanged with a customer on a thread, highlighted by the milestones they belong to.

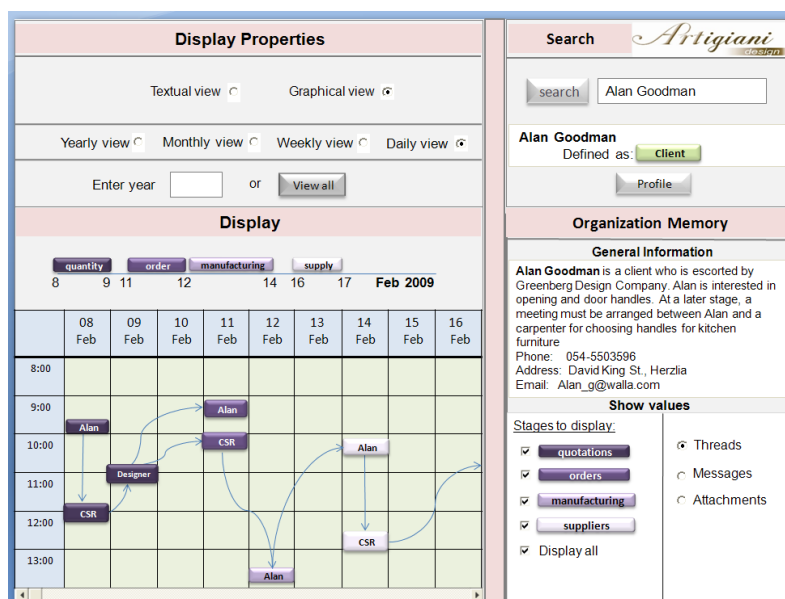

Figure 2: Contextualization of Contacts (Customers)

4. CONCLUSIONS

We focused on gaining a better sense of the various contexts relevant for communication and task management to design an effective e-mail prototype. Our first objectives were to evaluate communication processes between CSRs and their business clients, and to find the types of contextual information that help resolve breakdowns and miscommunications. Then, we examined possible ways to enhance effective CMC and finally we implemented our ideas in the design of an e-mail prototype. Since we were interested in receiving initial feedback from potential users prior to establishing a working prototype, our prototype is in an initial stage and therefore not yet a functional one. An additional limitation to our prototype derived from the first; is that we did not implement a threading algorithm (such as the algorithms existing in Netscape Mail; Fischer & Moody, 2001; Kerr, 2003) or message parsing for creating embedded links (Schwartz & Te'eni, 2000).

We presented the prototype to potential users and received very positive feedback. CSRs stated that the e-mail is most relevant for their daily work and were particularly excited about presenting conversations visually and about the embedded links to OM. They expressed their enthusiasm from the ability to do things faster and more conveniently and from the attractiveness of the design.

Our ideas are not limited only to the realm of customer service, but can be implemented to tasks and e-mail exchanges of other organizational roles and areas, such as purchasing and manufacturing. Our e-mail prototype follows an avenue for reinventing e-mail, which was derived from a vast body of work accumulated over the past 30 years in e-mail literature (Ducheneaut & Watts, 2005). Prototype features that we implemented, such as profiles, thread visualization and embedded links to OM connect components from

three levels at which e-mail operates: the individual; communicative; and socio-organizational, respectively. We believe that a multi level approach will support a variety of organizational tasks performed using e-mail.

INTRANET AND ITS INFLUENCE ON THE ABSORPTIVE CAPACITY OF ORGANIZATIONS

Nikola Radovanovic

Intellectual Property Office of the Republic of Serbia, nradovanovic@zis.gov.rs

Abstract: *The role of absorptive capacity in the knowledge management process has been in focus of vast research. Absorptive capacity reflects the potential of an organization to identify, adopt and apply (exploit) knowledge for its commercial needs. However, absorption capacity depends on the related knowledge an organization already has, so it is important that an organization identifies what it knows and what absorptive capacity can be built on. Organizations are increasingly using intranet as a knowledge management tool, since it can store and distribute important knowledge to customers, processes, technologies, trainings, etc. But not all information and knowledge equally support development of absorptive capacity. In relation to this, there are three important questions that organizations need to answer. With respect to absorptive capacity management, which knowledge and information and how many of them should be stored in an intranet? Who should have access to the intranet? Who should be given the possibility to modify the content? This paper provides analysis and recommendations for organizations in defining their optimal intranet content for absorptive capacity development.*

Keywords: *absorptive capacity, intranet, knowledge management, tacit knowledge, organization.*

1. ABSORPTIVE CAPACITY

Absorptive capacity refers to individual or organization's ability to identify, assimilate and exploit knowledge. It is a dynamic phenomenon, whose characteristics influence knowledge base in the organization and should be taken as an integral part for the knowledge management strategy development. The concept of absorptive capacity was defined by Cohen and Levinthal (1989), who emphasized its influence on a firm's ability to innovate. Modern organizations are in constant need of obtaining new knowledge in order to enhance effectiveness of their activities, upgrade products, create new opportunities for competitive edge, reinforce their knowledge base and predict future market development. Knowledge is embedded in products, methods, practices, experiences, skills, ideas, etc, and it can come from internal and external sources. Internal knowledge sources primarily include scientific research, new product development, new processes, skills development, experiences and organizational structure, while external sources include external scientific research, other firms' products and processes, lead-users, inter-organizational networks and other (Argote, McEvily, Reagans, 2003). In order to be able to effectively use knowledge from any source, organization should work on continuous absorptive capacity development. Putting efforts into eliminating barriers of knowledge flow from the external environment into the organization, but also within the organization itself, should result in higher probability of identifying potentially valuable knowledge.

It is important to identify and absorb every information, which could leverage competitive position of a firm. Capacity for absorbing relevant knowledge determines potential of an organization to react on new market demands, adjust to new environment, to use information and be ahead of competitors. When it comes to the knowledge from external knowledge flows, the first prerequisite is that those flows need to be available. This means, that the firms who search for external knowledge flows will benefit more if they are located in the environments with more research & development and innovative activities. Fact is that firms cannot benefit from external knowledge flows merely by being exposed to them (Cohen and Levinthal, 1989, 1990). Instead, they have to develop the ability to recognize the value of new external knowledge, and then assimilate and utilize such knowledge for commercial ends. For succeeding in this, firms need to develop similar cognitive structures, common skills and shared languages as those in the environment (Escribano, Fosfuri, Tribo, 2008). Communication culture and knowledge sharing climate play an important role in this process. The higher level the absorptive capacity is developed, the firm would be more efficient in managing external knowledge flows and stimulating innovative outcomes. Escribano, Fosfuri and Tribo propose absorptive capacity has an impact on innovation performance only when there are external knowledge flows that can be identified, integrated and exploited.

Absorptive capacity depends on existing knowledge depth in the organization and its prior knowledge, having in mind that the learning process might rely on already established learning routine. This means that new knowledge could be more easily absorbed in case it is related to the knowledge already learned by the organization. Organizations should therefore work on establishing wide knowledge base, comprising various experiences and fields of expertise. By establishing wide knowledge base, organization would become more sensitive to outside information and knowledge, which can ultimately result in making new knowledge from the environment more attractable. This is particularly important having in mind technology changes, which are influential driver of absorptive capacity development. Rapid changes in technology force firms to develop their absorptive capacity in order to respond to shortened technological cycles. In addition, companies may be able to predict the nature of future technological advances with more accuracy. Understanding new technological trends and taking advantage of emerging opportunities enable company to estimate future market behavior and new demands, and helps in reorganizing resources for future needs. For that to happen, organization has to support dynamic knowledge flow and remove all potential obstacles that would reduce its sensitivity to external information. Development of the organizational potential for finding relevant new knowledge and its efficient utilization for commercial ends depends on the possibility of the organization to adjust to abrupt changes in the environment and to adopt new information and communication technologies which can provide benefits in this process. Delivery of such technologies provide better results when the climate is such, that it fosters knowledge exchange and minimizes distortion of knowledge during its transfer (Wellman, 2009). However, another important aspect to be considered is whether the employees are capable enough to understand the importance of a particular knowledge, where it could be primarily used and who could benefit of it the most. Skilled workforce with wider knowledge base in an environment, which stimulates continuous knowledge absorption and sharing, offers greater possibility to adopt new technologies or, perhaps, new use of certain existing technology in the organization.

Zahra and George divide absorptive capacity into potential and realized absorptive capacity (Zahra, George 2002). Potential absorptive capacity (PAC) is related to acquisition and assimilation of knowledge, while realized absorptive capacity (RAC) is related to transformation and exploitation of knowledge. Going into more depth, PAC enables a firm's receptiveness to external knowledge, while RAC reflects a firm's capacity to leverage absorbed knowledge and transform it into innovation outcome. Zahra and George also identify two channels that support PAC accumulation: interaction with external knowledge sources (licensing, R&D collaborations, etc.) and experience with knowledge search. While developing its potential for absorbing external knowledge, organization has to strive towards maximized efficiency of its realization. Efficiency in use of knowledge can be increased by managing forms of knowledge by its origin (knowledge stock/new knowledge), designing channels for knowledge deployment and developing learning processes within the organizational structure. Information technology (IT) system can help organization in managing knowledge flows and knowledge use.

2. IT KNOWLEDGE MANAGEMENT STRUCTURE

Developing channels and routines is not enough for efficient knowledge capturing and use. What also matters is the speed of the process, because of overall "race for knowledge" and subsequent commercialization. An adequate IT knowledge management structure plays an important role in maintaining appropriate speed in the knowledge transfer process. Therefore, channels, processes and routines development should be supported with IT structure which would have enough capacity for handling efficient knowledge transfer. Apart from that, another important issue is the capacity of institutionalization, meaning that effectiveness of utilization of channels and routines for knowledge transfer will be challenged if the organization does not have will or means to make such IT system a key element for knowledge sharing. This might result in knowledge spillovers, distortion of knowledge or even loss of knowledge (Wellman, 2009). IT knowledge management structure can enhance internal knowledge channels flow with adequate databases of knowledge experts (or "old pros") and also with databases of best practices. Retrieving this kind of information will support a quest for particular knowledge within organization. It is clear that IT management plays an important role in information sharing.

Intranet

Virtual place to store this kind of information and knowledge is intranet, being one of crucial elements of the organizational IT system. Intranet is an internal IT system or network, which can include various information and knowledge considered less or more relevant to the organization, which can be retrieved, modified, used or deleted. It normally provides users with the possibility to add new information or knowledge. Intranet offers

new ways to communicate data, information and knowledge (Kim, 2003, p. 66). Mphidi and Snyman emphasize existence of strong awareness of the value of the intranet as a knowledge management tool (Mphidi and Snyman, 2004). By presenting findings from Siemens' IT system ShareNet, Ciabuschi proposes that there is a positive relation between deploying an IT system for knowledge sharing and direct interaction between corporate units (Ciabuschi, 2003). If we consider its role in handling information within the organization, intranet can be regarded both as an information and strategic management tool in the context of knowledge management. Great portion of information, such as news, statistics, business plans, research reports, forms and personal stories can be stored and distributed in a short time to a large number of people (Mansel-Lewis, 1997). Knowledge management has revolutionized intranet as a knowledge base, giving it the goal of providing knowledge, not just information or data, which means that it had a task of communicating both explicit and tacit resources to the user. However, not all information and especially knowledge can be stored and retrieved in its original way. Relevance of content alteration in such actions has been subject to debates (see Yahklef, 2002, p. 3, and Wellman, 2009, p. 106). The more the knowledge is tacit, the greater is the likelihood that it may be distorted in the storage and retrieval process. Polanyi argues that the rational effort to make tacit knowledge explicit in IT networks is challenged by the notion that tacit knowledge held in people's heads is hard to formalize completely (see Polanyi, 1967). Wellman adds that huge human effort is needed in order to transfer tacit knowledge in an effective way (e.g. by communities of practice, teamwork, process experts (Wellman, 2009). However, if an organization puts effort in finding the best solution for recording particular knowledge in a way that it can be easily retrieved, understood and applied, distortion tendency can be minimized. In respect to tacit knowledge, organizations tend to minimize the distortion of knowledge by codification or conceptualization. Wellman used a case study to present this process. In order to preserve tacit characteristics of knowledge in its storage and retrieval process, company stored its knowledge on a variety of multimedia applications which were made available to all of its engineers. High-level process maps were used for systems overview, while video clips were used to present particular process steps.

Storing knowledge in the intranet

Some of the important questions to be posed when considering intranet content are:

- *What knowledge should be stored?*
- *Whose knowledge should be kept?*
- *How can we avoid losing critical context of knowledge kept?*
- *Is there enough objectivity?*
- *Is the knowledge stored for the best retrieval?*
- *Did we identify who should retrieve it?*

Knowledge can sometimes provide more fuss than create order. Organization has to have in mind that its structure includes different influences and various individual perspectives, which can facilitate knowledge transfer process in such a way, that it would make some job more difficult, thus reflecting the effectiveness of entire organization. Also, Edenius and Borgerson compare uncontrolled loading and structuring of information on an intranet with a chaotic situation in a room where one can get all information at the same time (see Edenius, Borgerson, 2003). This situation would also make it very difficult to find important stuff on the intranet in a reasonable time. Particular knowledge is not always being recorded accurately and the critical context may be lost, due to different interpretations, simplification attempts or inadequate intranet capacity. This may result in awkward transfer with bad consequences. Also, organizations need to consider the time factor. This means that what was once absorbed and put on an intranet may be modified after some time, because of a tendency of an organization to modify its beliefs, where organizational memory tends to be aligned with them (Wellman, 2009). At the end, it is important that the application of knowledge is accurate and appropriate. Organization should consider the abovementioned aspects when making somebody responsible for administrating and putting content on the intranet.

Utilization of the intranet as a knowledge base

It is very important to establish such organizational culture which encourages employees to use intranet as a knowledge base. This is where organizational leaders play an important role. It is the leaders who should send the signal throughout organization that the retrieval of information and knowledge from the intranet, as well as "refinement" of intranet with the new content, provide employees with better insight into knowledge and information relevance, ease their work, increase their chances of being innovative and thus receive compensation for it, but also upgrade capability of organization to cope with new challenges in the environment. In this way, use of intranet could be institutionalized in an organization. When having

institutionalized learning in focus, Vera and Crossan divide leaders into transformational and transactional (Vera and Crossan, 2004). Transactional leaders reinforce institutionalized learning having their focus on control, routines, standardization and efficiency, while transformational leaders tend to challenge institutionalized learning being inspirational and stimulating. If we have use of intranet in focus, it is advisable to strike a balance between these characteristics, so that employees are inspired and stimulated to adopt and apply knowledge available in an environment where the use of intranet is standardized in order to maximize efficiency of institutionalization.

Although some factors, such as ignorance, can be tackled by institutionalizing appropriate culture, use of intranet as a knowledge providing tool may be hampered with the work overload faced by employees. Too much daily work may move employees away from using intranet during their work activities. In such situation where this can not be avoided, organizations tend to additionally motivate people to devote themselves to upgrade intranet with their knowledge and expertise by facilitating specific performance-based reward systems. In relation to this, Kim and Lee propose that the level of performance-based reward system is positively associated with employee knowledge acquisition and application capability (Kim and Lee, 2010). Several researchers (Argote and Epple, 1990; O'Dell and Grayson, 1998; Yahya and Goh, 2002) have noted the utility of incentive systems for motivating employees to generate new knowledge, to share existing one, and to help employees in other divisions or departments. General notion is that performance-based reward systems should increase involvement of all employees in knowledge base utilization. At the end, utilization of intranet should be reviewed periodically. For this purpose, organization should delegate a person which would be responsible for monitoring of intranet and reporting trends to the management.

3. TOWARDS OPTIMAL INTRANET CONTENT FOR ABSORPTIVE CAPACITY

After defining absorptive capacity and intranet with its potential as a knowledge management mechanism, focus should now turn to the development of an intranet content which should enable development of the absorptive capacity of an organization. Absorptive capacity is affected by employees' knowledge of technology, product and other development in the organization. In relation to this, when searching on the intranet, it is advisable that employees are able to retrieve reports which are related to organization's research and innovation strength. For this purpose, intranet may include idea bases, data on intellectual property rights of the organization, research reports and other. But organizational sections should also be aware of characteristics of the environment of the organization. In relation to this, intranet may include relevant information on suppliers, research institutions, competitors, customers and other important external parties which the organization may find important. Within this content, contracts, cooperation agreements and research and development projects which the organization has with the abovementioned external parties should also be recorded. Considering creation of legal and administrative framework for establishment of absorptive capacity mechanism, intranet should also include information on relevant legislation, internal processes, templates and similar.

Another important aspect for knowledge dissemination in the organization is that employees should be able to learn about changes, trends and other news with as less time delay as possible. Meera emphasized that important modes of knowledge dissemination include website, annual reports, newsletters, educational and informational events and similar (Meera, 2009). Intranet should also enable interactive discussion tools, such as forums, chat rooms and establishment of discussion groups (e.g. for particular communities of practice). Some authors suggest that these are commonly employed tools for tacit knowledge dissemination (Ganesh, 2009 and Senapathi, 2011). Forums may include both internal discussion platform accessible for organization's employees only and a platform for discussion with external parties (e.g. suppliers or research institutes). Chat groups are usually formed by listing chat rooms by name, location, number of people, topic of discussion, and so on (Senapathi, 2011).

If we recall that tacit knowledge makes most of the organizational knowledge, important issue is how this can be stored on an intranet. Wellman notes that besides textual content, information and knowledge on an intranet may also be formalized in video simulation, audio clips and other. It does not necessarily avoid the distortion of critical context in the transfer or codification process, but the distortion should be minimized. The issue of codification of tacit knowledge can also be tackled with online training modules available on the intranet. Video presentations of particular activity on the job that can be reviewed multiple times increases possibility of knowledge reuse in the original and proper form. Wellman also emphasized the importance of „old pros“, or experienced knowledge experts, whose skills and experience may form the critical knowledge base, which an organization should not allow to lose. Organizations should motivate these „old pros“ in order

to make them spread their knowledge to their colleagues in a most possible way that this knowledge keeps the original form. Therefore, it is suggested here that training modules should include textual, video and audio supported forms of training given by experienced knowledge experts.

It is up to organization to decide which groups of employees should have access to its intranet. It may decide to keep particular sections of intranet (or its entirety) restricted only to certain employees, in order to keep them strictly confidential. Another question to be considered is who should be given a possibility to modify the content on the intranet. Many modifications of the content may make a mess and confusion on what is relevant. Curry and Stancich point that relevance of information in the intranet should be „right“ (Curry and Stancich, 2000). Based on this, it is argued that the abovementioned content should provide a wide framework and guideline to organizations, but final content should be developed based on many factors which influence each particular organization – nature of knowledge which exists in the environment, organizational competitiveness factors, skills and knowledge of human resources and other. Following table includes proposed content and forms of information and knowledge on the intranet, which support development of absorptive capacity in an organization.

Table 1: Proposed content of an intranet with forms of information or knowledge, which supports absorptive capacity of an organization:

Element of the content	Form of information or knowledge
- information on products and technologies of the organization	text
- information on management of the organization	text
- reports on market analysis	text
- reports on past and current research of the organization	text
- data on customers of the organization	text
- data on competition	text
- data on suppliers of the organization	text
- information on business support institutions with which the organization cooperates	text
- information on academic and research institutes with which the organization cooperates	text
- history of relations with external parties	text
- best practice cases	text, video, audio
- information on how to avoid pitfalls	text, video, audio
- procedures, standards, regulations, business methods and other documents in relation to internal processes in the organization	text, video
- information on intellectual property rights of the organization	text
- organization's newsletters and other education and information publications	text
- idea base	text
- internal discussion platform (forums, chat rooms, blogs)	text, video, audio
- platform for discussion with external parties (e.g. suppliers)	text, video, audio
- on-line training modules	text, video, audio
- templates of organization's document forms	text
- news	text

As previously discussed, at knowledge which is often more tacit, than explicit, forms other than text support preservation of the knowledge context in retrieval process. It should be, however, noted that video or audio forms are not required for the content whose nature is rather explicit, such as templates or reports. Assessment of knowledge nature should be carried out prior to reaching decision on what form should it include in an intranet.

When it comes to the utilization of intranet for learning, Wellman suggests that the utilization metrics may include number of times information is entered into the system, the overall increase in volume of information available, the number of queries made seeking information, the percentage of the population entering or seeking information, the frequency of inquiries and other (Wellman, 2009). Here it is suggested that this can be used for the purpose of intranet as a knowledge management and knowledge absorption tool.

4. CONCLUSION

Absorptive capacity greatly depends on prior related knowledge that organization possess. However, appropriate communication climate and network are needed for the efforts for institutionalization of knowledge flows to be fruitful. For establishing knowledge flow in an organization, it is essential to develop an intranet system which supports establishment of channels and routines for knowledge sharing. Utilization of intranet as knowledge base system is another aspect to be considered. Organization can employ a mechanism for measuring activities in this regard. Such mechanism would take into account various metrics based on the use of intranet by employees, which has been discussed above. It is also advisable for organizational leaders to streamline appropriate discipline if the organization wants to make an intranet success. When it comes to knowledge absorption, communication climate in organization matters. Establishment of "knowledge channels" is efficient in organizations where climate is open and supportive with performance-based rewards.

Purpose of intranet as a mechanism which supports absorption of new knowledge is to store what the organization has learnt and to provide tools so that new knowledge can be used where it is useful. However, form of knowledge is of great importance, especially when it comes to the nature of knowledge - is it tacit or explicit. Therefore, an organization should carefully plan and implement forms of information and knowledge on an intranet, so that it could be retrieved, understood and shared with as less distortion and loss of context as possible.

Summary: *Knowledge-based economy creates a new frame for competitiveness of economy, where only innovative companies that invest in human capital can survive. The strategy Europe 2020 is designed in order to enable development of knowledge-based economy in all EU members and increase their competitiveness on global level. Countries of Southeastern Europe are at various stages of accession to the EU. The goal of the work is to show how far the countries of Southeastern Europe have reached in the development of knowledge society by comparison, both with leading countries of the EU and at global level. Comparative analysis is conducted on the basis of the methodology of the World Bank (KAM 2012), Global Index of Competitiveness and Global Innovation Index.*

Key words: *knowledge-based economy, competitiveness, innovations, Lisbon Strategy, indexes of knowledge-based economy development*

1. INTRODUCTION

Certain trends are present in the period of globalization to which countries must adapt themselves if they want to survive and keep competitiveness. Competitiveness of the European economies is improved by implementation of various economic measures. Market globalization and information-communication technologies significantly influenced creation of many possibilities, but also challenges and risks. Information-communication technologies and knowledge have become an important factor of economic changes and comprising part of social and economic structure and development of every country. Economic activities have been increased in sectors that intensively use knowledge and technology and in that way they increase productivity and employment. Developed countries have a goal to build knowledge-based economy. The European Union devised in 2000 so-called *Lisbon Strategy* and in 2010 the new strategy – *Strategy of Europe 2020*. Success in knowledge-based economy depends on ability to implement innovations. Researches [Prusak, Matson, 2006] identified the following characteristics of knowledge-based economies: physical distance is no more obstacle for economic development, development of communications, education, successful implementation of projects, and openness of national economy.

By implementation of Lisbon Strategy provisions and construction of knowledge-based economy and information society, the European economy has increased employment and economic growth. However, economic crisis has influenced a delay in accomplishing and achieving better economic performances in the world economy. Nevertheless, the EU has brought a new plan for overcoming the economic crisis and further implementation of knowledge-based economy construction that will influence accomplishment of higher level of the European economy development.

2. LISBON STRATEGY

Consequences of economic crisis are relatively high rate of unemployment, decrease of economic growth and increase of public debt. However, the EU has managed to stabilize the financial system and to adopt a recovery plan by increasing aggregate demand and regaining confidence in this system. This has been achieved by fiscal and monetary stimulative politics, i.e. by public investing in infrastructure, innovations, new skills and knowledge of labor and energy efficiency. Economic conditions have been improving gradually, but the recovery is rather slow. Rapid and frequent changes are present in the world economy; therefore, the European economy should primarily conquer globalization, limited resources and climate changes. The EU can accomplish the adaptation to changes and further progress only if all the members act collectively, correspondingly and together. Due to that, the European Commission set a *new strategy* in March 2010 – *Strategy of Europe 2020*, which has the target to take out the European economy from economic crisis and

prepare the EU for decades that follow. Besides, it is also the continuation of the Lisbon Strategy. According to this strategy, the EU should get out from the crisis and accomplish a smart, sustainable and inclusive growth and economy that would increase the level of employment, productivity and social cohesion. In order to achieve this, strong and successful state governance is necessary. The strategy Europe 2020 has set the three priorities: 1) *smart growth*, i.e. development of economy based on knowledge and innovations; within the smart growth there are three initiatives: *Innovation Union* (creating conditions for financing researches and innovations), *Youth on the move* (improving performances of education system and increasing the international reputation of the European higher education), *a digital agenda for Europe* (high-speed Internet and benefits of digital unique market for households and companies); 2) *sustainable growth*, i.e. promoting more efficient resources, more “green” and more competitive economy; this growth is based on the two initiatives: *efficient resources of Europe* (it refers to the climate, energy and mobility, promotion of renewable resources and energy efficiency) and *industry of politics for the period of globalization* (competitiveness and improving business climate, especially for small and middle-size companies); 3) *inclusive growth*, full employment in the economy that influences social and territorial cohesion. There are two initiatives for accomplishing this type of growth: *an agenda for new skills and jobs* (modernization of labor market for labor mobility and development of skills) and the *European platform against poverty* (social and territorial cohesion). [EBRD, 2009]

The new European strategy 2020 sets introduction of the new scheme of so-called monitoring of states and connecting programs of fiscal stabilization, with greater investments in science and education. The basic targets of the EU for the year 2020 are ambitious but achievable. The suggestion of the European Commission is that there should be five targets, which will be also the basic national aims, which are: employment, research and innovations, climate changes and energy, education and struggle against poverty. The EU has set the specific objectives and obligations, like: increasing employment rate of the population aged 20 - 64 from the current 69% to 75% and increasing investments in research and innovation from 1.9% of the EU's GDP to 3%. The target is also to decrease energy consumption by 20%. Emission of carbon dioxide and other harmful gases should be reduced by 20% regarding to 1990. Participation of energy from renewable sources should be increased by 20% of the total consumption. Great attention in the new strategy is given to education and applied science. It is predicted that population who complete higher education should make 40% instead of the current 30%. One of the targets is reduction of poverty from 80 to 60 million poor people. Because of the objectives defined by the new strategy, their authors have called it the plan for “smart, green and all-inclusive growth”. In order to achieve these targets, the reports and evaluations of the “Europe 2020” and Pact for stability and growth will be performed simultaneously for the reason of harmonizing the means and targets. [Jednak, Kragulj, 2010].

3. EUROPEAN PARTNERSHIPS FOR INNOVATIONS

Hence, the European Commission in the Strategy Europe 2020 and within the key initiative Innovation Union has announced establishing of European partnership for innovations. This partnership will test the new approach to research and innovations in the EU.

Firstly, it will be based on challenges, focusing to social benefits and rapid modernization of connected sectors and markets. This means that it will go further than technology focus existing instruments have, like Joint Technology Initiatives (JTI). Secondly, it will be active within the whole chain of research and innovation. Partnerships will gather all relevant partners at European, national and regional level in order to: (a) intensify efforts in the area of research and development, (b) coordinate investments into test and pilot projects, (c) anticipate and boost preparation of all regulations and standards, and (d) mobilize demand, especially by better coordination of public procurements and providing that all discoveries come out at the market very fast. Thirdly, it will harmonize, simplify and better coordinate existing instruments and initiatives and complement where necessary. This should make easier the cooperation of partners and provide faster accomplishing of better results comparing to the existing practice. From this point of view, it will be based on the existing instruments and activities. When meaningful (e.g. through joint programs, main markets, joint programs for public procurements of products that are not yet in the market and those that already are and analysis of regulations), it will integrate them to a unique frame of politics. Flexibility is important; there will be no single frame for everything.

Partnerships should be established only in those areas and only for those activities where intervention of state is clearly justified and where they will faster and more efficient accomplish the targets, together with activities in the area of research and development at European, national and regional level and with

measures on the side of demand. It is necessary to accomplish the following mutually interconnected conditions in order to be able to fulfill their promises:

- (1) Focus on a concrete social challenge that they are facing throughout the EU, with clear, ambitious and measurable goals whose accomplishment before 2020 will bring significant benefits for citizens and complete society and when there is a new potential for European companies.
- (2) Serious engagement of politics and interested parties: partnerships will have to mobilize key players and direct them to accomplishment of clearly defined goal until 2020, with support of significant long-term engagement. They will also provide platforms for opened innovations and engagement of citizens, including awards for researches. The Commission itself tends to play the key role in establishing partnerships.
- (3) A clear benefit for the EU: activities at the level of the EU should increase efficiency and accomplish great size effects through critical mass (e.g. simplification and rationalization, association and more efficient use of deficient public resources through e.g. harmonization of public procurement programs or research programs between member states, better quality solutions, interoperability and faster use).
- (4) Clear focusing on results, effects and influences: partnerships should be directed to results and therefore they should not be universal in domains. Solutions for social challenges should be divided into smaller "working packages", where different interested parties associated by mutual interests should define their own action plans with activities, holders and deadlines. Targets, intermediate targets and results should be defined in advance.
- (5) Suitable financial support: although one of the purposes of partnership for innovations is to provide the most efficient use of deficient financial resources by avoiding expensive doubling, there is no doubt that most of the challenges will require additional financial assets. Everyone will have to contribute. The Commission intends to increase additionally the level of financing assets within the budget of the EU. It will enable financing of the first partnerships within the existing budget period and estimation of their financial needs during the preparation of proposals for the next budget period. [European Commission, 2010]

4. WORLD BANK METHODOLOGY

International institutions, like OECD, World Bank, the United Nations and the European Union have developed their own methodologies and indicators that show how much have countries developed their economies. OECD uses so-called *Science and Technology Indicators (STI) Scoreboards*. These indicators are directed to humane and social developing indicators. The European Union based its methodology on measuring development based on systematic, strategic and planned processes. It uses so-called *European Innovation Scoreboards and Lisbon 2000 Indicators* as indicators. The United Nations base their indicators on information-communication technologies like: *ICT Index, Intellectual Property, e-Readiness*. World Bank has developed certain knowledge indexes with their basis in index of education, innovation and ICT and in economic-institutional regime. These are the two indexes: index KEI (*Knowledge Economy Index*) that is calculated by taking into account all four indexes, and index of knowledge, i.e. KI (*Knowledge Index*) that is calculated on basis of the first three indexes. [Rahimic, Kozo, 2009] Also other indicators display development of economy. These are: investments in research and development, investments in highly educated capital (researchers and doctor degree holders), capacities and quality of educational system (expenses of education and learning throughout the whole life), e-government (procurement of new equipment and modernization of public services), labor productivity, use of information-communication technologies, etc. [Cook, Leydesdorff, 2006] in this work indicators of the World Bank and the World Economic Forum will be shown. Table 1 shows knowledge indexes. These indexes are taken over from the base of the World Bank. Ranking of 158 states was performed on basis of these two indexes. Comparison of the chosen states was performed and ranking according to the indexes. Indexes of innovation, education, information-communication technologies and economic-institutional regimes are given in this table. These two indexes are calculated on basis of these indexes. The year 2000 was taken as the basis year and all the newest data are compared with it. These data are according to *KAM 2012*, in their base presented as *recent* (the newest data). There are certain differences in some indexes regarding these two years. Sweden is the best ranked state according to these indexes. This state applies knowledge in its economy.

Table 1: KEI and KI, the Index of knowledge according to the methodology of the World Bank in 2000 and 2012

Country	Rank KEI	KEI		KI		Economic Incentive and Institutional Regime		Innovation		Education		ICT	
		2012	2000	2012	2000	2012	2000	2012	2000	2012	2000	2012	2000
Sweden	1	9.43	9.65	9.38	9.73	9.58	9.42	9.74	9.72	8.92	9.67	9.49	9.79
Denmark	3	9.16	9.32	9	9.38	9.63	9.15	9.49	9.52	8.63	8.99	8.88	9.63
Germany	8	8.9	8.84	8.89	9.35	9.1	9.02	9.11	9.09	8.2	8.25	9.17	8.99
Switzerland	10	8.87	9.28	8.83	8.78	9.54	9.7	9.86	9.9	6.9	7.56	9.2	9.95
United States	12	8.77	9.28	8.65	9.14	8.41	9.07	9.46	9.55	8.7	9.04	8.51	9.47
France	24	8.21	8.53	8.36	8.55	7.76	8.49	8.66	8.75	8.26	8.54	8.16	8.35
Croatia	39	7.29	6.59	7.27	6.97	7.35	5.46	7.66	7.62	6.15	5.94	8	7.34
Romania	44	6.82	5.66	6.63	5.73	7.39	5.46	6.14	5.24	7.55	6.37	6.19	5.56
Bulgaria	45	6.8	5.89	6.61	n/a	7.35	4.25	6.94	5.76	6.25	7.31	6.66	6.24

Albania	82	4.53	3.52	4.48	3.87	4.69	2.47	3.37	2.98	4.81	5.54	5.26	3.11

Source: info.worldbank.org/etools/kam2/KAM_page8.asp

Comparing these two years, certain indexes are little increased, while some states even have a drop regarding the previous period (Switzerland, USA, Germany and France). States of the Southeastern Europe increased their knowledge indexes. The worst ranked state is Albania, while the best-ranked state is Croatia that is in the 39th place out of 158. States of the Southeastern Europe should continue with different reforms. The question is if they can accomplish simultaneous improving of traditional factors (capital, labor and technology) and knowledge. Some of the states have that possibility. The decision will depend on the government policy of these states.

5. GLOBAL INDEX OF COMPETITIVENESS

The World Economic Forum has been studying competitiveness for almost three decades. *The Global Competitiveness Report* represents an annual report that every year (since 1979) investigates great number of factors that enable states to achieve and sustain a stable economic growth and long-term prosperity. Business leaders use these reports for years as indicators of identification of obstacles for improving competitiveness, with a goal to stimulate discussion on strategies that would help in overcoming these obstacles. [World Economic Forum, 2012]

By permanent analysis of methodology for evaluation of competitiveness, new factors were incorporated in time and the methodology has evolved in this way. *The World Economic Forum* in 2004 introduced the *Global Competitiveness Index* (GCI), a universal index for measuring competitiveness at national level, which takes into account both microeconomic and macroeconomic aspects of national competitiveness. Competitiveness is defined for the needs of this index as *set of institutions, guidelines and factors that determine the level of productivity of a country*. The level of productivity, in turn, represents a sustainable level of progress that the economy of the given country can provide. In other words, countries with more competitive economies have a tendency to provide higher income levels to their citizens. Level of productivity determines ability and efficiency of returning assets invested in the economy. Since the ability and efficiency of returning invested assets represent one of the fundamental indicators of the economic prosperity level, more competitive economies form the economies that will probably develop faster, in short-term or long-term view. The concept of competitiveness includes also static and dynamic components: although the productivity of a country is clearly determined by its ability to sustain a high level of income, efficiency of returning invested assets is also one of the central indicators and represents one of the key factors that explain potential economic growth. GCI uses all characteristics to give a well-balanced average of many different components, where each represents an aspect of complex reality that is called competitiveness. All these components are grouped into 12 pillars that are called *the 12 Pillars of Competitiveness*. These pillars are grouped in sub-indexes: "Basic requirements", "Efficiency enhancers", "Innovation and sophistication factors", which are organized as follows:

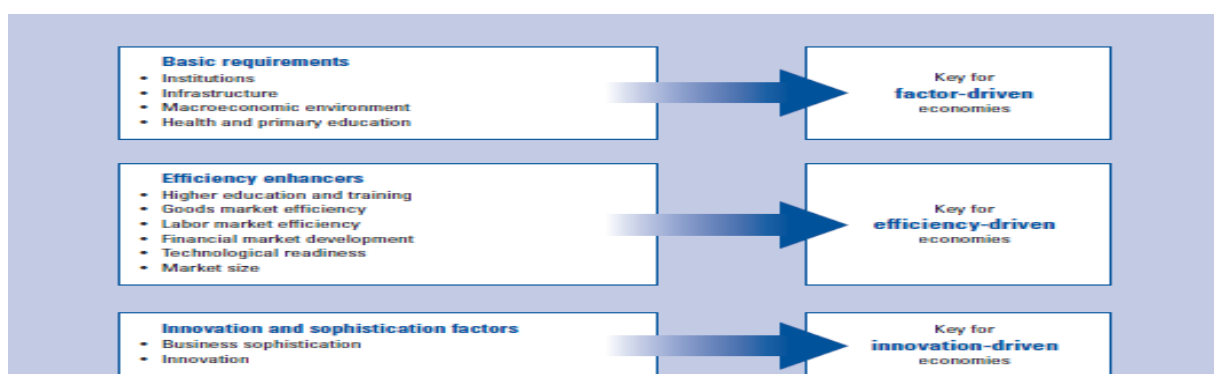

Figure 3: The 12 pillars of competitiveness, Source <http://reports.weforum.org/global-competitiveness-2011-2012>

Influence of each pillar on competitiveness differs from one country to another, depending on the stage of economic development. Three stages of economic development are distinguished: “Factors-driven stage”, “Efficiency-driven stage” and “Innovation-driven stage”. These stages are taken into account when calculating indexes, giving different weights to pillars. According to the Report of the World Economic Forum for 2011/2012, regarding the GCI Serbia is in the 95th place out of 142 countries for which comparison was performed. Among the countries of the region, Bosnia and Herzegovina is the only country that is worse placed in the 100th place. If we refer to the Innovation sub-index, Serbia is in the 118th place and B&H in the 108th place. Other countries of the region: Bulgaria, Croatia, Romania and Macedonia take the 74th – 78th place regarding the Competitiveness index. The best-placed economy regarding this index is the economy of Montenegro. In addition, all countries are much worse placed if the factors influencing innovations and business sophistication are considered. The leading economy regarding the competitiveness is the economy of Switzerland, which is also the leader in innovation. Scandinavian countries follow, then Germany, USA and Japan.

On basis of the factors that influence productivity of economy and GDP achieved in that country, the countries are allocated according to the stage of development (Table 2). Except for Croatia, all the countries of the region are in the phase 2 – the Efficiency-driven stage. Croatia is in the transitional phase to the innovation-driven economy.

Table 2: Sub-Index weights and income thresholds for stages of development

	STAGES OF DEVELOPMENT				
	Stage 1: Factor-driven	Transition from stage 1 to stage 2	Stage 2: Efficiency-driven	Transition from stage 2 to stage 3	Stage 3: Innovation-driven
GDP per capita (US\$) thresholds*	<2,000	2,000–2,999	3,000–8,999	9,000–17,000	>17,000
Weight for basic requirements subindex	60%	40–60%	40%	20–40%	20%
Weight for efficiency enhancers subindex	35%	35–50%	50%	50%	50%
Weight for innovation and sophistication factors subindex	5%	5–10%	10%	10–30%	30%

6. GLOBAL INNOVATION INDEX

Global Innovation Index ranks countries according to the parameters like “Institutions and their business policy”, “Humane capital”, “Infrastructure”, “Technological sophistication”, “Business markets”, etc. The index has been recorded since 2007 and ranks 130 countries according to more than 90 indicators considering different aspects of innovation. GII is based on the following basic principles:

(1) There is a difference between input and output when measuring innovations in economy. Inputs represent factors that contribute to enhancing innovations, while outputs show results of innovations within the economy.

(2) Global Innovation Index monitors five input factors: institutions and their business policy, humane capital, general and IT infrastructure, market sophistication and business sophistication.

(3) GII shows three output factors that make the results of economy innovation: development of knowledge, competence and making wealth. [INSEAD, 2011]

Table 3: Global Innovation Index in 2011

Global Innovation Index		
Rank	Country	Score
1	Switzerland	63.82
2	Sweden	62.12
7	United States of America	56.57
12	Germany	54.89
22	France	49.25
42	Bulgaria	38.42
44	Croatia	37.98
50	Romania	36.83
55	Serbia	36.31
65	Turkey	34.11
67	Macedonia (FYR)	33.47
76	Bosnia and Herzegovina	30.84
80	Albania	30.45

Source: www.globalinnovationindex.org/gii/main/analysis/rankings.cfm

GII data for 2011 are given in the Table 3. On basis of these data, we may conclude that Switzerland and Sweden are the most innovative economies of the world. Regarding the countries of the region according to GII 2011 the most innovative is the economy of Bulgaria, whole the worst placed is the economy of Albania (80th place out of 130 countries). This index is especially suitable for comparison of inputs and outputs in innovations through its sub-indexes.

Table 4: Sub-Index of Innovation input and innovation output in 2011

Innovation Input Sub-Index			Innovation Output Sub-Index		
Rank	Country	Score	Rank	Country	Score
3	Switzerland	66.07	1	Sweden	59.4
5	Sweden	64.85	2	Switzerland	58.2
11	United States of America	62.84	4	Germany	50.74
21	Germany	59.04	5	United States of America	50.3
23	France	55.61	21	France	42.9
45	Croatia	45	38	Serbia	33.53
47	Bulgaria	44.2	43	Bulgaria	32.64
54	Bosnia and Herzegovina	42.1	47	Romania	31.86
55	Romania	41.8	48	Croatia	30.96
61	Macedonia (FYR)	40.37	53	Turkey	30.25
71	Serbia	39.09	68	Macedonia (FYR)	26.57
78	Albania	38.29	95	Albania	22.62
80	Turkey	37.96	111	Bosnia and Herzegovina	19.58

Source: www.globalinnovationindex.org/gii/main/analysis/rankings.cfm

On basis of the data from the Table 4, we can see that Switzerland and Sweden have the greatest investment in innovations and the greatest innovation output, which speaks about efficiency of innovations in these countries. Regarding the countries of the region, Croatia invest the most in innovations, although it is placed a little bit worse regarding the innovation outputs. Albania is among the last countries both regarding the investment in innovation and regarding the innovation outputs. The case of Serbia is interesting, since it takes the 71st place regarding the investment in innovation and in 38th place regarding the innovation output. Serbia has the greatest innovation output comparing with the countries of the region. This illustrates a high efficiency of innovations, but also the need for much greater investment in innovations than before.

7. CONCLUSION

Although the competitiveness appears to be the key problem, factors that define it are not completely cleared. Tim [Tim, 2007] points out that many discussions on competitiveness are based on macroeconomic, social and political circumstances that create a successful economy. It is clear that optimal monetary and fiscal policy, together with efficient social system and existence of a series of democratic institutions, contribute to accomplishment of competitive advantages of a country. Not all these conditions, although necessary, are enough. They only determine environment in which companies create value. Knowledge-

based economy creates a new frame for competitiveness of economy, where only the companies that innovate and invest in humane capital can survive.

Comparing all four indexes, we can conclude that Switzerland and Sweden are innovation leaders and that they are the most competitive knowledge-based economies. Countries of the Southeastern Europe are significantly behind regarding the development of knowledge-based economy with reference to the developed countries of the EU. Progress of these countries regarding the innovations and active implementation of knowledge is slow and significant resources must be engaged in order to get these countries closer to the most competitive world economies.

The countries of the Southeastern Europe should use their natural sources, knowledge and technologies. Technological progress may be accomplished by implementation of available and potential knowledge of developed economies, more efficient business techniques may be implemented in all areas of the economy and the society. Efficient transfer and implementation of knowledge enable increase of growth and economy development. International organizations have developed different economic models that improve economic performances. These organizations have great experience and provide different types of help, consultations and financing forms. Different economic development and growth models are based on analyses of efficient allocations of the existing resources in the given economy, with changes of social and institutional structures. The important and necessary structural changes for accomplishing growth and development are: increase of industrialization, reducing participation of agriculture in total production, changes in the structure of export, increased level of implementation of humane capital and knowledge and undertaking basic institutional changes.

KNOWLEDGE: A BASIS FOR CREATING COMPETITIVE ADVANTAGE FOR CONTEMPORARY FIRMS AND ECONOMIES - THE CASE OF THE REPUBLIC OF MACEDONIA

Dimitar Eftimoski ¹, Bozidar Milenkovski ²

Abstract: *Competitiveness determines the productivity level of an economy, whereas the productivity level determines the sustainable prosperity level of an economy. Competitiveness rests on the essence of contemporary firms and economies' success. When a firm or economy achieves a competitive advantage, it actually possesses something which others lack, and does something that others cannot do or do not know how to do it. Therefore, the aim of this paper is to provide answers to the following two questions: 1) Why should contemporary firms and economies invest in new knowledge, i.e. in creating core competencies? and 2) What is the competitiveness level of the Macedonian firms and economy? In order to obtain the answers to these questions, we will make use of some theoretical experiences, supported by a comparative empirical analysis which, in essence, is based on the composite indicators - Knowledge Index and Global Competitiveness Index.*

Keywords: *Competitiveness of Macedonian firms and economy, knowledge, competitiveness, core competencies, Knowledge Index, Global Competitiveness Index.*

1. INTRODUCTION

Competitiveness is defined as a set of institutions, policy and factors which determine the productivity level of a country, whereas the productivity level determines the sustainable prosperity level of an economy.¹

Contemporary firms which operate in the global surroundings and which are bolstered by the latest information technological devices, most frequently, make use of knowledge as a major means of achieving a competitive advantage. The speed at which knowledge is processed, as well as the speed at which market performance strategies are developed, in compliance with the received information, determine the successfulness of firms' performance. Their success is also dependant on employees' readiness for life-long learning and training.

In a situation in which markets undergo considerable changes, technologies are rapidly upgraded and the number of competitors constantly rises, successful firms have to absorb and create new knowledge; then to disseminate it throughout the organization and to swiftly materialize it in a form of innovative products. At the same time, firms should also differentiate between two types of knowledge, i.e. specific and organizational knowledge.

The specific knowledge enables a firm to be different from its competitors. This type of knowledge generates a competitive advantage, for it is unique for each firm and it is harder to copy it from the competition.² Firms compete in this way evidently by creating distinct and unique products which are necessary for satisfying customers' fickle demands.³

The organizational knowledge is a technical type of knowledge concerning operations. It could also be in the form of organizational systems and routines. A greater competitive advantage could be created when the organizational knowledge is unique and it is adjusted to the firm's operations and it is of paramount

importance for one market, or several markets which are simultaneously provided with services. Davenport and Prusak in their paper "Working knowledge: How Organizations Manage What They Know"⁴, also underline that knowledge could make a sustainable competitive advantage of firms possible, exactly as a result of the fact that it is hard to copy. They explain that competitors, in the course of time, will manage to attain the same quality and price, but the firm which is rich in knowledge and qualitatively manages knowledge, could set a new level of quality and price during the same period of time.

In order to understand the specific nature of knowledge as an economic good, it is necessary to look into its features which differentiate it from the conventional goods. Thus, knowledge is: a) a hard-to-control good, i.e. it is an indispensable good, b) a non-competitive good, c) a cumulative good.

a) Knowledge could hardly be made exclusive, i.e. could hardly be individually controlled. It is a fluid and transferable good. Knowledge could be kept in secrecy, but once it is made public, it immediately gets out of control. The degree of exclusiveness of knowledge vigorously determines the manner of unveiling and allocating knowledge, and consequently, the intensity of deviation from the perfect competition. If one particular type of knowledge is completely un-exclusive, there will be no vested interest in its unveiling, so research and development in these areas must stem from another initiative (for instance, from state subsidizing). However, when knowledge is exclusive, the generators of this new knowledge could license the right to using the knowledge for a positive price (price greater than zero), and then hope they will make a profit due to their research and development efforts.

Controlling its knowledge on the part of a firm is much more difficult than controlling its capital goods, since in the case of knowledge as an economic good there are plenty of possibilities for outflow or spill-over. Certain analyses and research in this area, indicate that information on managers' decisions related to research and development become available to competitors in about 6 months on average, whereas technical details in one year's time.⁵

b) Knowledge is characterized by non-competition.⁶ The indirect implication of this fundamental feature of knowledge is that the generation and allocation of knowledge could not be controlled entirely by competitive market forces. At the same time, the marginal expense of a non-competitive good is equal (or close) to zero. Hence, the price for hiring knowledge from competitive markets is zero. But then, the creation of knowledge will not be triggered by the wish for vested economic interest. Accordingly, knowledge is either hired above its marginal cost, or its unveiling is not motivated by market forces. Therefore, a slight deviation of the competitive model is necessary.

Knowledge as a non-competitive good is being produced only once, and it has two dimensions: individual and collective. Firstly, the same knowledge can be used an unlimited number of times, free of charge (the individual dimension). Secondly, an unlimited number of users could use the same knowledge, without excluding anyone (the collective dimension). Thus, on the one hand, the same knowledge which is needed to generate m output units, will also be used to generate $m+1$ output units. On the other hand, the same knowledge used by n people, could also be used by $n+1$ person.

c) In the area of science and technology, very frequently, knowledge is cumulative and progressive. This means that knowledge externalities do not only increase customers' satisfaction, but also the accumulation of knowledge and collective progress (that is simply an opportunity for someone 'to stand on the shoulders of giants').

More precisely, knowledge as an expandable good which can be used an unlimited number of times, is not only a consumers' good, but also an intellectual input which can be used to create new products and consequently be

⁴ Davenport, T.H. & Prusak, L. (2000). Working knowledge: How Organizations Manage What They Know, Harvard Business School Press, Boston, p. 17.

⁵ Foray, D. (2006). The Economics of Knowledge, Massachusetts Institute of Technology, p. 92.

⁶ Knowledge usage by one entity does not restrict its usage by another entity.

⁷ "Thanks to the Giants" (lat. nanos gigantum humeris insidentes), is a metaphor which highlights the fact that the one who creates scientific values builds his deeds on his predecessors' achievements, as Isaac Newton did, for instance, when it comes to Johannes Kepler and his laws on planets' movement around the Sun - "If I have seen farther than others, it is because I was standing on the shoulders of giants!" This is important to be emphasised especially in the context of research and development externalities when the expressions: 'standing on shoulders' and 'stepping on toes' describe their positive and negative effects, respectively (see: Mankiw, G. (2002). Macroeconomics, fifth edition, TSI Graphics, p. 225).

used unrestrictedly.⁸ In the new knowledge-based economy, there are many types of strictly cumulative knowledge, such as databases (e.g. the international DNA database). These types of knowledge are in opposition to non-cumulative knowledge (the consumer good) such as songs, entertainment shows or the galleries of photos which are available on the Internet.

From a strategic point of view, the key to firms' corporate success is the development of a unique competitive advantage. However, the building of a competitive advantage is not a means to an end. The foundation for contemporary firms' success is based on building a sustainable competitive advantage. In the long run, a firm acquires a sustainable competitive advantage through its ability to develop a set of core competencies, which will ensure a better approach to satisfying customers/clients' needs in comparison with its competitors.

The core competencies could be defined as collective knowledge within an organization, especially with respect to how various production abilities should be coordinated and how diverse technological flows should be integrated. Namely, this is an accumulative diverse type of knowledge which contributes to achieving competitive success in operations. The core competencies make sense providing they make an access to new markets possible, they meet clients' specific needs and are hard to copy. They are the unique set of abilities which a firm develops in the key areas of its operations (such as, for instance: high quality, services intended for the customers, innovations, team building, flexibility etc.), which should assist the firm in overrunning competitors in the competitive race. These core competencies are normally important skills, abilities and experiences which the firm acquired and developed in the course of time. Customarily, firms develop core competencies in no more than five or six areas. Subsequently, these core competencies become the core of the firm's competitive advantage and usually they persist in the course of time. Markets, clients and competitors could change, but core competencies of firms remain intact in the long run. In order for them to be efficient, from a strategic point of view, firms should make sure that their competitors find it hard to copy those competencies and should ensure considerable benefits for their customers/clients.

Methodological background

In order to examine the competitive ability of the Macedonian firms and economy, from the perspective of knowledge accumulation, we make use of two composite indicators: Knowledge Index (KI)⁹ and Global Competitiveness Index (GCI)¹⁰.

As a source of KI, we use the database of The World Bank Institute (WBI), whereas the rest of the data, mostly derive from The Global Competitiveness Report of The World Economic Forum.

The competitiveness level of the Macedonian economy, is compared with economies which belong to the second and third stage of development¹¹. The group of economies in the second stage of development is made up of: the Czech Republic, Hungary, Bulgaria, Romania and the Slovak Republic, whereas the group of economies in the third stage of development consists of: Finland, Sweden, Germany and Switzerland.

The accumulated level of knowledge (measured in KI), depending on the development stage, is analyzed at two points in time - 2009/10 and 1995, whereas the level of the competitive ability of economies (measured in GCI) - in 2011/2012. GCI trend has been analyzed for the period from 2005/06 to 2011/12.

⁸ Thomas Jefferson wrote: "It is a fact that one idea leads to another, the other idea leads to a third one etc. in the course of time, until someone combines all of them together and generates something which is normally called an invention" (see: Foray, D. (2006). *The Economics of Knowledge*, p. 94).

⁹ For further reference on the structure and calculation of KI see 'The World Bank Institute (WBI), Knowledge for Development'.

¹⁰ For further references on the structure, weights and calculation of the index see 'The Global Competitiveness Report 2011-2012, World Economic Forum'.

¹¹ According to The Global Competitiveness Report 2011-2012, World Economic Forum.

2. KNOWLEDGE - DETERMINANT OF COMPETITIVENESS OF MACEDONIAN FIRMS AND ECONOMY

Following the logic used in The Global Competitiveness Report of the World Economic Forum, in relation with the classification of economies according to their stage of development¹², in addition we provide a presentation of an attempt to compare the performances of the knowledge competitiveness of the Macedonian firms and economy with the performances of the knowledge competitiveness of firms and economies which belong to the second and third stage of development. To that end, the average values of KI and GCI have been used for separate groups of economies.

Source: The World Bank Institute (WBI)

As to the potential of the country to create, absorb and diffuse knowledge, measured in KI, Macedonia is considerably lagging behind compared to the average of both efficiency-driven and innovation-driven economies. In the period from 1995 to 2009/10, the Macedonian economy managed to increase its KI by 0.1 index point, whereas in the same period, the remaining economies which belong to the second and third stage of development, on average, managed to increase their KI by 0.21 and 0.19 index points, respectively (Figure 1).

Table 1. KI components by the stage of development (2009/10 and most recent and 1995)

Economies	Innovation		Education		ICT	
	2009/2010 and most recent	1995	2009/2010 and most recent	1995	2009/2010 and most recent	1995
Inovation – driven economies	9.56	9.53	8.77	9.33	9.38	9.52
Efficiency – driven economies	7.01	6.80	7.47	7.19	7.33	7.19
Macedonia	4.67	4.43	5.42	5.23	6.88	7.00

Source: The World Bank Institute (WBI)

¹² See: The Global Competitiveness Report 2011-2012, World Economic Forum.

Bearing in mind the structure of KI, Macedonia marks its greatest lagging behind in the 'innovation' variable (4.89 index points below the average of the innovation-driven economies and 2.34 index points below the average of the efficiency-based economies), which reflects a low level of development of the innovative system of the country, which results in a small number of registered patents on the part of both firms and individuals. The 'education' variable marks a growing tendency, first and foremost, owing to the increased rate of enrolment in the secondary and tertiary education, whereas, as far as the decline in the 'information technologies and communications' variable is concerned, no logical conclusion can be drawn (Table 1).

Even though Macedonia is still far off from the competitive performances of the innovation-based economies, yet during the past couple of years it exhibits a slight tendency of convergence towards the efficiency-driven economies - in the period from 2005/06 to 2011/2012, GCI grew by 0.79 index points. In the same period, the growth in the average GCI of the innovation-based economies reaches 0.02 index points, whereas the growth in the average GCI of the efficiency-driven economies reaches 0.14 index points (Figure 2).

Figure 2. GCI trends by the stage of development

Source: The Global Competitiveness Report 2011-2012, World Economic Forum.

More precisely, as to the main determinants (pillars) of competitiveness, which stem from GCI, it could be concluded that the Macedonian economy marks certain deficiencies with respect to: infrastructure, higher education and training, technological readiness, market size, business sophistication and innovations. As far as the remaining determinants are concerned, the Macedonian economy reaches average values typical of the efficiency-driven economies (Figure 3).

Furthermore, the problem with the ability for absorption of new knowledge and technologies on the part of the Macedonian firms, seems to be one of the most serious problems when it comes to the level of the competitiveness of the Macedonian firms. Thus, the relations between the new technologies absorption capacity of the firms and new knowledge absorption ability of the employees (presented through the quality of the education system), indicates that: 1) Firms' capacity for absorption of new technologies is lower than the ability for absorption of new knowledge on the part of their employees; 2) Firms' capacity for absorption of new technologies exhibits a significant negative deviation from the average of the efficiency-based economies; 3) Employees' ability for absorption of new knowledge is greater than the average of the efficiency-driven economies; 4) Firms and employees' abilities for absorption of new technologies and knowledge is significantly lower than the average of the innovation-driven economies (Figure 4).

Source: The Global Competitiveness Report 2011-2012, World Economic Forum.

3. CONCLUSION

Knowledge and the remaining intellectual resources are rather unique in firms which are characterized with high level of knowledge, dynamic technology and short life cycle of products. At the same time, continually advancing and increasing knowledge is an imperative for the firms, since their competitive advantage depends on it. To what extent a firm could set 'barriers' to its competitors, depends on the knowledge

specificity and the competencies developed on the basis of that knowledge, as well as on its differentiation and deficiency.

Thanks to the competencies at its disposal, a firm achieves a competitive advantage. Each competitive advantage is connected to a competence, but not every competence ensures a competitive advantage. An organization with a high level of ability for absorption of new knowledge and technologies is required to develop products which imply superiority over competitors.
